Abstract

The perceptual strength in learning styles refers to obtain knowledge most easily by different sensory systems. Discovering the perceptive strengths and weaknesses of each student and finding ways to optimize their learning is always a challenge for the professor. In extreme cases such as in the visual impairment touch-and-go approaches can be an alternative. This paper aims at sharing the usage of tactual resources as a learning strategy in a case of visual impairment, developed by a group of professors for supporting classes of Linear Algebra and Analytic Geometry at Sorocaba Engineering College (Faculdade de Engenharia de Sorocaba - FACENS). As a result, there was ease of handling tactile resources by the student, considerable gain in understanding the theoretical subjects and of practical cases analyzed in classroom. According to professors' perception, the concrete experimentation by using the touch-and-go strategy provided satisfactory support for the classes. Therefore, the usage of touch-and-go by means of the tactile resources can be considered as a promising approach as a learning strategy in cases of visual impairment.

Keywords: Learning strategy. Visual impairment. Hands-on. Linear Algebra.

Résumé

La force perceptive dans les styles d'apprentissage se réfère à l'obtention de connaissances plus facilement par différents systèmes sensoriels. Découvrir les forces et les faiblesses perceptives de chaque élève et trouver des moyens d'améliorer son apprentissage est toujours un défi pour l'enseignant. Dans les cas extrêmes, tels que la basse vision, l'approche tactile peut être une alternative. Ce travail vise à partager l'expérience pédagogique de l'utilisation des ressources tactiques comme une stratégie d'apprentissage dans un cas de déficience visuelle, développé pour soutenir les classes en algèbre linéaire et géométrie analytique à Faculdade de Engenharia de Sorocaba (Facens). De ce fait, il a été facile de gérer les ressources tactiques de l'élève, de réaliser des progrès considérables dans la compréhension des concepts théoriques et des cas pratiques analysés en classe. Selon les perceptions des enseignants, l'expérimentation concrète à l'aide d'une stratégie tactile (touch-and-go) a fourni un soutien satisfaisant aux cours. Par conséquent, l'approche tactile peut être considérée comme une stratégie prometteuse en cas de déficience visuelle.

Mots-clés: Stratégie d'apprentissage. Déficience visuelle. Les mains dans la pâte. Algèbre linéaire.

Resumen

La fuerza perceptual en los estilos de aprendizaje se refiere a obtener conocimiento más fácilmente por diferentes sistemas sensoriales. Descubrir las fuerzas y debilidades perceptivas de cada alumno y encontrar maneras de mejorar su aprendizaje es siempre un desafío para el profesor. En casos extremos, como los de baja visión, el enfoque touch-and-go puede ser una alternativa. Este trabajo tiene por objetivo compartir la experiencia pedagógica del uso de recursos tácticos como estrategia de aprendizaje en un caso de deficiencia visual, desarrollada para apoyar clases de Álgebra Lineal y Geometría Analítica en la Facultad de Ingeniería de Sorocaba (Facens). Como resultado, se verificó facilidad en el manejo de los recursos tácticos por el alumno, ganancia considerable en la comprensión de los conceptos teóricos y de los casos prácticos analizados en el aula. De acuerdo con la percepción docente, la experimentación concreta usando la estrategia basada en recursos táctiles (touch-and-go) proporcionó apoyo satisfactorio para las clases. Por lo tanto, el enfoque touch-and-go puede ser considerado una estrategia prometedoras en casos de deficiencia visual.

Palabras clave: Estrategias de aprendizaje. Deficiencia visual. Manos en la masa. Álgebra lineal.

Resumo

A força perceptual nos estilos de aprendizagem refere-se a obter conhecimento mais facilmente por diferentes sistemas sensoriais. Descobrir as forças e fraquezas perceptivas de cada aluno e encontrar maneiras de melhorar sua aprendizagem é sempre um desafio para o professor. Em casos extremos, como os de baixa visão, a abordagem touch-and-go pode ser uma alternativa. Este trabalho tem por objetivo compartilhar a experiência pedagógica do uso de recursos táteis como estratégia de aprendizagem em um caso de deficiência visual, desenvolvida para apoiar aulas de Álgebra Linear e Geometria Analítica na Faculdade de Engenharia de Sorocaba (Facens). Como resultado, verificou-se facilidade no manejo dos recursos táteis pelo aluno, ganho considerável na compreensão dos conceitos teóricos e dos casos práticos analisados em sala de aula. De acordo com a percepção docente, a experimentação concreta usando a estratégia baseada em recursos táteis (touch-and-go) proporcionou apoio satisfatório para as aulas. Portanto, a abordagem touch-and-go pode ser considerada uma estratégia promissora em casos de deficiência visual.

Introduction

Teaching-learning processes have always existed as a natural process resulting from different forms of social interaction, from simple observation by the most rudimentary animals until those by means of the most sophisticated man-made technological tools (BRESSANE; RIBEIRO; MEDEIROS, 2015, 39p.).

The perceptual strength in learning styles refers to obtain practical and theoretical knowledge most easily by hearing, seeing, verbalizing, or actively experiencing. Naturally, the learning process results from a combination of different sensory and mental abilities, but according to the biological characteristics of each individual some of them can be more effective than others (Rogowsky & Calhoun; Tallal, 2015).

Discovering the perceptual strengths and weaknesses of each student and finding ways to optimize their learning is always a challenge for the professor. In extreme cases, mental and physical impairments may partially or totally affect a particular sensory ability, as occurs in cases of visual impairment, in which touch-and-go approaches, i.e, teaching and learning with tactual resources can be an alternative in replacing the visual perception (Galassi & Akos, 2017; Camargo, 2010; Mantoan, 1997).

Some experiences have been reported in the literature (Xavier, 2018; Sobral *et al.*,

2017; Maravalhas & Bastos 2015; FONTES; Cardoso & Ramos, 2012; Camargo, 2010; Camargo, Nardi & Veraszto, 2008; Costa, Neves & Barone, 2006; Moreira, 2014, 2015, 2016; Moreira & Manrique, 2014a, 2014b).

Moreira (2014, 2015, 2016a, 2016b) they have been working with materials, methods, activities and teacher training that teach mathematics to students with special educational needs (SEN). According to the researcher, the inclusion of schoolchildren with deficiencies has had important repercussions in the most different levels of organization of the world's educational systems, with a strong growth in Brazil in the last decades. In communion with their work, it can be seen that there are few studies related to the inclusion of students with SEN in mathematics classes, which makes the field of research rich and in need of research that bring a look at the diversity of the Mathematics classroom.

This diversity of views on what still needs to be exhaustively studied, which lacks the better pedagogical work conditions of the student with SEN, has been presented in some investigations. Camargo (2010) analyzes the communication difficulties between professors and students with visual impairment. In conclusion, the author emphasizes the importance of creating adequate communication channels as a basic condition for the inclusion of these students.

Maravalhas and Bastos (2015) pointed out the use of inclusive tools and resources as an alternative to overcome barriers and enable autonomy of students with visual impairment. In this sense, Xavier (2018) highlights mathematics as a component of great visual character, and describes the use of a hand-held calculator adapted for visually impaired students.

Fontes, Cardoso and Ramos (2012) share an experience on the teaching-learning process of graphics in physics classes. Such authors describe the use of the 'multiplane'; an educational kit specialized for tactile perception, as a substitutive alternative to visual perception with satisfactory results. Sobral et al. (2017) describe the use of Role Playing Digital Games as a tool for learning the visually impaired.

Moreira and Manrique (2014a) highlight that "collectivity is able to transfer knowledge that would not be possible in social isolation" (p. 472). What these researchers have been saying is that we need to insert the student with SEN in all classes, especially in Mathematics, since one of the biggest problems related to inclusion lies in the postures adopted by teachers of the exact ones.

In contrast to the gradual advances cited above, it is observed that the thinking and the action in the schools in relation to Mathematics, often, consider the students, both so-called "normal" and those with some SEN (Moreira, 2014, 2015, 2016a, 2016b). It is disregarded how students with SEN need to be involved in interventions, especially in relation to higher psychological functions, mental processes and the formation of mathematical concepts. What we have in reality, many times, are teachers who do not

know very well how to include these students, mainly due to the reflection of a weak and weak formation that needs to be rethought from the point of view of the diversity present in the classes of Mathematics (Moreira, 2016a, 2016b; Sandes & Moreira, 2018). Despite these examples, there is still a few number of outcomes reported in the literature on the inclusive teaching-learning of visually impaired students (Fontes, Cardoso & Ramos, 2012; Moreira, 2014, 2015, 2016a, 2016b). Therefore, the present paper aims to share a touch-and-go approach as a learning strategy in a case of visual impairment, developed by a group of professors for supporting classes of Linear Algebra and Analytic Geometry in Sorocaba Engineering School (Faculdade de Engenharia de Sorocaba - FACENS). More narrowly, we intend to discuss the inclusion / mathematics dyad; to present successful experiences on the inclusion of students with SEN in Mathematics classes and also to demonstrate the contributions that the use of didactic resources has in the teaching and learning process of Mathematics for students with visual impairment.

Teaching-learning strategy in case of visual impairment

The teaching-learning strategy addressed in this paper is based on two set of touch-and-go resources. The first one corresponds to tactile resources built by professors of FACENS, using low-cost materials. In turn, an educational kit specialized for tactile perception has been also used during the classes, as described ahead.

The discussion about inclusion in mathematics classes and the relation between teaching and learning are essential in this scenario and will be anchored in the discussion about the production of materials, technologies and strategies to assist in the organization of mathematical reasoning, since they contribute greatly to the discussion and expansion of the pedagogical action by arguing that students with SEN deserve to have school attendance based on social, pedagogical and cultural interactions, as well as the conception that learning generates development.

Currently, as people with disabilities are coming out of invisibility, under the auspices of Human Rights and the legal provisions that ensure social inclusion in all areas of life, these examples of overcoming are increasing, always in direct relation to the conditions of accessibility, with the reception in the social spaces and, fundamentally, with the awareness of all towards the right to diversity and human differences (Alves, 2015, p. 90).

According Moreira *et al.* (2016, p. 83), “quando se investigam ou dialogam sobre a inclusão de alunos com necessidades educativas especiais (NEE) em classes regulares” it is necessary “to develop innovative strategies and methodologies that support the

school units so that they can meet the requirements of all students with and without SEN in all their specifics”.

In this sense, tactile resources can be understood as assistance technologies or support to learning, since they involve pedagogical resources. According to Sartoretto and Bersch (2019), resources include any equipment, or part of it, a manufactured product or system used to increase, maintain, or improve the functional capabilities of persons with disabilities.

If "student training should have as its main objective and acquisition of basic knowledge, [...] to use the different technologies related to the areas of activity, [...]the ability to learn, create, formulate, rather than the simple exercise of memorization" (Secretaria de Educação Fundamental [SEF], 1998, p. 5), must be a recurring element in the classroom, since the technologies are pedagogical tools and mechanisms increasingly available to school environments, mainly available to specific knowledge areas for the active participation of students with SEN.

Therefore, the use of tactile resources in mathematics classes opens a range of possibilities for intervention and action with students in general, as it allows the prospective look, that is, even if the student has limitations due to his special needs, to do development and learning, which is one of the central objectives of education.

Tactile resources built using low-cost materials

When we refer to the various types of resources for working with SEN learners, we need to keep in mind all kinds of instruments that can minimize impacts. These instruments refer to Assistive Technology (AT), which can be products, equipment, devices, resources, methodologies, strategies, practices and services that aim to promote autonomy, independence, quality of life and social inclusion of persons with disabilities (Secretaria Nacional de Promoção dos Direitos da Pessoa com Deficiência [SNPD], 2008).

The AT presents a humanistic potential of social value in the face of possible mismatches in the learning rhythm (as a process that is plural, complex and multiple of sense), since it can aid and create stimuli to the capacity of perception, language and ontological understanding, since articulates different forms of being together and a multiplicity of knowledge. It is about claiming the right of social recognition in the experience with socially validated AT, which has repercussions on all dimensions of life, as a means by which people share their experiences and learn from each other, that is, it is an exercise in citizenship and cultural experience. (Conte, Ourique & Basegio, 2017, p. 13).

Low-cost materials used in the construction of tactile resources included a wood

sanding paper (Figure 1a), wire structure coated by a cloth woven together (Figure 1b), wooden sticks and a stylus (Figure 1c). The woven wireframe structure was employed for providing the tactile perception of a Cartesian plane in the representation and operations with vectors.

We consider that "an inclusive school is thus a school where every child is respected and encouraged to learn to the limit of his abilities" (Correia, 2008, p. 7), which can be done through the use of adequate and well thought-out assistive technology resources, based on the pedagogical presuppositions of inclusion of people with SEN in mathematics classes.

Figure 1. Materials used in the composition of the tactile resource.

Source: produced by the authors.

The strong tactile appeal was a pedagogical strategy because

I cannot be a teacher if I do not perceive more and better that, because I cannot be neutral, my practice demands of me a definition, a positioning. Decision. Break. It requires me to choose between this and that. I cannot be a teacher and simply make of Man or Humanity, a vague phrase too much contrast with the concreteness of educational practice (Freire, 1996a, p. 115).

The texture of the wire structure coated by a cloth woven together, highlighted in Figure 2, sought to simulate the partitions of the orthogonal decomposition bases (xOy), as well as the pairs of Cartesian points (x, y) formed at the intersections of these partitions.

Figure 3. Tactile Simulation of the Cartesian plane with the wire structure coated by a cloth woven together.

Source: produced by the authors.

Figure 2 refers to the thought of Kensk (2015). For her, in any discipline, for any teacher or any student, it is possible to make use of new technologies to teach and learn, both collectively and individually.

New communication technologies (ICTs) have driven education and brought new mediations between approach, understanding and content. The image, the sound and the movement offer more realistic information regarding what is being taught. When well used, they provoke the alteration of the behaviors of teachers and students, leading them to better knowledge and to deepen the studied content (Kensk, 2015, p. 45).

The student's handling of the wooden sticks sought the tactile perception of the representation of the vector as a straight line, as well as working the concept of a module associated with the length of these sticks (Figure 3a).

Figure 3. Tactile simulation of the vector with wooden sticks.

Source: produced by the authors.

Maintaining the straight stick shape at one of its tips allowed us to work on the vector origin concept (Figure 3b). In turn, the use of the stylus and the sandpaper made it possible to accentuate the thinning of the other end of the stick and, in this way enhancing the tactile perception of the extremity and to work the concept of direction (vector orientation).

Consistently, Moreira (2016a, p. 752) believes that

It is important that teachers who teach mathematics have at their disposal instructional, instructional, appropriate and quality materials, [...] leading students to construct mathematical concepts, either through the use of didactic games or through play activities to mobilize all students in the classroom towards effective mathematical learning.

As a result from the usage of touch-and-go resources during the classes, the structure coated by a cloth woven together and the wooden sticks allowed to work the tactile perception of the geometrical methods and operation with vectors (Figure 4a), both in the 2D-plane (Figure 4b) and in 3D-space (Figure 4c).

Figure 4. Usage of touch-and-go resources for tactile perception in 2D-plane (a) and 3D-space (b, c).

Source: produced by the authors.

The usage in class of the resources described gave quite satisfactory results. By consulting the visually impaired student at the end of the classes, s/he reported ease of resource handling and considerable gain in understanding the concepts and operations worked in the classroom (Figure 5).

Figure 5. Use of tactile perception resources in the classroom by the visually impaired student.

Source: produced by the authors.

Similarly, Moreira (2014) has been insisting that, from a practical class in which mathematical knowledge is brought into the everyday life of students, they present "better learning conditions, retention of content, and develop other skills" (p. 47), whether at the level of language or at the level of mathematics.

Educational kit specialized for tactile perception

In the mid-2000's, the Multiplane Classroom Kit was developed by professor Rubens Ferronato, who was facing difficulties in teaching math to a blind student. Since then, this kit has been upgraded and traded for educational purposes, especially for concrete experimentation of theoretical concepts (Figure 6).

Figure 6. Commercial multiplane classroom kit.

Source: produced by the authors.

The commercial kit includes a perforated plate, which can be used as Cartesian plane (Figure 6a), a set of pieces to construct geometric elements (Figure 6b) and graphical representations (Figure 6c). As represented in Figure 7, these components allow the tactile perception of the vector, as well as of geometric operations. To standardize the use of the kit, the professors defined specific pieces to represent the origin (Figure 7a) and the extremity (Figure 7b) of vectors hence supporting the concrete experimentation of vector direction and orientation.

Wisely, the teacher understood that "the hand of the blind is the extension of his vision, hence the touch has a special meaning in its autonomy and independence", because in this case, it is the school and the teacher to stimulate "this tactile sense, creating an environment that can develop the spatial notion " (Coimbra, 2003, p. 223).

Figure 7. Tactile simulation of the vector with pieces from multiplane classroom kit.

Source: produced by the authors.

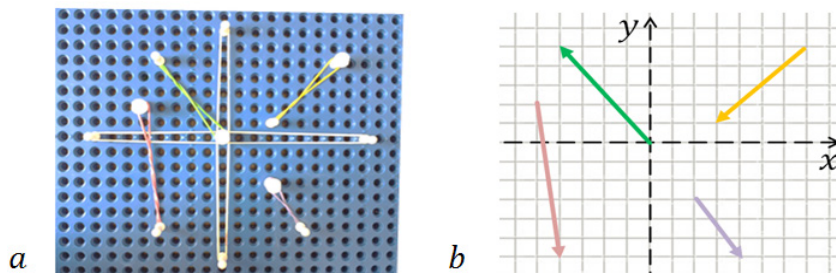

It is evident that the incessant search to attend the visually impaired students, in this specific activity, makes the teacher a true researcher of his practice (Moreira, 2014, 2015, 2016a). Because,

What is a researcher in the teacher is not a quality or a way of being or acting that is added to that of teaching. It is part of the nature of the teaching practice the inquiry, the search, the research. What is needed is that, in its permanent formation, the teacher

perceives and assumes, because teacher, as researcher (Freire, 1996b, p. 29).

Then rubber bands were used for connecting such pieces and, this way, providing the tactile perception of vector module (Figure c). Prior to use by the blind student, a monitor prepared the multiplane (Figure 8a) representing the cases under analysis (Figure 8b). It can be seen in Figure 8 that the axes of orthogonal basis were represented by a double line, to differentiate such axes from vectors.

Figure 8. Usage of multiplane classroom kit for tactile perception of cases under analysis.

Source: produced by the authors.

It can be seen in Figure 8 that the axes of orthogonal basis were represented by a double line, to differentiate such axes from vectors. As a result from usage of multiplane kit in the classroom, the student reported ease of handling and satisfactory understanding the cases under analysis (Figure 9).

Figure 9. Usage of multiplane classroom kit in the classroom by the visually impaired student.

Source: produced by the authors.

We have observed that the light and inefficient teacher training that teaches Mathematics does not take care of attending all students, especially those with atypical development (Moreira, 2014, 2015, 2016a, 2016b). Thus, ideas related to exclusion reinforce stereotypes and attitudes by reference to a homogeneous "standard student", participant in a heterogeneous classroom:

As a result, many teachers entering the profession with these stereotyped views take quite some time to undo them. Others never exceed them, carrying out a practice that ends up contributing to the production of the huge contingent of those excluded from and in school (Freitas, 2006, p. 170).

Finally, it should be said that the history of teachers who seek to improve the teaching and learning of students with disabilities is directly influenced by the teaching profession, because these teachers, in a brutal effort to internalize knowledge, skills, beliefs and values that structure and shape their personalities, make relations with the other more equanimous from the point of view of acceptance and experiences of the practices themselves (Tardif, 2010).

Final considerations

The present paper aimed at sharing an experience of the use of activities based on tactile resources, as a teaching-learning strategy in case of visual impairment, developed to support classes of Linear Algebra and Analytical Geometry, discussing the inclusion / mathematic dyad. Moreover, we demonstrate the contributions that the use of didactic resources has in the teaching and learning process of mathematics for students with SEN, especially for those with visual impairment and / or blindness.

In addition to presenting different materials constructed by ourselves, we have evoked different researchers who have been working with issues related to inclusion in mathematics classes, which has allowed a rich and possible debate in the face of the difficulties found in schools and colleges (Camargo, 2010; Coimbra, 2003; Correia, 2008; Freitas, 2006; Mantoan, 1997; Moreira, 2014, 2015, 2016a, 2016b; Xavier, 2018).

Allied to these questions, we have brought information related to the use of assistive technologies in Mathematics classes, which were also discussed, being anchored in renowned researchers who affirm that these technologies can contribute significantly to the improvement of the teaching and learning process of Mathematics, besides the indispensability of its use when working with apprentices with visual impairment, as is the case (Conte, Ourique & Basegio, 2007; Fontes, Cardoso & Ramos, 2012; Kensk, 2015; Maravalhas & Bastos, 2015; Sartoretto & Bersch, 2018).

Fortunately, it is well known that classes in Linear Algebra and Analytical Geometry rely on visual resources such as graphical representations and geometric methods developed on the Cartesian plane. This approach is widely used and generally delivers good results to students. However, traditional methodologies may not be appropriate in cases of visual impairment, requiring approaches that provide an inclusive education, as signaled by us.

From the outcomes reported in this paper, it can be concluded that the usage of touch-and-go by means of the tactile resources built by professors, as well as using the commercial multiplane classroom kit, represents a promising approach as a learning strategy in cases of visual impairment.

It is obvious to us that “[...] the research in Brazil is past the time when it proclaimed only in general: “We have to generate a reflective teacher”, giving a great leap “to a stage in which already presents more elaborate discussions that are at the same time the fruit and seed of new questions” about the new knowledge necessary to the teachers who teach Mathematics (Borba, 2006, p. 13).

According to the visually impaired student, there was ease of handling tactile resources, considerable gain in understanding the theoretical subjects and of cases analyzed in classroom. In the perception of professor, the concrete experimentation by using the touch-and-go strategy provided satisfactory support for approaching the course contents of Linear Algebra and Analytic Geometry. Therefore, the authors recommend the use of this approach for similar cases.

Acknowledgment

The authors thank the whole team of the Faculdade de Engenharia de Sorocaba, for the broad support in the developing of the approach herein described. They also thank the Universidade de Brasília – UnB and to Fundação de Apoio à Pesquisa do Distrito Federal – FAPDF, for the support and encouragement of the Research Project “Teacher training of Mathematics in the Field Education Perspective: teacher training and practice, specific Mathematics didactics and follow-up of student learning”
