#### Abstract

\title{ SECTION I: THERMODYNAMIC PROPERTIES OF HYDROCARBON RADICALS, PEROXY HYDROCARBON AND PEROXY CHLOROHYDROCARBON MOLECULES AND RADICALS }

\title{ SECTION II: KINETICS AND REACTION MECHANISMS FOR: <br> (1) CHLOROFORM PYROLYSIS AND OXIDATION <br> (2) BENZENE AND TOLUENE OXIDATION UNDER ATMOSPHERIC CONDITIONS }

by<br>Tsan-Horng Lay

Alkyl radicals are important active intermediates in gas phase photochemistry and combustion reaction systems. With the exception of a limited number of the most elementary radicals, accurate thermodynamic properties of alkyl radicals are either not available or only rough estimations exist. An H atom Bond Increment approach is developed and a data base is derived, for accurately estimating thermodynamic properties ( $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }^{\circ} 298, \mathrm{~S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ ) for generic classes of hydrocarbon radical species.

Reactions of alkyl radicals with molecular oxygen are one of the major reaction paths for these radicals in atmospheric photochemistry, oxidation of hydrocarbon liquids and combustion process. Alkyl hydroperoxides are subsequently formed through the alkyl peroxy radicals reactions with varied chemical species present in the reaction system. Thermodynamic properties of the alkyl hydroperoxides and related radicals are therefore frequently required in gas phase modeling and kinetic studies on these systems. The thermodynamic properties of alkyl hydroperoxides, alkyl peroxy radicals and
hydroperoxyl-1-ethyl radicals including the species with fluorine and chlorine substituents on the $\alpha$-carbon are evaluated using molecular orbital calculations.

Chloroform is used as a model chlorocarbon system with high $\mathrm{Cl} / \mathrm{H}$ ratio to investigate thermal decomposition processes of chlorocarbons in oxidative and pyrolytic reaction environments. A detailed reaction mechanism is developed to describe the important features of products and reagent loss and is shown to predict the experimental data well. Reaction pathways and rate constants are developed for $\mathrm{CCl}_{3}, \mathrm{CCl}_{2}$ and $\mathrm{C}_{2} \mathrm{Cl}_{3}$ radical addition to $\mathrm{O}_{2}$ and combination with $\mathrm{O}, \mathrm{OH} \mathrm{HO}_{2}$ and ClO .

The reversible addition reaction of OH radical with benzene to form the hydroxyl-2,4- cyclohexadienyl (benzene-OH) adduct and the subsequent reactions of this benzeneOH adduct with $\mathrm{O}_{2}$ are important initial steps for the photooxidation of benzene and other aromatic species in the atmosphere. OH addition to the benzene ring, the subsequent reaction of $\mathrm{O}_{2}$ with the hydroxyl-2,4-cyclohexadienyl to form hydroxyl-2-peroxy-4cyclohexenyl (benzene- $\mathrm{OH}-\mathrm{O}_{2}$ adduct), are chemical activation reactions and are a function of both pressure and temperature. The kinetics of these two reaction systems at various pressure \& temperatures using a quantum version of Rice-Ramsperger-Kassel theory (QRRK) and a modified strong collision approach are analyzed and calculated. The analogue reaction system of toluene photooxidation is also analyzed. Reaction mechanisms are developed for initial steps of atmospheric oxidation of benzene and toluene, which include reverse reaction rates determined from thermodynamic parameters and microscopic reversibility. The model results show good agreement with the limited available experimental data.

SECTION II: KINETICS AND REACTION MECHANISMS FOR:
(1) CHLOROFORM PYROLYSIS AND OXIDATION
(2) BENZENE AND TOLUENE OXIDATION UNDER ATMOSPHERIC CONDITIONS

## ACKNOWLEDGMENT

The author wishes to express his earnest gratefulness to his advisor, Dr. Joseph W Bozzelli, for his instruction, encouragement and friendship. Special appreciation to Dr. Lev N. Krasnoperov and Dr. Carol A. Venanzi for timely help and generous support. The author also thanks Dr. Barbara B. Kebbekus, Dr. Richard Trattner, Dr. Daniel J. Watts and Dr. William H. Green for serving as members of the committee and their valuable corrections

It is the author's pleasure to acknowledge his colleagues at NJIT Thermodynamics and Kinetics Research Group: Mr. Hong-Ming Chiang, Mr. Hsien-Tsung Chern, Dr. YoPing Wu, Dr. Yang Soo Won and Dr. Wen-Pin Ho who shared with me their experience and knowledge. The appreciation for friendship and assistance from current and past students in this research group cannot be exaggerated.

The author shall be endlessly grateful to his wife, Hsiu-Fen, and his parents for all they did. All of this would not have been possible without their constant support and encouragement.

## TABLE OF CONTENTS

Chapter Page
SECTION I: THERMODYNAMIC PROPERTIES OF HYDROCARBON RADICALS, PEROXY HYDROCARBON AND PEROXY CHLOROHYDROCARBON MOLECULES AND RADICALS
1 INTRODUCTION ..... 1
1.1 Thermodynamic Properties of Hydrocarbon Radicals ..... 1
1.2 Importance of Alkyl Peroxy Radicals and Alkyl Hydroperoxides in Gas Phase Kinetics ..... 2
1.3 Thermodynamic Properties of Alkyl Hydroperoxides with and without Chlorine and Fluorine Substituents ..... 4
1.4 Ab Initio Study ..... 4
1.4.1 The General Performance of Ab Initio MO Calculations at HF/6-31 G* Level of Theory ..... 5
1.4.2 Comparison of Semiempirical and Ab Initio MO Calculations ..... 6
1.5 Hindered Rotor ..... 7
1.6 Modeling Study of Chloroform Pyrolysis and Oxidation: Effects of Added $\mathrm{O}_{2}$ ..... 9
1.7 Detailed Analysis of Initial Reactions of Photochemical Oxidation of Benzene and Toluene in the Atmosphere ..... 9
2 HYDROGEN ATOM BOND INCREMENTS (HBI) FOR CALCULATION OF THERMODYNAMIC PROPERTIES OF HYDROCARBON RADICAL SPECIES ..... 12
2.1 Introduction ..... 12
2.2 Methology and Calculations ..... 16
2.2.1 Heats of Formation ..... 16
2.2.2 Entropies $\left(\mathrm{S}^{\circ}{ }_{298}\right)$ and Heat Capacities $(\mathrm{Cp}(\mathrm{T}), 300 \leq \mathrm{T} / \mathrm{K} \leq 1500)$ ..... 17

## CHAPTER 1

## INTRODUCTION

### 1.1 Thermodynamic Properties of Hydrocarbon Radicals

Alkyl radicals are important active intermediates in gas phase reaction systems. With the exception of a limited number of the most elementary radicals, however, the accurate thermodynamic properties of most alkyl radicals are not available or only rough estimations. This is because of the difficulty of using calorimetric measurements or in determining structure and spectroscopy on these unstable species. ${ }^{1}$

An H atom Bond Increment ( HBI ) approach is developed and a data base is derived in Chapter 2, for accurately estimating thermodynamic properties $\left(\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298} \mathrm{~S}^{\circ}{ }_{298}\right.$ and $\mathrm{Cp}(\mathrm{T}), 300 \leq \mathrm{T} / \mathrm{K} \leq 1000$ ) for generic classes of hydrocarbon (HC) radical species relevant to combustion, atmospheric chemistry and the general organic chemistry community. The HBI group technique is based on known thermodynamic properties of the parent molecule and calculated changes that occur upon formation of a radical via loss of a H atom. The HBI method incorporates
(i) evaluated literature bond energies,
(ii) calculated entropy and heat capacity $(\mathrm{Cp}(\mathrm{T})$ ) increments resulting from loss and change in vibration frequencies (including inversion),
(iii) increments resulting from changes in barriers and reduced moments of inertia to internal rotation, and
(iv) increment resulting from the change in spin degeneracy.

26 HBI groups are defined and the group values are calculated in this work. The HBI groups, when coupled with the thermodynamic properties of the appropriate "parent" molecules, yield accurate thermodynamic properties for the respective radicals. Corrections due to the change of translational and external rotation motions are considered only for small and light radicals where they are of significance. These HBl groups can be applied to determine accurate thermodynamic properties of any radical in the homology series.

### 1.2 Importance of Alkyl Peroxy Radicals and Alkyl Hydroperoxides in Gas Phase Kinetics

Reactions of alkyl radicals with molecular oxygen are one of the major reaction paths for these radicals in atmospheric photochemistry, oxidation of hydrocarbon liquid and in combustion process. These reactions are complex and their rates strongly depend on both pressure and temperature. An example for ethyl radical shows that, the energized adduct, ethyl peroxy $\left[\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO} \text {. }\right]^{*}$ which is initially formed from the ethyl radical adding to $\mathrm{O}_{2}$ can undergo the following pathways: ${ }^{2}$
(i) to be stabilized,
(ii) to dissociate back to ethyl $+\mathrm{O}_{2}$ reactants,
(iii) to isomerize by H atom shift to a hydroperoxyl-1-ethyl radical $\left(\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}\right)$
(iv) to isomerize by H atom shift to a hydroperoxyl-2-ethyl radical ( $\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OOH}$ ),
(v) to dissociate to ethoxy +O atom.

These pathways are often the major routes of transformation of alkyl radicals in combustion and atmospheric oxidation process. The products for ethyl radical can be summarized as following (* denotes energized complex):

$$
\begin{aligned}
\mathrm{CH}_{3} \mathrm{C} \cdot \mathrm{H}_{2}+\mathrm{O}_{2} \leftrightarrow\left[\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO} .\right]^{*} & \leftrightarrow\left[\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}\right]^{*} \rightarrow \mathrm{CH}_{3} \mathrm{CHO}+\mathrm{OH} \\
& \leftrightarrow\left[\mathrm{C}_{2} \mathrm{CH}_{2} \mathrm{OOH}\right]^{*} \rightarrow \mathrm{C}_{2} \mathrm{H}_{4}+\mathrm{HO}_{2} \\
& \rightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}+\mathrm{O} \\
\text { stabilized adduct } \downarrow & \\
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO} . &
\end{aligned}
$$

Alkyl hydroperoxides are subsequently formed through the alkyl peroxy radicals reactions with hydroperoxy radicals which are typically present in the reaction system ...4.5.6
$\mathrm{ROO}+\mathrm{HO}_{2} \Rightarrow \mathrm{ROOH}+\mathrm{O}_{2}$

Alkyl hydroperoxides can also be produced via H atom abstraction of alkyl hydroperoxy radicals from aldehydes or other hydrocarbon species (chain propagation step in the reaction mechanism): ${ }^{7}$
$\mathrm{ROO}+\mathrm{R}^{\prime} \mathrm{CHO}=\mathrm{ROOH}+\mathrm{R}^{\prime} \mathrm{C} . \mathrm{O}$
ROO. $+\mathrm{R}^{\prime} \mathrm{H} \Rightarrow \mathrm{ROOH}+\mathrm{R}^{\prime}$.,
ROO. $+\mathrm{H}_{2} \mathrm{C}=\mathrm{CHCH}_{3} \Rightarrow \mathrm{ROOH}+\mathrm{H}_{2} \mathrm{C}=\mathrm{CHC} . \mathrm{H}_{2}$ (Allylic radical)

The thermodynamic properties of the alkyl hydroperoxide and related radicals are therefore frequently required in gas phase kinetic studies. In this work the thermodynamic
properties of alkyl hydroperoxides (Chapter 3 and 4), alkyl peroxy radicals (Chapter 5) and hydroperoxyl-1-ethyl radicals (Chapter 6) including the species with fluorine (Chapter 3 ) and chlorine substitution on $\alpha$-carbon (Chapter 3-6) are studied.

### 1.3 Thermodynamic Properties of Alkyl Hydroperoxides with and without Chlorine and Fluorine Substituents

A data base of thermodynamic properties $\left(\Delta \mathrm{H}_{\mathrm{f} 298}^{\circ}, \mathrm{S}^{\circ}{ }_{298}, \mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T}), 300 \leq \mathrm{T} / \mathrm{K} \leq 1000\right)$ of gasphase one to four carbon alkyl and monochloro and monofluoro hydroperoxides is presented in Chapter 3. Enthalpies of formation are obtained by evaluation of literature data. Entropies and heat capacities for stable species are calculated using the Rigid Rotor Harmonic Oscillator ${ }^{8}$ approximation taking into account the contributions from translations, rotations, vibrations and internal rotations. Proper account is also taken for symmetry and optical isomers. Moments of inertia and fundamental frequencies are obtained using semiempirical, MNDO/PM3 ${ }^{9}$ calculations in MOPAC6.0 ${ }^{10}$ package. Barriers for internal rotations are adopted from appropriate experimental data or ab initio studies. Pitzer and Gwinn's ${ }^{11}$ approach is used to calculate the contributions of hindered rotors. Group values for thermodynamic estimations are derived and allow applications to other hydroperoxide molecules and corresponding radicals.

### 1.4 Ab Initio Study

The thermodynamic properties of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}, \mathrm{CH}_{3} \mathrm{CHClOOH}, \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}$ (in Chapter 4), $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}, \mathrm{CH}_{3} \mathrm{CHClOOH}, \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}$ (in Chapter 5) $\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}$ and $\mathrm{CH}_{3} \mathrm{C} C \mathrm{ClOOH}$ (in Chapter 6) are studied using ab initio Molecular Orbital (MO)
calculations. Conformational analysis, calculation of internal rotational barriers and vibrational frequencies are also carried out. The ab initio MO calculations are performed by means of the Gaussian92 system of programs ${ }^{12}$ using the Hartree-Fock (HF) method and second order Møller-Plesset perturbation theory (MP2) with the 6-31G* (6-31G(d)) and $6-31 \mathrm{G}^{* *}(6-31 \mathrm{G}(\mathrm{d}, \mathrm{p}))$ basis sets. ${ }^{13,14,15}$ Unrestricted HF (UHF) is used for the calculations of open shell free radicals.

Several isodesmic reactions ${ }^{16, p 271}$ are constructed for evaluation of the enthalpies of formation on the above 8 species. The "isodesmic reactions" are defined as "transformations in which the numbers of bonds of each formal type are conserved and only the relationships among the bonds are altered". ${ }^{16 . p 298}$ All species involved in isodesmic reactions are calculated at the same level of theory. The use of isodesmic reactions for the calculation of reaction energies has been demonstrated by Hehre et al. ${ }^{16 . p 298-508}$ as a generally accurate method. Thus determined reaction energies are combined with the known enthalpies of formation (experimentally determined) of species in reactions to obtain the unknown enthalpies of formation for the desired species.

### 1.4.1 The General Performance of $A b$ Initio MO Calculations at HF/6-31G* Level of Theory

The performance of $a b$ initio MO calculations using the Gaussian system of programs is studied by Hehre et al. ${ }^{16, p 133-341}$ The mean absolute bond lengths deviation from experiment is $0.014 \AA$ for one-heavy-atom hydrides $\left(\mathrm{AH}_{n} \text { type molecules }\right)^{16, \mathrm{p} 142}$ at $\mathrm{HF} / 6$ $31 \mathrm{G}^{*}$ level. The mean absolute error in bond lengths of single bonds between heavy atoms in two-heavy-atom hydrides $\left(\mathrm{AH}_{\mathrm{n}}-\mathrm{BH}_{\mathrm{m}}\right.$ type molecules) is $0.030 \AA$ for 30 comparisons.

16,p164
It is also found that single bonds involving second-row elements are well described using the $\mathrm{HF} / 6-31 \mathrm{G}^{*}$ basis set and electron correlation effects are less significant in influencing the structures of these second-row systems than they are for the analogous first-row compounds. ${ }^{16, p^{154}}$ The mean absolute errors in calculated vs experimental bond lengths between heavy atoms are $0.023 \AA$ for larger molecules than $\mathrm{AH}_{n}-\mathrm{BH}_{\mathrm{m}} .{ }^{16 . \mathrm{p} 165}$

The mean absolute percentage deviation from directly measured (anharmonic) values of the Hartree-Fock vibrational frequencies at the $\mathrm{HF} / 6-31 \mathrm{G}^{*}$ level is $13.9 \%$. When experimental anharmonic frequencies are corrected with harmonicity, the magnitude of the error is reduced to $9-11 \%$. ${ }^{16 . p 260}$

It is also found ${ }^{16 . p^{26.3}}$ that the rotational barriers calculated using $6-31 \mathrm{G}^{*}$ basis set reproduce observed trends in the methyl-group rotation barrier height reasonably well $\left(\mathrm{CH}_{3} \mathrm{CH}_{3}>\mathrm{CH}_{3} \mathrm{NH}_{2}>\mathrm{CH}_{3} \mathrm{OH}\right)$. For hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$, the calculated trans barrier ( $0.9 \mathrm{kcal} / \mathrm{mol}$ ) and cis barrier ( $9.2 \mathrm{kcal} / \mathrm{mol}$ ) using the $6-31 \mathrm{G}^{*}$ level are reasonably close to experimental values $\left(1.1 \mathrm{kcal} / \mathrm{mol}\right.$ and $7.0 \mathrm{kcal} / \mathrm{mol}$, respectively) ${ }^{16 . \mathrm{p} 265}$

### 1.4.2 Comparison of Semiempirical and Ab Initio MO Calculations

The general performance of semiempirical MO calculations for the molecules calculated in this work is also of interest since the two methods, MNDO/AM1 $1{ }^{17}$ or $\mathrm{PM} 3{ }^{28}$ are often used for calculations on large molecules, where ab initio calculations are not feasible.

The MNDO ${ }^{17}$ method with standard AM1 and PM3 parameters in the MOPAC6.0 $0^{10}$ package is used to perform the semiempirical MO calculations. The equilibrium molecular geometries are calculated using AM1 and PM3, and the results are
compared to those obtained by ab initio studies at the (U)HF/6-31G* level of theory. Harmonic vibrational frequencies are also calculated using AM1 and PM3 and compared to the Hartree-Fock frequencies. The keyword "PRECISE" is used to set up a more strict criteria of $10^{-8}$ for the self-consistent-field (SCF) convergence in the geometry optimization process.

### 1.5 Hindered Rotor

One of the most uncertain aspects in calculating thermodynamic functions is the method for calculating the contribution of hindered internal rotations. Pitzer and Gwinn's method and tables ${ }^{11}$ are widely used to calculate this contribution of hindered internal rotors to free energy, entropy and heat capacity of a molecule. However, Pitzer and Gwinn's approach is applicable only for a sinusoidal hindered potential (uniform barrier). In most cases the calculated potential for internal rotations actually cannot be represented by the single sine or cosine function. Here it is found that the use of Pitzer and Gwinn's tables lead to significant errors in internal rotor contributions to the thermodynamic functions (see Chapter 4,5,6).

A technique for calculation of thermodynamic functions from hindered rotations with arbitrary potentials therefore has been developed. ${ }^{18}$ This technique employs expansion of the hindrance potential in Fourier series, calculation of the Hamiltonian matrix in the basis of free rotation wave functions and subsequent calculation of energy levels by direct diagonalization of the Hamiltonian matrix.

The following form of the Fourier series is often used for conventional representation of the dependence of hindered potential on torsional angle: ${ }^{19.20 .21}$
$V(\phi)=1 / 2 V_{1}(1-\cos \phi)+1 / 2 V_{2}(1-\cos 2 \phi)+1 / 2 V_{3}(1-\cos 3 \phi)+1 / 2 V^{\prime}{ }_{1} \sin \phi+1 / 2 V^{\prime}{ }_{2} \sin 2 \phi$

In this work the torsional potential calculated at a discreet torsional angle is fitted by a truncated Fourier series in the following:

$$
\begin{equation*}
V(\phi)=a_{0}+a_{1} \cos \phi+a_{2} \cos 2 \phi+a_{3} \cos 3 \phi+b_{1} \sin \phi+b_{2} \sin 2 \phi \tag{E2}
\end{equation*}
$$

The matrix elements of individual sine and cosine terms in the basis of free rotor wave functions have a simple appearance. The terms $\sin (m \phi)$ and $\cos (m \phi)$ induce transitions with $\Delta \mathrm{K}= \pm \mathrm{m}$, where K is the rotational quantum number. Moreover, the matrix element does not depend on K , which leads to a simple form of the Hamiltonian matrix. The matrix has a band structure and consists of diagonal terms that are equal to those of the free rotor and subdiagonales of constant values that correspond to a different terms in the potential expansion, (E2).

The Hamiltonian matrix can therefore be truncated to the size of $2 \mathrm{~K}_{\text {max }}+1$, where $\mathrm{K}_{\text {max }}$ is the maximum rotational quantum number. The truncated matrix (in reduced dimensionless form) is diagonalized, and calculated eigenvalues are used to calculate partition function, entropy, heat capacity, etc., using direct summation over the calculated
energy levels. This description briefly outlines the procedure used. A detailed description with examples and comparisons will be published by Krasnoperov, Lay and Shokhirev. is

### 1.6 Modeling Study of Chloroform Pyrolysis and Oxidation

Chloroform is used by Won ${ }^{22}$ as a model chlorocarbon system with high $\mathrm{Cl} / \mathrm{H}$ ratio to investigate thermal decomposition processes of chlorocarbons over oxidative and pyrolytic reaction environments. The reactions are studied in tubular flow reactors at a pressure of 1 atm with residence times of $0.3-2.0$ seconds in the temperature range $535-800{ }^{\circ} \mathrm{C}$ Chloroform decay and product distributions are distinctly different in the absence and presence of added $\mathrm{O}_{2}$. Increases in $\mathrm{O}_{2}$ are observed to speed chloroform loss and increase $\mathrm{CCl}_{4}$ and CO production, while decreasing $\mathrm{C}_{2} \mathrm{Cl}_{4}$. In $\mathrm{CHCl}_{3} / \mathrm{O}_{2}$, the products are $\mathrm{C}_{2} \mathrm{Cl}_{4}$. $\mathrm{HCl}, \mathrm{CCl}_{4}, \mathrm{C}_{2} \mathrm{HCl}_{5}, \mathrm{C}_{2} \mathrm{HCl}_{3}, \mathrm{CO}$ and $\mathrm{CO}_{2}$ over a wide temperature range. A detailed reaction mechanism to describe the important features of products and reagent loss is developed. Reaction pathways and rate constants are developed for $\mathrm{CCl}_{3}, \mathrm{CCl}_{2}$ and $\mathrm{C}_{2} \mathrm{Cl}_{3}$ radical addition to $\mathrm{O}_{2}$ and chlorocarbon radical combination with $\mathrm{O}, \mathrm{OH} \mathrm{HO}_{2}$ and ClO

### 1.7 Detailed Analysis of Initial Reactions of Photochemical Oxidation of Benzene and Toluene in the Atmosphere

The reversible addition reaction of OH radical with benzene to form the hydroxyl-2,4cyclohexadienyl (benzene-OH) adduct and the subsequent reactions of this benzene-OH adduct with $\mathrm{O}_{2}$ are important initial steps for the photooxidation of benzene and all other aromatics in the atmosphere (see references in Chapter 8). The OH addition to benzene ring, the subsequent reaction of $\mathrm{O}_{2}$ with the hydroxyl-2,4-cyclohexadienyl to form
hydroxyl-2-peroxy-4-cyclohexenyl (benzene- $\mathrm{OH}-\mathrm{O}_{2}$ adduct), are chemical activation reactions and are a function of both pressure and temperature. The atmospheric oxidation process for the aromatic ring in toluene is analogous to the reactions of benzene in many ways. The kinetics of these two reaction systems at various pressure \& temperature using a quantum version of Rice-Ramsperger-Kassel theory (QRRK) and a modified strong collision approach are analyzed and calculated in Chapter 8 . The analogue reaction system of toluene photooxidation is also analyzed.

Potential energy diagrams of the reactions and thermodynamic properties $\left(\mathrm{H}_{1}{ }^{\circ}\right.$ 298. $\mathrm{S}^{\circ}{ }_{298}$ and $\left.\mathrm{Cp}(\mathrm{T})^{\prime} \mathrm{s}\right)$ of reactants, intermediates and products are calculated. Group Additivity (GA) techniques are used to calculate thermodynamic properties of stable molecules. When GA method is not adequate, the semiempirical Molecular Orbital (MO) calculation, MNDO/PM3 is used to derive the required Group values for specific species like the bicyclic benzene- $\mathrm{OH}-\mathrm{O}_{2}$ adducts. Several Hydrogen Atom Bond Increment groups $(\mathrm{HBI})$ are introduced to allow calculations of the thermodynamic properties for the relevant free radical intermediates.

Rate constants for elementary reaction steps are determined from literature values or estimated from Transition State Theory and principles of thermochemical kinetics. Apparent rate constants are calculated for conditions of atmospheric oxidation as well as other temperature and pressure regimes. Two short reaction mechanisms are developed for initial steps of atmospheric oxidation of benzene and toluene, which include reverse reaction rates determined from thermodynamic parameters and microscopic reversibility. The results for atmospheric conditions are compared with available experimental data.

Calculated kinetic and mechanistic data in this study can be used in modeling of photochemical oxidation of combustion and aromatic compounds in atmosphere. Results show that calculation and consideration of equilibrium levels of benzene- OH and benzene-$\mathrm{OH}-\mathrm{O}_{2}$ adducts (or toluene- OH and toluene- $\mathrm{OH}-\mathrm{O}_{2}$ adducts), and other active species in the systems are important in the determining conversion of the aromatic species as well as nature of specific products.

## CHAPTER 2

## HYDROGEN ATOM BOND INCREMENTS (HBI) FOR CALCULATION OF THERMODYNAMIC PROPERTIES OF HYDROCARBON RADICAL SPECIES

### 2.1 Introduction

Detailed kinetic reaction models using mechanisms based upon fundamental thermodynamic and kinetic principles are presently used and being developed by researchers attempting to optimize or more fully understand a number of systems comprised of many elementary chemical reactions. These include pyrolysis, combustion ${ }^{2.23}$, ignition ${ }^{24}$, atmospheric smog formation and transport ${ }^{25.26}$, stratospheric ozone depletion, municipal and hazardous waste incineration ${ }^{27-29}$, chemical vapor deposition and semiconductor etching ${ }^{31}$, rocket propulsion, ${ }^{31}$ and other related fields. One important requirement for reliable simulation of these systems is accurate thermodynamic property data for the molecular and radical species in the chemical mechanism. This data allows determination of the thermodynamic feasibility of reaction paths, equilibrium constants ( $\mathrm{K}_{\mathrm{eq}}$ ), as well as reverse rate constants ( $\mathrm{k}_{\mathrm{r}}$ ) from the forward rate constant $\left(\mathrm{k}_{\mathrm{f}}\right)$ and $\mathrm{K}_{\mathrm{eq}}$. It also serves a vital role in estimating rate constants for endothermic reactions.

Benson's Group Additivity (GA) estimation technique is an accurate method for the estimation of ideal gas phase heat capacities, heats of formation, and entropies of stable molecules. This technique is discussed in Benson's Thermochemical Kinetics ${ }^{32}$ and other reference sources ${ }^{33,34}$. The method assumes that the properties for a chemical substance are the sum of the contributions from each group or polyvalent atom (central
atom) in that molecule. It is referred to as a second order estimation technique since next-nearest-neighbor corrections, and to some extent, chemical structure, are accounted for Estimations based upon chemical bond additivity alone are known as first order estimation techniques, while those based upon atomic contributions alone are referred to as zero order techniques. ${ }^{33}$ The second order estimates are naturally more accurate than lower order techniques; but also requires a larger data base. Several other estimation techniques based upon group contribution principles are presented in Reid, Prausnitz, and Sherwood ${ }^{33}$, and Pedley, Naylor and Kirby ${ }^{35}$ (for enthalpies only). Benson's method is the most widely accepted one because of its ease of use and relative accuracy when compared with other techniques. In addition Benson's GA approach has been programmed ${ }^{36,37}$ for use in computer codes.

Group contributions (Group Values for GA) were derived by Benson and coworkers ${ }^{11}$ and various other researchers ${ }^{34.37 .38}$ by dividing similar molecules with known thermodynamic properties into their constituent groups and then performing multivariable linear regressions to find group contributions which gave the best fit to available experimental property data. The enthalpy group values for this GA approach were comprehensively reviewed and updated by Cohen and Benson ${ }^{39}$ in 1993 to make the prediction results more consistent with current experimental data.

Benson and co-workers also derived several corresponding group values for estimating thermodynamic properties $\left(\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298,} \mathrm{~S}^{\circ}{ }_{298}\right.$ and $\left.\mathrm{Cp}(\mathrm{T})^{\prime} \mathrm{s}\right)$ for free radicals in the same manner as for stable molecules. ${ }^{11.39}$ Two classes of radical groups were derived: (i) groups for the radical-centered atoms and (ii) groups for radical-adjacent atoms Every
radical contains at least one of the two radical type groups plus the normal groups for atoms not next to radical center. The values for several radical-related groups for alkyl radicals were revised by Cohen. ${ }^{34}$

In this work, we present an alternative approach, i.e a single group, to estimate the thermodynamic properties ( $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298, \mathrm{~S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T}), 300 \leq \mathrm{T} / \mathrm{K} \leq 1500$ ) for hydrocarbon free radicals. Our method utilizes the thermodynamic properties of the parent molecules incorporated with a H -atom Bond Increment ( HBI ) for each respective property of the parent which reflects the change due to loss of an H atom. We demonstrate that HBI groups are based on fundamental principles of statistical mechanics and thermochemistry. An advantage of this approach is the straightforward modification of the group if improved molecular data are developed.

Consider the following homolytic reaction:

$$
\begin{equation*}
\mathrm{RH} \Rightarrow \mathrm{R} .+\mathrm{H}_{.}, \quad \Delta \mathrm{H}^{\circ}{ }_{\mathrm{rxn.298}}=\mathrm{D}(\mathrm{R}--\mathrm{H}) \tag{1}
\end{equation*}
$$

The radical enthalpy of formation can be written as:

$$
\begin{equation*}
\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298(\mathrm{R} .)=\mathrm{D}(\mathrm{R}--\mathrm{H})+\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298(\mathrm{RH})-52.1 \mathrm{kcal} / \mathrm{mol}, \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298(\mathrm{H} .) \tag{2}
\end{equation*}
$$

Thus one can calculate $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298(\mathrm{R}$.$) if one has a value for the bond strength for the$ bond broken to form the radial. The values of bond energies, $\mathrm{D}(\mathrm{R}-\mathrm{-H})$ in HBI data base for the corresponding radicals are adopted from evaluation of the literature.

To some extent, the molecular structure of a radical (R.) is similar to that of corresponding stable molecule ( RH ). The unpaired electron at the radical-centered atom of the free radical is replaced by an H atom in the stable molecule while the rest of the atom sequence and chemical bonds are basically the same for the two species. If all the of differences of molecular structures for R. and RH are properly taken into account, one could expect that $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ of R . can be calculated from those of corresponding RH plus the values of increments, $\Delta \mathrm{Cp}(\mathrm{T})$ and $\Delta \mathrm{S}^{\circ}{ }_{298}$ as:

$$
\begin{align*}
& \mathrm{S}_{298}^{\circ}(\mathrm{R} .)=\mathrm{S}_{298}^{\circ}(\mathrm{RH})+\Delta \mathrm{S}_{298}^{\circ}  \tag{3}\\
& \mathrm{Cp}(\mathrm{~T})(\mathrm{R} .)=\mathrm{Cp}(\mathrm{~T})(\mathrm{RH})+\Delta \mathrm{Cp}(\mathrm{~T}) \tag{4}
\end{align*}
$$

The increments of $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})(300 \leq \mathrm{T} / \mathrm{K} \leq 1500)$ are group values and termed Hydrogen atom Bond Increment (HBI) $\left(\Delta \mathrm{S}^{\circ}{ }_{298}(\mathrm{HBI})\right.$ and $\Delta \mathrm{Cp}(\mathrm{T})(\mathrm{HBI})$ ), since they are used to calculate $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's for a free radical formed from its parent molecule. The values we report for $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})$ are obtained by applying the principles of the Rigid-Rotor-Harmonic-Oscillator (RRHO) ${ }^{19}$ model to account for the differences of molecular structures between R . and the corresponding RH (parent). They may, however, also be determined from accurate literature data on the respective properties of a parent molecule and the corresponding radical when available.

The classification of HBI terms is based on the generic types of R--H bonding. In addition, a change in the potential barriers of internal rotations about C-C bond next to the
radical center are taken into account. This work considers 26 types of hydrocarbon radicals.

This analysis approach incorporates the following:

- Evaluated literature data corresponding to the bond energies, $\mathrm{D}(\mathrm{R}-\mathrm{H})$ of the specific R--H bond; e.g. primary, secondary, tertiary....etc.
- Entropy and heat capacity increments accounting for loss and for the differences in vibrational frequencies of a parent molecule losing an H atom to form the radical,
- Gain of inversion frequencies at radical centers of carbon atoms,
- Entropy and heat capacity corrections accounting for the differences of rotational barriers of internal rotors in parent and radical,
- Entropy corrections for electron spin degeneracy,
- Corrections to translational and rotational entropy for small molecules where a change in this property results from loss of the H atom,

Entropy corrections accounting for changes in symmetry are not included in the HBI group values, as they need to be considered separately for each radical and parent molecule.

### 2.2 Methology and Calculations

### 2.2.1 Heats of Formation

The calculation of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ (R.) for a specific radical species uses literature values or Group Additivity (GA) values of enthalpy for the parent molecule $\left(\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{RH})\right)$ and an evaluated bond energy ( BDE ), $\mathrm{D}(\mathrm{R}-\mathrm{H})$, for the specific H atom removed from the parent molecule to form the desired radical, see equation (2). Table 2.1 lists the BDE values.

### 2.2.2 Change in Vibrational Frequencies and Rotational Barriers

The $\mathrm{S}^{\circ}{ }_{298}$ and heat capacities $\mathrm{Cp}(\mathrm{T})$ 's of free radicals are calculated by applying HBI values ( $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})^{\prime} \mathrm{s}$ ) via the equation (3) and (4). The change in both entropy and heat capacity values, due to loss of a hydrogen atom, are selected, because $\mathrm{R}-\mathrm{H}$ bond properties are typically the most accurately known. The loss of one H atom from the parent molecule causes the daughter radical to lose 3 degrees of freedom for intramolecular motions (vibrations plus internal rotations) relative to the parent molecule ( RH ).

As an example, consider formation of $\mathrm{C}_{2} \mathrm{H}_{5}$ from $\mathrm{C}_{2} \mathrm{H}_{6}$, Figure 2.1 illustrates the calculation of $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})$ 's values. The loss of a hydrogen atom results in the loss of one C-H stretch, two $\mathrm{H}-\mathrm{C}-\mathrm{H}$ bend and one $\mathrm{H}-\mathrm{C}-\mathrm{C}$ bend. The radical center in ethyl is no longer the normal tetrahedral structure, and it becomes more flexible. The flexibility of radical center is coupled with the appearance of one low frequency ${ }^{40.41}$ in the spectrum of ethyl, corresponding to inversion of the radical center. The loss of four frequencies and the gain of one frequency are taken into account for the difference of frequencies between the ethyl and ethane.

The description of changes which occur in the loss of an H atom from ethane is still not complete. The rotational barriers about the C-C bond are very different for ethyl ${ }^{41}$ and ethane. ${ }^{42}$ The difference of rotational barriers accounts for the significant fraction of $\mathrm{HBI} \Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})$ 's contributions. The correction of spin degeneracy is added to the value of $\Delta \mathrm{S}^{\circ}{ }_{298}$.

### 2.2.3 Vibrational Frequencies

The assignment of fundamental frequencies is adopted in part from the analysis of molecular vibrational frequencies by Shimanouchi ${ }^{43}$ and other studies of hydrocarbon radical structure and spectra. These studies include ethyl, $n$-propyl, $i$-propyl and $t$-butyl by Pacansky and co-workers, ${ }^{40.44 .45}$ sec- $n$-butyl by Chen et al., ${ }^{46} \mathrm{C}_{2} \mathrm{H}\left({ }^{2} \Sigma_{-}\right)$by Kiefer et al. ${ }^{47}$ All of the vibrational frequencies needed in this study are unfortunately not all available. We therefore performed MNDO/PM3 ${ }^{9}$ Molecular Orbital (MO) calculations using the MOPAC $6.0^{10}$ program to obtain vibrational frequencies via normal mode analysis of nuclear coordinates for model radicals on which the information is sparse, e.g. $\mathrm{CH}_{2}=\mathrm{C} . \mathrm{H}$, $\mathrm{CH}_{2}=\mathrm{C} . \mathrm{CH}_{3}$ and $\mathrm{CH}_{2}=\mathrm{C}=\mathrm{C} . \mathrm{H}$. The vibrational frequencies of several stable molecules and free radicals are listed in Table 2.2. These data help determine the differences and similarities for vibrations between a radical species and the parent molecule.

A data base of fundamental frequencies is assembled for relevant vibrational modes in Table 2.3. The harmonic vibration frequencies for bond stretching and bond bending motions assigned and listed in Table 2.3 originate from Benson (Table A.13. in ref. 11). Most assignments adopt an average value of characteristic frequencies identified in previous studies ${ }^{11,43}$ representing the standard stretching or bending motions. For the PM3 vibrational frequencies we use the animation analysis in the Hyperchem package ${ }^{48}$ for assistance in the assignment of the approximate type of mode. This is helpful for frequencies of hydrocarbon radicals not well characterized in the literature Vibrations with low wavenumber, e.g. $\leq 1000 \mathrm{~cm}^{-1}$, have a larger contribution to the values of $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})(300 \leq \mathrm{T} / \mathrm{K} \leq 1500)$ than high frequency vibrations. Cohen also points out that
the low-frequency out-of-plane methylene bend $\left(541 \mathrm{~cm}^{-1}\right)$ in the ethyl radical $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)$ and ( $530 \mathrm{~cm}^{-1}$ ) in n-propyl ( $\mathrm{C} . \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ ) are very important in determining the values of $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})$ 's for these two radicals. ${ }^{34} \mathrm{We}$ assign an inversion mode of $550 \mathrm{~cm}^{-1}$ to this low-frequency vibration. We also assign inversion modes for C-C.H-C ( $420 \mathrm{~cm}^{-1}$ ) and C.-(C) $3\left(200 \mathrm{~cm}^{-1}\right)$ based on the spectra data determined by Pacansky and co-workers for isopropyl radical ${ }^{44}$ and for tert-butyl radical. ${ }^{45}$

### 2.2.4 Hindered Internal Rotations

Barriers to hindered internal rotation adjacent to a radical center are another very important contribution factor to $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})$ in the term values. The rotational barrier about the $\mathrm{C}-\mathrm{C}$ bond in the ethyl radical, $\mathrm{C} . \mathrm{H}_{2}-\mathrm{CH}_{3}$, has a upper limit $0.1 \mathrm{kcal} / \mathrm{mol}^{34}$ while that in ethane is $2.9 \mathrm{kcal} / \mathrm{mol} .{ }^{42}$ The barriers of hindered internal rotations for stable molecules and free radicals considered in this work are listed in Table 2.4. The majority of data on rotational barriers in Table 2.4 are results of experimental determinations or ab initio quantum mechanical calculations. When literature data are not available, the barriers are assigned by interpolation of the values from similar, studied internal rotor systems. The method and tables of Pitzer and Gwinn ${ }^{11}$ were then used to calculate the contribution of hindered internal rotations to the thermodynamic functions.

### 2.2.5 Spin Degeneracy and Symmetry

All free radicals estimated in this approach are considered to have only one unpaired electron (doublet) and assumed spin degeneracy equal to $2(\mathbf{S}=2)$. The occupied orbitals of
stable molecules in their ground state generally have paired electrons ( $\mathbf{S}=1$ ). The correction factor for spin degeneracy in the entropy increment is, therefore, $\mathrm{R} \ln 2$ ( R is Ideal Gas Constant) which has been added into all group values of $\Delta S^{\circ}{ }_{298}$.

Entropy corrections accounting for changes in symmetry are not included in the HBI group values, as they need to be considered separately for each radical and parent molecule. The symmetry is not included in the values of $\Delta S^{\circ}{ }_{298}(\mathrm{HBI})$, therefore the calculation of $\mathrm{S}^{\circ}{ }_{298}$ for radicals is :

$$
\begin{equation*}
\mathrm{S}^{\circ}{ }_{298}(\mathrm{R} .)=\mathrm{S}^{\circ}{ }_{298}(\mathrm{RH})+\Delta \mathrm{S}^{\circ}{ }_{298}(\mathrm{HBI})-\mathrm{R}^{*} \ln \left(\sigma_{\text {radical }} / \sigma_{\text {parent }}\right) \tag{5}
\end{equation*}
$$

where $\sigma_{\text {radical }}$ and $\sigma_{\text {parent }}$ are the symmetry number for radical and the corresponding parent molecule, respectively.

No further correction is required for the calculation of $\mathrm{Cp}(\mathrm{T})$ using HBI term values:

$$
\begin{equation*}
\mathrm{Cp}(\mathrm{~T})(\mathrm{R} .)=\mathrm{Cp}(\mathrm{~T})(\mathrm{RH})+\Delta \mathrm{Cp}(\mathrm{~T})(\mathrm{HBI}) \tag{6}
\end{equation*}
$$

### 2.3 Calculation Details in Determining the Values of $\Delta S^{\circ}{ }_{298}(\mathrm{HBI})$ and $\Delta \mathrm{Cp}(\mathrm{T})(\mathrm{HB} \mathbf{I})$

The values of $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})^{\prime} \mathrm{s}$ that result from changes in the vibration frequencies and internal rotation barriers between a radical and its parent are presented in Table 2.5 for each HBI group. Contributions to $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})$ 's are listed for each vibrational frequency and internal rotor, in addition to the sum of the respective contributions.

Assignment of frequencies lost and gained, and adjustment in potential barriers of internal rotation for the $\mathrm{HBI} \Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})$ 's are discussed below.

### 2.3.1 Primary Alkyl Radicals (CCJ, RCCJ, ISOBUTYL and NEOPENTYL)

These four groups are all for primary alkyl radicals, $\mathrm{C}(\mathrm{C})_{x} \mathrm{H}_{3-x}-\mathrm{C} . \mathrm{H}_{2}$. The difference between the four groups is the number of substituted alkyl groups on the $\alpha$-carbon (carbon next to the radical center), i.e no alkyl substitution on $C C J$, one for RCCJ, two for ISOBUTYL and three for NEOPENTYL. The adjustments in frequencies accounting for loss of an H atom are based on the comparison of vibrational frequencies for ethane and ethyl as illustrated in Figure 2.1 and discussed above. Frequencies lost and gained are assumed identical for all four. Rotational barriers account for the differences in the three HBI terms.

The rotational barriers of the methyl group $\left(\mathrm{C}_{-} \mathrm{CH}_{3}\right)$ vary in this series (see Table 2.4): ethane ( $2.9 \mathrm{kcal} / \mathrm{mol}$ ), propane ( $3.3 \mathrm{kcal} / \mathrm{mol}$ ), isobutane ( $3.8 \mathrm{kcal} / \mathrm{mol}$ ), and neopentane ( $4.7 \mathrm{kcal} / \mathrm{mol}$ ). The barriers for methylene group ( $\mathrm{C}-\mathrm{C}_{2} \mathrm{H}_{2}$ ) are similar for ethyl ( $<0.1 \mathrm{kcal} / \mathrm{mol}$ ), $n$-propyl ( $<0.1 \mathrm{kcal} / \mathrm{mol}$ ), isobutyl ( $0.17 \mathrm{kcal} / \mathrm{mol}$ ) and neopentyl ( 0.16 $\mathrm{kcal} / \mathrm{mol}) .{ }^{34}$ This difference in rotational barriers of methyl group $\left(\mathrm{C}-\mathrm{CH}_{3}\right)$ in the parent molecules is the primary reason that one needs four HBI terms to account for all types of primary alkyl radicals.

### 2.3.2 Secondary Alkyl Radicals (CCJC, RCC.JC and RCCJCC)

The adjustments in frequencies are based on analysis of fundamental vibrations for n propane and isopropyl (see Table 2.2). One C-H stretch, one $\mathrm{H}-\mathrm{C}-\mathrm{H}$ bend and two $\mathrm{H}-\mathrm{C}-\mathrm{C}$ bends are lost from $\mathrm{C}-\mathrm{CH}_{2}-\mathrm{C}$ to $\mathrm{C}-\mathrm{C} . \mathrm{H}-\mathrm{C}$. The $\mathrm{H}-\mathrm{C}-\mathrm{C}$ bend in methylene group is assigned a higher wavenumber ( $1150 \mathrm{~cm}^{-1}$ ) than that in the methyl group $\left(850 \mathrm{~cm}^{-1}\right)$ based on the experimental observations, ${ }^{43}$ see Table 2.3. Gain of the frequency associated with inversion of the radical center (C-C.H-C) which was determined as $420 \mathrm{~cm}^{-1}$ is included

The barriers for C.-C bond rotations in secondary alkyl radicals (R-C.H-R') have very different values, $0.7 \mathrm{kcal} / \mathrm{mol}$ for the isopropyl radical $\mathrm{CH}_{3}-\left(\mathrm{C}^{2} \mathrm{HCH}_{3}\right)$, (or 051 $\mathrm{kcal} / \mathrm{mol}$ for $\left.\mathrm{CH}_{3}-\mathrm{C} . \mathrm{HCH}_{2} \mathrm{CH}_{3}\right)$, and $2.16 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{CH}_{3} \mathrm{C} . \mathrm{H}_{-\mathrm{CH}_{2} \mathrm{CH}_{3} \text {, see Table } 2.4}$ and references therein. The methyl group is nearly a free rotor about the $\mathrm{CH} 3-(\mathrm{C} . \mathrm{HC})$ bond, while the ethyl group in the iso-butyl radical has a significant rotational barrier. The rotational barrier of the ethyl group is only about $1 \mathrm{kcal} / \mathrm{mol}$ lower than that in the parent molecule. Three secondary HBI terms are needed to account for all types of secondary alkyl radicals

### 2.3.4 Tertiary Alkyl Radicals (TERTALKYL)

Isobutane and tert-butyl are the model parent and radical for the calculation of the TERTALKYL group. The spectra for tert-butyl vibrational frequencies were reported by Pacansky et al., ${ }^{45}$ while the assignment of vibrational frequencies for tert-butane are studied in this work by means of PM3 MO calculations. One C-H stretch and three H-C-C bends are lost from $(\mathrm{C})_{3} \mathrm{CH}$ to $(\mathrm{C})_{3} \mathrm{C}$., and one frequency, inversion of radical center, ( 200
$\mathrm{cm}^{-1}$ ) is gained. In addition the frequencies for CCC symmetric and asymmetric bending are very different for tert-butane and the tert-butyl radical. The rotational barrier of methyl rotors in tert-butane is $4.7 \mathrm{kcal} / \mathrm{mol}$ while that in the tert-butyl radical is only $1.5 \mathrm{kcal} / \mathrm{mol}$.

### 2.3.5 Acetylenic Radicals ( $C \equiv C J$ )

$\mathrm{C}_{2} \mathrm{H}_{2}$ and $\mathrm{C}_{2} \mathrm{H}\left({ }^{2} \Sigma^{+}\right)$are the model parent and radical. The vibrational frequencies for $\mathrm{C}_{2} \mathrm{H}$ $\left({ }^{2} \Sigma^{+}\right)$were determined by Kiefer at al., ${ }^{47}$ while the assignment of frequencies for $\mathrm{C}_{2} \mathrm{H}_{2}$ is taken form Schimonouchi. ${ }^{43}$ The $\mathrm{H}-\mathrm{C} \equiv \mathrm{C}$ bending frequency substantially shifts from 420 $\mathrm{cm}^{-1}$ in $\mathrm{C}_{2} \mathrm{H}_{2}$ to $310 \mathrm{~cm}^{-1}$ in $\mathrm{C}_{2} \mathrm{H}$.

### 2.3.6 Vinyl Radicals (VIN)

The model parent and radical are $\mathrm{CH}_{2}=\mathrm{CH}_{2}$ and $\mathrm{CH}_{2}=\mathrm{C} . \mathrm{H}$. The vibrational frequencies of $\mathrm{C}_{2} \mathrm{H}_{3}$ were determined by an ab initio MO study. ${ }^{49}$ Like the case of $\mathrm{C}_{2} \mathrm{H}_{2}$ and $\mathrm{C}_{2} \mathrm{H}$, the frequency of the $\mathrm{H}-\mathrm{C}=\mathrm{C}$ bend significantly shifts from $1050 \mathrm{~cm}^{-1}$ in $\mathrm{C}_{2} \mathrm{H}_{4}{ }^{43}$ to $785 \mathrm{~cm}^{-1}$ in $\mathrm{C}_{2} \mathrm{H}_{3}{ }^{49}$

### 2.3.7 Allenic Radicals ( $C=C=C J$ )

This group is very different from VIN. The value of $\mathrm{D}\left(\mathrm{CH}_{2} \mathrm{CC}(\mathrm{H})-\mathrm{H}\right)$ was determined to be $89 \mathrm{kcal} / \mathrm{mol},{ }^{51}$ which is different from the bond energy of $\mathrm{C}-\mathrm{H}$ bond in $\mathrm{C}_{2} \mathrm{H}_{4}(1112$ $\mathrm{kcal} / \mathrm{mol}){ }^{35}$ The $\mathrm{H}-\mathrm{C}=\mathrm{C}$ bending frequency in allene ${ }^{43}$ is $840 \mathrm{~cm}^{-1}$ while in ethylene it is $1050 \mathrm{~cm}^{-1} .{ }^{43}$

### 2.3.8 Secondary Vinyl Radicals (VINS)

The group is for vinyl radicals with a alkyl group substituted at the radical carbon (secondary vinyl). 1-Propene and $\mathrm{CH}_{2}=\mathrm{C} \cdot \mathrm{CH}_{3}$ are the model parent and radical. The bond energy $\mathrm{D}\left(\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right)--\mathrm{H}\right)$ is evaluated from $\mathrm{D}\left(\mathrm{CH}_{2} \mathrm{C}(\mathrm{H})-\mathrm{H}\right)$ plus the difference between $\mathrm{D}\left(\mathrm{CH}_{3} \mathrm{C}\left(\mathrm{H}_{2}\right)-\mathrm{-H}\right)$ and $\mathrm{D}\left(\mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CH}_{3}\right)-\mathrm{H}, 111.2+(98.45-101.1)=108.6 \mathrm{kcal} / \mathrm{mol}\right.$, see Table 2.1.

The vibrational frequencies for $\mathrm{CH}_{2}=\mathrm{C} . \mathrm{CH}_{3}$ are calculated in this study by PM3 as given in Table 2.2. The frequency of the $\mathrm{C}=\mathrm{C}-\mathrm{C}$ bend is found to shift from $420 \mathrm{~cm}^{-1}$ in the parent to $310 \mathrm{~cm}^{-1}$ in the radical. The internal rotation of the methyl group in 1 propene is a three-fold rotation, with a moderate barrier height, $2.1 \mathrm{kcal} / \mathrm{mol},{ }^{52}$ which is assumed to be identical for the secondary vinyl radical, $\mathrm{CH}_{2}=\mathrm{C} . \mathrm{CH}_{3}$

### 2.3.9 Primary Allyl Radicals (ALLYL_P)

1-Propene and allyl are the model parent and radical. Like the case of $C C J$ group, one CH stretch, two $\mathrm{H}-\mathrm{C}-\mathrm{H}$ bends and one $\mathrm{H}-\mathrm{C}-\mathrm{C}$ bend are lost from $\mathrm{C}-\mathrm{CH} 3$ to $\mathrm{C}-\mathrm{C} . \mathrm{H} 2$. In addition the frequencies of $\mathrm{C}-\mathrm{C}\left(1000 \mathrm{~cm}^{-1}\right)$ and $\mathrm{C}=\mathrm{C}$ stretch $\left(1650 \mathrm{~cm}^{-1}\right)$ in 1-propene are both shifted to an intermediate value ( $1350 \mathrm{~cm}^{-1}$ ) for C.-C (one and half bond) stretch in allyl. The H-C-H wag of the vinyl group of 1 -propene ( $950 \mathrm{am}^{-1}$ ) is also different from that in allyl $\left(500 \mathrm{~cm}^{-1}\right.$, termed as H-A-H wag), see Table 2.3 and Table 2.5. Another important change from the parent to the radical is the lose of methyl rotor and gain of one H-A-H wag.

### 2.3.10 Secondary Allyl Radicals (ALLYL_S)

1-Butene and $\mathrm{CH}_{2}=\mathrm{CHC} . \mathrm{HCH}_{3}$ are the model parent and radical. Similar to CCJC , one C H stretch, one $\mathrm{H}-\mathrm{C}-\mathrm{H}$ bend and two $\mathrm{H}-\mathrm{C}-\mathrm{C}$ bends are lost from $\mathrm{C}-\mathrm{CH}_{2}-\mathrm{C}$ to $\mathrm{C}-\mathrm{C} . \mathrm{H}-\mathrm{C}$. The frequencies of the $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}=\mathrm{C}$ stretch in the parent are shifted to an intermediate value for $\mathrm{C} .-\mathrm{C}$ stretch in the radical, analogous to $A L L Y L_{-} P$. The most important change, however, is about the internal rotations. The ethyl group rotation in l-butene is replaced by the torsion motion about the C-.C 1.5 order bond (termed as H-A-C, see Table 2.3) in the radical. The barrier height of the methyl group changes from $3.3 \mathrm{kcal} / \mathrm{mol}$ in 1 -butene to $2.1 \mathrm{kcal} / \mathrm{mol}$ in $\left(\mathrm{CH}_{2}=\mathrm{CHC} . \mathrm{H}\right)-\mathrm{CH}_{3}$ which is estimated from that of 1-propene

### 2.3.11 Tertiary Allyl Radicals (ALLYL_T)

3-Methyl-1-butene and $\mathrm{CH}_{2}=\mathrm{CHC} .\left(\mathrm{CH}_{3}\right)_{2}$ are the model parent and radical. One $\mathrm{C}-\mathrm{H}$ stretch and three $\mathrm{H}-\mathrm{C}-\mathrm{C}$ bends are lost from $(\mathrm{C})_{3}-\mathrm{CH}$ to $(\mathrm{C})_{3}-\mathrm{C}$., in addition to the shift of $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}=\mathrm{C}$ stretches to two $\mathrm{C} .-\mathrm{C}$ stretches, parallel to $A L L Y L_{-} P$ and $A L L Y L_{-} S$ The rotation iso-propyl group in the parent is replaced by the torsion motion about the $C-C$ 1.5 order bond (termed as C-A-C, see Table 2.3) in the radical. The rotational barriers of the two methyl groups change from $3.3 \mathrm{kcal} / \mathrm{mol}$ in the parent to $2.1 \mathrm{kcal} / \mathrm{mol}$ in radical as in $A L L Y L_{-} S$.

### 2.3.12 Benzyl Radicals (BENZYL_P, BENZYL_S and BENZYL_T)

BENZYL_P, BENZYL_S $\boldsymbol{S}_{-}$and $B E N Z Y L_{-} T$ are for primary, secondary and tertiary benzyl radicals with zero, one and two alkyl groups substituted at the radical carbon, respectively.

Toluene, ethylbenzene and iso-propylbenzene are the three model parents, while $\mathrm{Ph}-\mathrm{C} \mathrm{H}_{2}$. $\mathrm{Ph}-\mathrm{C} . \mathrm{HCH}_{3}$ and $\mathrm{Ph}-\mathrm{C} .\left(\mathrm{CH}_{3}\right)_{2}$ ( Ph - equal to $\mathrm{C}_{6} \mathrm{H}_{5}^{-}$) are the three model radicals, respectively. The calculations for $B E N Z Y L_{-} P, B E N Z Y L_{-} S$ and $B E N Z Y L_{-} T$ follow the $A L L Y L_{-} P, A L L Y L_{-} S$ and $A L L Y L_{-} T$. See Table 2.5 for the calculation details. The most significant difference between the $B E N Z Y L_{-} P$ and $A L L Y L_{-} P$ is that the methyl rotor on the benzene ring $\left(\mathrm{Ph}_{-}-\mathrm{CH}_{3}\right)$ is nearly a free rotor, ${ }^{11,42}$ while that in propene $\left(\left(\mathrm{CH}_{2}=\mathrm{CH}\right)\right.$ $\mathrm{CH}_{3}$ ) has a barrier as $2.1 \mathrm{kcal} / \mathrm{mol}$. ${ }^{52}$ This also holds for $\operatorname{BENZYL_{-}} S$ and $B E N Z Y L_{-} T$.

### 2.3.13 Other Radicals

$\left(C \equiv С С Ј, C \equiv С С Ј С, C \equiv С С Ј C_{2}, C=C C=C С J, C=С С Ј C=C, C J C=C \equiv C, C=С J C=C\right)$
Application of the above procedures relies on the similarity of the fundamental vibration modes and internal rotations for the respective radicals and the corresponding parents These processes based on the similarity of molecular structures are not as feasible for radicals with conjugated electronic resonance structure, like $\mathrm{C} \cdot \mathrm{H}_{2} \mathrm{CH}=\mathrm{CHCH}=\mathrm{CH}_{2}$ and $\mathrm{C} . \mathrm{H}_{2} \mathrm{CH}=\mathrm{CHC} \equiv \mathrm{CH}$. An alternative method is to obtain $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T}) \mathrm{HBI}$ values by "direct subtraction", i.e. subtracting the $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's values of the radical from the corresponding values of its parent.

The $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})$ 's values of seven HBI groups in this work are derived by this direct subtraction method:
$C \equiv C C J$,

$$
\begin{aligned}
& \Delta \mathrm{S}^{\circ}{ }_{298}\left(C \equiv C C J=\mathrm{S}^{\circ}{ }_{298}\left(\mathrm{HC} \equiv \mathrm{CCH}_{3}\right)-\mathrm{S}^{\circ}{ }_{298}\left(\mathrm{HC} \equiv \mathrm{CC} . \mathrm{H}_{2}\right),\right. \\
& \Delta \mathrm{Cp}(\mathrm{~T})(C \equiv C C J)=\mathrm{Cp}(\mathrm{~T})\left(\mathrm{HC} \equiv \mathrm{CCH}_{3}\right)-\mathrm{Cp}(\mathrm{~T})\left(\mathrm{HC} \equiv \mathrm{CC} . \mathrm{H}_{2}\right),
\end{aligned}
$$

$C \equiv C C J C$,
$\Delta \mathrm{S}^{\circ}{ }_{298} \& \Delta \mathrm{Cp}(\mathrm{T})(C \equiv C C J C)=\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{T})\left(\mathrm{HC} \equiv \mathrm{CCH}_{2} \mathrm{CH}_{3}\right)$

$$
-\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{~T})\left(\mathrm{HC} \equiv \mathrm{CC} . \mathrm{HCH}_{3}\right),
$$

$C \equiv C C J C_{2}$,

$$
\begin{aligned}
\Delta \mathrm{S}^{\circ}{ }_{298} \& \Delta \mathrm{Cp}(\mathrm{~T})\left(C \equiv C C J C_{2}\right) & =\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{~T})\left(\mathrm{HC} \equiv \mathrm{CCH}\left(\mathrm{CH}_{3}\right)_{2}\right) \\
& -\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{~T})\left(\mathrm{HC} \equiv \mathrm{CC} \cdot\left(\mathrm{CH}_{3}\right)_{2}\right),
\end{aligned}
$$

$C=C C=C C J$,
$\Delta \mathrm{S}^{\circ}{ }_{298} \& \Delta \mathrm{Cp}(\mathrm{T})(C=C C=C C J)=\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{T})\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{CHCH}=\mathrm{CHCH}_{3}\right)$

$$
-\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{~T})\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{CHCH}=\mathrm{CHC} \cdot \mathrm{H}_{2}\right)
$$

$C=C C J C=C$,
$\Delta \mathrm{S}^{\circ}{ }_{298} \& \Delta \mathrm{Cp}(\mathrm{T})(C=C C J C=C)=\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{T})\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{CHCH}_{2} \mathrm{CH}=\mathrm{CH}_{2}\right)$
$-\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{T})\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{CHC} \cdot \mathrm{H}_{2} \mathrm{CH}=\mathrm{CH}_{2}\right)$,
$C J C=C C \equiv C$,

$$
\Delta \mathrm{S}^{\circ}{ }_{298} \& \Delta \mathrm{Cp}(\mathrm{~T})(C J C=C C \equiv C)=\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{~T})\left(\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CHC} \equiv \mathrm{CH}\right)
$$

$$
-\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{~T})\left(\mathrm{C} \cdot \mathrm{H}_{2} \mathrm{CH}=\mathrm{CHC} \equiv \mathrm{CH}\right)
$$

$C=C J C=C$,
$\Delta \mathrm{S}^{\circ}{ }_{298} \& \Delta \mathrm{Cp}(\mathrm{T})(C=C J C=C)=\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{T})\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{CHCH}=\mathrm{CH}_{2}\right)$
$-\mathrm{S}^{\circ}{ }_{298} \& \mathrm{Cp}(\mathrm{T})\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{C}-\mathrm{CH}=\mathrm{CH}_{2}\right)$,

Data of $S^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})^{\prime}$ for above stable molecules and free radicals are listed in Table 2.6. $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's of stable molecules are taken from literature, or calculated in
this work using Group Additivity. ${ }^{37}$ Data for $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's of free radicals are determined in this work as follows.
$\mathrm{CH} \equiv \mathrm{CC} \cdot \mathrm{H}_{2}, \mathrm{CH} \equiv \mathrm{CC} \cdot \mathrm{HCH}_{3}$ and $\mathrm{CH} \equiv \mathrm{CC} .\left(\mathrm{CH}_{3}\right)_{2}$ have the resonance structures as $\mathrm{C} . \mathrm{H}=\mathrm{C}=\mathrm{CH}_{2}, \mathrm{C} . \mathrm{H}=\mathrm{C}=\mathrm{CHCH}_{3}$ and $\mathrm{C} . \mathrm{H}=\mathrm{C}=\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}$, respectively. We obtain their $\mathrm{S}^{\circ}{ }_{298}$ and $C p(T)$ 's by applying the approach of $C=C=C J \quad \mathrm{HBI}$ values on each parent, $\mathrm{CH}_{2}=\mathrm{C}=\mathrm{CH}_{2}, \mathrm{CH}_{2}=\mathrm{C}=\mathrm{CHCH}_{3}$ and $\mathrm{CH}_{2}=\mathrm{C}=\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}$, respectively. This series allow us to evaluate the usefulness of the HBI Group data base where only one $C=C=C J \mathrm{HBI}$ term is used to calculate the thermodynamic properties of the above three radicals. The calculated $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ values for $\mathrm{CH} \equiv \mathrm{CC} \cdot \mathrm{H}_{2}, \mathrm{CH} \equiv \mathrm{CC} \cdot \mathrm{HCH}_{3}$ and $\mathrm{CH} \equiv \mathrm{CC} .\left(\mathrm{CH}_{3}\right)_{2}$ are listed in Table 2.6.

For $\quad \mathrm{CH}_{2}=\mathrm{C} . \mathrm{CH}=\mathrm{CH}_{2}, \quad \mathrm{CH}_{2}=\mathrm{CHCH}=\mathrm{CHC} . \mathrm{H}_{2} \quad\left(\mathrm{CH}_{2}=\mathrm{CHC} . \mathrm{HCH}=\mathrm{CH}_{2}\right) \quad$ and $\mathrm{CH} \equiv \mathrm{CCH}=\mathrm{CHC} . \mathrm{H}_{2}$, we perform PM 3 MO calculations using the MOPAC 6.0 program with standard parameters to obtain their $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's values. The parameters needed to calculate thermodynamic properties for these three radicals, which includes moments of inertia for external rotation and fundamental vibration frequencies are listed in Table 2.7

### 2.4 Discussion

The HBI Groups have one simplifying advantage that only one HBI term is needed for a given generic class radical. In the normal GA scheme a radical group is needed for each radical site, in addition to the groups for each central atom adjacent to the radical center.

It is important to note that the first requirement in obtaining thermodynamic property data on radical species using the HBI Group approach is to acquire the
corresponding properties of the parents. It means the absolute accuracy of thermodynamic data for radicals using HBI Group approach also relies on the accuracy of the data for the corresponding stable molecules. The discussion of the accuracy of current thermodynamic data for the hydrocarbon (HC) compounds is beyond the scope and context of this paper. In most cases the thermodynamic data for HC stable molecule are determined by experiments or high level ab initio MO calculations which are more reliable than values for the HC free radicals. Benson's GA approach has been proven to be an very accurate alternative for thermodynamic properties of HC stable molecules. Errors in the determination of the thermodynamic properties of the corresponding free radicals using our HBI procedure resulting from the errors of parent's thermodynamic data should be minor. When the thermodynamic data of the parent molecules are not correct, equilibrium calculations for free radicals relative to the parent will not be affected, but both will be in error relative to other radicals and molecules.
$\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})(300 \leq \mathrm{T} / \mathrm{K} \leq 1500)$ values in the HBI data base are strongly affected by low frequency motions. We evaluate the frequencies of inversion at radical centers from literature data. We also rely on semiempirical MO calculations, MNDO/PM3, to obtain the fundamental vibration frequencies for the model radicals which have not been studied previously. PM3 is easily accessible, not CPU time expensive; and a number of systematic studies ${ }^{56}$ show that PM3 generally provides an acceptable match of vibrational frequencies across the entire spectrum without any empirical adjustment required The harmonic vibrational frequencies calculated by ab initio MO theory at the intermediately high level of theory, such as (U)HF/6-31G* level, however, need to be scaled by 0.89 for
use in thermodynamic calculations. ${ }^{38}$ We understand that there may exist some error in the vibrational frequencies using PM3 MO calculations, especially in the region of wavenumber lower than $1000 \mathrm{~cm}^{-1}$. But PM3 is a reasonable choice to derive the HBI values without the availability of experimental or higher level calculations. The HBI data base will be improved when more reliable data are available.

The potential barriers to internal rotation are also significant in determining the $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})$ values. For some HBI terms like TERTALKYL, the loss of high barrier ( $>3 \mathrm{kcal} / \mathrm{mol}$ ) rotors and gain of low barrier rotors accounts for major increases in $\Delta \mathrm{S}^{\circ}{ }_{298}$ and decreases in $\Delta \mathrm{Cp}(\mathrm{T})(300 \leq \mathrm{T} / \mathrm{K} \leq 1500)$.

Some assumptions included in our calculation scheme may be considered to limit its accuracy. For example, we use one frequency for the C-H stretch, and one for the H -C-H bend, where literature indicates that there are actually ranges covering several hundred $\mathrm{cm}^{-1}$ for these vibrations. C-H stretches, for example typically range from 2800 to $3200 \mathrm{~cm}^{-1}$ and H-C.H bends typically range from 1300 to $1500 \mathrm{~cm}^{-1}$. These effects on $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})(300 \leq \mathrm{T} / \mathrm{K} \leq 1500)$ are fortunately very small. Frequencies ranging from 1000 to $2000 \mathrm{~cm}^{-1}$ effect $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}_{298}$ only by $\leq 0.1 \mathrm{cal} / \mathrm{mol}$, and they effect $\Delta \mathrm{Cp}(\mathrm{T})$ less at higher temperature.

A second assumption is that we only consider a select number of changes - trying to focus on the most significant, while in actuality loss of an H atom may effect the vibrations of the entire molecule. Fortunately H is a light atom and its loss is usually accurately described by the vibrations, inversion frequencies and internal rotation changes we have included.

The objective of developing the HBI data base is to develop an accessible and fundamental approach to estimate thermodynamic properties for radicals for which data are not currently available. A comparison to data in literature with the data determined in this work is presented in Table 2.9.

A computer code THERM (Thermo Estimation for Radicals and M molecules) for IBM PC's and PC compatibles can be used to estimate this thermodynamic property data for gas phase radicals and molecules, using Benson's group additivity method. ${ }^{37}$ Thermodynamic properties are generated in NASA polynomial format for compatibility with the CHEMKIN ${ }^{53}$ reaction modeling code or the NASA equilibrium code ${ }^{54}$. In addition, thermodynamic, kinetic and equilibrium analysis are also performed by the code.

One valuable aspect of THERM is its ability to easily estimate thermodynamic properties for a wide range of organic radical species, using the HBI values presented in this work and the thermodynamic properties of the stable parent. In this paper we present an initial data base for a number of such HBI terms for hydrocarbon radicals relevant to hydrocarbon chemistry for the combustion and atmospheric modeling communities. Details on methods utilized in determining these Hydrogen atom Bond Increment and comparisons with literature data are presented for evaluation and reference. Improvements in our knowledge and understanding of vibration and inversion frequencies, internal rotation barriers, their symmetry and reduced moments, as well as bond energies can be readily implemented by substitution into the data files and recalculation.

### 2.5 Summary

We have evaluated HBI values, which when applied to the respective thermodynamic properties of a parent hydrocarbon molecule, determine the thermodynamic properties $\left(\Delta \mathrm{H}_{\mathrm{f}, 298,} \mathrm{~S}^{\circ}{ }_{298}\right.$ and $\left.\mathrm{Cp}(\mathrm{T}), 300 \leq \mathrm{T} / \mathrm{K} \leq 1500\right)$ of a radical corresponding to loss of an H atom, based on the principles of statistical mechanics. Databases on vibrational frequencies and internal rotational barriers in both stable molecules and radicals are also developed.

The Enthalpy term ( $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ ) in HBI data base is related to the bond energy (BDE) of the corresponding C-H bond for each radical groups. The Entropy term ( $\Delta \mathrm{S}^{\circ}{ }_{298}$ ) and Heat Capacity terms $(\Delta \mathrm{Cp}(\mathrm{T}))$ in HBI data base are to be added to the corresponding properties of the parent molecule, to obtain the thermodynamic properties of the radical. The corrections are included for changes in barriers of internal rotations and vibrational frequencies (including frequencies of radical center inversions). The entropy values include correction for the electron spin degeneracy, but do not include symmetry corrections in going from the parent to the radical.

### 2.6 Expressions Used in Thermodynamic Calculations

For stable molecules (without electronic degeneracy), entropy and heat capacities are calculated by:

$$
\begin{align*}
& S^{\theta}(\text { tot })=S^{\theta}(\text { trans })+S^{\theta}(\text { ext-rot })+\Sigma_{j} S_{j}^{\theta}(\text { int }- \text { rot })+\sum_{n} S_{n}^{\theta}(\text { vib })  \tag{El}\\
& C_{p}^{\theta}(\text { tot })=C_{p}^{\theta}(\text { trans })+C_{p}^{\theta}(\text { ext-rot })+\Sigma_{j} C_{p}{ }_{j}^{\theta}(\text { int-rot })+\sum_{n} C_{p}^{\theta}(\text { vib }) \tag{E2}
\end{align*}
$$

where (trans) is translation, and (ext-rot) and (int-rot) are external and internal rotation, respectively.

The molar translational and rotational components of the entropy and heat capacities are given by: ${ }^{8}$

$$
\begin{align*}
& \left.\mathrm{S}^{\theta} \text { (trans }\right)=(5 / 2) \mathrm{R}+\mathrm{R} \ln \left\{\left(2 \pi \mathrm{mkT} / \mathrm{h}^{2}\right) 3 / 2\left(\mathrm{RT} / \mathrm{p}^{\theta} \mathrm{NA}\right)\right\}  \tag{E3}\\
& \mathrm{S}^{\theta}(\text { ext-rot })=(3 / 2) \mathrm{R}+\mathrm{R} \ln \left\{\left(\pi^{1 / 2} / \sigma\right)\left(8 \pi^{2} \mathrm{kT} / \mathrm{h}^{2}\right) 3 / 2\left(\mathrm{I}_{x} \mathrm{I}_{y} \mathrm{I}_{2}\right)^{1 / 2}\right\}  \tag{E4}\\
& \left.C p^{\theta} \text { (trans }\right)=(5 / 2) \mathrm{R}  \tag{E5}\\
& \left.C p^{\theta} \text { (ext-rot) }\right)=\mathrm{R} \text { for linear molecules; }(3 / 2) \mathrm{R} \text { for non-linear molecules } \tag{E6}
\end{align*}
$$

where
m is molecular mass, T is temperature, R is ideal gas constant,
$I_{x}, I_{y}, I_{z}$ are the main moments of inertia, $\sigma$ is the symmetry number for external rotations,
$h$ is Planck's constant, $k$ is Boltzmann constant,
$\mathrm{p}^{\theta}$ is the standard pressure ( $\mathrm{p}^{\theta}=1 \mathrm{~atm}=101325 \mathrm{~Pa}$ was used in this work). The vibrational contribution of the nth frequency to the entropy and heat capacity is given by:

$$
\begin{align*}
& S_{\text {vib,n }}^{\circ}=\left(U_{\text {vib,n }}-F_{\text {vib.n }}\right) / T ; C p_{\text {vib.n }}^{o}=R u_{n}^{2} \exp \left(u_{n}\right) /\left(\exp \left(u_{n}\right)-1\right)^{2}  \tag{E7}\\
& U_{\text {vib,n }}=R T u_{n} /\left(\exp \left(u_{n}\right)-1\right)  \tag{E8}\\
& F_{\text {vib,n }}=-R T \ln Q_{\text {vib,n }}  \tag{E9}\\
& Q_{\text {vib,n }}=1 /\left(1-\exp \left(-\left(u_{n}\right)\right)\right.  \tag{E10}\\
& u_{n}=\operatorname{ch} v_{n} / k T \tag{Ell}
\end{align*}
$$

where
$v_{\mathrm{i}}$ is vibration frequency in wavenumbers $\left(\mathrm{cm}^{-1}\right), \mathrm{c}$ is speed of light.
There is no simple equation to express $\mathrm{S}^{\theta}$ (int-rot) and $\mathrm{Cp}^{\theta}$ (int-rot). These parameters are calculated using the method and tables of Pitzer and Gwinn. ${ }^{11}$

According to equation (E1) to (E6), the differences of entropy and heat capacity between parent molecule and daughter free radical are:

$$
\begin{align*}
& \delta S^{\theta}(\text { tot })=\delta S^{\theta}(\text { trans })+\delta S^{\theta}(\text { ext-rot })+\delta S^{\theta}{ }_{j}(\text { int-rot })+\delta S^{\theta}{ }_{n}(\text { vib }) \\
& +\delta S^{\theta}(\text { spin degeneracy })  \tag{E12}\\
& \delta \mathrm{Cp}^{\theta}(\text { tot })=\delta \mathrm{Cp}_{\mathrm{j}}^{\theta}(\text { int-rot })+\delta \mathrm{Cp}_{\mathrm{n}}{ }^{\theta}(\mathrm{vib}),(\delta \mathrm{Cp}(\text { trans })=\delta \mathrm{Cp}(\text { ext-rot })=0)  \tag{E13}\\
& \delta S^{\theta}(\text { trans })=(3 / 2) R \ln \{(M-1) / M\}+R \ln (\text { OI of radical })-R \ln (\text { OI of parent })  \tag{E14}\\
& \delta S^{\theta}(\text { ext-rot })=\delta\left\{\mathrm{R}\left[\ln (\text { IxIyIz })^{1 / 2}-\ln \sigma\right]\right\}  \tag{E15}\\
& \delta S^{\theta}(\text { spin degeneracy })=R \ln 2 \tag{E16}
\end{align*}
$$

where $M$ is the molecular mass of the parent molecule, OI is the number of optical isomers and the other symbols are the same as those used and defined in (E1) to (E11). $\delta S^{11}$ (trans) and $\delta \mathrm{R}^{*} \ln (\mathrm{IxIyIz})^{\prime}$ : are usually quite small and are neglected in this study. Spin degeneracy of free radicals is assumed to be equal to $2 . \delta S^{\theta}($ tot $)$ and $\delta C p^{\theta}($ tot $)$ therefore can be expressed as:

$$
\begin{align*}
& \delta S^{\theta}(\text { tot })=-\mathrm{R} \ln \left(\sigma_{\text {radical }} / \sigma_{\text {parent }}\right)+\delta S_{j}^{\theta}(\text { int-rot })+\delta S_{\mathrm{n}}^{\theta}(\text { vib })+\mathrm{R} \ln 2  \tag{E17}\\
& \left.\delta \mathrm{Cp}^{\theta}(\text { tot })=\delta \mathrm{Cp}_{\mathrm{j}}^{\theta} \text { (int-rot }\right)+\delta \mathrm{Cp}_{\mathrm{n}}^{\theta} \text { (vib) } \tag{E18}
\end{align*}
$$

$\delta S(\mathrm{HBI})$ and $\delta \mathrm{Cp}(\mathrm{HBI})$ are defined as:

$$
\delta S(\mathrm{HBI})=\delta \mathrm{S}(\text { tot })-\mathrm{R} \ln \left(\sigma_{\text {radical }} / \sigma_{\text {parent }}\right)=\delta \mathrm{S}_{\mathrm{j}}^{\ominus}(\text { (int-rot })+\delta \mathrm{S}_{\mathrm{n}}^{\theta}(\mathrm{vib})+\mathrm{R} \ln 2
$$

$$
\begin{equation*}
\delta \mathrm{Cp}(\mathrm{HBI})=\delta \mathrm{Cp}(\mathrm{tot})=\delta \mathrm{Cp}_{\mathrm{j}}^{\theta}(\text { int-rot })+\delta \mathrm{Cp}_{\mathrm{n}}{ }_{\mathrm{n}}(\mathrm{vib}) \tag{E19}
\end{equation*}
$$

## CHAPTER 3

# THERMODYNAMIC PROPERTIES OF GAS-PHASE ALKYL HYDROPEROXIDE COMPOUNDS WITH AND WITHOUT CHLORINE AND FLUORINE SUBSTITUENTS 

### 3.1 Introduction

Alkyl hydroperoxides and their corresponding alkyl and peroxy radicals are critical intermediates in combustion of hydrocarbons, in atmospheric photochemical smog formation, oxidation and degradation of liquid hydrocarbons, low temperature oxidations and internal combustion. ${ }^{57.58 .59}$

The study of standard entropy ( $\mathrm{S}^{\circ}{ }_{298}$ ) and heat capacities ( $\mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$ 's) of these species has, however, experienced little activity since the review of Shaw and Benson ${ }^{38}$ in 1970 where the generic data of $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$ 's of HOOH were available and used to derive data for all other alkyl hydroperoxides. Baldwin had reviewed the thermochemistry of peroxides in $1983{ }^{60}$ which updated some of the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ of alkyl hydroperoxicies and hydroperoxy radicals, but the $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$ 's remained identical to those estimated by Shaw and Benson.

Benson's Group Additivity (GA) approach has proven to be an useful method for the estimation of thermodynamic properties of molecules. ${ }^{32,33}$ The approach is based on the assumption that the specific thermodynamic property of a chemical substance is the sum of the contributions from each group or polyvalent atom (central type atom) in the molecule. It is referred to as a second order estimation technique since next-nearest-
neighbor corrections, and to some extent, chemical structure are accounted for. Second order estimates consider more factors and therefore are more accurate than lower order, bond and atom additivity, techniques. ${ }^{33}$ Benson's GA approach has been programmed 61 for use in computer codes and has become widely accepted due to its ease of use and relative accuracy when compared to other techniques. ${ }^{33}$

Benson's GA scheme utilized the generic thermodynamic data of HOOH , $\mathrm{CH}_{3} \mathrm{OOCH}_{3}$ and alkyl hydroxides ( ROH ) to estimate the corresponding alkyl hydroperoxides ( ROOH ). ${ }^{62}$ These values were widely used in thermodynamics and kinetics studies related to these species. ${ }^{60.63,64}$ Baldwin reported that $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ of dialkyl peroxides and alkyl hydroperoxides can be well reproduced by Benson's GA scheme and group values. ${ }^{60}$ The $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$ data estimated by Benson's GA has, however, not been verified by substantial generic data from experimental results or theoretical calculations. Group values required to estimate the thermodynamic properties of flouro and chloro hydroperoxides and vinyl hydroperoxides with or without chlorine substitutions are in addition not available at present.

In this study generic $S^{\circ}{ }_{298}$ and $\mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$ 's $(300 \leq \mathrm{T} / \mathrm{K} \leq 1000)$ of monochloro- and monofluoro- hydroperoxides, primary, secondary and tertiary alkyl hydroperoxides and vinyl hydroperoxides, with or without fluorine or chlorine substituents, were calculated using the Rigid Rotor Harmonic Oscillator method (RRHO). ${ }^{8}$ The RRHO contributions to $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$ 's adopt harmonic vibration frequencies and moments of inertia from the semiempirical quantum Molecular Orbital (MO) calculations. Specifically, the MNDO/PM3 ${ }^{9}$ method in MOPAC6. $0^{10}$ computer package. Hindered internal rotations
are treated by the approximation method of Pitzer and Gwinn ${ }^{11}$ with reduced moments of inertia and barriers derived from experimental data or high level ab initio calculations. These $S^{\circ}{ }_{298}$ and $C_{p}{ }^{\circ}(\mathrm{T})$ 's data, when combined with corresponding enthalpies of formation ( $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ ) determined by evaluation of literature data, are used to derive group values in a modified GA scheme.

### 3.2 Calculation Method

Thermodynamic properties considered in this paper are referred to a standard state of an ideal gas at 1 atm . The standard state for molecules with optical isomers is defined as an equilibrium mixture of enantiomers at the total pressure 1 atm .

### 3.2.1 Standard Enthalpy of Formation, ${\Delta H_{r}{ }^{\circ} 298}$

Literature data and the data estimated from literature results on standard enthalpies of formation ( $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }^{298}$ ) of stable molecules are listed in Table 3.1. The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ data marked by subscript "a" in Table 3.1 are adapted into the data base of this work.

Gutman and co-workers ${ }^{65,66.67}$ have studied a series of $\mathrm{R}+\mathrm{O}_{2}=\mathrm{ROO}$ reactions that include $\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CH}_{2} \mathrm{Cl}, \mathrm{CHCl}_{2}, \mathrm{CCl}_{3}, \mathrm{C}_{2} \mathrm{H}_{5}$ and $\mathrm{CH}_{3} \mathrm{CHCl}$. Boyd, S. L. et al. ${ }^{68}$ have studied theoretically the bond energy of $(\mathrm{CH} 3) \mathrm{C}-\mathrm{OO}$ and $\mathrm{CH} 2=\mathrm{CH}-\mathrm{OO}$. The bond energy of the R-OO. determined in those experiments or theoretical studies combined with the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ of corresponding alkyl radicals are used to obtain the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ of ROO . radicals (see Table 3.1). These data can serve as a primary source to obtain $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ of ROOH if the bond dissociation energy of the corresponding ROO-H bond, ( $\mathrm{D}^{\circ}(\mathrm{ROO}-\mathrm{H})$ ) can be
presumed. Some $\mathrm{D}^{\circ}(\mathrm{ROO}-\mathrm{H})$ bond energies are listed in Table 3.2 . We use $88 \mathrm{kcal} / \mathrm{mol}$ as the generic value of $\mathrm{D}^{\circ}(\mathrm{ROO}-\mathrm{H})$ in this work for all alkyl hydroperoxides with and without chlorine and fluorine substituents with one exception. This is value of 95.1 $\mathrm{kcal} / \mathrm{mol}$ reported for the bond energy of $\mathrm{D}^{\circ}\left(\mathrm{CF}_{3} \mathrm{OO}-\mathrm{H}\right)$ based on Melius's MAC/MP4 calculations ${ }^{69}$ (see Table 3.2).

### 3.2.2 Entropy ( $\mathrm{S}^{\circ}{ }_{298}$ ) and Heat Capacity ( $\mathrm{Cp}^{\circ}(\mathrm{T})$ )

While the standard enthalpies of formation of some alkyl hydroperoxides and some alkyl peroxy radicals are investigated by experiment or theoretical calculation on the MO level (see Table 3.1 and references therein), there have been no or very few measurements or reports of standard entropies and heat capacities of these species since the review of Shaw and Benson. ${ }^{38}$ In this work we calculate the generic $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$ of these alkyl hydroperoxides listed in Table 3.3 using $\mathrm{RRHO}^{8}$ which then allows calculation of the contributions of from translation, external rotation, vibrations and internal rotations of molecules. The detailed expressions used to calculate $S^{\circ}{ }_{298}$ and $\mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$ are described in the Appendix of Chapter 2.

Optimized molecular geometry and vibrational frequencies were obtained using PM3 ${ }^{9}$ in the MOPAC ${ }^{10}$ computer package. These geometries were then used to determine moments of inertia for external rotation. The Restricted Hartree-Fock (RHF) method with Self Consistent Field (SCF) Molecular Orbital (MO) treatment using the PM3 parameter set is employed for the calculations of all close shell molecules. Systematic studies ${ }^{56,70,72}$ of MNDO calculations have shown that it provides reliable molecular
structures and vibration frequencies with good overall agreement between calculated values and experimental ones. The calculated frequencies and moments of inertia are listed in Table 3.3. The torsion vibration modes were replaced by hindered internal rotors when calculating $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$. The method of Pitzer and Gwinn ${ }^{11}$ was used to calculate the contribution of hindered internal rotations to the thermodynamic functions. Data on rotation barriers listed in Table 3.4 are either results of experimental studies or estimated from available data of ab initio theoretical calculations. Results of our calculations using GAUSSIAN92 ${ }^{30}$ on the RHF/ or UHF/6-31G* level corrected by second order MøllerPlesset (MP2) perturbation theory on 6-31G** (MP2/6-31G**//HF/6-31G*) (see Chapter 4) are also included in Table 3.4. The correction of zero point vibration energies (ZPVE) by $\mathrm{HF} / 6-31 \mathrm{G}^{*}$ frequencies was included in calculating the potential barriers for internal rotations. The thermodynamic properties data calculated in this study are illustrated in Table 3.5.

### 3.2.3 Comparison of Currently Available Thermodynamic Properties with Benson's Group Additivity Scheme

Group Additivity approach assumes that the specific thermodynamic properties $\left(\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\right.$. $\mathrm{S}^{\circ}{ }_{298} \mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$ ) of a molecule can be represented by the sum of the contributions from each group which is an analogy of the polyvalent atom in the molecule together with its ligands.

For example, CH 3 CH 2 OH can be represented by:
$\mathrm{C} / \mathrm{C} / \mathrm{H} 3$ : group of the carbon bonded to 1 carbon and 3 hydrogens,
$\mathrm{C} / \mathrm{C} / \mathrm{H} 2 / \mathrm{O}$ : group of the carbon bonded to 1 carbon, 2 hydrogens and 1 oxygen,
$\mathrm{O} / \mathrm{C} / \mathrm{H}$ : group of the oxygen bonded to 1 carbon and 1 hydrogen.

Benson assumed the thermodynamic properties of alkyl hydroperoxides can be reproduced by the general GA scheme as exemplified above. ${ }^{62}$ This general GA scheme is currently used ${ }^{63.64 .2}$ to estimate the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298 . \mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$ of most alkyl hydroperoxides A comparison of thermodynamic data obtained in this work with the data obtained from Benson's GA scheme is performed and listed in Table 3.5.

An evaluation of Benson's GA scheme can be performed using the thermodynamic properties for these alkyl hydroperoxides where data are measured or calculated at a high level of theory (e.g. ab initio MO theory). First we verify the GA scheme using currently available $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ data of $\mathrm{HOOH}, \mathrm{CH}_{3} \mathrm{OOCH}_{3}$ and $\mathrm{CH}_{3} \mathrm{OOH}$ (see Table 3.1):

$$
\begin{align*}
& \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{OOCH}_{3}\right)=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\{(\mathrm{C} / \mathrm{H} 3 / \mathrm{O})+2(\mathrm{O} / \mathrm{C} / \mathrm{O})\}  \tag{Gl}\\
& \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{OOH}\right)=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\{(\mathrm{C} / \mathrm{H} 3 / \mathrm{O})+(\mathrm{O} / \mathrm{C} / \mathrm{O})+(\mathrm{O} / \mathrm{H} / \mathrm{O})\} \tag{G2}
\end{align*}
$$

Therefore, (G2) - $1 / 2 *(\mathrm{Gl})=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298(\mathrm{O} / \mathrm{H} / \mathrm{O})$. The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298(\mathrm{HOOH})$ can also be expressed as :

$$
\begin{equation*}
\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298(\mathrm{HOOH})=2 \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298(\mathrm{O} / \mathrm{H} / \mathrm{O}) \tag{G3}
\end{equation*}
$$

and thus $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{O} / \mathrm{H} / \mathrm{O})$ can also be obtained from $1 / 2 * \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298(\mathrm{HOOH})$.
According to values listed in Table 3.1, the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298(\mathrm{O} / \mathrm{H} / \mathrm{O})$ obtained from (G2) $1 / 2 * G(2)=-14.62 \mathrm{kcal} / \mathrm{mol}$, however, this is not equal to that obtained from $1 / 2^{*}$ $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298(\mathrm{HOOH})=-16.3 \mathrm{kcal} / \mathrm{mol}($ see Table 3.6).

The consistency of group values between alkyl hydroxides ( ROH ) and corresponding alkyl hydroperoxides ( ROOH ) can also be verified. Benson's GA approach can be applied to $\mathrm{CH}_{3} \mathrm{OH}, \mathrm{CH}_{3} \mathrm{OOH}, \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ and $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ :

$$
\begin{align*}
& \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{OH}\right)=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\{(\mathrm{C} / \mathrm{H} 3 / \mathrm{O})+(\mathrm{O} / \mathrm{C} / \mathrm{H})\}  \tag{G4}\\
& \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298  \tag{G2}\\
& \left(\mathrm{CH}_{3} \mathrm{OOH}\right)=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\{(\mathrm{C} / \mathrm{H} 3 / \mathrm{O})+(\mathrm{O} / \mathrm{C} / \mathrm{O})+(\mathrm{O} / \mathrm{H} / \mathrm{O})\}  \tag{G5}\\
& \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }^{\circ} 298  \tag{G6}\\
& \left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}\right)=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\{3(\mathrm{C} / \mathrm{C} / \mathrm{H} 3)+(\mathrm{C} / \mathrm{C} 3 / \mathrm{O})+(\mathrm{O} / \mathrm{C} / \mathrm{H})\} \\
& \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\left(\mathrm{CH}_{3}\right)_{3} \mathrm{OOH}\right)=\Delta \mathrm{H}_{\mathrm{r}}{ }^{\circ} 298\{3(\mathrm{C} / \mathrm{C} / \mathrm{H} 3)+(\mathrm{C} / \mathrm{C} 3 / \mathrm{O})+(\mathrm{O} / \mathrm{C} / \mathrm{O})+(\mathrm{O} / \mathrm{H} / \mathrm{O})\}
\end{align*}
$$

The value of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\{(\mathrm{O} / \mathrm{C} / \mathrm{O})+(\mathrm{O} / \mathrm{H} / \mathrm{O})-(\mathrm{O} / \mathrm{C} / \mathrm{H})\}$ is $14.88 \mathrm{kcal} / \mathrm{mol}$ by subtracting (G4) from (G2) which is $5 \mathrm{kcal} / \mathrm{mol}$ different from that obtained by subtracting (G5) from (G6), $19.89 \mathrm{kcal} / \mathrm{mol}$. More examples of theses comparisons are illustrated in Table 3.6.

In the above calculations, $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ of $\mathrm{HOOH}, \mathrm{CH}_{3} \mathrm{OOCH}_{3}, \mathrm{CH}_{3} \mathrm{OH},\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}$ and $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COOH}$ are experimentally measured values, $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{OOH}\right)$ is derived from the experimentally measured $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{OO}\right)$ under the assumption of bond dissociation energy $\mathrm{D}^{\circ}(\mathrm{ROO}-\mathrm{H})$ equal to $88 \mathrm{kcal} / \mathrm{mol}$. In using Benson's scheme for peroxide species the discrepancy can be up to $5 \mathrm{kcal} / \mathrm{mol}$. This can be caused by using the enthalpy of $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}$ which is not accurately determined, or the general failure of the original additivity scheme. Therefore an alternative GA scheme (Scheme II) is developed in this work.

### 3.2.4 Scheme II

An alternative GA scheme for alkyl hydroperoxides hereafter defined as Scheme II is based on treatment of -OO- as one polyvalent atom, e.g. in this scheme the expressions for $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ of $\mathrm{CH}_{3} \mathrm{OOCH}_{3}, \mathrm{CH}_{3} \mathrm{OOH}$ and $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ in scheme II are:

$$
\begin{align*}
& \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{OOCH}_{3}\right)=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\{(\mathrm{C} / \mathrm{H} 3 / \mathrm{OO})+(\mathrm{OO} / \mathrm{C} 2)\}  \tag{G7}\\
& \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{OOH}\right)=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\{(\mathrm{C} / \mathrm{H} 3 / \mathrm{OO})+(\mathrm{OO} / \mathrm{C} / \mathrm{H})  \tag{G8}\\
& \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}\right)=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\{(\mathrm{C} / \mathrm{C} / \mathrm{H} 3)+(\mathrm{C} / \mathrm{C} / \mathrm{H} 2 / \mathrm{OO})+(\mathrm{OO} / \mathrm{C} / \mathrm{H})\} \tag{G9}
\end{align*}
$$

The discrepancy in Benson's GA scheme illustrated in Table 3.6 can thus be avoided. The $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})$ 's can also be treated by Scheme II as the illustration of (G7), (G8) and (G9)

The group values for the calculations of thermodynamic properties of peroxides using Scheme II are listed in Table 3.7. The thermodynamic properties of four molecules ( $n$-propyl, $n$-butanyl, $i$-butyl and $\alpha$-methyl propyl hydroperoxide) listed in Table 3.5 are calculated using Scheme II with these group values.

### 3.3 Results and Discussion

Vibration frequencies and moments of inertia obtained by MNDO/PM3 are listed in Table 3.3. The accuracy of vibration frequencies determined by MNDO/PM3 was examined by Coolidge et al. ${ }^{56}$ Their results indicate that for vibration frequencies of closed shell molecules, "PM3 generally gives an acceptable match across the entire spectrum" ;"PM3
provides values that can be compared directly to experiment". ${ }^{56}$ The estimate of average systematic error based on the 61 small molecules with a total of 674 calculated vibration frequencies is $-2.6 \mathrm{~cm}^{-1}$ and the average relative deviation of the calculated from the experimental value is $-2.6 \%$. It should be noted that PM3 does not predict the frequencies of O-H stretching modes accurately, ${ }^{56}$ typically $3900 \mathrm{~cm}^{-1}$ instead of $3200 \mathrm{~cm}^{-1}$ to 3600 $\mathrm{cm}^{-1}$. However, these frequencies are large and this deviation does not cause any significant error in calculating entropies and heat capacities over the temperature range 300K-1000K.

Higher level $a b$ initio calculations using Gaussian92 provide more accurate predictions of molecular geometry. However, the consistency of experimental and calculated vibration frequencies using Gaussian92 at the HF/6-31G* level is not very good. According to a systematic study by Hehre et al. ${ }^{16}$ on the performance of various basis sets, 'The mean absolute percentage deviations of $3-21 G\left(^{*}\right)$ and $6-31 \mathrm{G}^{*}$ frequencies from directly measured values are $12.4 \%$ and $13.9 \%$ respectively', and if the comparison are performed with experimental harmonic frequencies the deviation of $6-31 \mathrm{G}^{*}$ is about $+12.8 \%$.

Since usually $a b$ initio methods are considered to be a more preferable approach compared to semiempirical MO calculations (like PM3), we performed a limited comparison of vibrational frequencies calculated by PM3 with those calculated by $\mathrm{HF} / 6$ $31 \mathrm{G}^{*}$ on $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}, \mathrm{CH}_{3} \mathrm{CHClOOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}$ molecules (see Chapter 4). Our comparison indicates that there is no reason to use higher level calculation to acquire
vibration frequencies for calculations of the corresponding vibrational contributions to thermodynamic properties.

Barriers for internal rotations used in this work are listed in Table 3.3. These barriers were directly adapted or estimated from literature data, see Table 3.4. Internal rotations of molecules are often treated either as harmonic torsional vibrations, or as a free rotations with application of classical statistics in calculating thermodynamic properties. These approximations could result in a significant error in entropies and heat capacities Pitzer and Gwinn's analysis and tabulated thermodynamic properties present a more accurate method to account for hindered internal rotors than the approximations using torsional frequencies or free-rotor model.

The thermodynamic properties of gas-phase, one to four carbon, alkyl, monochloro- and monofluoro- hydroperoxides are listed in Table 3.5. Group values derived in this work are listed in Table 3.7. Groups obtained in this work can be used for calculation of thermodynamic properties of other alkyl hydroperoxide molecules that are not considered here.

### 3.4 Conclusion

We have developed a data base of thermodynamic properties $\left(\Delta \mathrm{H}_{\mathrm{f}}{ }_{298}, \mathrm{~S}^{\circ}{ }_{298}, \mathrm{C}_{\mathrm{p}}{ }^{\circ}(\mathrm{T})\right)$ ) for gas-phase alkyl, monochloro- and monofluoro- hydroperoxides, where experimental or accessible literature data are not available. Enthalpies of formation are evaluated using experimental and theoretical literature data. Contributions to entropies and heat capacity were determined using calculated molecular parameters: optimized geometry of molecular
structure, moments of inertia, vibrational frequencies and potential barriers for internal rotations. Group values of an alternative scheme of Group Additivity have also been derived.

## CHAPTER 4

## AB INITIO STUDY OF $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}, \mathrm{CH}_{3} \mathrm{CHClOOH}$ AND $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}$ : CONFORMATIONAL ANALYSIS, INTERNAL ROTATION BARRIERS, VIBRATIONAL FREQUENCIES, AND THERMODYNAMIC PROPERTIES

### 4.1 Introduction

There have been few studies on determination of thermodynamic properties of alkyl hydroperoxides (see Chapter 3). One reason is the difficulty in defining the experimental structures with accuracy due to the strong influence of intramolecular and intermolecular forces in the condensed phase (solvent effects, crystal packing effect...etc.), the rapid interaction of conformers, and the inherent instability of alkyl hydroperoxides. ${ }^{73}$ The facts that hydroperoxides usually dissociate to alkoxy (RO.) and hydroxy (OH) under condition of high temperature, or rapidly react with other active species, and thus do not appear in the product profiles of gas phase reactions, also contribute to the reasons for lack of the thermodynamic studies of alkyl hydroperoxides.

The objective of this work was primarily proposed to calculate thermodynamic functions $\left(\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}, \quad \mathrm{~S}^{\circ}{ }_{298}\right.$ and $\left.\mathrm{Cp}(\mathrm{T}), \quad 300 \leq \mathrm{T} / \mathrm{K} \leq 5000\right)$ for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ (a), $\mathrm{CH}_{3} \mathrm{CHClOOH}$ (b) and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}$ (c) using ab initio MO theory for the analysis of molecular conformations, barriers to internal rotation, and harmonic vibrational frequencies.

### 4.2 Literature Survey

### 4.2.1 Molecular Structure of Hydroperoxides

HOOH was the first molecule in the hydroperoxide family which has been studied extensively. Cremer ${ }^{74}$ has reviewed the experimental results for the conformational analysis and rotational barrier for $\mathrm{H}_{2} \mathrm{O}_{2}$ and $\mathrm{D}_{2} \mathrm{O}_{2}$. This is organized as Table 4.1 which includes the results of Cremer's ab initio study. The skew conformation of HOOH with a dihedral angle about $110^{\circ}$ to $120^{\circ}$ is the most stable. The potential energy surface, however, is rather flat in the region of HOOH internal rotation around the trans conformation $\left(\angle \mathrm{HOOH}=180^{\circ}\right.$, see Table 4.1 and Figure 1) with a ca. $1 \mathrm{kcal} / \mathrm{mol}$ barrier height. The potential barrier of the cis conformation $\left(\angle \mathrm{HOOH}=0^{\circ}\right)$ was determined as $7.03 \mathrm{kcal} / \mathrm{mol}$ by Hunt et al. ${ }^{75}$ using infrared spectroscopy, compared to $7.94 \mathrm{kcal} / \mathrm{mol}$ reported by Radom et al. ${ }^{21}$ and 7.4 by Cremer ${ }^{74}$ using an intermediate level of theory, $\mathrm{HF} / 4-31 \mathrm{G}$ and (11s6p2d/6s2p) basis sets, respectively. The O-O bond length ( $r_{\mathcal{O O}^{\prime}}$ ) in $\mathrm{H}_{2} \mathrm{O}_{2}$ was determined as $1.475 \AA$ by Redington et al. ${ }^{76}$ using IR spectroscopy and was interpreted as $1.463 \AA$ by Cremer, ${ }^{74}$ compared to the value of $1.452 \AA$ which was reported by Khacuruzov and Przhevalskii. ${ }^{77}$ Cremer's ab initio calculations ${ }^{74}$ were basically in good agreement with experimental results in the prediction of HOOH geometry (see Table 4.1). It is notable that using higher level of theory than $\mathrm{HF} / 4-31 \mathrm{G}^{21}$ does not improve the agreement with experimental values for the rotational barrier and $r_{O O}$ of HOOH . Hehre et al. ${ }^{16}$ reported $9.2 \mathrm{kcal} / \mathrm{mol}$ as the barrier height for cis conformations and $1.393 \AA$ as $r_{O O}$ for the equilibrium structure at $\mathrm{HF} / 6-31 \mathrm{G}^{*}$ level.

There were several studies using MO calculations to determine the molecular geometries and rotational barriers for FOOH and $\mathrm{ClOOH},{ }^{21.78}$ but no experimental results have been reported. Radom et. al. ${ }^{21}$ predicted that the rotational barriers for FOOH were $3.33 \mathrm{kcal} / \mathrm{mol}$ for the cis conformation and 7.39 for the trans (see Fig. I) using a $4-31 \mathrm{G}$ basis set. This result gives a quite different feature of the potential energy surface for internal rotation of FOOH compared to that for HOOH 's. The former has a maximum barrier at the trans conformation and the latter at the cis. Francisco et al. ${ }^{78}$ optimized the geometry for ClOOH at a high level of theory, $\operatorname{CCSD}(\mathrm{T}) / \mathrm{TZ2P}$. The skew conformation was determined as the most stable at all theory levels. ${ }^{78}$ The trans conformation of ClOOH was predicted to have a barrier height ranging from 3.1 to $3.8 \mathrm{kcal} / \mathrm{mol}{ }^{78}$ depending on the basis set used in the calculation. The rotational barrier for the cis conformation of ClOOH was calculated to be $7.0 \mathrm{kcal} / \mathrm{mol}$ at the MP2/6-31G* level, 5.7 at the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{TZ2P}$ level, and 5.1 at the $\operatorname{CCSD}(\mathrm{T}) / \operatorname{ANO} 4$ level, the highest level of the calculations. ${ }^{78}$ The O-O bond length $\left(r_{(0)}\right)$ at the skew conformation was determined as $1.437 \AA, 1.408 \AA$ and $1.443 \AA$ at the MP2/6-31G*, MP2/6-311G** and $\operatorname{CCSD}(\mathrm{T}) / \mathrm{TZ} 2 \mathrm{P}$ levels, respectively. ${ }^{78}$ In such cases as the study of $\mathrm{ClOOH}{ }^{78}$ where there is experimental data, it is rather difficult to select the values of $r_{(0)}$ and barrier height for the cis conformation for use in calculation of thermodynamic functions.

The equilibrium geometry for $\mathrm{CH}_{3} \mathrm{OOH}$ was determined experimentally to be the COOH skew conformation with the values as follows: $1.443 \AA$ and $1.437 \AA$ as $r_{O O}$ and $r_{\mathrm{CO}}$, respectively; $114^{\circ}$ as the COOH dihedral angle. ${ }^{79.80}$ No experimental data for rotational barriers for $\mathrm{CH}_{3} \mathrm{OOH}$ has been published. Several studies using ab initio MO calculations
have been performed for $\mathrm{CH}_{3} \mathrm{OOH} .{ }^{73,21,80}$ The COOH dihedral angle in the skew conformation was calculated as $140^{\circ}$ at the HF/4-31G level of theory, ${ }^{21}$ and $118.8^{\circ}$ at the HF/6-31G* level. The rotational barrier for the COOH cis conformation was determined as $7.80 \mathrm{kcal} / \mathrm{mol}$ at the $\mathrm{HF} / 4-21 \mathrm{G}$ level, ${ }^{80} 7.99 \mathrm{kcal} / \mathrm{mol}$ at the $\mathrm{HF} / 4-31 \mathrm{G}^{21}$ level and 7.74 $\mathrm{kcal} / \mathrm{mol}$ at the $\mathrm{HF} / 6-31 \mathrm{G}^{*}$ level. ${ }^{73}$ Another internal rotation for $\mathrm{CH}_{3} \mathrm{OOH}$ was about $\mathrm{C}-\mathrm{O}$ bond which barrier height was determined as 2.93 at the $\mathrm{HF} / 4-21 \mathrm{G}$ level. ${ }^{80}$

A recent comparison ${ }^{81}$ of $a b$ initio MO calculations to experimental data for peroxides concluded that there was no general computational procedure that will yield accurate molecular geometries. Large basis sets including polarization functions predict correct skew conformations, but give too short O-O bond lengths. Inclusion of electron correlation corrections can improve $\mathrm{O}-\mathrm{O}$ bond length yet bond angles were hardly affected. ${ }^{73.81}$ The recommended procedure ${ }^{81}$ was MP2 or MP4 single point calculation at the $\mathrm{HF} / 3-21 \mathrm{G}$-optimized molecular geometries.

To our knowledge neither experimental nor $a b$ initio MO studies have been published for the determination of molecular structures, rotational barriers and vibrational frequencies for alkyl hydroperoxides with more than 2 carbons.

### 4.2.2 Thermochemistry of Hydroperoxides

Few heats of formation $\left(\Delta H_{f}{ }^{\circ} 298\right)$ for alkyl hydroperoxides have been studied experimentally. The experimental values of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ were available for only $\mathrm{CH}_{3} \mathrm{OOH}$, $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OOH}, i-\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OOH}$ and $t-\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OOH}$ according to a recent review. ${ }^{73}$ The only known experimental value of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ for ethyl hydroperoxide was measured in $1940,{ }^{82}$ and the
reported number contained a high uncertainty, i.e. $45 \pm 12 \mathrm{kcal} / \mathrm{mol} .{ }^{82.83}$ The $\Delta \mathrm{H}_{\mathrm{r}}{ }^{\circ}{ }^{2}{ }^{298}$, $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ for the alkyl hydroperoxides are generally estimated using Benson's Group Additivity (GA) scheme and Group Values, ${ }^{60}$ if experimental data or the values from high level of MO calculations are not available. Benson's GA approach has proven to be an useful method for the estimation of thermodynamic properties of most molecules. The accuracy of Benson's GA scheme for (chloro-) alkyl hydroperoxide, however, was not comprehensively assessed since limited reliable thermodynamic property datáa exist. (See Chapter 3 for review of Benson's GA scheme for alkyl hydroperoxides)

### 4.2.3 Comparison of Semiempirical and $A b$ Initio MO Calculations

The general performance of semiempirical MO calculations on alkyl hydroperoxides is also of interest since these methods, like CNDO, ${ }^{84} \mathrm{MNDO} / \mathrm{AM} 1{ }^{17}$ or $\mathrm{PM} 3,{ }^{9}$ are often used when ab initio MO calculations were not accessible nor economical. A study by Ohkubo et al. ${ }^{85}$ showed that the $\mathrm{O}-\mathrm{O}$ bond length in $\mathrm{HOOH}, \mathrm{CH}_{3} \mathrm{OOH}$ and $\mathrm{CH}_{3} \mathrm{OOCH}_{3}$ cannot be correctly predicted by some semiempirical MO methods. INDO and $\mathrm{CNDO} / 2$ seriously underestimate the $r_{\mathrm{OO}}$ for equilibrium geometries, while the former gives $1.22 \AA$ for that of HOOH and the latter yields $1.23 \AA$ for that for $\mathrm{CH}_{3} \mathrm{OOH} .{ }^{85}$ This situation is improved by using MINDO/2' which gives $1.404 \AA$ for $r_{\mathrm{OO}}$ of HOOH and $1.414 \AA$ for $r_{\mathrm{oO}}$ of $\mathrm{CH}_{3} \mathrm{OOH}$. However, MINDO/2' predicts a too large HOO bond angle in $\mathrm{HOOH}\left(+21^{\circ}\right)$, and too large COO bond angle $\left(+14^{\circ}\right)$ in $\mathrm{CH}_{3} \mathrm{OOH}^{-85}$ The authors concluded that 'the slight underestimation of $r_{\mathrm{OO}}$ was mainly attributable to the underestimate of the lone pair-lone pair interactions between the two oxygen atoms (caused by the neglect of two center integrals
involving one-centered overlap), while the overestimation of the bond angles was due to an insufficient parameterization for the heteroatom." ${ }^{85}$

### 4.3 Method

All $a b$ initio calculations were performed using Gaussian92 system of programs ${ }^{12}$ on the Cray YMP at Pittsburgh Supercomputing Center (PSC) and the Vax-6430 at New Jersey Institute of Technology. Equilibrium and saddle-point geometries were completely optimized at the close shell restricted Hatree-Fock (RHF) level of theory with analytical gradients ${ }^{86}$ using the $6-31 \mathrm{G}^{*}(6-31 \mathrm{G}(\mathrm{d}))$ basis set (HF/6-31G*). ${ }^{13.14 .15}$ Then single-point energies for all rotational conformers were calculated using second-order Meller-Plesset perturbation theory at the $6-31 \mathrm{G}^{* *}(6-31 \mathrm{G}(\mathrm{d}, \mathrm{p}))$ level ${ }^{13.14,15}$ (MP2/6-31G**//HF/6$31 \mathrm{G}^{*}$ ). Vibrational frequencies were calculated for all rotational conformers using analytical second derivatives at $\mathrm{HF} / 6-31 \mathrm{G}^{*}$ level. Zero-point vibrational energies (ZPVE) were scaled by 0.9 for all calculations because the HF-SCF harmonic vibrational frequencies were found to be overestimated by about $10 \%$ in a study of systematic performance. ${ }^{16}$

To calculate the rotational barriers, the potential energy surface (PES) was first calculated for the selected dihedral angle for each internal rotation. For instance, a PES was calculated for changes in the HCCO dihedral angle to study the barriers for the internal rotation about $\mathrm{CH}_{3}-\mathrm{CH}_{2} \mathrm{OOH}$ bond. In this case, the frequency of $\mathrm{CH}_{3}--$ $\mathrm{CH}_{2} \mathrm{OOH}$ torsional motion in the equilibrium structure (staggered) was not included in the calculation of ZPVE.

Three isodesmic reactions ${ }^{16}$ were used to study the enthalpies of reactions:

$$
\begin{align*}
& \mathrm{CH}_{3} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}=\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{OH}  \tag{8}\\
& \mathrm{CH}_{3} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{CHClOH}=\mathrm{CH}_{3} \mathrm{CHClOOH}+\mathrm{CH}_{3} \mathrm{OH}  \tag{9}\\
& \mathrm{CH}_{3} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}=\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{OH} \tag{10}
\end{align*}
$$

The total energies for $\mathrm{CH}_{3} \mathrm{OH}, \mathrm{CH}_{3} \mathrm{OOH}, \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}, \mathrm{CH}_{3} \mathrm{CHClOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ were calculated at the same level of theory as that used for the title species, MP2/6-31 $\mathrm{G}^{* *} / / \mathrm{HF} / 6-31 \mathrm{G}^{*}$. The energies of the reactions were obtained from the total energies of the reactants and products with the corrections of the scaled (x0.9) ZPVE. The calculated reaction energies were then combined with experimental data or evaluated values of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ for $\mathrm{CH}_{3} \mathrm{OH}, \mathrm{CH}_{3} \mathrm{OOH}, \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}, \mathrm{CH}_{3} \mathrm{CHClOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ to obtain the enthalpies of formation for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ (a), $\mathrm{CH}_{3} \mathrm{CHClOOH}$ (b) and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}(\mathbf{c})$.

The standard entropies $\left(\mathrm{S}^{\circ}{ }_{298}\right)$ and heat capacities $(\mathrm{Cp}(\mathrm{T}), 300 \leq \mathrm{T} / \mathrm{K} \leq 5000)$ as function of temperature were calculated using the Rigid-Rotor-Harmonic-Oscillator (RRHO) model. ${ }^{8}$ A method described in Chapter 1 was used to calculate contributions of hindered rotors to the entropy and heat capacities.

The AM1 ${ }^{17}$ and PM3 ${ }^{9}$ methods in the MOPAC6.0 ${ }^{10}$ package were used to perform the semiempirical MO calculations. The molecular geometries in the equilibrium states for tittle species were calculated with AM1 and PM3 parameters, and the results were compared to those obtained from $a b$ initio studies at the HF/6-31G* level of theory.

The harmonic vibrational frequencies of $\mathrm{MNDO} / \mathrm{AM} 1$ and PM 3 were also calculated using normal mode analysis of nuclear coordinates and were compared to Hartree-Fock frequencies.

### 4.4 Results and Discussion

### 4.4.1 Molecular Geometries

The definition and nomenclature for all rotational conformers in this work are illustrated in Figure 4.2. The optimized geometries for the rotational conformers of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ (a). $\mathrm{CH}_{3} \mathrm{CHClOOH}(\mathbf{b})$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}(\mathbf{c})$ are listed in Table 4.2, Table 4.3 and Table 4.4, respectively. The equilibrium structures for $\mathbf{a}, \mathbf{b}$, and $\mathbf{c}$ are further illustrated in Figure 4.3 $\mathrm{C}-\mathrm{C}$ bond lengths are quite consistent in the equilibrium states, while the $\mathrm{C}-\mathrm{O}$ bond length decreases consistently from $1.406 \AA$ in $\mathbf{a}$, to $1.374 \AA$ in $\mathbf{b}$ and $1.368 \AA$ in $\mathbf{c}$. The O-O bond length also decreases in this series from $1.393 \AA$ in $\mathbf{a}$, to 1.387 in $\mathbf{b}$ and $1.364 \AA$ in $\mathbf{c}$.

The skew conformations are the most stable in all cases, with the COOH dihedral angles as $116.52^{\circ}, 97.89^{\circ}$ and $97.54^{\circ}$ for $\mathbf{a}, \mathbf{b}$ and $\mathbf{c}$, respectively. These results are consistent with the former studies for HOOH and $\mathrm{CH}_{3} \mathrm{OOH}$ (see Figure 4.1). The trans: conformation of $\left(\mathrm{CH}_{3}\right) \mathrm{CHCl}-\mathrm{O}(\mathrm{OH})$ and $\left(\mathrm{CH}_{3}\right) \mathrm{CCl}_{2}-\mathrm{O}(\mathrm{OH})$ (dihedral angle $\mathrm{CCOO} \approx$ $180^{\circ}$ ) are more stable than the gauche $\left(\mathrm{COOO} \approx 60^{\circ}\right.$ or $-60^{\circ}$ ), indicating that the electronic repulsion between $\mathrm{C}_{1}$ and $\mathrm{O}_{8}$ was stronger than that between $\mathrm{O}_{8}$ and H atom or $C_{1}$ atom for these two molecules. The atomic Mulliken charge ${ }^{16}$ distributions for each molecule are listed in Table 4.5.

### 4.4.2 Vibrational Frequencies

Harmonic vibrational frequencies were calculated for all rotational conformers and the unscaled frequencies are listed in Table 4.6, 4.7 and 4.8. The equilibrium structures, which are supposed to be the local minimum point on energy surface, were confirmed by no appearance of imaginary frequencies. The presence of one and only one imaginary frequency was an index of the transition state being located. All vibrational frequencies and ZPVE were scaled by 0.9 for all following calculations in this work ${ }^{16}$ due to the $10 \%$ overestimation of HF-SCF procedure.

Three frequencies of torsion motions were assigned through the normal mode analysis of nuclei coordinates, which represent the torsions about $\mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{O}$ and $\mathrm{O}-\mathrm{O}$ bonds. In the rotational transition states, the corresponding torsion frequencies are imaginary. For instance, the frequencies for the torsion motions about $\mathrm{C}-\mathrm{O}$ and $\mathrm{O}-\mathrm{O}$ bonds are 138 and $215 \mathrm{~cm}^{-1}$ in aSTS, 146 and $219 \mathrm{~cm}^{-1}$ in aETS, respectively, while the frequency, $262 \mathrm{~cm}^{-1}$ in aSTS and the imaginary frequency, $-256 \mathrm{~cm}^{-1}$ in aETS represents the torsional motion about $\mathrm{C}-\mathrm{C}$ bond in $\mathbf{a}$. The location of all rotational conformers on the potential energy surface can be further checked in this manner (see Table 4.6, 4.7, 4.8).

### 4.4.3 Rotational Barriers

The calculated energy, ZPVE (unscaled) and rotational barrier (i.e. the energy difference compared to the equilibrium state) for each conformer are given in Table 4.9. The following discussion is based on the values of barriers calculated at MP2/6-31G**//HF/6$31 G^{*}$ level with the corrections of scaled ZPVE (x0.9) unless otherwise noted.

The barriers of the methyl group rotations increase from $3.32 \mathrm{kca} / \mathrm{mol}$ in a to 4.39 $\mathrm{kcal} / \mathrm{mol}$ in $\mathbf{b}$ and $4.65 \mathrm{kcal} / \mathrm{mol}$ in $\mathbf{c}$, reflecting the increase of electronic repulsion with the increase of chlorine substitution on the $\alpha$-carbon. The eclipse of methyl groups with groups of $\alpha$-carbon also makes the $\mathrm{C}-\mathrm{C}$ bond length longer than that in the staggered conformation; increases are $0.0146 \AA, 0.0157 \AA, 0.0214 \AA$ for $\mathbf{a}, \mathbf{b}$ and $\mathbf{c}$, respectively.

The barriers for internal rotations about the $\mathrm{C}-\mathrm{O}$ bond are more complex. The most stable form for $\mathbf{a}$ is aSTS, $0.38 \mathrm{kcal} / \mathrm{mol}$ lower than aSGS at the HF/6-31G*//6$31 \mathrm{G}^{*}$ level. However, the total energies calculated at the MP2/6-31G**//HF/6-31 $\mathrm{G}^{*}$ level indicate that aSTS is $0.11 \mathrm{kcal} / \mathrm{mol}$ higher than aSGS. The maximum rotational barrier about $\mathrm{C}-\mathrm{O}$ bond in a occurs at $\mathrm{aSE}_{\mathrm{C}} \mathrm{S}$ which is $3.24 \mathrm{kcal} / \mathrm{mol}$ higher than $\mathrm{aSE} \mathrm{E}_{\mathrm{H}} \mathrm{S}$.

For $\mathbf{b}$ the potential energy surface of the CCOO dihedral angle from $60^{\circ}$ to $120^{\circ}$ is rather flat. A scan calculation of rotational energy surface as a function of CCOO dihedral angle at the $\mathrm{HF} / 6-31 \mathrm{G}^{*}$ level was performed keeping all the parameters fixed and varying CCOO at $15^{\circ}$ intervals, to confirm the location of the transition state, see Figure 4.7. The barriers of rotations on the scanned potential energy surface using the rigid geometries are higher than those calculated by allowing geometry optimization. However, the scan investigation indicates that there is no obvious saddle point (local maximum) in the range of the CCOO dihedral angle from $60^{\circ}$ to $180^{\circ}$ and that the energy diagram fitted from our calculations of rotational barriers about C-O bond is reliable.

The maximum rotational barrier about the $\mathrm{C}-\mathrm{O}$ bond in $\mathbf{b}$ occurs at $\mathrm{bSE}_{\mathrm{CI}} \mathrm{S}, 3.23$ $\mathrm{kcal} / \mathrm{mol}$ higher than $\mathrm{bSE}_{\mathrm{C}} \mathrm{S}$. It is also notable that the barrier for the rotation across the
overlap of $\mathrm{O}_{8}$ and $\mathrm{C}_{1}$ at $\mathrm{C}_{2}$ from the equilibrium state $\left(\mathrm{CCOO}=180^{\circ}\right)$ in $\mathbf{c}$ is lower than that in $\mathbf{b}$ by about $2.7 \mathrm{kcal} / \mathrm{mol}$.

The COOH skew conformations are the most stable form in all cases. This is consistent with the fact that the orthogonal conformation of $\mathrm{X}-\mathrm{O}-\mathrm{O}-\mathrm{Y}$ allows for the delocalization of lone pair electrons more than coplanar conformations (cis and trans). ${ }^{21}$ The internal rotational barriers about the O-O bond in alkyl hydroperoxides are strongly dependent on the $\alpha$-carbon substituent groups. However, the rotational barriers for the cis and trans conformation do not increase with the increase of the number of substituent chlorine atoms on the $\alpha$-carbon. The bSTC has the highest barrier at $8.43 \mathrm{kcal} / \mathrm{mol}$ while aSTC and cSTC have lower barriers of 6.67 and $5.35 \mathrm{kcal} / \mathrm{mol}$, respectively.

The values of the Fourier expansion components (see Chapter 1), $\mathrm{V}_{\mathrm{i}}$ and $\mathrm{V}_{\mathrm{i}}$ in equation (E1) and $\mathrm{a}_{\mathrm{i}}$ and $\mathrm{b}_{\mathrm{i}}$ in equation (E2) are obtained by curve fitting at $3^{\circ}$ intervals for entire potential energy surface. These values are given in Table 4.10.

### 4.4.4 Heat of Formation

Two sets of isodesmic reactions may be used to study the enthalpies of reactions theoretically. The first option is the reaction with alkane and $\mathrm{CH}_{3} \mathrm{OOH}$ as the reactants and the desired alkyl hydroperoxide and $\mathrm{CH}_{4}$ as products.

## Scheme I

$$
\begin{align*}
& \mathrm{CH}_{3} \mathrm{OOH}+\mathrm{C}_{2} \mathrm{H}_{6}=\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}+\mathrm{CH}_{4}  \tag{1}\\
& \mathrm{CH}_{3} \mathrm{OOH}+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl}=\mathrm{CH}_{3} \mathrm{CHClOOH}+\mathrm{CH}_{4}  \tag{2}\\
& \mathrm{CH}_{3} \mathrm{OOH}+1,1-\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}=\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}+\mathrm{CH}_{4} \tag{3}
\end{align*}
$$

One other alternative is reaction with the alcohol and $\mathrm{CH}_{3} \mathrm{OOH}$ as reactants and the desired alkyl hydroperoxide and $\mathrm{CH}_{3} \mathrm{OH}$ as products:

## Scheme II

$$
\begin{align*}
& \mathrm{CH}_{3} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}=\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{OH}  \tag{4}\\
& \mathrm{CH}_{3} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{CHClOH}=\mathrm{CH}_{3} \mathrm{CHClOOH}+\mathrm{CH}_{3} \mathrm{OH}  \tag{5}\\
& \mathrm{CH}_{3} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}=\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{OH} \tag{6}
\end{align*}
$$

Scheme II should be the better choice than Scheme I for the isodesmic reactions. But to our knowledge there are no reliable data for $\Delta \mathrm{H}^{\circ}{ }^{\circ} 298$ of $\mathrm{CH}_{3} \mathrm{CHClOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$, while $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ for all alkane species in the reactions in Scheme I is more precisely known. We performed both two sets of calculations in order to compare the results of the schemes.

For Scheme II, we need to have the values of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right)$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}\right)$. The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right)$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}\right)$ are estimated from $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }^{298}$ of $\left(\mathrm{C} . \mathrm{H}_{2} \mathrm{CHClOH}\right)$ as $20.20 \mathrm{kcal} / \mathrm{mol}$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}\right)$ as 18.80 $\mathrm{kcal} / \mathrm{mol}$, (results of BAC/MP4 calculation by Melius), ${ }^{69}$ with $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{H})$ equal to 52.1 $\mathrm{kcal} / \mathrm{mol}$ and the average bond dissociation energy of primary $\mathrm{C}-\mathrm{H}$ bond as 101.1 $\mathrm{kcal} / \mathrm{mol} .^{88}$

The total energies, ZPVE (unscaled) and experimental data or evaluated values of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ for the species in all isodesmic reactions are given in Table 4.11. The reaction
energies and the calculated $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ (a), $\mathrm{CH}_{3} \mathrm{CHClOOH}$ (b) and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}$ (c) are listed in Table 4.12.

The results of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ for ethyl hydroperoxide using the Scheme I and Scheme II isodesmic reactions are consistent, but the discrepancy between the values for the two schemes dramatically increases for $\mathrm{CH}_{3} \mathrm{CHClOOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}$. Since the isodesmic reactions in Scheme II are better choices than those in Scheme I, the data calculated from the $\Delta \mathrm{H}^{\circ}{ }_{\mathrm{rxn}}$ of reactions in Scheme II are recommended.

The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ is calculated to be $-39.42 \mathrm{kcal} / \mathrm{mol}$ using reaction (4) in scheme 2, while the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ of $\mathrm{CH}_{3} \mathrm{OOH}$ is equal to $-31.3 \mathrm{kcal} / \mathrm{mol}$. It is -41.32 $\mathrm{kcal} / \mathrm{mol}$ while $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ of $\mathrm{CH}_{3} \mathrm{OOH}$ is equal to $-33.2 \mathrm{kcal} / \mathrm{mol}$. The latter result is in good agreement with another value, $-41.09 \mathrm{kcal} / \mathrm{mol},{ }^{89}$ which is evaluated using the experimentally-determined $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO},-5.19 \mathrm{kcal} / \mathrm{mol}{ }^{67}$ and the average bond energy $\mathrm{D}^{\circ}(\mathrm{ROO}-\mathrm{H}), 88 \mathrm{kcal} / \mathrm{mol}^{89}$ The isodesmic reactions in scheme 2 and the value of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{OOH}\right)=-33.2 \mathrm{kcal} / \mathrm{mol}$ is also used to evaluate the enthalpies of formation for $\mathrm{CH}_{3} \mathrm{CHClOOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}$.

The calculated $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CHClOOH}\right)$ is $-49.26 \mathrm{kcal} / \mathrm{mol}$ using $\Delta \mathrm{H}^{\circ}{ }_{\text {rxn }}$ of reaction (5) and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right)=-64.2 \mathrm{kcal} / \mathrm{mol}$. It is consistent with the value -48.98 $\mathrm{kcal} / \mathrm{mol}$, which is evaluated from $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CHClOO}\right)=-13.08 \mathrm{kcal} / \mathrm{mol}^{90}$ and the average bond energy $\mathrm{D}^{\circ}(\mathrm{ROO}-\mathrm{H})=88 \mathrm{kcal} / \mathrm{mol} .{ }^{89}$
$\Delta \mathrm{H}_{\mathrm{f}}{ }^{2}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}\right)$ is calculated as $-52.84 \mathrm{kcal} / \mathrm{mol}$. This value is calculated using $\Delta \mathrm{H}^{\circ}{ }_{\mathrm{rxn}}(6)$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}\right)=-71.8 \mathrm{kcal} / \mathrm{mol}$. No comparable data are known for $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}\right)$.

We are also interested in bond dissociation energy differences between $\mathrm{DH}^{\circ}(\mathrm{R}-$ $\mathrm{OOH})$ and $\mathrm{DH}^{\circ}(\mathrm{R}-\mathrm{OH})$ which are useful information for estimating the enthalpies of formation for alkyl hydroperoxides with $\alpha$-chlorine substituted from the that of corresponding alcohols. These values can be calculated by following procedure:

$$
\begin{align*}
& \mathrm{CH}_{3} \mathrm{OH}=\mathrm{CH}_{3}+\mathrm{OH}, \Delta \mathrm{H}_{\mathrm{r} \times n}^{\circ}=\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3}-\mathrm{OH}\right)  \tag{7}\\
& \mathrm{CH}_{3} \mathrm{OOH}=\mathrm{CH}_{3}+\mathrm{OOH}, \Delta \mathrm{H}^{\circ}{ }_{\mathrm{rxn}}=\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3}-\mathrm{OOH}\right)  \tag{8}\\
& \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}=\mathrm{C}_{2} \mathrm{H}_{5}+\mathrm{OH}, \Delta \mathrm{H}_{\mathrm{rxn}^{\circ}}=\mathrm{DH}^{\circ}\left(\mathrm{C}_{2} \mathrm{H}_{5}-\mathrm{OH}\right)  \tag{9}\\
& \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OOH}=\mathrm{C}_{2} \mathrm{H}_{5}+\mathrm{OOH}, \Delta \mathrm{H}_{\mathrm{rxn}}^{\circ}=\mathrm{DH}^{\circ}\left(\mathrm{C}_{2} \mathrm{H}_{5}-\mathrm{OOH}\right)  \tag{10}\\
& (8)+(9)=(7)+(10), \\
& \mathrm{CH}_{3} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}=\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}+\mathrm{CH}_{3} \mathrm{OH}  \tag{4}\\
& \Delta \mathrm{H}_{\mathrm{r} \times \mathrm{n}}^{\circ}=\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3}-\mathrm{OOH}\right)+\mathrm{DH}^{\circ}\left(\mathrm{C}_{2} \mathrm{H}_{5}-\mathrm{OH}\right)-\mathrm{DH}^{\circ}\left(\mathrm{C}_{2} \mathrm{H}_{5}-\mathrm{OOH}\right)-\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3}-\mathrm{OH}\right)
\end{align*}
$$

The $\Delta \mathrm{H}^{\circ}{ }_{\mathrm{rxn}}$ of isodesmic reaction (4) is therefore equal to $\left\{\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3}-\mathrm{OOH}\right)\right.$ -$\left.\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3}-\mathrm{OH}\right)\right\}+\left\{\mathrm{DH}^{\circ}\left(\mathrm{C}_{2} \mathrm{H}_{5}-\mathrm{OH}\right)-\mathrm{DH}^{\circ}\left(\mathrm{C}_{2} \mathrm{H}_{5}-\mathrm{OOH}\right)\right\}$. The value of $\left\{\mathrm{DH}^{\circ}\left(\mathrm{C}_{2} \mathrm{H}_{5}-\mathrm{OH}\right)-\right.$ $\left.\mathrm{DH}^{\circ}\left(\mathrm{C}_{2} \mathrm{H}_{5}-\mathrm{OOH}\right)\right\}$ can be obtained with the known data of $\Delta \mathrm{H}^{\circ}{ }_{\text {rxn }}(4)$ and $\left\{\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3}-\right.\right.$ $\left.\mathrm{OOH})-\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3}-\mathrm{OH}\right)\right\}$. The values of $\left\{\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3} \mathrm{CHCl}-\mathrm{OH}\right)-\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3} \mathrm{CHCl}-\mathrm{OOH}\right)\right\}$ and $\left\{\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2}-\mathrm{OH}\right)-\mathrm{DH}^{\circ}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2}-\mathrm{OOH}\right)\right\}$ can also be obtained in the same manner. The results of the bond strength differences are given in Table 4.13. The data indicate that the bond energies of the C-O bond in alkyl hydroperoxides ( ROOH ) are higher than those in alcohols (ROH) by about 20 to $26 \mathrm{kcal} / \mathrm{mol}$. The differences of bond strength for the two kinds of $\mathrm{C}-\mathrm{O}$ bond are about $21.6 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{OOH}$ vs

## $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{OH}$ and $\mathrm{CH}_{3} \mathrm{CHCl}-\mathrm{OOH}$ vs $\mathrm{CH}_{3} \mathrm{CHCl}-\mathrm{OH}$, but it is $25.8 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{CH}_{3} \mathrm{CCl}_{2}-$ OOH vs $\mathrm{CH}_{3} \mathrm{CCl}_{2}-\mathrm{OH}$.

### 4.4.5 Thermodynamic Properties

The thermodynamic properties are listed in Table 4.14. The contribution of entropies and heat capacities from internal hindered rotors are calculated by direct diagonalization of the Hamiltonian Matrix. The difference of using this technique and Pitzer and Gwinn's approximation and Tables are illustrated in Table 4.15.

### 4.4.6 Coupling Effects of Internal Rotations

The calculation of entropies and heat capacities is based on the assumption that the internal hindered rotations are not coupled. The contribution of entropies and heat capacities from hindered rotors are calculated separately and summed to give the total entropies and heat capacities. There is one important concern in the calculations of thermodynamic functions using the above procedure, i.e. for these three molecules, how much can the three internal rotors affect each other, or, what would be the rotational barriers if the rotations are coupled.

It obviously requires a great deal of computer CPU time to calculate the total energies for all possible rotational conformers at a level of theory like $\mathrm{HF} / 6-31 \mathrm{G}^{*}$ in order to partly answer these questions. However, we performed the calculations at the smaller 3-21G* basis set to scan the possible coupling effects of rotational barriers for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$. The calculations were performed at the MP2/3-21G**//HF/3-21G* level
with scaled ZPVE (0.9) for all theoretically local maximum and minimum points on the different potential energy surfaces. The coupling effects were investigated by calculating the total energies of conformers with various dihedral angles. The results are illustrated in Figure 4.8, 4.9 and 4.10.

Generally speaking, the shapes of PES of internal rotations remain and the barrier heights vary when coupling is considered. For the rotation about $\mathrm{C}-\mathrm{C}$ bond, the barriers increase to about $6 \mathrm{kcal} / \mathrm{mol}$ (from $3 \mathrm{kcal} / \mathrm{mol}$ ) with the dihedral angle CCOO and COOH both equal to $0^{\circ}$. They increase to about $4 \mathrm{kcal} / \mathrm{mol}$ when CCOO is equal to $0^{\circ}$ with COOH in the skew conformation.

For the rotation about the $\mathrm{C}-\mathrm{O}$ bond, the barriers increase to about $7 \mathrm{kcal} / \mathrm{mol}$ with the dihedral angle COOH equal to $0^{\circ}$ and HCCO in the staggered conformation. The rotational barriers about the $\mathrm{O}-\mathrm{O}$ bond remain on the same scale while the dihedral angle CCOO is varied. These scan studies indicate that the rotations coupled with the COOH cis conformation have the most significant effects for rotational barriers.

The coupling effects of internal rotations for $\mathrm{CH}_{3} \mathrm{CHClOOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}$ were not investigated due to limited computer resources.

### 4.4.7 Comparison of MNDO/AM1 and PM3 Molecular Geometries and Vibrational Frequencies

The comparison of bond lengths between $a b$ initio and semiempirical MO calculations is given in Table 4.16. The results indicate that the $\mathrm{O}-\mathrm{O}$ bond length is highly underestimated by AM1 as an average $0.10 \AA$ shorter, but overestimated by PM3 as $0.13 \AA$ longer, compared to geometries optimized in the HF/6-31G* basis set. The C-O bond lengths in
the alkyl hydroperoxides are also not correctly predicted by both AM1 and PM3 Hamiltonians. Here the PM3 gives a more consistent $\mathrm{C}-\mathrm{O}(\mathrm{OH})$ bond with an average deviation of $-0.02 \AA$, whereas $\mathrm{AM1}$ yields a $\mathrm{C}-\mathrm{O}(\mathrm{OH})$ bond length too large by $0.066 \AA$ on average. The comparison of bond angles and dihedral angles is given in Table 4.17.

The comparison of vibrational frequencies is illustrated in Figure 4.11, 12 and 13. Very large deviations occur at the three lowest frequencies. But in practical consideration, these three frequencies which correspond to the three torsion motions are not included in the calculations of entropies and heat capacities. The entropies and heat capacity contributed from vibrational frequencies ( $\mathrm{S}^{\circ}{ }_{298 \text {,vib }}$ and $\mathrm{Cp}_{500, \text { vib }}$ ) are also compared in these three figures. The mean absolute deviation of $\mathrm{S}^{\circ}{ }_{298 \text {,vib }}$ form AM1 to $6-31 \mathrm{G}^{*}$ is -0.75 $\mathrm{cal} / \mathrm{mol}-\mathrm{K}$, and it is $+0.40 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$ from PM3 to $6-31 \mathrm{G}^{*}$. The mean absolute deviation of $\mathrm{Cp}_{298 \text {, wib }}$ form $\mathrm{AM1}$ to $6-31 \mathrm{G}^{*}$ is $-1.03 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$, and it is $+0.63 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$ from PM 3 to $6-31 G^{*}$. This indicates that when the resources for sophisticated ab initio calculations are not available, the semiempirical PM3 Hamiltonian is a fairly good alternative for the calculation of vibrational frequencies and thus $\mathrm{S}_{\text {vib }}$ and $\mathrm{Cp}_{\text {vib. }}$.

### 4.5 Summary

The molecular geometries of equilibrium states and rotational transition states for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}, \mathrm{CH}_{3} \mathrm{CHClOOH}$ and $\mathrm{CH}_{3} \mathrm{CCl} 2 \mathrm{OOH}$ were calculated at the $\mathrm{HF} / 6-31 \mathrm{G}^{*}$ level. Potential barriers of internal rotations were calculated at MP2/6-31G**/HF/6-31G* level. The potential constants for Fourier expansions were derived. Standard entropies ( $\mathrm{S}^{\circ}{ }_{298}$ ) and heat capacities ( $\mathrm{Cp}(\mathrm{T})^{\prime} \mathrm{s}, 300 \leq \mathrm{T} / \mathrm{K} \leq 5000$ ) were calculated using the RRHO
model and the information obtained from the $a b$ initio studies, accompanied with the method described in section 1.5 for handing the energy levels of hindered internal rotations. The enthalpies of formation for these three molecules were calculated by means of isodesmic reactions. The $\Delta \mathrm{H}_{\mathrm{f} 298}^{\circ}$ of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH},-41.32 \mathrm{kcal} / \mathrm{mol}$, calculated by the method of isodesmic reactions is in very good agreement with previously published values. The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}$ 298 for $\mathrm{CH}_{3} \mathrm{CHClOOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}$ were calculated to be $\mathbf{- 4 9 . 2 6 \mathrm { kcal } / \mathrm { mol }}$ and $\mathbf{- 5 2 . 7 4} \mathrm{kcal} / \mathrm{mol}$, respectively. The major uncertainty in above two values arises from the uncertainty of the estimated data of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right)$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}\right)$. The accuracy for $\Delta \mathrm{H}_{\mathrm{f} 298}^{\circ}$ of $\mathrm{CH}_{3} \mathrm{CHClOOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}$ can definitely be further improved when more reliable data of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }^{298}\left(\mathrm{CH}_{3} \mathrm{CHClOOH}\right)$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}\right)$ are obtained.

Semiempirical MO calculations with the AM1 and PM3 Hamiltonians were also compared with the $a b$ initio HF-SCF results. The comparisons show that neither AM1 nor PM3 can predict correct molecular geometries for alkyl hydroperoxides, while the vibrational frequencies calculated by PM3 were, on average, within an acceptable range.

## CHAPTER 5

# AB INITIO STUDY OF $\alpha$-CHLORINATED ETHYL PEROXY RADICALS, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}, \mathrm{CH}_{3} \mathrm{CHClOO}$ AND $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}$ : <br> CONFORMATIONAL ANALYSIS, INTERNAL ROTATION BARRIERS, VIBRATIONAL FREQUENCIES, AND THERMODYNAMIC PROPERTIES 

### 5.1 Introduction

The alkyl peroxy radicals have received a lot of attention recently in the study of combustion ${ }^{2.65-67.91-95}$ and atmospheric photochemistry ${ }^{96,97}$ of hydrocarbon compounds, because they are the primary adducts while the alkyl radicals react with molecular oxygen (see Chapter 1):
$\mathrm{RH}+\mathrm{OH}\left(\right.$ or $\left.\mathrm{O}_{2}\right)=>\mathrm{R} .+\mathrm{H}_{2} \mathrm{O}\left(\right.$ or $\left.\mathrm{HO}_{2}\right)$
R. $+\mathrm{O}_{2}<\Rightarrow$ ROO. $\Leftrightarrow>$ Products

Enthalpies of formation for $\mathrm{CH}_{3} \mathrm{OO}^{98}, \mathrm{CH}_{2} \mathrm{ClOO}^{99}, \mathrm{CHCl}_{2} \mathrm{OO}^{99}, \mathrm{CCl}_{3} \mathrm{OO}{ }^{1001}$, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO},{ }^{67}$ and $\mathrm{CH}_{3} \mathrm{CHClOO}{ }^{90}$ was reported by Gutman and co-workers. They reported that the bond strength $\left(\mathrm{DH}^{\circ}{ }_{298}\right)$ of the $\mathrm{C}-\mathrm{O}$ bond in alkyl peroxy radicals decreased from $32.5 \mathrm{kcal} / \mathrm{mol}{ }^{98}$ in $\mathrm{CH}_{3}-\mathrm{O}_{2}$ to $19.8 \mathrm{kcal} / \mathrm{mol}{ }^{100}$ in $\mathrm{CCl}_{3}-\mathrm{O}_{2}$ with intermediate values of $28.9 \mathrm{kcal} / \mathrm{mol}^{99}$ for $\mathrm{CH}_{2} \mathrm{Cl}-\mathrm{O}_{2}$ and $25.3 \mathrm{kcal} / \mathrm{mol}^{99}$ for $\mathrm{CHCl}_{2}-\mathrm{O}_{2}$. The $\mathrm{DH}^{\circ}{ }_{298}$ of the $\mathrm{C}-\mathrm{O}$ bond for $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{O}_{2}{ }^{67}$ and $\mathrm{CH}_{3} \mathrm{CHCl}-\mathrm{O}_{2}{ }^{90}$ were also determined as 34.1 and $31.3 \mathrm{kcal} / \mathrm{mol}$, respectively.

Vibrational frequencies were determined experimentally for the $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}$ radical. ${ }^{101}$ Conformational analysis and vibrational frequency assignment for $\mathrm{CH}_{3} \mathrm{OO}^{68}$, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}^{68,102}, \mathrm{CH}_{3} \mathrm{CHClOO}^{90},\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOO}^{68}$ and $\left(\mathrm{CH}_{3} \mathrm{CH}_{2}\right)_{2} \mathrm{CHOO}^{68}$ were also carried out using a high level basis set and electron correlation theory.

Besler et al. ${ }^{103}$ reported that the $\mathrm{CH}_{3}$ group rotation in $\mathrm{CH}_{3} \mathrm{OO}$ has a very low barrier of $0.43 \mathrm{kcal} / \mathrm{mol}$ at the MP2 $/ 6-31 \mathrm{G}^{*}$ level of theory and should behave nearly as a free rotor at room temperature, ${ }^{103}$ although a quite different number, $1.3 \mathrm{kcal} / \mathrm{mol}{ }^{103}$ as this barrier height calculated at the UHF/6-31G* level was also reported in the same article.

Using DZP/CISD level of theory, Quelch et. al. ${ }^{102}$ found the potential energy surface (PES) of the rotation about $\mathrm{C}-\mathrm{O}$ bond in $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}\left(\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{OO}\right.$ rotation) to be a triple well with one higher peak and two lower peaks. The maximum rotation barrier of $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{OO}$ rotation occurs at the CCOO cis conformation, as $2.7 \mathrm{kcal} / \mathrm{mol}$, while the eclipse of the $\alpha$-hydrogen with terminal oxygen has a lower barrier of $1.0 \mathrm{kcal} / \mathrm{mol}$. The PES for the methyl group rotation about the $\mathrm{C}-\mathrm{C}$ bond in $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}\left(\mathrm{CH}_{3}--\mathrm{CH}_{2} \mathrm{OO}\right.$ rotation) was a periodic triple well with a barrier of $2.9 \mathrm{kcal} / \mathrm{mol}$ at the $\mathrm{DZP} / \mathrm{CISD}$ level. ${ }^{102}$

For $\mathrm{CH}_{3} \mathrm{CHClOOH}$, the PES of the rotation about the $\mathrm{C}-\mathrm{O}$ bond was determined to be more like a double well with one broad and one narrow minimum at the MP2/6$31 \mathrm{G}^{* *} / / \mathrm{UHF} / 6-31 \mathrm{G}^{*}$ level of theory. ${ }^{90}$ The maximum of the sharper peak is found around the dihedral angle ClCOO close to $0^{\circ}$ with the barrier of $4.46 \mathrm{kcal} / \mathrm{mol}{ }^{90}$ The maximum of the broader peak is found around the dihedral angle ClCCO equal to $0^{\circ}$ with
a barrier of $2.96 \mathrm{kcal} / \mathrm{mol} .{ }^{90}$ The PES around dihedral angle $\alpha \mathrm{HCOO}=0^{\circ}$ has a rather flat potential energy surface (see Figure 4.5). The barrier of rotation about the C-C bond $\left(\mathrm{CH}_{3}-\mathrm{CHClOO}\right.$ rotation) was determined to be $3.89 \mathrm{kcal} / \mathrm{mol} .{ }^{90}$

The objective of this study is performed primarily for determining the thermodynamic functions, $\left(\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298, \mathrm{~S}^{\circ}{ }_{298}\right.$ and $\left.\mathrm{Cp}(\mathrm{T}), 300 \leq \mathrm{T} / \mathrm{K} \leq 5000\right)$ for the ethyl peroxy radicals with chlorine substitution on the $\alpha$-carbon. $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}$ (a), $\mathrm{CH}_{3} \mathrm{CHClOO}$ (b) and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}$ (c) were selected to study the substitution effect of chlorine on the $\alpha$-carbon. Although the enthalpies of formation for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}^{67}, \mathrm{CH}_{3} \mathrm{CHClOO}{ }^{90}$ have been determined by experiment, the theoretical calculations were performed to further analyze these values.

### 5.2 Method

All ab initio calculations were performed using Gaussian92 system of program ${ }^{12}$ on the Cray YMP at Pittsburgh Supercomputing Center (PSC.) or the Vax-6430 at New Jersey Institute of Technology. Equilibrium and saddle-point geometries were completely optimized at the open shell unrestricted Hatree-Fock (UHF) level of theory with analytical gradients ${ }^{86}$ using the $6-31 G^{*}$ basis set (UHF/6-31G*). ${ }^{13,14,15}$ Single-point energies for all rotational conformers were then calculated using second-order Møller-Plesset perturbation theory at $6-31 \mathrm{G}^{* *}$ level (MP2/6-31G**//UHF/6-31G*). Vibrational frequencies were calculated for all rotational conformers using analytical second derivatives at UHF/6-31G* level. Zero-point vibrational energies (ZPVE) were scaled by
0.9 for all calculations because the HF-SCF harmonic vibrational frequencies were found to be overestimated by about $10 \%$ in a study of systematic performance. ${ }^{16}$

To calculate the rotational barriers, the potential energy surface (PES) was first calculated for the selected dihedral angle for each internal rotation. For example, a PES was calculated for changes in the CCOO dihedral angle to study the barriers for the internal rotation about $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{OO}$ bond. In this case, the corresponding frequency of $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{OO}$ torsion motion for each equilibrium structure was not included in the calculation of ZPVE. Several isodesmic reactions were used to evaluate the enthalpies of reactions.

The total energies for $\mathrm{CH}_{3} \mathrm{O}, \mathrm{CH}_{3} \mathrm{OO}, \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}, \mathrm{CH}_{3} \mathrm{CHClO}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}$ were calculated at the same level of theory as that used for the title species, MP2/6$31 \mathrm{G}^{* *} / / \mathrm{UHF} / 6-31 \mathrm{G}^{*}$. The energies of the reactions were obtained from the total energies of the reactants and products with the corrections of the scaled (x0.9) ZPVE. The calculated reaction energies were then combined with experimental data or evaluated values of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}$ 298 for $\mathrm{CH}_{3} \mathrm{O}, \mathrm{CH}_{3} \mathrm{OO}, \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}, \mathrm{CH}_{3} \mathrm{CHClO}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}$ to obtain the enthalpies of formation for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}(\mathbf{a}), \mathrm{CH}_{3} \mathrm{CHClOO}$ (b) and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}$ (c).

The standard entropies $\left(\mathrm{S}^{\circ}{ }_{298}\right)$ and heat capacities $(\mathrm{Cp}(\mathrm{T}), 300 \leq \mathrm{T} / \mathrm{K} \leq 5000)$ as function of temperatures were calculated using the Rigid-Rotor-Harmonic-Oscillator (RRHO) model ${ }^{8}$ which utilizes the calculated harmonic vibrational frequencies, moments of inertia, and the hindered internal rotations. For the contributions of hindered rotors to entropies and heat capacities, the effects of coupled internal rotations with each other were assumed to be insignificant. The contributions of each hindered rotor were calculated
separately with the corresponding potential energy surface and summed into the total entropies and heat capacities.

The MNDO ${ }^{17}$ semiempirical MO calculations were performed using MOPAC6.0 ${ }^{10}$ package with standard AM1 ${ }^{10}$ and PM3 ${ }^{9}$ parameters at UHF level of theory. The keyword 'PRECISE" was used to set up a more strict criteria of $10^{-8}$ for the self-consistent-field (SCF) convergence in the geometry optimization process. The molecular geometry and vibrational frequencies of the equilibrium states for the three title species were calculated and compared with the values from ab initio studies.

### 5.3 Results and Discussion

### 5.3.1 Molecular Geometries

Definition and nomenclature for rotational conformers in this work are illustrated in Figure 5.1. Although the conformational studies of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}$ were previously carried out at about the same or higher level, ${ }^{68,102}$ we still list the all optimized molecular geometries calculated in this work at the UHF/6-31G* level for the purpose of comparison.

The calculations by Knyazev et al. for $\mathrm{CH}_{3} \mathrm{CHClOO}^{90}$ are actually at the same level as this work, but the rotational transition states locating method is slightly different here. The rotational transition states calculated by Knyazev at al. are saddle points on potential energy surfaces (PES's) with all geometric parameters fully optimized. ${ }^{90}$ The geometries of the eclipsed structures defined in this work are optimized with one specific dihedral angle fixed at $0^{\circ}$, (i.e. $\mathrm{CCOO}=0^{\circ}$ for $\mathrm{bCis}_{\mathrm{C}}, \mathrm{HCOO}=0^{\circ}$ for $\mathrm{bCis}_{\mathrm{H}}$ and ClCOOH $=0^{\circ}$ for $\mathrm{bCis}_{(1)}$ ), and all other parameters relaxed. The transition state $(4)^{90}$ in the work of

Knyazev et al. is analogous to $\mathrm{bCis}_{\mathrm{C}}$ here and has the CCOO dihedral angle equal to $-14^{\circ}$, while it is manually fixed at $0^{\circ}$ in $\mathrm{bCis}_{\mathrm{c}}$. It is valuable to show the difference between these two approaches, since the approach used here has the advantage of less calculation time, and thus is widely used to study the rotational barriers, ${ }^{104}$ and the one used by Knyazev et al. is theoretically more correct in finding the rotational transition states.

The optimized geometries for rotational conformers of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}$ (a), $\mathrm{CH}_{3} \mathrm{CHClOO}$ (b) and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}$ (c) are listed in Table 5.1, Table 5.2 and Table 5.3, respectively. Table 5.4 presents the Mulliken charge distribution for the three radicals.
$\mathrm{C}-\mathrm{C}$ bond and $\mathrm{O}-\mathrm{O}$ lengths are consistent in the equilibrium states ( CCOO trans conformations) of $\mathbf{a}, \mathbf{b}$ and $\mathbf{c}$, while the $\mathrm{C}-\mathrm{O}$ bond length decreases consistently from $1.42490 \AA$ in a, $1.40095 \AA$ in b and $1.39605 \AA$ in c. Anther interesting feature is the comparison of $\mathrm{C}-\mathrm{O}$ and $\mathrm{O}-\mathrm{O}$ bond lengths in the $\alpha$-chlorinated ethyl peroxy radicals with those in the corresponding hydroperoxides calculated at the RHF/6-31G* level of theory ${ }^{38}$ (see Figure 5.2). The O-O bond lengths in the ROO radical are shorter than in ROOH by $-0.092 \AA$ for $\mathrm{R}=\mathrm{C}_{2} \mathrm{H}_{5},-0.08 \AA$ for $\mathrm{R}=\mathrm{CH}_{3} \mathrm{CHCl}$, and $-0.075 \AA$ for $\mathrm{R}=\mathrm{CH}_{3} \mathrm{CCl}_{2}$. The C O bond lengths in ROO radical are longer than those in ROOH molecules by $0.019 \AA$ for $\mathrm{R}=\mathrm{C}_{2} \mathrm{H}_{5}, 0.027 \AA$ for $\mathrm{R}=1-\mathrm{Cl}^{2}-\mathrm{C}_{2} \mathrm{H}_{4}, 0.019 \AA$ for $\mathrm{R}=1,1-$ di- $\mathrm{Cl}-\mathrm{C}_{2} \mathrm{H}_{3}$.

### 5.3.2 Vibrational Frequencies

Harmonic vibrational frequencies are calculated for all rotational conformers and the unscaled frequencies are listed in Table 5.5. The presence of one imaginary frequency is an index for location of the transition-state. Two frequencies of torsion motions about C-C
and C-O bond are assigned for each conformer. For each rotational transition-state, one specific torsion frequency is imaginary. For instance, the frequency for the torsion motion about $\mathrm{C}-\mathrm{C}$ bond is $252.2 \mathrm{~cm}^{-1}$ in $\mathrm{aCis}_{\mathrm{H}}$, and the imaginary frequency, $-101.6 \mathrm{~cm}^{-1}$ presents the torsion motion about the $\mathrm{C}-\mathrm{O}$ bond.

### 5.3.3 Rotational Barriers

The calculated energy, ZPVE (unscaled) and the energy difference compared to the equilibrium state for rotational barriers of each conformer are given in Table 5.6. Spin contamination are determined to be not important as the unrestricted HF procedure is applied for each conformers, as the theoretical $\mathbf{S}^{2}$ values given in Table 5.6. The following discussions are based on the values of barriers calculated at the MP2/6-31G**//HF/6$31 \mathrm{G}^{*}$ level with the corrections of scaled ZPVE (x0.9) if not otherwise noted.

The rotational barriers about the $\mathrm{C}-\mathrm{C}$ bond for $\mathbf{a}$ and $\mathbf{b}$ are adopted from the work by Quelch et al. ${ }^{102}$ and Knyazev et al., ${ }^{90}$ respectively, and that for c is calculated in this work. The PES's for the methyl rotors in $\mathbf{a}, \mathbf{b}$, and $\mathbf{c}$ are periodic triple wells, which are illustrated in Figure 5.3. The barrier of methyl group rotation increases from 2.7 $\mathrm{kca} / \mathrm{mol}^{102}$ in a to $3.89 \mathrm{kcal} / \mathrm{mol}^{90}$ in $\mathbf{b}$ and $4.68 \mathrm{kcal} / \mathrm{mol}$ in $\mathbf{c}$, reflecting the increase of electronic repulsion with the increase of chlorine substitution on the $\alpha$ carbon.

The PES's of internal rotations about the C-O bond are more complex. The PES of the rotation about the $\mathrm{C}-\mathrm{O}$ bond for $\mathbf{a}$ is a triple well with one higher barrier and two lower barriers, see Figure 5.4. The most stable structure for a is aTrans, a $0.10 \mathrm{kcal} / \mathrm{mol}$ lower potential energy than aGauch at $\mathrm{HF} / 6-31 \mathrm{G}^{*} / / 6-31 \mathrm{G}^{*}$, while the total energies
calculated at the MP2/6-31 $\mathrm{G}^{* *}$ level indicate that aTrans is $0.42 \mathrm{kcal} / \mathrm{mol}$ higher than aGauch. The maximum rotational barrier about the C-O bond in a occurs at $\mathrm{aCIS}_{C}$ which is $1.54 \mathrm{kcal} / \mathrm{mol}$ higher than $\mathrm{aCis}_{\mathrm{H}}$. The PES constructed from the values of rotational barriers by Quelch et al. ${ }^{102}$ at DZP/CISD level of theory is also illustrated in Table 5.6 and Figure 5.4 for comparison.

For $\mathbf{b}$, the PES of the CCOO dihedral angle from $60^{\circ}$ to $120^{\circ}$ is rather flat because the relative energies of $b G_{C-H}$ and $b C i s H$ are similar, see Figure 5.5. The maximum rotational barrier about the $\mathrm{C}-\mathrm{O}$ bond in $\mathbf{b}$ occurs at $\mathrm{bCis}_{\mathrm{Cl}_{1}}$ which is $1.51 \mathrm{kcal} / \mathrm{mol}$ higher than $\mathrm{bCis} \mathrm{c}_{\mathrm{c}}$. The relative energies for the rotational conformers of $\mathrm{CH}_{3} \mathrm{CHClOO}$ calculated by Knyazev et al. ${ }^{90}$ are listed in Table 5.6 for comparison with the barriers calculated in this work. The values are almost identical to each other at the MP2/6-31G** level of theory although the slightly different approaches are used to search the saddle points on PES (see 5.3.1).

The PES for rotation about the C-O bond in $\mathbf{c}$ is a triple well with one lower barrier and two higher barriers, see Figure 5.6. The barrier for the rotation across the overlap of O 8 and Cl at $\mathrm{C} 2\left(\mathrm{ClCCO}=0^{\circ}\right)$ from the equilibrium state $\left(\mathrm{CCOO}=180^{\circ}\right)$ in $\mathbf{c}$ is lower than that in $\mathbf{b}$ by about $0.9 \mathrm{kcal} / \mathrm{mol}$.

The PES of rotation about the $\mathrm{C}-\mathrm{O}$ bond for the $\alpha$-chlorinated ethyl hydroperoxides corresponding to $\mathbf{a}, \mathbf{b}$ and $\mathbf{c}\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}, \mathrm{CH}_{3} \mathrm{CHClOOH}\right.$ $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OOH}$, respectively) calculated at the MP2/6-31G**//RHF/6-31G* level ${ }^{38}$ are also illustrated in Figure 5.4, 5.5 and 5.6. These three figures illustrate the difference in rotational barriers about the $\mathrm{C}-\mathrm{O}$ bond, with and without a hydrogen on the peroxy group.

The results indicate that there is significant decrease in the CCOO rotational barriers from ROOH to ROO , with the difference as large as $8 \mathrm{kcal} / \mathrm{mol}$, see bCisCl in Figure 5.5. The shorter C-O bond length in ROOH vs ROO (see Figure 5.2) partly explains the reduced barrier when ROOH loses its hydrogen.

The values of Fourier expansion components (see Chapter 1 ), $V_{i}$ and $V_{i}$ in (E1) and $a_{i}$ and $b_{i}$ in (E2) are obtained by curve fitting for each PES, see Table 5.7.

### 5.3.4 Heat of Formation

Two sets of isodesmic reactions may be used to study the enthalpies of reactions. The first option is the reaction with $\mathrm{R}-\mathrm{OH}\left(\mathrm{R}=\mathrm{C}_{2} \mathrm{H}_{5}\right.$ for $\mathbf{a}, \mathrm{R}=\mathrm{CH}_{3} \mathrm{CHCl}$ for $\mathbf{b}$ and $\mathrm{R}=\mathrm{CH}_{3} \mathrm{CCl}_{2}$ for c ) and $\mathrm{CH}_{3} \mathrm{OO}$ as the reactants and ROO and $\mathrm{CH}_{3} \mathrm{OH}$ as products, respectively.

## Scheme I

$$
\begin{align*}
& \mathrm{CH}_{3} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}=\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{OH}  \tag{1}\\
& \mathrm{CH}_{3} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{CHClOH}=\mathrm{CH}_{3} \mathrm{CHClOO}+\mathrm{CH}_{3} \mathrm{OH}  \tag{2}\\
& \mathrm{CH}_{3} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{CHClOH}=\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{OH} \tag{3}
\end{align*}
$$

A second alternative is RO and $\mathrm{CH}_{3} \mathrm{OO}$ as reactants and the desired ROOH and $\mathrm{CH}_{3} \mathrm{O}$ as products:

## Scheme II

$$
\begin{align*}
& \mathrm{CH}_{3} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}=\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{O}  \tag{4}\\
& \mathrm{CH}_{3} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{CHClO}=\mathrm{CH}_{3} \mathrm{CHClOO}+\mathrm{CH}_{3} \mathrm{O}  \tag{5}\\
& \mathrm{CH}_{3} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}=\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{O} \tag{6}
\end{align*}
$$

Two other reactions can be used to validate the consistency of the above theoretical enthalpies using experimental data of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}\right)$ : ${ }^{67}$

## Scheme III

$\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{CHClO}=\mathrm{CH}_{3} \mathrm{CHClOO}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}$
$\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}=\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}$

The total energies, ZPVE (unscaled) along with experimental data or evaluated values of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ for the species in all isodesmic reactions are given in Table 5.8. The reaction energies and the calculated $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}$ (a), $\mathrm{CH}_{3} \mathrm{CHClOO}$ (b) and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}$ (c) are listed in Table 5.9.

Using reaction(1) $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}\right)$ is calculated as $-5.37 \mathrm{kcal} / \mathrm{mol}$ which is in excellent agreement with the experimental value, $-5.19 \mathrm{kcal} / \mathrm{mol}$. ${ }^{67}$ The value of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}\right)$ is calculated to be $-6.69 \mathrm{kcal} / \mathrm{mol}$ using reaction(4) and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}\right)=-4 \mathrm{kcal} / \mathrm{mol} .{ }^{32}$ If $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}\right)$ is adjusted to be $-2.5 \mathrm{kcal} / \mathrm{mol}$, the experimental value of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}\right),-5.19 \mathrm{kcal} / \mathrm{mol}$ can be fitted using reaction(4).

All three schemes cannot predict $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CHClOO}\right)$ to be in good agreement with experimental value, $-13.07 \mathrm{kcal} / \mathrm{mol} . \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CHClOO}\right)$ is calculated as -14.01 $\mathrm{kcal} / \mathrm{mol}$ by reaction(2); $-10.87 \mathrm{kcal} / \mathrm{mol}$ by reaction(5); and $-9.27 \mathrm{kcal} / \mathrm{mol}$ by reaction(7). The deviation of the calculated $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CHClOO}\right)$ from experimental data result from the uncertainty of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ of $\mathrm{CH}_{3} \mathrm{CHClOH}$ and $\mathrm{CH}_{3} \mathrm{CHClO}$. If the measured value,
$\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CHClOO}\right)=-13.07 \mathrm{kcal} / \mathrm{mol}{ }^{90}$ is used to validate $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right)$ using reaction(1), and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CHClO}\right)$ using reaction(4), the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right)$ appears as $\mathbf{- 6 3 . 2 5} \mathrm{kcal} / \mathrm{mol}, \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CHClO}\right)$ appears as $\mathbf{- 1 4 . 5} \mathrm{kcal} / \mathrm{mol}$.

No comparable data have been reported for $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}\right)$. Since the reaction( 8 ) is the best choices as an isodesmic reaction, the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}\right)$ calculated using Scheme III are recommended, as $\mathbf{- 1 6 . 1 6} \mathbf{~ k c a l} / \mathrm{mol}$.

### 5.3.5 Thermodynamic Properties

The thermodynamic properties are listed in Table 5.10. The contribution of entropies and heat capacities from internal hindered rotors are calculated by directly diagonalization of the Hamiltonia Matrix. The difference between using this technique and Pitzer and Gwinn's approximation and Tables are illustrated in Table 5.11.

### 5.3.6 Comparison of MNDO/AM1 and PM3 Molecular Geometries and Vibrational Frequencies

A comparison of bond length between $a b$ initio and semi-empirical MO calculations is listed in Table 5.12. The results indicate that the O-O bond length is highly underestimated by AM1, an average $0.15 \AA$ shorter, and by PM3 only $0.05 \AA$ shorter, than predicted at UHF/6-31G*. The C-O bond lengths in the alkyl peroxy are also not correctly predicted by both the AM1 and PM3 Hamiltonians. The PM3 method gives a more consistent C$\mathrm{O}(\mathrm{O}$.) bond length with an average deviation of $+0.05 \AA$, whereas AM1 on the average gives a $\mathrm{C}-\mathrm{O}(\mathrm{O}$. ) bond length too large by $+0.1 \AA$. The comparison of bond angles and dihedral angles are given in Table 5.13 and Table 5.14.

Comparison of vibrational frequencies are illustrated in Figure 5.7, 5.8 and 5.9 which do not include two torsion frequencies. The contributions of vibrational frequencies to entropies and heat capacities ( $\mathrm{S}_{\text {vib }}$ at 298 K and $\mathrm{Cp}_{\text {vib }}$ at 500 K ) are also compared in the three figures. The results clearly indicate that when sophisticated $a b$ initio calculations are not available, the semi-empirical MNDO/PM3 Hamiltonian is a fairly good alternative to calculate vibrational frequencies and thus $\mathrm{S}_{\text {vib }}$ and $\mathrm{Cp}_{\text {vib }}$ when the torsion frequencies are excluded.

### 5.4 Summary

Molecular geometries of equilibrium states and rotational transition states for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}$, $\mathrm{CH}_{3} \mathrm{CHClOO}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}$ were calculated at UHF/6-31G*. The potential barriers of internal rotations were calculated at MP2/6-31G**//HF/6-31G* and the potential constants for Fourier expansions were derived. Standard entropies ( $\mathrm{S}^{\circ}{ }_{298}$ ) and heat capacities $(\mathrm{Cp}(\mathrm{T})$ 's, $300 \leq \mathrm{T} / \mathrm{K} \leq 5000$ ) were calculated using the RRHO model which was incorporated with the information obtained in the $a b$ initio studies, and a new technique for calculating the energy levels of hindered internal rotations.

The enthalpies of formation for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}, \mathrm{CH}_{3} \mathrm{CHClOO}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}$ were calculated by means of isodesmic reactions. The $\Delta \mathrm{H}_{\mathrm{f}}{ }_{298}$ of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}$ calculated by the method of isodesmic reactions as $-5.37 \mathrm{kcal} / \mathrm{mol}$, is in very good agreement with experimental values. If the $\Delta \mathrm{H}_{\mathrm{f} 298}^{\circ}\left(\mathrm{CH}_{3} \mathrm{CHClO}\right)$ is adjusted to be $-14.5 \mathrm{kcal} / \mathrm{mol}$, and $\Delta \mathrm{H}_{\mathrm{f} 298}^{\circ}\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right)$ is adjusted to be $\mathbf{- 6 3 . 2 5} \mathrm{kca} / \mathrm{mol}$, the experimental value of $\Delta \mathrm{H}_{\mathrm{f} 298}^{\circ}\left(\mathrm{CH}_{3} \mathrm{CHClOO}\right), 13.07 \mathrm{kcal} / \mathrm{mol}$, can be reproduced using isodesmic reactions.
$\Delta \mathrm{H}_{\mathrm{f} 298}^{\circ}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}\right)$ is calculated to be $\mathbf{- 1 6 . 1 6} \mathrm{kcal} / \mathrm{mol}$ with $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}\right)$ equal to $-19.9 \mathrm{kcal} / \mathrm{mol}$. The major uncertainty in the value of $\Delta \mathrm{H}_{\mathrm{f} 298}^{\circ}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}\right)$ arises from the uncertainty in $\Delta \mathrm{H}_{\mathrm{f} 298}^{\circ}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}\right)$. The accuracy of $\Delta \mathrm{H}_{\mathrm{f} 298}^{\circ}\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OO}\right)$ can be further improved when a more reliable value of $\Delta \mathrm{H}_{\mathrm{f}}^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}\right)$ is obtained

Semiempirical MO calculations with MNDO/AM1 and PM3 were also compared and evaluated with $a b$ initio HF-SCF calculation results. The comparisons show that neither AM1 nor PM3 can predict correct molecular geometries for alkyl peroxy radicals, while the vibrational frequencies calculated by MNDO/PM3 were generally within an acceptable range.

## CHAPTER 6

# AB INITIO STUDY OF HYDROPEROXYL-1-ETHYL AND 1-CHLORO-1ETHYL RADICALS, $\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}$ AND $\mathrm{CH}_{3} \mathrm{C} . \mathrm{CIOOH}$ : <br> CONFORMATIONAL ANALYSIS, INTERNAL ROTATION BARRIERS, VIBRATIONAL FREQUENCIES, AND THERMODYNAMIC PROPERTIES 

### 6.1 Introduction

The ethyl peroxy radicals are formed from reactions of alkyl radicals with molecular oxygen (see Chapter 1). The ethyl peroxy radicals can isomerize to corresponding hydroperxyl ( $\alpha$-chlorinated) 1-ethyl radicals which then rapidly undergo an exothermic beta-scission to the corresponding alkanals plus OH radical.
$\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OO}<\Rightarrow \mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}$
$\mathrm{CH}_{3} \mathrm{CH} . \mathrm{OOH} \Rightarrow \mathrm{CH}_{3} \mathrm{CHO}+\mathrm{OH}$
$\mathrm{CH}_{3} \mathrm{CHClOO}<=>\mathrm{CH}_{3} \mathrm{C} . \mathrm{ClOOH}$
$\mathrm{CH}_{3} \mathrm{CCl} . \mathrm{OOH} \Rightarrow \mathrm{CH}_{3} \mathrm{CClO}+\mathrm{OH}$

This study is performed primarily to determine the thermodynamic functions, $\left(\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}, \mathrm{~S}^{\circ}{ }_{298}\right.$ and $\mathrm{Cp}(\mathrm{T}), 300 \leq \mathrm{T} / \mathrm{K} \leq 5000$ ) for the hydroperoxyl 1-ethyl and 1-chloro-1ethyl radicals, and to estimate the bond strength of the $\alpha \mathrm{C}-\mathrm{H}$ bond of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ and $\mathrm{CH}_{3} \mathrm{CHClOOH}$.

### 6.2 Method

The calculation procedure is fully described in Chapter 5, section 5.2.

### 6.3 Results and Discussion

### 6.3.1 Molecular Geometries

Definition and nomenclature for all rotational conformers in this work are illustrated in Figure 6.1. The optimized geometries for the rotational conformers of $\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}$ (a) and $\mathrm{CH}_{3} \mathrm{C} . \mathrm{ClOOH}(\mathbf{b})$ are listed in Tables 6.1 and 6.2, respectively. The Mulliken charge distribution in the equilibrium state (aSTS and bSTS) of the two radical species are given in Table 6.3.

The radical centers are non-planar for both radicals, with the out-of-plane (OOP) angle $(\gamma) 41.3^{\circ}$ for aSTS and $45.1^{\circ}$ for bSTS. (see Figure 6.2 for definition of OOP angle, y) The OOP angle at the radical center varies with each rotational conformer since the relaxed model is used to study the rotational barriers, see Table 6.4. The OOP angle for a varies from $41.3^{\circ}(\mathrm{aSTS})$ to $28.8^{\circ}\left(\mathrm{aSE}_{C} \mathrm{~S}\right)$, and for $\mathbf{b}$, from $45.1^{\circ}(\mathrm{bSTS})$ to $37.3^{\circ}$ (bSE ${ }_{C} S$ ).

The COOH skew conformations are the most stable in both species with the CCOO dihedral angle about $100^{\circ}\left(-254^{\circ}=106^{\circ}\right.$ in aSTS and $-256^{\circ}=104^{\circ}$ in bSTS $)$. This is consistent with the higher delocalization of lone pair electrons in the orthogonal conformation of X-O-O-Y relative to coplanar conformations (cis and trans) (see section 4.2.1 for further discussion).

When the $\alpha$-hydrogen in $\mathrm{CH} 3 \mathrm{C} . \mathrm{HOOH}$ is substituted by chlorine (b, $\mathrm{CH} 3 \mathrm{C} . \mathrm{ClOOH}$ ), the $\mathrm{C}-\mathrm{C}$ bond length remains nearly constant, the $\mathrm{C}-\mathrm{O}$ bond length decreases from $1.3695 \AA$ (aSTS) to $1.3481 \AA$ (bSTS), and O-O bond lengths increase slightly from $1.3895 \AA$ to $1.3933 \AA$.

Comparisons of bond lengths are also made between the radicals and the corresponding saturated hydroperoxides, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ and $\mathrm{CH}_{3} \mathrm{CHClOOH}$. Molecular geometries of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ and $\mathrm{CH}_{3} \mathrm{CHClOOH}$ are calculated at the MP2/6$31 \mathrm{G}^{* *} /$ RHF/6-31G* level of theory, see Chapter 4. These comparisons show that when the $\alpha$-hydrogen is lost from the saturated (chlorinated) alkyl hydroperoxides, the C-C bond lengths slightly decrease $(-0.0229 \AA$ in $\mathbf{a},-0.0159 \AA$ in $\mathbf{b})$. The $\mathrm{C}-\mathrm{O}$ bond lengths also decrease ( $-0.0365 \AA$ in a, and $-0.0258 \AA$ in $\mathbf{b}$ ). The O-O bond lengths are unchanged, see Figure 6.3.

### 6.3.2 Vibrational Frequencies

Harmonic vibrational frequencies are calculated for all rotational conformers and the unscaled frequencies are listed in Table 6.5 and Table 6.6. Three frequencies (including the imaginary ones) corresponding to torsion motions about the $\mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{O}$ and $\mathrm{O}-\mathrm{O}$ bonds are assigned for each conformer. One specific torsion frequency is imaginary for each rotational transition-state, e.g. the frequency for the torsion motion about $\mathrm{C}-\mathrm{C}$ bond as $136.7 \mathrm{~cm}^{-1}$ is imaginary in $\mathrm{aE}_{\mathrm{H}} \mathrm{TS}$. All vibrational frequencies and Zero-point vibrational energies (ZPVE) are scaled by 0.9 .

### 6.3.3 Rotational Barriers

Calculated total energy, ZPVE (unscaled) and rotational barrier for each conformer are given in Table 6.7. The following discussions are based on the values of barriers calculated at MP2/6-31 $\mathrm{G}^{* *} / / \mathrm{UHF} / 6-31 \mathrm{G}^{*}$ with the corrections of scaled ZPVE (x0.9) unless further noted

### 6.3.3.1 Rotation about the C-C Bonds

We first perform scan studies of potential energy surfaces (PES's) of the rotation about the $\mathrm{C}-\mathrm{C}$ bond. The rotational PES's as a function of $\mathrm{H}_{3} \mathrm{C}_{1} \mathrm{C}_{2} \mathrm{O}_{7}$ dihedral angle are calculated at UHF/6-31G* level of theory using fixed geometries (rigid model) varying the HCCO dihedral angle at $10^{\circ}$ intervals, see Figure 6.4 for a and Figure 6.5 for $\mathbf{b}$. These two PES's calculated using rigid geometries illustrate a triple well for the methyl group rotation in both $\mathbf{a}$ and $\mathbf{b}$. Corrections of ZPVE are not included in the scan calculations.

Rotational barriers about the C-C bonds are also calculated using a relaxed model, yielding $1.83 \mathrm{kcal} / \mathrm{mol}$ for $\mathbf{a}$ (see Figure 6.4) and $2.02 \mathrm{kcal} / \mathrm{mol}$ for $\mathbf{b}$ (see Figure 6.5). These calculations include the corrections of ZPVE. The barriers calculated using relaxed geometries are close to those using rigid geometries.

Figure 6.4 and Figure 6.5 also illustrate the rotational barriers about the $\mathrm{C}-\mathrm{C}$ bond of the stable molecules, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ and $\mathrm{CH}_{3} \mathrm{CHClOOH}$, respectively. Comparison shows that when one $\alpha$-hydrogen is removed from $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$, the rotational barrier about the $\mathrm{C}-\mathrm{C}$ bond decreases from $3.3 \mathrm{kcal} / \mathrm{mol}$ to $1.8 \mathrm{kcal} / \mathrm{mol}$. The rotational barrier
about the $\mathrm{C}-\mathrm{C}$ bond decreases from $5.3 \mathrm{kcal} / \mathrm{mol}$ in $\mathrm{CH}_{3} \mathrm{CHClOOH}$ to $2.0 \mathrm{kcal} / \mathrm{mol}$ of $\mathrm{CH}_{3} \mathrm{C} . \mathrm{ClOOH}$.

### 6.3.3.2 Rotation about the C-O Bonds

The PES's for rotation about the C-O bonds are determined to be a double well with two different barriers, see Figures 6.6 and 6.7 for $\mathbf{a}$ and $\mathbf{b}$, respectively The conformer of dihedral angle $\mathrm{CCOO}=0^{\circ}\left(\mathrm{aSE}_{C} \mathrm{~S}\right)$ for a has a higher barrier ( $2.67 \mathrm{kcal} / \mathrm{mol}$ ) than that of $\mathrm{HCOO}=0^{\circ}\left(\mathrm{aSE}_{\mathrm{H}} \mathrm{S}, 0.5 \mathrm{kcal} / \mathrm{mol}\right)$. The high barrier for $\mathbf{b}$ occurs at the dihedral angle $\mathrm{ClCOO}=0^{\circ}\left(\mathrm{aSE}_{\mathrm{Cl}} \mathrm{S}\right), 6.22 \mathrm{kcal} / \mathrm{mol}$, while $\mathrm{CCOO}=0^{\circ}$ has a barrier $3.52 \mathrm{kcal} / \mathrm{mol}$.

### 6.3.3.3 Rotation about the $\mathrm{O}-\mathrm{O}$ Bonds

The COOH skew conformation is the most stable form for both radicals, the cis conformation has a higher barrier and the trans conformation has a much lower barrier. It is significant that the barrier of the COOH cis conformation for a (aSTC), $5.23 \mathrm{kcal} / \mathrm{mol}$, is higher than that for $\mathbf{b}(\mathrm{bSTC}), 4.21 \mathrm{kcal} / \mathrm{mol}$, although $\mathbf{b}$ has a larger $\alpha$-substituent, i.e. the Cl atom rather than H in a, see Figures 6.8 and 6.9.

The loss of an $\alpha-\mathrm{H}$ in saturated alkyl hydroperoxides also affects the rotational barriers about the $\mathrm{O}-\mathrm{O}$ bond. Comparison of the rotational barriers about the $\mathrm{O}-\mathrm{O}$ bond between a and $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}, \mathbf{b}$ and $\mathrm{CH}_{3} \mathrm{CHClOOH}$, are illustrated in Figure 6.8 and 6.9, respectively. The maximum rotational barrier about the O-O bond (cis) decreases from $6.67 \mathrm{kcal} / \mathrm{mol}$ in $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ to $5.23 \mathrm{kcal} / \mathrm{mol}$ in a when $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ loses its $\alpha-\mathrm{H}$.

The decrease of the rotational barrier about the $\mathrm{O}-\mathrm{O}$ bond from $\mathrm{CH}_{3} \mathrm{CHClOOH}$ ( 8.43 $\mathrm{kcal} / \mathrm{mol})$ to $\mathbf{b}(4.21 \mathrm{kcal} / \mathrm{mol})$ is more significant.

Values of Fourier expansion components (see Chapter 1), $V_{i}$ and $V_{i}$ in (El) and $a_{i}$ and $b_{i}$ in (E2) are obtained by curve fitting for each PES, see Table 6.8.

### 6.3.4 Enthalpies of Formation ( $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ )

Two isodesmic reactions are used to study the enthalpies of hydroperoxyl 1-ethyl and 1-chloro-1-ethyl radicals:

$$
\begin{align*}
& \mathrm{CH}_{3} \mathrm{C} . \mathrm{HOH}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}=\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}+\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}  \tag{1}\\
& \mathrm{CH}_{3} \mathrm{C} . \mathrm{HOH}+\mathrm{CH}_{3} \mathrm{CHClOOH}=\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}+\mathrm{CH}_{3} \mathrm{C} . \mathrm{ClOOH} \tag{2}
\end{align*}
$$

### 6.3.4.1 Determination of $\Delta \mathrm{H}_{\mathrm{r}}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}\right)$

The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOH}\right)$ was calculated as $-14.3 \mathrm{kcal} / \mathrm{mol}^{3}$ by Melius using the BAC/MP4 approach. We also estimate this data from experimentally measured value of bond energy of $\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{CH}_{2} \mathrm{OH}\right)$ and the results of $a b$ initio studies for the following isodesmic reaction:

$$
\begin{align*}
& \mathrm{C} \cdot \mathrm{H}_{2} \mathrm{OH}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}=\mathrm{CH}_{3} \mathrm{OH}+\mathrm{CH}_{3} \mathrm{C} \cdot \mathrm{HOH} .  \tag{3}\\
& \mathrm{CH}_{3} \mathrm{OH}=>\mathrm{C} \cdot \mathrm{H}_{2} \mathrm{OH}+\mathrm{H}, \Delta \mathrm{H}_{\mathrm{rxn}}^{\circ}(12)=\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{CH}_{2} \mathrm{OH}\right) \tag{4}
\end{align*}
$$

$$
\begin{equation*}
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH} \Rightarrow \mathrm{CH}_{3} \mathrm{C} \cdot \mathrm{HOH}+\mathrm{H}, \Delta \mathrm{H}_{\mathrm{rxn}}^{\circ}(5)=\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOH}\right) \tag{5}
\end{equation*}
$$

(5) - (4) $=(3), \Delta \mathrm{H}^{\circ} \times \mathrm{rx}(3)=\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOH}\right)-\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{CH}_{2} \mathrm{OH}\right)$

Two very different numbers have been reported for the value of $\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{CH}_{2} \mathrm{OH}\right)$ : $93.9 \mathrm{kcal} / \mathrm{mol}$ by Benson and Golden, ${ }^{107}$ and $98.0 \mathrm{kcal} / \mathrm{mol}$ by Seetula and Gutman. ${ }^{108}$ The latter number is adopted in the following calculations.

The difference of $\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOOH}\right)-\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{CH}_{2} \mathrm{OH}\right)$ is thus determined to be $-0.8 \mathrm{kcal} / \mathrm{mol}$ using isodesmic reaction (3) and the results of $a b$ initio calculations by Pardo et al. ${ }^{109}$ at the MP2/6-31G*//UHF/6-31G level of theory. $\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOH}\right)$ is thus determined to be $96.3 \mathrm{kcal} / \mathrm{mol}$ using $\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{CH}_{2} \mathrm{OH}\right)=98.0 \mathrm{kcal} / \mathrm{mol}$. Using $\mathrm{D}^{\circ}(\mathrm{H}--$ $\left.\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOH}\right)=96.2 \mathrm{kcal} / \mathrm{mol}^{55}$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)=-56.12 \mathrm{kcal} / \mathrm{mol}$, ${ }^{\text {s }}$ $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOH}\right)$ is determined to be $-11.9 \mathrm{kcal} / \mathrm{mol}$, which is $2.4 \mathrm{kcal} / \mathrm{mol}$ different from the value, -14.3 calculated by Melius. ${ }^{69}$

### 6.3.4.2 Determination of $\Delta \mathrm{H}_{\mathrm{r}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}\right)$ and $\Delta \mathrm{H}_{\mathrm{r}}{ }^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{C} . \mathrm{ClOOH}\right)$

The total energies, ZPVE (unscaled) and the experimental derived or evaluated values of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ for the species in all isodesmic reactions are given in Table 6.9. The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ for a and $\mathbf{b}$ are determined as $5.0 \mathrm{kcal} / \mathrm{mol}$ and $\mathbf{- 1 . 0} \mathrm{kcal} / \mathrm{mol}$, as given in Table 6.10 , using isodesmic reactions (1) and (2) and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left(\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOH}\right)=-11.9 \mathrm{kcal} / \mathrm{mol}$.

### 6.3.4.3 Difference of Bond Dissociation Energy for the $\alpha$ C-H Bonds

Reactions (1) and (2) also provide a way to calculate the difference of the $\alpha \mathrm{C}-\mathrm{H}$ bond dissociation energy.
$\Delta \mathrm{H}^{\circ}{ }_{\mathrm{rxn}}(1)=\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOOH}\right)-\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOH}\right)$
$\Delta \mathrm{H}^{\circ}{ }_{\mathrm{rxn}}(2)=\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOOH}\right)-\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOH}\right)$

The values of $\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOOH}\right)-\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOH}\right)$ and $\mathrm{D}^{\circ}(\mathrm{H}--$ $\left.\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOOH}\right)-\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOH}\right)$ are determined to be $2.08 \mathrm{kcal} / \mathrm{mol}$ and 4.14 $\mathrm{kcal} / \mathrm{mol} . \mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOOH}\right)$ and $\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOOH}\right)$ are then determined to be $98.4 \mathrm{kcal} / \mathrm{mol}$ and $100.4 \mathrm{kcal} / \mathrm{mol}$ using $96.3 \mathrm{kcal} / \mathrm{mol}$ as $\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOH}\right)$. These results indicate that the relative order of the $\alpha \mathrm{C}-\mathrm{H}$ bond strength is: .
$\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOOH}\right)>\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOOH}\right)>\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{CH}_{2} \mathrm{OH}\right)>\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOH}\right)$

The degree of stabilization by hybridization of the unpaired electron at $\alpha$-carbon with the connected oxygen atom is lowest in $\mathrm{CH}_{3} \mathrm{C} . \mathrm{ClOOH}$, intermediate in $\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}$ and in $\mathrm{C} . \mathrm{H}_{2} \mathrm{OH}$, and highest in $\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOH}$.

The difference of $\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOOH}\right)-\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOH}\right)$ can also be calculated
$\mathrm{CH}_{3} \mathrm{C} . \mathrm{ClOH}+\mathrm{CH}_{3} \mathrm{CHClOOH}=\mathrm{CH}_{3} \mathrm{CHClOH}+\mathrm{CH}_{3} \mathrm{C} . \mathrm{ClOOH}$
$\Delta \mathrm{H}^{\circ}{ }_{\mathrm{rin}}(6)=\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOOH}\right)-\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOH}\right)$
$\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOOH}\right)-\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOH}\right)$ is calculated to be $0.53 \mathrm{kcal} / \mathrm{mol}$, as the data given in Table 6.10, indicating that Cl atom stabilizes $\mathrm{C}-\mathrm{H}$ bond on the $\alpha$-carbon by about $0.5 \mathrm{kcal} / \mathrm{mol}$.

### 6.3.5 Thermodynamic Properties

The radical centers in $\mathbf{a}$ and $\mathbf{b}$ are considered more flexible than a saturated carbons which have more rigid structure of tetrahedral bonding. The radical centers can have umbrella bending or inversion oscillation motions. The calculations of entropy and heat capacities do not consider the effects of hindered internal rotations coupled with inversion (or umbrella bending) at the radical center. Fortunately the out-of-plane (OOP) angle at radical center of each rotational conformer only varies within a small range, ca. $\pm 6.3^{\circ}$ for $\mathbf{a}$ and $\pm 3.7^{\circ}$ for $\mathbf{b}$, see Table 6.4. In this case, the coupling effects of umbrella bending to internal rotations are considered to be insignificant. Contributions to $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ ( $300 \leq T / K \leq 5000$ ) from each internal rotation of $\mathbf{a}$ and $\mathbf{b}$ are calculated separately and summed to total entropies and heat capacities.

The thermodynamic properties are listed in Table 6.11. The contribution of entropies and heat capacities from internal hindered rotors are calculated by directly diagonalization of the Hamiltonia Matrix. The difference of using this technique versus Pitzer and Gwinn's method is illustrated in Table 6.12.

### 6.3.5 Comparison of MNDO/AM1 and PM3 Molecular Geometries and Vibrational Frequencies

Comparisons of bond length between $a b$ initio and semiempirical MO calculations, AM1 and PM3 are given in Table 6.13. Results indicate that the O-O bond length is underestimated by $\mathrm{AM1}$ on the average by $0.09 \AA$, and is highly overestimated by PM3 on the average by $0.63 \AA$, in comparison with geometries optimized at the UHF/6-31G* level. It is significant that PM3 gives $1.93 \AA$ as the O-O bond length of the radicals such as
hydroperxyl 1-ethyl. The C-O bond length predicted by PM3 is $1.21 \AA$ which is too short, more like a $\mathrm{C}=\mathrm{O}$ double bond. Comparison of bond angles and dihedral angles are given in Table 6.14. PM3 again fails to predict the COOH skew conformation as the most stable with the dihedral angle COOH close to $180^{\circ}$ in the equilibrium state. The use of PM3 to perform the general studies for such hydroperxyl 1-ethyl radical species therefore seems to be unacceptable. The geometries calculated by AM1 are generally more consistent with $a b$ initio results at the UHF/6-31G* level of theory.

The comparison of vibrational frequencies calculated by the AM1 and PM3 methods with those by the UHF/6-31G* method are illustrated in Figure 6.10 and Figure 6.11 which have three torsion frequencies removed. The frequencies predicted by AM1 are not consistent with scaled $a b$ initio frequencies for the entire spectra, especially in the region below $1400 \mathrm{~cm}^{-1}$ where values of entropy and heat capacity are most sensitive. The discrepancy between the PM3 and UHF/6-31G* frequencies is even larger, because PM3 tends to treat the $\mathrm{C} .-\mathrm{O}$ bonds as $\mathrm{C}=\mathrm{O}$ along with the long $\mathrm{O}-\mathrm{O}$ bond (i.e. with a leaving OH group) for both hydroperoxyl 1 -ethyl radicals. The contributions of vibrational frequencies to entropies and heat capacities ( $S_{\text {vib }}$ at 298 K and $\mathrm{Cp}_{\text {vib }}$ at 500 K ) are also compared and given in Figure 6.10 and 6.11. AM1 tends to overestimate frequencies below $1400 \mathrm{~cm}^{-1}$ and underestimates $\mathrm{S}_{\text {vib }}$ and $\mathrm{Cp}_{\text {vib }}$. PM3 highly underestimates the frequencies in the region below $1400 \mathrm{~cm}^{-1}$ and highly overestimate $S_{\text {vib }}$ and $\mathrm{Cp}_{\text {vib }}$.

### 6.4 Summary

Molecular geometries of the equilibrium states and rotational transition states for $\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}$ and $\mathrm{CH}_{3} \mathrm{C} . \mathrm{ClOOH}$ are calculated at the UHF/6-31G* level. Potential barriers to internal rotations are calculated at the MP2/6-31G**//UHF/6-31G* level and potential constants for Fourier expansions are derived. Standard entropies ( $\mathrm{S}^{\circ}{ }_{298}$ ) and heat capacities $(\mathrm{Cp}(\mathrm{T})$ 's, $300 \leq \mathrm{T} / \mathrm{K} \leq 5000)$ are calculated using the RRHO model and the information obtained in the $a b$ initio studies.

The enthalpies of formation for these two free radicals are calculated using isodesmic reactions. $\Delta \mathrm{H}_{\mathrm{f} 298}^{\circ}$ of $\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOOH}$ and $\mathrm{CH}_{3} \mathrm{C} . \mathrm{ClOOH}$ are determined as $\mathbf{5 . 8 6}$ $\mathrm{kcal} / \mathrm{mol}$ and $-\mathbf{0 . 1 2} \mathrm{kcal} / \mathrm{mol}$, respectively. The $\Delta \mathrm{H}_{\mathrm{f}}^{\circ} 298$ of $\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOH}$ is also calculated as -11.0 $\mathrm{kcal} / \mathrm{mol}$. The bond dissociation energies, $\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOH}\right), \quad \mathrm{D}^{\circ}(\mathrm{H}--$ $\left.\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOOH}\right), \mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOH}\right)$ and $\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{ClOOH}\right)$ are calculated as 96.3 $\mathrm{kcal} / \mathrm{mol}, 98.4 \mathrm{kcal} / \mathrm{mol}, 99.9 \mathrm{kcal} / \mathrm{mol}$, and $100.4 \mathrm{kcal} / \mathrm{mol}$, respectively, using the experimental data, $98.0 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{CH}_{2} \mathrm{OH}\right),{ }^{108}$ and the isodesmic reactions.

Semiempirical MO calculations with MNDO/AM1 and PM3 are also compared and evaluated with ab initio HF-SCF calculation results. The comparisons show that PM3 does not predict correct molecular geometries for both hydroperoxyl 1-ethyl radical species, with severely short $\mathrm{C}-\mathrm{O}$ bonds and long $\mathrm{O}-\mathrm{O}$ bonds. AM1 gives more consistent results for molecular geometries and vibrational frequencies than does PM3. However, with AM 1 the $\mathrm{O}-\mathrm{O}$ bond lengths, and $\mathrm{S}_{\text {vib }}$ and $\mathrm{Cp}_{\text {vib }}$ are underestimated.

## CHAPTER 7

## CHLOROFORM PYROLYSIS AND OXIDATION: EFFECTS OF ADDED $\mathrm{O}_{2}$

### 7.1 Introduction

Hazardous waste incineration involving chlorine compounds merits attention because the behavior of chlorine is unique among the halogenated compounds. Organic chlorine compounds serve as a source of chlorine atoms, which readily abstract H atoms from other organic hydrocarbons accelerating the onset reactions. Chlorine, as HCl , can inhibit combustion through reactions like $\mathrm{OH}+\mathrm{HCl}=>\mathrm{H}_{2} \mathrm{O}+\mathrm{Cl}$, which depletes OH needed for CO burnout ${ }^{1}$.

Several investigations into the thermal decomposition of chloroform have been conducted. Semeluk and Bernstein ${ }^{2}$ investigated the decomposition kinetics of chloroform where they estimated a $72 \mathrm{kcal} / \mathrm{mol}$ upper limit for the activation energy of a proposed initiation reaction: $\mathrm{CHCl}_{3}=\mathrm{CHCl}_{2}+\mathrm{Cl}$.

Kung and Bissinger ${ }^{3}$ studied the pyrolysis of chloroform in cyclohexene. They reported on the formation of dichloronorcane (insertion of dichlorocarbene into the double bond to form a 1,1 dichlorocyclopropane ring) in addition to toluene, which is a known decomposition product from dichloronorcane. This suggested that $\mathrm{CCl}_{2}$, dichlorocarbene, was the major intermediate from unimolecular dissociation of chloroform.

Chloroform pyrolysis reaction and an elementary mechanism were previously studied extensively by Won in this NJIT Kinetics Research Group. His mechanism used a
value of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left({ }^{1} \mathrm{CCl}_{2}\right)$ of $39 \mathrm{kcal} / \mathrm{mol}$. We have since learn that the accurate value of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left({ }^{1} \mathrm{CCl}_{2}\right)$ is $53 \mathrm{kcal} / \mathrm{mol}$. It is critically important to note that the use of an incorrect $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298\left({ }^{1} \mathrm{CCl}_{2}\right)$ value off by more than $13 \mathrm{kcal} / \mathrm{mol}$ resulted in a mechanism that was not a thermodynamically correct or accurate reaction set. All of the chemical activated and other elementary reactions involving ${ }^{1} \mathrm{CCl}_{2}$ would have not been properly accounted to this 13 $\mathrm{kcal} / \mathrm{mol}$.

A revised mechanism for both pyrolysis and oxidation is therefore required. This new mechanism has each reaction of ${ }^{1} \mathrm{CCl}_{2}$ (the key radical in $\mathrm{CHCl}_{\text {s }}$ reaction system) reevaluated. The chemical activated reactions for combination, insertion, addition and reaction with $\mathrm{O}_{2}$ are of particular importance

Three studies (Benson and Spokes ${ }^{4}$, Schug et al. ${ }^{5}$, Herman, Lee et al. ${ }^{6}$ ) were directed at determining the activation energy and pathway of the initial step in chloroform thermal decomposition. Benson and Spokes favor an Arrhenius A factor of ca. 5.0E13 with an Ea greater than $56 \mathrm{kcal} / \mathrm{mol}$ for HCl elimination of chloroform from a very low pressure pyrolysis study. They also reported that when oxygen was added to reaction system, the products yielded a pair of mass peaks at 63 and 65 amu , possibly due to COCl from phosgene. This was an expected product from the reaction of dichlorocarbene with $\mathrm{O}_{2},: \mathrm{CCl}_{2}+\mathrm{O}_{2}=>\mathrm{CCl}_{2} \mathrm{O}+\mathrm{O}$.

Schug et al. ${ }^{5}$ measured the appearance of $\mathrm{C}_{2} \mathrm{Cl}_{4}$ by ultraviolet adsorption after a shock tube pulse, reporting a $54.5 \mathrm{kcal} / \mathrm{mol}$ activation energy at 1200 K . The photolysis of chloroform by Herman et al. ${ }^{6}$ examined the pulsed $\mathrm{CO}_{2}$ laser ( $11 \mu \mathrm{~m}$ ) multiple-photon dissociation of deuterated chloroform $\left(\mathrm{CDCl}_{3}\right)$ in a molecular beam. The only observed
dissociation pathway was hydrogen chloride ( DCl ) elimination ( $>99.1 \%$ ), with no evidence of simple chloride atom cleavage ( $<0.9 \%$ ).

Taylor and Dellinger ${ }^{7}$ evaluated the thermal degradation characteristics of the four chloromethanes as pure compounds as a function of feed composition and fuel/air equivalence ratio. Their results indicated chloroform was the most fragile molecule, and methyl chloride was the least fragile under both pyrolytic and oxidative conditions.

The reaction of chloroform diluted in hydrogen and water vapor has been studied in the temperature range $550-1200{ }^{\circ} \mathrm{C}$ by Chuang and Bozzelli. ${ }^{8}$ The major products of chloroform pyrolysis in $\mathrm{H}_{2}$ at temperatures above $1100^{\circ} \mathrm{C}$ were $\mathrm{HCl}, \mathrm{C}(\mathrm{s})$ and $\mathrm{CH}_{4}$. The most stable chlorocarbon products observed were chloromethane and $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{Cl}$ for the reaction of chloroform with excess hydrogen. This study also demonstrated that selective formation of HCl can result from thermal reaction of chloroform under an atmosphere of hydrogen.

In the present study, we focus on variations in chloroform decay rates and product distributions in presence and absence of added oxygen, but with no added hydrogen fuel source. Future research will incorporate $\mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{2}, \mathrm{CH}_{4}$ and supplemental hydrogen sources, which are most important to obtain quantitative HCl formation as well as application to actual incineration problems. A revised mechanism is developed from analysis of the experimental data and thermochemical principles, for chloroform pyrolysis and oxidation.

### 7.2 Experimental

### 7.2.1 Method

The thermal reaction of $\mathrm{CHCl}_{3}$ in both oxidative and pyrolytic reaction environments was studied by Won ${ }^{9}$ in a tubular flow reactor at 1 atm pressure. Reactant mole ratios were: $\mathrm{CHCl}_{3}(1 \%), \mathrm{O}_{2}(0-3 \%)$, Ar bath. Experiments were performed using a tubular flow reactor which has been described in detail in Won's thesis. ${ }^{9}$

Small amounts of $\mathrm{O}_{2}(0-3 \%)$ were added to the $\mathrm{CHCl}_{3} / \mathrm{Ar}$ flow. A quartz reactor tube, 10.5 mm ID, was housed within a three zone electric tube furnace 46 cm length. Temperature profiles were obtained using a type K thermocouple probe moved coaxially within the reactor under representative flows. The reactor effluent stream was analyzed by an on-line gas chromatograph with flame ionization detector (FID). A catalytic convertor was employed to increase the accuracy of quantitative analysis for CO and $\mathrm{CO}_{2}$. The $5 \%$ ruthenium on alumina ( $30 / 40$ mesh) at $315^{\circ} \mathrm{C}$ was used to catalyze CO and $\mathrm{CO}_{2}$ reduction with $\mathrm{H}_{2}(10 \mathrm{ml} / \mathrm{min})$.

Quantitative analysis of HCl was performed for each run; reactor effluent was diverted through a dual bubbler train containing 0.01 M NaOH before being exhausted to a fume hood. The HCl was then calculated based upon titration of the combined bubbler solutions with 0.01 M HCl to the phenolphthalein endpoint. The NaOH solution also collected $\mathrm{CO}_{2}$ and the $\mathrm{CO}_{2} / \mathrm{FDD}$ results were used to correct for this.

### 7.2.2 Result and Discussion

The thermal decomposition of the three reactant ratio sets were studied by Won to determine important chlorocarbon reaction pathways before initiating development of the detailed reaction mechanism.

Study 1: $\mathrm{CHCl}_{3}: \mathrm{Ar}=1: 99$
Study 2: $\mathrm{CHCl}_{3}: \mathrm{O}_{2}: \mathrm{Ar}=1: 1: 98$
Study 3: $\mathrm{CHCl}_{3}: \mathrm{O}_{2}: \mathrm{Ar}=1: 3: 96$

Figure 7.1 compares chloroform decay as a function of temperature in Ar bath gas at 1.0 sec reaction time for each reaction environment. $\mathrm{O}_{2}$ has a significant effect on the decomposition of parent $\mathrm{CHCl}_{3}$ in this reaction system; higher $\mathrm{O}_{2}$ results in faster $\mathrm{CHCl}_{3}$ decay. The accelerated decomposition of $\mathrm{CHCl}_{3}$, when $\mathrm{O}_{2}$ is present results from the bimolecular reactions of $\mathrm{O}_{2}$ and O with $\mathrm{CHCl}_{3}$ to $\mathrm{HO}_{2}+\mathrm{CCl}_{3}$ and $\mathrm{OH}+\mathrm{CCl}_{3}$ products respectively.

These reactions occur in parallel with the unimolecular dissociation of chloroform.

$$
\begin{aligned}
& \mathrm{CHCl}_{3} \Rightarrow \mathrm{CCl}_{2}+\mathrm{HCl} \\
& \mathrm{CHCl}_{3} \Rightarrow \mathrm{CHCl}_{2}+\mathrm{Cl}
\end{aligned}
$$

Increases in $\mathrm{O}_{2}$ concentration consistently increased reagent loss which is also observed in chlorobenzene oxidation. ${ }^{10}$ The O responsible for the increased reaction with $\mathrm{O}_{2}$ is from $\mathrm{CCl}_{2}+\mathrm{O}_{2}=>\mathrm{CCl}_{2} \mathrm{O}+\mathrm{O}$, where O can then react with $\mathrm{CHCl}_{3}$ and $\mathrm{CCl}_{2}$ results from reaction (1).

The OH radical is not as important to the destruction of $\mathrm{CHCl}_{3}$ since limited hydrogen is available when no supplemental fuel is added. In fact only small (ca 1\%) amounts of hydrogen substituted products are found in the presence of $\mathrm{O}_{2}$.

Data in Figure 7.2 indicate that oxygen has a significant effect on the formation of $\mathrm{CCl}_{4}$; the level of $\mathrm{CCl}_{4}$ in oxidative reaction is higher than in pyrolysis. The hydrogen atom present in the parent chloroform is lost by reaction with $\mathrm{O}, \mathrm{O}_{2}$ and OH , resulting in the $\mathrm{CCl}_{3}$ radical as shown above. The presence of $\mathrm{O}_{2}$ results in higher $\mathrm{CCl}_{3}$, and consequently higher $\mathrm{CCl}_{4}$, which is formed by Cl addition to $\mathrm{CCl}_{3}$ and Cl abstraction by $\mathrm{CCl}_{3}$.

$$
\mathrm{CCl}_{3}+\mathrm{RCl}=>\mathrm{CCl}_{4}+\mathrm{R} . \text { and } \mathrm{CCl}_{3}+\mathrm{Cl} \Rightarrow \mathrm{CCl}_{4}
$$

$\mathrm{C}_{2} \mathrm{Cl}_{4}$ is the main product observed over a wide range of temperatures for all cases as shown in Figure 7.3, where the symbols represent experimental data and the lines represent model prediction. This product mainly results from combination of two : $\mathrm{CCl}_{2}$ radicals and insertion of $\mathrm{CCl}_{2}$ into $\mathrm{CHCl}_{3}$ as reported by Won and Bozzelli. ${ }^{9}$

$$
\begin{aligned}
& \mathrm{CCl}_{2}+\mathrm{CCl}_{2}=\mathrm{C}_{2} \mathrm{Cl}_{4} \\
& \mathrm{CHCl}_{3}+\mathrm{CCl}_{2}<\Rightarrow\left[\mathrm{C}_{2} \mathrm{HCl}_{5}\right]^{*} \Rightarrow \mathrm{C}_{2} \mathrm{Cl}_{4}+\mathrm{HCl}
\end{aligned}
$$

There is, however, significantly less $\mathrm{C}_{2} \mathrm{Cl}_{4}$ formed when $\mathrm{O}_{2}$ is added. This implies that the reaction, $: \mathrm{CCl}_{2}+\mathrm{O}_{2}=>\mathrm{CCl}_{2} \mathrm{O}+\mathrm{O}$, suppresses the formation of $\mathrm{C}_{2} \mathrm{Cl}_{4}$. Here the $\mathrm{C}_{2} \mathrm{Cl}_{4}$ yield is decreased relative to its yield in $\mathrm{CHCl}_{3}$ pyrolysis in argon as shown in Figure 7.4. The presence of $\mathrm{O}_{2}$, therefore, results in suppressed $\mathrm{C}_{2} \mathrm{Cl}_{4}$ formation and faster decomposition of $\mathrm{C}_{2} \mathrm{Cl}_{4}$ as illustrated in Figures 3 and 4. The production of $\mathrm{C}_{2} \mathrm{Cl}_{4}$ increases with increasing temperature to a maximum near $680^{\circ} \mathrm{C}$ and then drops when CO begins to increase as indicated in Figures 5 and 6.

The $\mathrm{C}_{2} \mathrm{Cl}_{4}$ reaches a steady state value accounting for almost $100 \%$ of the parent $\mathrm{CHCl}_{3}$ carbon between 680 and $800{ }^{\circ} \mathrm{C}$ in pyrolysis ( 1.0 second reaction time). $\mathrm{C}_{2} \mathrm{Cl}_{4}$ is apparently thermodynamically stable in the pyrolysis throughout this time and temperature regime. There is, in addition, limited hydrogen available to undergo reaction with this species and chlorine abstraction by Cl is unlikely, due to the large endothermicity. This indicates that chlorinated compounds (such as $\mathrm{C}_{2} \mathrm{Cl}_{4}$ and $\mathrm{CCl}_{4}$ ) have a relatively high degree of stability up to $800{ }^{\circ} \mathrm{C}$ in reaction systems, which are deficient of $\mathrm{O}_{2}$ and hydrogen source. Data of Tirey et al. ${ }^{11}$ reported that $\mathrm{C}_{2} \mathrm{Cl}_{4}$ exhibited only minimal degradation at $800{ }^{\circ} \mathrm{C}$ and 2.0 second reaction time in a $\mathrm{C}_{2} \mathrm{Cl}_{4} / \mathrm{He}$ system and further observed that poly-aromatic compounds were formed above $900^{\circ} \mathrm{C}$.

### 7.3 Quantum RRK Calculations

The minor products of the C 2 species $\left(\mathrm{C}_{2} \mathrm{HCl}_{3}, \mathrm{C}_{2} \mathrm{HCl}_{5}, \mathrm{C}_{2} \mathrm{H}_{2} \mathrm{Cl}_{2}\right.$..etc.) observed in this reaction system are formed as a consequence of Cl radicals $\left(\mathrm{CHCl}_{2}, \mathrm{CCl}_{3}\right.$ and $\left.\mathrm{CCl}_{2}\right)$ which undergo combination and insertion processes (formation of chemically activated adducts)
as discussed by Won and Bozzelli. ${ }^{12}$ The reaction versus stabilization of these adducts are strongly pressure- and temperature-dependent and we find the Quantum Rice-Ramsperger- Kassel (QRRK) statistical analysis (Dean et al.) ${ }^{13}$ important to analyze the rate constants as a function of pressure and temperature.

All input parameters for QRRK calculations of important reactions considered in the reaction systems of pyrolysis and oxidation are listed in the Appendix as Table 7.A. 1 through Table 7.A.11. The potential energy diagram accompanied with Arrhenius plots which present the results of QRRK calculations are given as Figures 7.A. 1 through 7.A. 11.

### 7.3.1 Chloroform Pyrolysis

Figure 7.A. 1 presents the potential energy diagram and Arrhenius plot for three possible pathways of chloroform decomposition:

$$
\begin{align*}
& \mathrm{CHCl}_{3} \Rightarrow \mathrm{CCl}_{2}+\mathrm{HCl}  \tag{1}\\
& \mathrm{CHCl}_{3}=>\mathrm{CHCl}_{2}+\mathrm{Cl}  \tag{2}\\
& \mathrm{CHCl}_{3} \Rightarrow \mathrm{CCl}_{3}+\mathrm{H} \tag{3}
\end{align*}
$$

The reaction rate of (1) is sensitive to the rates of $\mathrm{CHCl}_{3}$ decay and $\mathrm{CCl}_{2}$ is the active intermediate of most importance in the pyrolysis system. The adjustment of the A factor and the reaction barrier of (1) will cause a dramatic change in the modeling prediction. The HCl elimination for CHCl 3 is expected via a three center Transition State (TS1).

The semiempirical MO calculation, MNDO/PM3 ${ }^{14}$ is used to define the molecular structure of TS1 and to obtain the vibrational frequencies, moments of inertia of external rotations, and thus the entropy of TS1. From conventional transition state theory, the preexponential factor, A is calculated by:
$A=\left(e h_{p} T / k_{b}\right) \exp \left(\Delta S^{\ddagger}\right)$,
where $h_{p}$ is Planck's constant, $k_{b}$ is the Boltzmann constant, $T$ is the temperature and $\Delta S^{\ddagger}$ is the entropy difference between the product and the TS. The PM3 calculations give $\Delta \mathrm{S}^{\ddagger}{ }_{298}=5.18 \mathrm{cal} / \mathrm{mol},{ }^{15}$ yielding $\mathrm{A}=7.18 \mathrm{El} 4 \mathrm{~s}^{-1}$ at the average temperature 950 K . The barrier, $\mathrm{Ea}_{1}$, equal to $57.5 \mathrm{kcal} / \mathrm{mol}$ is the result of the best fit of modeling to the experimental data of $\mathrm{CHCl}_{3}$ pyrolysis in the Ar bath. This value of $\mathrm{Ea}_{1}$ implies that the insertion of singlet dichlorocarbene, ${ }^{1}: \mathrm{CCl}_{2}$ into HCl to form $\mathrm{CHCl}_{3}$, as the backward reaction of (1), has a small barrier, c.a. $3.3 \mathrm{kcal} / \mathrm{mol}$.

Another important reaction is the insertion of the primary product, ${ }^{1}: \mathrm{CCl}_{2}$, into $\mathrm{CHCl}_{3}$ (see Figure 7.A.2):

$$
\begin{align*}
{ }^{1}: \mathrm{CCl}_{2}+\mathrm{CHCl} 3 \Leftrightarrow\left[\mathrm{C}_{2} \mathrm{HCl}_{5}\right]^{*} & \Rightarrow \mathrm{C}_{2} \mathrm{Cl}_{4}+\mathrm{HCl}  \tag{4}\\
& \Rightarrow \mathrm{C}_{2} \mathrm{HCl}_{3}+\mathrm{Cl} \tag{5}
\end{align*}
$$

Reaction (4) is also sensitive to the rates of $\mathrm{CHCl}_{3}$ decay and is an important path of $\mathrm{C}_{2} \mathrm{Cl}_{4}$ formation. The input parameters for QRRK calculations are listed in Table 7.A.2.

Three other important paths of $\mathrm{C}_{2} \mathrm{Cl}_{4}$ formation, (6), (7) and (8), are also analyzed. See Figure 7.A. 4 to 7.A. 5 and Table 7.A. 3 to 7.A. 5 for reaction (6), (7) and (8), respectively.

$$
\begin{align*}
\mathrm{CCl}_{2}+\mathrm{CCl}_{2} \Leftrightarrow\left[\mathrm{C}_{2} \mathrm{Cl}_{4}\right]^{*} & \Rightarrow \mathrm{C}_{2} \mathrm{Cl}_{3}+\mathrm{Cl}  \tag{6}\\
\mathrm{CCl}_{3}+\mathrm{CCl}_{2} \Leftrightarrow\left[\mathrm{C}_{2} \mathrm{Cl}_{5}\right]^{*} & \Rightarrow \mathrm{C}_{2} \mathrm{Cl}_{4}+\mathrm{Cl}  \tag{7}\\
\mathrm{CCl}_{3}+\mathrm{CCl}_{3} \Leftrightarrow\left[\mathrm{C}_{2} \mathrm{Cl}_{6}\right]^{*} & \Rightarrow \mathrm{C}_{2} \mathrm{Cl}_{4}+\mathrm{Cl}_{2}  \tag{8}\\
& \Rightarrow \mathrm{C}_{2} \mathrm{Cl}_{5}+\mathrm{Cl}
\end{align*}
$$

### 7.3.2 Chloroform Oxidation

Oxygen obviously plays an important role in limiting formation of heavy chlorocarbons under fuel lean combustion conditions. The reactions of the oxygen molecule and the oxygen atom with chlorocarbon radicals relevant to this study are important to the development of mechanism. These are addition and combination reactions and are analyzed using QRRK calculations.

The reaction paths of dichlorocarbene, ${ }^{1}: \mathrm{CCl}_{2}+\mathrm{O}_{2}$, is analyzed as the potential energy diagram presented in Figure 7.A.6. The input parameters of the QRRK calculations are given in Table 7.A.6.

$$
\begin{aligned}
{ }^{1}: \mathrm{CCl}_{2}+{ }^{3} \mathrm{O}_{2} \Leftrightarrow{ }^{3}\left[\mathrm{CCl}_{2} \mathrm{OO}\right]^{*} & =>\mathrm{CCl}_{2} \mathrm{O}+{ }^{3} \mathrm{O} \\
& =\mathrm{CClO}+\mathrm{ClO}
\end{aligned}
$$

The barrier of ${ }^{1}: \mathrm{CCl}_{2}$ addiction to $\mathrm{O}_{2}$ is determined to be $14 \mathrm{kcal} / \mathrm{mol}$, from the best model fit to experimental data. The well depth is estimated to be $12.4 \mathrm{kcal} / \mathrm{mol}$. The energized complex $\left[\mathrm{CCl}_{2} \mathrm{OO}\right]^{*}$ is expected to immediately beta-scission to $\mathrm{CCl}_{2} \mathrm{O}+\mathrm{O}$, because the reaction $\mathrm{CCl}_{2} \mathrm{OO} \Rightarrow \mathrm{CCl}_{2} \mathrm{O}+\mathrm{O}$ has low barrier and is highly exothermic. One other possible pathway, $\left[\mathrm{CCl}_{2} \mathrm{OO}\right]^{*} \Rightarrow \mathrm{CClO}+\mathrm{ClO}$ is estimated to be hindered by a high reaction barrier (c.a. $28.6 \mathrm{kcal} / \mathrm{mol}$ ), see potential energy diagram and the calculated Arrhenius plot in Figure 7.A.6.

The chemical activated combination reaction of $\mathrm{CCl}_{2}+\mathrm{O}$ is analyzed with the potential energy diagram presented in Figure 7.A.7.

$$
\begin{aligned}
\mathrm{CCl}_{2}+\mathrm{O} \Leftrightarrow\left[\mathrm{CCl}_{2} \mathrm{O}\right]^{*} & \Rightarrow \mathrm{CClO}+\mathrm{Cl} \\
& \Rightarrow \mathrm{CO}+\mathrm{Cl}_{2}
\end{aligned}
$$

The energized complex $\left[\mathrm{CCl}_{2} \mathrm{O}\right]^{*}$ mainly dissociates to CO and $\mathrm{Cl}_{2}$, which is identified as the important path of CO formation in the modeling prediction of $\mathrm{CHCl}_{3}$ oxidation.
$\mathrm{CCl}_{2}+\mathrm{OH}$ presents a more complex situation as the analysis of reaction paths given in Figure 7.A.8. Although the reactions of OH are not so important in our reaction system (see Section 7.2.2), it is important in flame, and it is analyzed for completeness of the mechanism. $\mathrm{CCl}_{2}+\mathrm{OH}=>\mathrm{CCl}_{2} \mathrm{O}+\mathrm{H}$ is the dominate path of the chemical activated reaction of $\mathrm{CCl}_{2}+\mathrm{OH} \Rightarrow$ products.

The reaction of $\mathrm{O}_{2}$ with $\mathrm{CCl}_{3}$, another important radical fragment of $\mathrm{CHCl}_{3}$ is analyzed as Figure 7.A.9:
$\mathrm{CCl}_{3}+\mathrm{O}_{2}<=>\left[\mathrm{CCl}_{3} \mathrm{OO}\right]^{*} \Leftrightarrow=>\left[\mathrm{C} . \mathrm{Cl}_{2} \mathrm{OOCl}\right]^{*}=>\mathrm{CCl}_{2} \mathrm{O}+\mathrm{ClO}$

The [ $\left.\mathrm{CCl}_{3} \mathrm{OO}\right]^{*}$ energized complex can be stabilized, decompose back to initial reactants, decompose to $\mathrm{CCl}_{3} \mathrm{O}+\mathrm{O}$, or isomerize (via Cl shift) to $\mathrm{CCl}_{2} \mathrm{OOCl}$, which immediately dissociates to $\mathrm{CCl}_{2} \mathrm{O}+\mathrm{ClO}$. The reaction to $\mathrm{CCl}_{3} \mathrm{O}+\mathrm{O}$ does not occur due to thermodynamic limitations (high energy barrier) as shown in Figure 7.A.9. The [C. $\left.\mathrm{Cl}_{2} \mathrm{OOCl}\right]^{*}$, if formed, will rapidly decompose to $\mathrm{CCl}_{2} \mathrm{O}+\mathrm{ClO}$, but there is a barrier here also and the primary reaction of this adduct is the dissociation back to reactants. Addition of $\mathrm{CCl}_{3}$ to $\mathrm{O}_{2}$ was determined to have a shallow well, $19.9 \mathrm{kcal} / \mathrm{mol}{ }^{16}$ This shallow well limits adduct formation and only a fraction of the collisions proceed to $\mathrm{CCl}_{2} \mathrm{O}$ +ClO at temperature $>1000 \mathrm{~K}$, see the Arrhenius plot in Figure 7.A.9.

In contrast to the situation of $\mathrm{CCl}_{3}+\mathrm{O}_{2}$, the reaction of $\mathrm{CCl}_{3}+\mathrm{O}$ has a deep energy well (c.a. $79 \mathrm{kcal} / \mathrm{mol}$ ), see the potential energy diagram in Figure 7.A.10. The combination-beta-scission channel $\mathrm{CCl}_{3}+\mathrm{O}=>\mathrm{CCl}_{2} \mathrm{O}+\mathrm{Cl}$ is the dominate path of the chemical activated reaction $\mathrm{CCl}_{3}+\mathrm{O}=>$ products, as the Arrhenius plot shows in Figure 7.A. 10.

### 7.4 Mechanism

Two elementary reaction sets describe the high temperature pyrolysis (Ar bath) and oxidation of $\mathrm{CHCl}_{3}$, and are presented in Tables 7.1 and 7.2 , respectively. The mechanisms are listed together with the rate parameters for the forward reaction paths and references for the rate constants. Reverse reaction rates were calculated from thermodynamics and microscopic reversibility (MR). In the initial phase of model development, the thermal decomposition of $\mathrm{CHCl}_{3}$ in argon bath gas was studied to determine the rate constants of the initiation reaction of $\mathrm{CHCl}_{3}$. The pyrolysis reaction system is the most straightforward $\left(\mathrm{CHCl}_{3} / \mathrm{Ar}\right.$ only) and it does not include the more complex effects from additive fuels and $\mathrm{O}_{2}$ on decay of $\mathrm{CHCl}_{3}$. The second phase of model development considers the effects of $\mathrm{O}_{2}$ addition to the $\mathrm{CHCl}_{3} / \mathrm{Ar}$ system.

The detailed oxidative/pyrolysis mechanism was constructed by systematically considering the elementary reactions of $\mathrm{CHCl}_{3} / \mathrm{O}_{2} / \mathrm{Ar}$ and intermediate stable species consistent with experimental observations. Recommended rate parameters based on recent experimental data or evaluations are used whenever possible. Kinetic data do not. however, exist for some of the needed elementary reactions, consequently, kinetic parameters were estimated for these by using thermodynamics, micro-reversibility, Transition State Theory ${ }^{17}$ and by generic analysis of the reaction, i.e. comparison of the reaction to a similar one where the rate parameters are known.

For reactions such as radical addition to an unsaturated species and radical-radical combination, where pressure and temperature effects can be important to determine the reaction paths of a chemically activated adduct, kinetic parameters were calculated using

Quantum RRK Theory (Dean et al.). ${ }^{13,18}$ Examples are described above for CHCl 3 dissociation, $\mathrm{CCl}_{3}$ and $\mathrm{CCl}_{2}$ additions to $\mathrm{O}_{2}$. The mechanism development also includes the analysis on the combination reactions of $\mathrm{CCl}_{2}$ and chlorinated hydrocarbon radicals (e.g. $\mathrm{CCl}_{3}$ and $\mathrm{CHCl}_{2}$ ) with $\mathrm{OH}, \mathrm{O}, \mathrm{HO}_{2}$ to correctly describe the temperature and pressure dependencies of plausible reaction pathways. Simple dissociation and isomerization reactions are analyzed with unimolecular QRRK analysis for treatment of the fall-off dependency.

The CHEMKIN computer program package (Kee et al. ${ }^{19,20}$ ) is used in interpreting and integrating the detailed reaction mechanisms (models) of the systems studied. Thermochemical data are required to determine the energy balance in chemical reactions, and in determining the Gibbs Free Energy of a reaction as a function of temperature. The thermodynamics also provide a convenient way to determine reverse reaction rate constants from the calculated equilibrium constant of the reaction and the known forward rate ${ }^{21}$ and play a very important role in determination of rate constants (A factors and activation energies).

The thermochemical information was acquired from the recent literature values. Data for some of the species in the mechanism are not available. Consequently, they were estimated by Benson's Group Additivity methods or THERM, ${ }^{22}$ a computer code which utilizes the Benson's Group Additivity scheme and the HBI estimation method (see Chapter 2 for example) based on bond dissociation energies and loss of a H atom from the corresponding parent of the radical. Bond energies for radicals can be obtained from evaluations of current literature. Entropies and heat capacities (versus temperature) are
calculated using thermochemical methods incorporating loss of the appropriate vibrational frequencies, changes in symmetry, spin and rotational barrier changes. The values determined are checked or compared with similar compounds or series of species to verify they are reasonably accurate. The thermodynamic properties and references listed in ref. 9 and 12 have been validated in this work.

### 7.5 Comparison of Model Predictions with Experimental Data

The thermal decomposition of $\mathrm{CHCl}_{3}$ in argon $\left(\mathrm{CHCl}_{3} / \mathrm{Ar}\right)$ was first studied to determine the rate constants of $\mathrm{CHCl}_{3}$ dissociation and to develop a mechanism for the pyrolysis system. The detailed reaction mechanism for $\mathrm{CHCl}_{3}$ pyrolysis in argon is listed in Table 7.1.

Figure 7.4 compares and shows good agreement between the pyrolysis experimental data and model predictions for $\mathrm{CHCl}_{3}$ decay plus product distributions versus temperature at 1 second reaction time. The lines represent model prediction and the symbols are the experimental data. Figure 7.5 presents the modeling prediction of $\mathrm{CHCl}_{3}$ decay in a pyrolyic environment versus reaction time ( 0 to 2.0 sec ) at five reaction temperatures. Figure 7.6 and Figure 7.7 illustrate model prediction and experimental data for product distribution versus reaction time at 873 K and 908 K , respectively.

Modeling $\mathrm{CHCl}_{3}$ oxidation required the listed reactions in Table 7.2 in addition to the pyrolysis mechanism in Table 7.1. Experimental data for $\mathrm{CHCl}_{3}$ oxidation, initial $1 \%$ $\mathrm{CHCl}_{3}+1 \% \mathrm{O}_{2}$ in Ar bath, are compared with model predictions in Figures 7.8 for $\mathrm{CHCl}_{3}$ decomposition and product distributions as function of temperature at 1 second reaction
time. Figure 7.9 and Figure 7.10 further compare the experimental data for the $1 \% \mathrm{CHCl}_{3}$ $+1 \% \mathrm{O}_{2}$ initial conditions with model prediction versus reaction time at 953 K and 1008 K , respectively.

Experimental data for $\mathrm{CHCl}_{3}$ oxidation, initial $1 \% \mathrm{CHCl}_{3}+3 \% \mathrm{O}_{2}$ in Ar bath, are compared with model predictions in Figures 7.11, for product distributions versus temperature at 1 second reaction time. Figure 7.12 presents the model prediction of product distribution as function of time at 673 K in $1 \% \mathrm{CHCl}_{3}+3 \% \mathrm{O}_{2}$ initial concentration.

The predictions shown are quite reasonable in all three cases. The $\mathrm{CHCl}_{3}$ pyrolysis mechanism is a subset of the $\mathrm{CHCl}_{3}$ oxidation mechanism which fits all of the pyrolysis data. Rate parameters for a few reactions appearing in Table 7.1 were varied over small intervals to give a better fit to our experimental data. For example, one important value optimized was the reaction barrier, Ea $a_{1}$ of chloroform dissociation to ${ }^{1}: \mathrm{CCl}_{2}+\mathrm{HCl}$. Here it was found that only $\pm 0.5 \mathrm{kcal} / \mathrm{mol}$ dramatically changed to the reaction predictions. The references to each elementary reaction listed in Table 7.1 and Table 7.2 actually describe the sources or how the rate constants were estimated. There is slight modification of a few key rate constants to fit our experimental results, if they are not accurately known from previous studies. The shape of the experimental $\mathrm{CHCl}_{3}$ loss and product profiles over a wide range of temperature, are reproduced quite well by the model.

### 7.6 Conclusion

The elementary reaction mechanisms are revised for chloroform pyrolysis and oxidation, which were previously studied in tubular flow reactors at 1 atm with a residence time 0.3 to 2.0 seconds in the temperature range $535-800^{\circ} \mathrm{C}$. The thermodynamic data for the species in the reaction systems are updated. Bimolecular Quantum RRK calculations for important reactions have been recalculated with the input parameters (high pressure limit rate constants) which are based on revised thermodynamic properties or taken from more recently reported kinetic data. High pressure limit rate constants have been evaluated for the following:

$$
\begin{aligned}
& \mathrm{CHCl}_{3} \Rightarrow \mathrm{CCl}_{2}+\mathrm{HCl}, \mathrm{~A}=7.18 \mathrm{El} 4 \mathrm{~s}^{-1}, \mathrm{Ea}=57.5 \mathrm{kcal} / \mathrm{mol} \\
& \mathrm{C}_{2} \mathrm{HCl}_{5} \Rightarrow \mathrm{C}_{2} \mathrm{Cl}_{4}+\mathrm{HCl}, \mathrm{~A}=1.60 \mathrm{E}_{1} 4 \mathrm{~s}^{-1}, \mathrm{Ea}=48.6 \mathrm{kcal} / \mathrm{mol}
\end{aligned}
$$

A barrier, $14 \mathrm{kcal} / \mathrm{mol}$ is determined for : $\mathrm{CCl}_{2}+\mathrm{O}_{2} \Rightarrow>$ products from best model-fitting to experimental data.

Chloroform decay and product distributions are distinctly different in the absence and presence of added $\mathrm{O}_{2}$. The presence of $\mathrm{O}_{2}$ was observed to speed reagent loss, decrease $\mathrm{C}_{2} \mathrm{Cl}_{4}$ formation and increase CO production. The major products from $\mathrm{CHCl} / \mathrm{O}_{2} / \mathrm{Ar}$ oxidation are $\mathrm{C}_{2} \mathrm{Cl}_{4}, \mathrm{CCl}_{4}, \mathrm{HCl}, \mathrm{CO}$ and $\mathrm{CO}_{2}$ over a wide temperature range. Minor products include $\mathrm{C}_{2} \mathrm{HCl}_{3}$ and $\mathrm{C}_{2} \mathrm{HCl}_{5}$.

An elementary reaction mechanism to describe the important features of product formation and reagent loss in pyrolysis and oxidation of chloroform with no added fuel has
been validated. The mechanism consists of 82 species and 198 elementary reactions and is based on thermochemical principles. Mechanism development includes QRRK analysis for the combination of $\mathrm{CCl}_{3}+\mathrm{CCl}_{3}, \mathrm{CCl}_{3}+\mathrm{CCl}_{2}, \mathrm{CCl}_{2}+\mathrm{CCl}_{2}$, and chlorinated hydrocarbon radicals with $\mathrm{OH}, \mathrm{O}, \mathrm{HO}_{2}, \mathrm{ClO}$ and radical addition to $\mathrm{O}_{2}$.

## CHAPTER 8

# DETAILED ANALYSIS OF PHOTOCHEMICAL OXIDATION OF BENZENE AND TOLUENE IN THE ATMOSPHERE: <br> BENZENE + OH AND THE ADDUCT (HYDROXYL-2,4-CYCLOHEXADIENYL) $+\mathrm{O}_{2}$ TOLUENE + OH AND THE ADDUCT (HYDROXYL-2,4-METHYLCYCLOHEXADIENYL) $+\mathrm{O}_{\mathbf{2}}$ 

### 8.1 Introduction

A number of researchers have studied photochemical oxidation of aromatic hydrocarbons, such as benzene, ${ }^{23,24,25}$ toluene ${ }^{23-30}$ and xylenes, ${ }^{23,28,31,32}$ since aromatics comprise a substantial portion of the reactive hydrocarbon in the urban atmosphere. ${ }^{30,33,34}$ Toluene represents one-third of the atmospheric aromatics and probably is the most extensively studied aromatic up to date. ${ }^{30,33}$ Several reaction mechanisms were proposed for the interpretation of the experimental data of toluene photooxidation, ${ }^{26,30,35-37}$ and the model prediction of formation and decay of a limited number of products appear to fit the observed major features. ${ }^{26,30}$

Detailed interpretations of experimental results using reaction mechanisms are limited due in part to the paucity of thermodynamic property data and barriers to formation of the key intermediates in the reaction systems. ${ }^{26,38,39}$ The evaluations of rate constants are difficult and sometimes questionable without the available enthalpies and entropies of reactants and products. In addition, the reaction mechanisms currently used for modeling of photooxidation of toluene and other aromatics contain only apparent rate constants for many important reactions, due in part to the difficulty in determination of
absolute rate constants from overall reaction rates without required thermodynamic data, and also to lack of microscopic reversibility in the rate parameters.

Absolute rate constants for the initial reactions of aromatic oxidation of the benzene and toluene, especially the reactions of benzene and toluene +OH , and the adducts (benzene- OH and toluene- OH ) $+\mathrm{O}_{2},{ }^{25,26,38}$ are derived and validated in this study. Reaction path analysis, reaction barriers, Arrhenius A factors, and energy well depth of each reaction step have been calculated for:

$$
\begin{align*}
& \text { Benzene }+\mathrm{OH}=\text { Benzene- } \mathrm{OH} \text { adduct }  \tag{1}\\
& \text { Benzene-OH adduct }+\mathrm{O}_{2}=\text { Benzene- } \mathrm{OH}-\mathrm{O}_{2} \text { adduct }\left(\mathrm{C}_{6} \mathrm{H}_{7} \mathrm{O}_{3}\right)  \tag{2}\\

$$
\begin{equation*}
+ \text { 2-methyl-butene-1,4-dial (or precursor radical) }+\mathrm{NO}_{2} \tag{13}
\end{equation*}
$$

One important requirement in the evaluation of reaction rate constants and derivation of detailed mechanisms is the thermodynamic properties $\left(\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}, \mathrm{~S}^{\circ}{ }_{298}\right)$ of reactants, intermediates and products in the reactions studied. We calculate values of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}, \mathrm{~S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's $(\mathrm{T}=300 \mathrm{~K}$ to 1500 K$)$ for species including:
-aromatic stable molecule and free radicals

- OH -aromatic adduct
-peroxy adducts and radicals (data not previously available)
-bicyclic ring species resulting from OO internal addition across the rings
-radicals and stable species resulting from reactions of the above species with NOx
-radicals and stable species resulting from beta scission of the above species,
We also develop elementary kinetic mechanisms, including microscopic reversibility for each step, for production of species like glyoxal and butene-dial and the intermediates leading to them.

The thermodynamic properties of bicyclic peroxy rings adducts are particularly important to evaluate the kinetic factors for ring opening steps which lead to the final stable products. Examples include: the bicyclic-(benzene-OH- $\mathrm{O}_{2}$ ) adduct in benzene system and the bicyclic-(toluene- $\mathrm{OH}-\mathrm{O}_{2}$ ) adduct in the toluene system. Calculations of ring strain energy and thermodynamic properties of these species are also carried out.

Quantum Rice-Ramsperger-Kassel (QRRK) analyses ${ }^{13}$ which incorporate the modified strong collision ( $\beta$-collision) approach of Gilbert, Luther and Troe for fall off, are performed on chemical activated reactions (1)-(5), (7)-(11) for pressure and temperature dependence. Results are presented here only for latm pressure. High pressure limit kinetic parameters (A factor and Ea's) of the reactions used as input of the QRRK calculations are taken from generic reactions in the literature or estimated from thermodynamic and kinetic principles, e.g. Transition State Theory (TST). The estimation of kinetic factors for ring opening and $\beta$-scission reactions in the photooxidation of benzene and toluene are also carried out.

Modeling calculations on selected limited reaction sets are performed. It is important to note that in these modeling calculations:
-All reactions are elementary or treated in a way that the elementary reaction steps are properly incorporated.
-All reactions are reversible
-Reverse reaction rates are calculated from thermodynamics and microscopic reversibility (MR) principles.

The reasons for using MR, i.e. considering reverse reactions, are both thermodynamically consistent and resulting in more accurate determination of species concentrations near steady state. Inclusion of MR allows use of accurate elementary rate constants. Inclusion of reverse reactions eliminates the need to use adjusted or apparent rate constants for reactions where the reverse reaction is important. These adjustments are
often just the values of average estimate or the estimated conversion rate, and are usually not correct at all operating condition over a given experimental study.

### 8.2 Calculations and Results of Benzene Photooxidation System

### 8.2.1 Chemical Activated Reactions of $\mathrm{OH}+$ Benzene

The addition of the OH radical to the aromatic ring of benzene forms an energized benzene-OH adduct ( I ). This energized benzene- OH adduct can dissociate back to reactants, be stabilized, or react to form phenol +H atom via $\beta$-scission.

$$
\begin{align*}
& \mathrm{C}_{6} \mathrm{H}_{6}+\mathrm{OH} \Leftrightarrow\left[\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{OH}\right]^{*} \\
& {\left[\mathrm{C}_{6} \mathrm{H}_{6}-\mathrm{OH}\right]^{*}+\mathrm{M}=>\mathrm{C}_{6} \mathrm{H}_{6}-\mathrm{OH}+\mathrm{M}} \\
& {\left[\mathrm{C}_{6} \mathrm{H}_{6}-\mathrm{OH}\right]^{*}=>\text { Phenol }\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\right)+\mathrm{H}} \tag{B2}
\end{align*}
$$

### 8.2.1.1 Thermodynamic Properties for Benzene-OH Adduct

The thermodynamic properties of the benzene-OH adduct (I) are estimated from those of hydroxyl 2,4-cyclohexadiene (II) which are calculated using the Group Additivity (GA) method. ${ }^{17,22}$ The hydroxyl-2,4-cyclohexadiene (II) stable molecule, is called the parent molecules for the free radical, hydroxyl-2,4-cyclohexadienyl (benzene-OH) (I).

I

II

The above oxyhydrocarbons, both daughter radical and parent molecule, closely parallel to cyclohexadienyl and cyclohexadiene whose thermochemistry have been extensively studied. ${ }^{1,40-44}$ The HC-H bond energy for cyclohexadienyl was evaluated by Tsang as $76.0 \mathrm{kcal} / \mathrm{mol}(318 \mathrm{~kJ} / \mathrm{mol})^{44}$ which is adopted in this work. $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{II})$ is calculated using GA method as $-13.73 \mathrm{kcal} / \mathrm{mol}$. This results in $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{I})$ of 10.17 $\mathrm{kcal} / \mathrm{mol}$, using Tsang's $\mathrm{HC}-\mathrm{H}$ bond energy and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{H}).(52.1 \mathrm{kcal} / \mathrm{mol}) .{ }^{45}$

The entropy $\left(\mathrm{S}^{\circ}{ }_{298}\right)$ and heat capacities $(\mathrm{Cp}(\mathrm{T}), 300 \leq \mathrm{T} / \mathrm{K} \leq 1000)$ for I are also evaluated from II, by applying the incremental values of $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's from cyclohexadiene to cyclohexadienyl. This approach is termed as the "Hydrogen Atom Bond Increment" (HBI) group, ${ }^{46}$ which is based on known thermodynamic properties of the parent and calculated changes that occur upon formation of a radical via loss of a H atom. The HBI group values for radicals of cyclohexadienyl type $(\mathrm{HBI}(\mathrm{CHD}))$ is applied to compound I to obtain entropies and heat capacities of radical II.

The values of $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's for 1,3-cyclohexadiene are taken from the work of Dorofeeva et al. ${ }^{47}$ The entropies and heat capacities of cyclohexadienyl were evaluated by Tsang ${ }^{44}$ using the vibrational frequencies which were assessed from those of benzene and 1,4-cyclohexadiene. The selection of frequencies for cyclohexadienyl by Tsang was desired to fit the experimental value of entropy at 550 K equal to $89.7 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$. We separately performed a semiempirical MO calculation, MNDO/PM3 (PM3) ${ }^{14}$ using MOPAC $6.0^{48}$ to further determine the vibrational frequencies of cyclohexadienyl and thus the $S^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's of cyclohexadienyl as given in Table 8.1. Our values of $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's are slightly different from Tsang's. The PM3 MO calculation gives 90.1
$\mathrm{cal} / \mathrm{mol}-\mathrm{K}$ as the entropy of cyclohexenyl at 550 K which is in excellent agreement with the experimental data, without any further adjustment. The $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's of the PM3 MO calculation for cyclohexadienyl and the work of Dorofeeva et al. for 1,3cyclohexadiene are therefore used to derive the groups values ( $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})^{\prime}$ 's) of $\mathrm{HBI}(\mathrm{CHD})$ by subtracting the intrinsic entropy $\left(\mathrm{S}_{\text {int }}{ }^{\circ}{ }^{298}\right)$ and heat capacities $(\mathrm{Cp}(\mathrm{T})$ 's) of cyclohexadiene from those of cyclohexadienyl, e. g.
$\Delta \mathrm{S}^{\circ}{ }_{298}(C H D)=\mathrm{S}_{\text {int }}{ }^{\circ}{ }_{298}(1,3$-cyclohexadiene $)-\mathrm{S}_{\text {int }}{ }^{\circ}{ }_{298}($ cyclohexadienyl $)=-0.68 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$.
$\Delta \mathrm{Cp}_{300}(C H D)=\mathrm{Cp} \mathrm{p}_{300}(1,3$-cyclohexadiene $)-\mathrm{Cp} \mathrm{p}_{300}($ cyclohexadienyl $)=-0.80 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$, and so on for $\Delta \mathrm{Cp}_{400}(C H D)$ to $\Delta \mathrm{Cp}_{1000}(C H D)$.

And $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's for I are calculated as:
$\mathrm{S}_{\text {int }}{ }^{\circ}{ }_{298}(\mathrm{I})=\mathrm{S}_{\mathrm{int}}{ }^{\circ}{ }_{298}(\mathrm{II})+\Delta \mathrm{S}^{\circ}{ }_{298}($ CHD $)$ and $\mathrm{Cp}(\mathrm{T})(\mathrm{I})=\mathrm{Cp}(\mathrm{T})(\mathrm{II})+\Delta \mathrm{Cp}(\mathrm{T})(C H D)$

The thermodynamic properties for species I and II are given in Table 8.1.

### 8.2.1.2 Quantum RRK Calculation for Benzene $+\mathbf{O H}$

The potential energy diagram for the reaction of benzene +OH is illustrated in Figure 8.1. The well depth for OH addition to benzene is $19.1 \mathrm{kcal} / \mathrm{mol}$ according to our thermochemical calculation. The high pressure limit rate constant of reaction (B1) needed for the QRRK input parameters has the pre-exponential factor (A factor) estimated to be $2.29 \mathrm{E} 12 \mathrm{cc} / \mathrm{mol}-\mathrm{s}$ with a small barrier $0.68 \mathrm{kcal} / \mathrm{mol}$ following the recommendation of

Baulch et al. ${ }^{49} \mathrm{k}_{\mathrm{B} 1}$ is calculated via the principle of microscopic reversibility (MR) ${ }^{17}$ using the thermodynamic data given in Table 8.1. The rate constant for addition of the H atom to benzene is used to evaluate $\mathrm{k}_{-\mathrm{B} 2}$ and then $\mathrm{k}_{\mathrm{B} 2}$ :

$$
\begin{equation*}
\mathrm{H}+\mathrm{C}_{6} \mathrm{H}_{6} \Rightarrow \mathrm{C}_{6} \mathrm{H}_{7} \tag{B3}
\end{equation*}
$$

The value of $\mathrm{A}_{\mathrm{B} 3}$ is reported ${ }^{50}$ as $3.98 \mathrm{E} 13 \mathrm{~mol} / \mathrm{cc}-\mathrm{s}$ with a barrier, $\mathrm{Ea}_{\mathrm{B} 3}=4$ $\mathrm{kcal} / \mathrm{mol}$. $\mathrm{A}_{-\mathrm{B} 2}$ and $E a_{-\mathrm{B} 2}$ are assumed equal to $\mathrm{A}_{\mathrm{B} 3}$ and $E a_{\mathrm{B} 3}$, and thus $\mathrm{A}_{\mathrm{B} 2}$ and $E a_{\mathrm{B} 2}$ can be determined via MR. The input data for the QRRK calculation of benzene +OH and the calculation results are give in Table 8.3. The calculated apparent rate constants as a function of temperature are also listed in Table 8.3. The Arrhenius plot for the apparent rate constants is illustrated in Figure 8.2.

As Figure 8.2 illustrates, the stabilization channel is dominant at room temperature and l atm. The apparent rate constant of benzene $+\mathrm{OH} \Rightarrow$ benzene- OH adduct at 298 K is calculated to be $7.23 \mathrm{E} 11 \mathrm{~mol} / \mathrm{cc}-\mathrm{s}$ which is identical to the value measured by means of flash photolysis-resonance fluorescence technique. ${ }^{23}$ The formation of phenol is obviously the minor reaction path in the temperature regime lower than 500 K , although it is important at high temperature.

### 8.2.2 Chemical Activated Reactions of Benzene- OH Adduct $+\mathrm{O}_{2}$

The addition of the benzene- OH adduct to $\mathrm{O}_{2}$ first forms the benzene- $\mathrm{OH}-\mathrm{O}_{2}$ adduct (hydroxyl-2,4-cyclohexadienyl-6-peroxy). This adduct can dissociate back to reactants,
isomerize to one of several bicyclic adducts, or react via hydrogen transfer following $\beta$ scission to form 2,4-hexadienyl-1,6-dial +OH , or to phenol $+\mathrm{HO}_{2}$, see Figure 8.3. Calculation of the thermodynamic properties of these species, and the evaluations of the kinetic parameters are carried out as follows.

### 8.2.2.1 Thermodynamic Properties for Benzene-OH-O $\mathrm{O}_{2}$ Adduct

The benzene- $\mathrm{OH}-\mathrm{O}_{2}$ adduct is formed via the addition of benzene- $\mathrm{OH}+\mathrm{O}_{2}$. The addition reactions can happen at either position 2 or 4 of the ring. ${ }^{26,38}$ However, we only discuss the addition at position 2 to form adduct V as the primary adduct as a mean to simplify the reaction system and the further detailed analyses of the reactions of the peroxy adduct.

The thermodynamic properties of the parent molecule of III, e.g. the hydroperoxide IV (or marked as $\mathrm{III}_{+\mathrm{H}}$ ) is first calculated using the GA method. The enthalpy for IV appears as $-37.3 \mathrm{kcal} / \mathrm{mol}$. The average bond energy $\mathrm{D}^{\circ}{ }_{298}(\mathrm{ROO}--\mathrm{H})$ was determined as $88.0 \mathrm{kcal} / \mathrm{mol}\left(\mathrm{R}\right.$ is an alkyl group) ${ }^{51,52}$ which leads to $-1.2 \mathrm{kcal} / \mathrm{mol}$ for $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ of III.

The entropy and heat capacities for III are estimated from IV by using the HBI PEROXY group $(\mathrm{HBI}($ PEROXY $)) .{ }^{46}$ e.g.
$\mathrm{S}_{\text {int }}{ }^{\circ}{ }_{298}(\mathrm{IV})=\mathrm{S}_{\text {int }}{ }^{\circ}{ }_{298}(\mathrm{III})+\Delta \mathrm{S}^{\circ}{ }_{298}($ PEROXY $)$
$\mathrm{Cp}(\mathrm{T})(\mathrm{IV})=\mathrm{Cp}(\mathrm{T})(\mathrm{III})+\Delta \mathrm{Cp}(\mathrm{T})(\boldsymbol{P E R O X Y}), 300 \leq \mathrm{T} / \mathrm{K} \leq 1000$

The group values for $\mathrm{HBI}(\mathbf{P E R O X Y})$ as given in Table 8.2 are the $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's increments resulting from loss and/or change in vibration frequencies and changes in barriers to internal rotation, from alkyl hydroperoxide ( ROOH ) to alkyl peroxy radical (ROO.). The $\mathrm{S}^{\circ}{ }_{298}, \mathrm{Cp}(\mathrm{T})$ 's and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ for species III and IV are given in Table 8.1.

### 8.2.2.2 Thermodynamic Properties and Ring Strain Energy for Bicyclic Peroxy Species

Adduct III can isomerize to bicyclic species via the addition of the peroxy radical to a double bond of the ring:

VIII

The thermodynamic properties $\left(\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\right.$ and $\left.\mathrm{S}^{\circ}{ }_{298}\right)$ of theses bicyclic peroxy radicals are extremely important in evaluating the kinetic parameters of consequent reactions of benzene- $\mathrm{OH}+\mathrm{O}_{2}$. Unfortunately, the thermodynamic properties of these species have not been previously studied, and the corresponding group values for use in GA method are not available. We calculate the thermodynamic properties of their parent (stable) molecules prior to calculating the thermodynamic properties of the bicyclic radicals. Ring strain energies are required in estimating the thermodynamic properties of the parent molecules by our GA approach. These are also evaluated from the calculated enthalpies of these bicyclic molecules. Several HBI groups (see Chapter 2) are then used to estimate the thermodynamic properties of the radical adducts V to VIII, after parameters of the corresponding parent molecules are obtained.

### 8.2.2.2.1 Enthalpy and Ring Strain Energy of the Bicyclic Peroxides

MO calculations of the three bicyclic compounds were carried out to investigate the ring strain energies, e.g.

We utilized the PM3 MO method to determine the theoretical enthalpies ( $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298, \mathrm{PM} 3}$ ) of $\mathrm{A}, \mathrm{B}$ and C . An analysis was performed to determine a correlation factor
for the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298, \mathrm{PM} 3}$ with the experimental values of $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }^{298, \text { expt. }}\right.$ ) for relevant monocyclic and bicyclic hydrocarbons. A plot of this correlation, $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$, expt. vs. $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298, \mathrm{PM} 3}$ is illustrated in Figure 8.4. The regressed line is found to pass through $(0,0)$ with a slope 0.83 , resulting $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298, \text { expt. }}=0.83 \times \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298, \text { expt. }}$. The empirical factor 0.83 is used to scale the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }^{298, \mathrm{PM} 3}$ values of $\mathrm{A}, \mathrm{B}$ and C .

The PM3 values for enthalpy of formation are: $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298, \mathrm{PM} 3}(\mathrm{~A})=-2.37 \mathrm{kcal} / \mathrm{mol}$, $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298, \mathrm{PM} 3}(\mathrm{~B})=-5.73 \mathrm{kcal} / \mathrm{mol}$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298, \mathrm{PM} 3}(\mathrm{C})=+24.08 \mathrm{kcal} / \mathrm{mol}$. The scaled values are: $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{~A})=-1.97 \mathrm{kcal} / \mathrm{mol}, \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{~B})=-4.76 \mathrm{kcal} / \mathrm{mol}$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{C})=+20.00$ $\mathrm{kcal} / \mathrm{mol}$. The total ring stain energy (R.S.) can be obtained using the GA groups ${ }^{22}$ for centered atoms in the molecules.

The enthalpy of formation of compound $A$ is expressed by groups in GA approach as, $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{~A})=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left\{2\left(\mathrm{C}_{\mathrm{d}} / \mathrm{C} / \mathrm{H}\right)+2\left(\mathrm{C} / \mathrm{C} / \mathrm{C}_{\mathrm{d}} / \mathrm{H} / \mathrm{O}\right)+2(\mathrm{O} / \mathrm{C} / \mathrm{O})+(\mathrm{C} / \mathrm{C} 2 / \mathrm{H} / \mathrm{O})+\right.$ $(\mathrm{O} / \mathrm{C} / \mathrm{H})+(\mathrm{C} / \mathrm{C} 2 / \mathrm{H} 2)\}+$ Ring Strain of A (R.S.(A)); where the symbol $\mathrm{C}_{\mathrm{d}} / \mathrm{C} / \mathrm{H}$, $\mathrm{C} / \mathrm{C} / \mathrm{C}_{\mathrm{d}} / \mathrm{H} / \mathrm{O}, \ldots .$. etc. are the terms of the GA approach used in THERM package. ${ }^{22}$ The ring strain energy of compound A is therefore calculated as:
R.S. $(\mathrm{A})=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{~A})-\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left\{2\left(\mathrm{C}_{\mathrm{d}} / \mathrm{C} / \mathrm{H}\right)+2\left(\mathrm{C} / \mathrm{C} / \mathrm{C}_{\mathrm{d}} / \mathrm{H} / \mathrm{O}\right)+2(\mathrm{O} / \mathrm{C} / \mathrm{O})+(\mathrm{C} / \mathrm{C} 2 / \mathrm{H} / \mathrm{O})+\right.$ $(\mathrm{O} / \mathrm{C} / \mathrm{H})+(\mathrm{C} / \mathrm{C} 2 / \mathrm{H} 2)\}$, and so on for the R.S.(B) and R.S.(C).

The calculated total ring strain energies are: R.S. $(\mathrm{A})=14.77 \mathrm{kcal} / \mathrm{mol}$, R.S. $(\mathrm{B})=$ $13.01 \mathrm{kcal} / \mathrm{mol}$ and R.S. $(\mathrm{C})=38.80 \mathrm{kcal} / \mathrm{mol}$. These enthalpy increments due to ring strain
are assigned to three new GA groups, $\mathrm{BCY} / \mathrm{C} 2 \mathrm{E} / \mathrm{O} 2 / \mathrm{C} 2, \mathrm{BCY} / \mathrm{C} 3 \mathrm{E} / \mathrm{O} 2 / \mathrm{C} 1$ and $\mathrm{BCY} / \mathrm{C} 4 \mathrm{E} / \mathrm{O} 2 / 0$ in use for the type $\mathrm{A}, \mathrm{B}$ and C bicyclic peroxy hydrocarbons, respectively.

Enthalpies of the hydroxyl bicyclic peroxides (the parent molecules for radical adducts V to VIII , identified as $\left.\mathrm{V}_{+\mathrm{H}}, \mathrm{VI}_{+\mathrm{H}}, \mathrm{VII}_{+\mathrm{H}}, \mathrm{VIII}_{+\mathrm{H}}\right)$ are calculated using the GA method coupled with the three groups developed above. The enthalpy of $\mathrm{V}_{+\mathrm{H}}$ (the parent molecule of V ), for example, is calculated as:
$\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{~V}_{+\mathrm{H}}\right)=\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left\{2\left(\mathrm{C}_{\mathrm{d}} / \mathrm{C} / \mathrm{H}\right)+\left(\mathrm{C} / \mathrm{C} / \mathrm{C}_{\mathrm{d}} / \mathrm{H} 2\right)+\left(\mathrm{C} / \mathrm{C} / \mathrm{C}_{\mathrm{d}} / \mathrm{H} / \mathrm{O}\right)+2(\mathrm{O} / \mathrm{C} / \mathrm{O})+\right.$ $(\mathrm{C} / \mathrm{C} 2 / \mathrm{H} / \mathrm{O})+(\mathrm{O} / \mathrm{C} / \mathrm{H})+(\mathrm{BCY} / \mathrm{C} 3 \mathrm{E} / \mathrm{O} 2 / \mathrm{C} 1)\}$

The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ of each hydroxyl bicyclic radical (V, VI, VII, VIII) is obtained from the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ of the parent hydroxyl cyclic peroxide $\left(\mathrm{V}_{+\mathrm{H}}, \mathrm{VI}_{+\mathrm{H}}, \mathrm{VII}_{+\mathrm{H}}, \mathrm{VIII}_{+\mathrm{H}}\right)$ and the corresponding $\mathrm{C}-\mathrm{H}$ bond energy, $\mathrm{D}^{\circ}{ }_{298}(\mathrm{C}-\mathrm{H})$. The secondary $\mathrm{D}^{\circ}{ }_{298}(\mathrm{C}-\mathrm{H}), 98.45$ $\mathrm{kcal} / \mathrm{mol},{ }^{53}$ is used to estimate $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{VI})$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{VII})$. The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{VI} \mathrm{I}_{\mathrm{H}}\right)$ is determined as $-42.14 \mathrm{kcal} / \mathrm{mol}$ using the GA method, which leads to a $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{VI})$ equal to $3.86 \mathrm{kcal} / \mathrm{mol}$.

Adducts V and VIII are allylic and the secondary allylic C--H bond energy is estimated to be $85.6 \mathrm{kcal} / \mathrm{mol} .{ }^{54} \Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{~V})=-13.2 \mathrm{kcal} / \mathrm{mol}$ is estimated from $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ of its parent $\left(\mathrm{V}_{+\mathrm{H}}\right),-44.93 \mathrm{kcal} / \mathrm{mol}$ with this secondary allylic bond energy.

### 8.2.2.2.2 Entropy and Heat Capacities

PM3 in the MOPAC 6.0 package was used to calculate the entropies and heat capacities for compound $\mathrm{A}, \mathrm{B}$ and C . These data were used to derive the group values of $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's for above three new groups, $\mathrm{BCY} / \mathrm{C} 2 \mathrm{E} / \mathrm{O} 2 / \mathrm{C} 2, \mathrm{BCY} / \mathrm{C} 3 \mathrm{E} / \mathrm{O} 2 / \mathrm{C} 1$ and $\mathrm{BCY} / \mathrm{C} 4 \mathrm{E} / \mathrm{O} 2 / 0 . \quad \mathrm{S}^{\circ}{ }_{298}(\mathrm{BCY} / \mathrm{C} 2 \mathrm{E} / \mathrm{O} 2 / \mathrm{C} 2)$ is obtained, for example, by taking the increment of $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's for this bicyclic ring form $\mathrm{S}_{\mathrm{int}}{ }^{\circ}{ }_{298}(\mathrm{~A})$ minus the $\mathrm{S}^{\circ}{ }_{298}$ group values of all the centered atoms:
$\mathrm{S}^{\circ}{ }_{298}(\mathrm{BCY} / \mathrm{C} 2 \mathrm{E} / \mathrm{O} 2 / \mathrm{C} 2)=\mathrm{S}_{\text {int }}{ }^{\circ}{ }_{298}(\mathrm{~A})-\mathrm{S}^{\circ}{ }_{298}\left\{2\left(\mathrm{C}_{\mathrm{d}} / \mathrm{C} / \mathrm{H}\right)+2\left(\mathrm{C} / \mathrm{C} / \mathrm{C}_{\mathrm{d}} / \mathrm{H} / \mathrm{O}\right)+2(\mathrm{O} / \mathrm{C} / \mathrm{O})+\right.$ $(\mathrm{C} / \mathrm{C} 2 / \mathrm{H} / \mathrm{O})+(\mathrm{O} / \mathrm{C} / \mathrm{H})+(\mathrm{C} / \mathrm{C} 2 / \mathrm{H} 2)\}$,
and so on for $\mathrm{S}^{\circ}{ }_{298}(\mathrm{BCY} / \mathrm{C} 3 \mathrm{E} / \mathrm{O} 2 / \mathrm{C} 1)$ and $\mathrm{S}^{\circ}{ }_{298}(\mathrm{BCY} / \mathrm{C} 4 \mathrm{E} / \mathrm{O} 2 / 0)$ and the $\mathrm{Cp}(\mathrm{T})$ group values

The availability of the $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's group values for $\mathrm{BCY} / \mathrm{C} 2 \mathrm{E} / \mathrm{O} 2 / \mathrm{C} 2$, $\mathrm{BCY} / \mathrm{C} 3 \mathrm{E} / \mathrm{O} 2 / \mathrm{Cl}$ and $\mathrm{BCY} / \mathrm{C} 4 \mathrm{E} / \mathrm{O} 2 / 0$ enable the calculation of corresponding parameters for the hydroxyl bicyclic peroxides, $\mathrm{V}_{+\mathrm{H}}, \mathrm{VI}_{+\mathrm{H}}, \mathrm{VII}_{+\mathrm{H}}$ and $\mathrm{VIII}_{+\mathrm{H}}$ (parent molecules of V to VIII) using the GA method. The $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's of the bicyclic radical adducts, V, VI, VII and VIII are then estimated from the properties of their parent molecules and HBI group. Two HBI groups are introduced to carry out these calculations.

The HBI groups CHENE (secondary cyclohexadienyl) and CHENEA (allylic cyclohexadienyl) were used in the estimation of the $S^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's for the 4cyclohexenyl type and 3-cyclohexenyl type of radicals, respectively. Group values ( $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\triangle \mathrm{Cp}(\mathrm{T})$ 's) of $\mathrm{HBI}($ CHENE $)$ and $\mathrm{HBI}($ CHENEA $)$ were determined as the increments of $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})$ 's from cyclohexene to 4-cyclohexenyl and 3-cyclohexenyl,
respectively. The $\Delta \mathrm{S}^{\circ}{ }_{298}$ and $\Delta \mathrm{Cp}(\mathrm{T})$ 's data for cyclohexene were taken from the work of Dorofeeva et al., the these parameters of two cyclohexenyl radicals are obtained using PM3 MO calculations.

## HBI group

CHENE

4-Cyclohexenyl (non-allylic type)

## CHENEA

$S^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's of adducts V and VIII were calculated using the $\operatorname{HBI}(C H E N E A)$ group. The $\mathrm{HBI}(C H E N E)$ group is used to determine those properties of adducts VI and VII. Entropies, heat capacities and enthalpies of formation of the radical species and their parent molecules are given in Table 8.1.

### 8.2.2.3 Quantum RRK Kinetic Calculation of Benzene-OH Adduct $+\mathbf{O}_{2}$

The potential energy diagram for the benzene- OH adduct reaction with $\mathrm{O}_{2}$ is illustrated in Figure 8.3. The well depth of benzene- $\mathrm{OH}+\mathrm{O}_{2} \Rightarrow$ benzene- $\mathrm{OH}-\mathrm{O}_{2}$ is determined as $10.17 \mathrm{kcal} / \mathrm{mol}$. The first reaction path considered of this benzene- $\mathrm{OH}-\mathrm{O}_{2}$ adduct is the hydrogen transfer from the OH group to peroxy group with a subsequent $\beta$-scission to form 2,4-hexadiene-1,6-dial +OH , see channel BA in Figure 8.3 and Figure 8.5. The first step (hydrogen transfer) from the peroxy radical to the 1-hydroperoxyl-2-oxy radical has a
reaction barrier of $16 \mathrm{kcal} / \mathrm{mol}$, see Figure 8.5 . This is the rate-determining step because the following steps are thermochemical favorable $\beta$-scissions with lower barriers.

The second reaction path considered is H transfer from the carbon with OH substitution (C1) to the peroxy group, and subsequent beta-scission to form phenol + $\mathrm{HO}_{2}$., see channel BB in Figure 8.3 and Figure 8.6. This reaction path has a lower barrier than channel BA because the C-H bond is doubly allylic with a much lower bond energy $(80 \mathrm{kcal} / \mathrm{mol})$ than $\mathrm{O}-\mathrm{H}$ bond $(104 \mathrm{kcal} / \mathrm{mol})$.

Channels $\mathrm{BC}, \mathrm{BD}, \mathrm{BE}$ and BF involve the cyclization of the peroxy group to form the 4 bicyclic adducts V, VII, VI and VIII, respectively. The reaction barriers for cyclization channels result primarily from the potential energy increment of ring strain and the peroxy radical addition to a $C=C$ double bond. Since the adducts V, VI and VII have the similar RS energy ( $13 \sim 15 \mathrm{kcal} / \mathrm{mol}$ ) and the adduct VIII has much higher RS energy ( $39 \mathrm{kcal} / \mathrm{mol}$ ), channel BF is much less thermochemically favorable than the other three cyclization channels.

Evaluations of the A factors and Ea 's for the benzene- $\mathrm{OH}+\mathrm{O}_{2}$ reaction system for the QRRK input parameters are based on thermodynamic properties and literature data as listed in Table 8.4. The results of QRRK calculations are also listed in Table 8.4 and the Arrhenius plot is illustrated in Figure 8.7. The apparent rate constant for benzene-OH + $\mathrm{O}_{2}=>$ benzene $-\mathrm{OH}-\mathrm{O}_{2}$ adduct is calculated to be $6.58 \mathrm{E} 11 \mathrm{cc} / \mathrm{mol}-\mathrm{s}$, while $\mathrm{k}_{\mathrm{BB}}, \mathrm{k}_{\mathrm{BC}}, \mathrm{k}_{\mathrm{BD}}$, and $\mathrm{k}_{\mathrm{BE}}$ are about of the same order, $10^{6} \mathrm{cc} / \mathrm{mol}-\mathrm{s}$ at 1 atm and 298.15 K . Channel BB could be the major pathway for the formation of phenol in benzene photooxidation system. The three bicyclic adducts V, VII and VI formed via channel BC, BD and BB could be the
important precursors of the ring cleavage products, which will be discussed latter. Formation of 2,4-cyclohexadiene-1,6-dial (channel BA) and the bicyclic adduct VIII (channel BF) is relatively slow at room temperature. The low $\mathrm{k}_{\mathrm{BA}}$ is consistent with the experimental product data which indicate that 2,4-cyclohexadiene-1,6-dial is not the primary product of benzene photooxidation. Channel BF is not thought to compete with other reaction channels in the system, thus further reactions of adduct VIII will be excluded from further discussion.

### 8.2.2.4 Reactions of Ring Cleavage: Estimation of $\beta$-Scission Reaction Parameters (Transition State Study)

The bicyclic benzene-OH- $\mathrm{O}_{2}$ adducts, V, VI and VII formed from reaction (5) will react with the $\mathrm{O}_{2}$ to from a second series of peroxy radicals. These will subsequently become oxy radicals after one oxygen is abstracted by NO. ${ }^{4,38}$

The calculation details of thermodynamic properties follow the procedure described above. The $\mathrm{HBI}($ ALKOXY $)$ group was used for estimating thermodynamic properties of these oxy radicals along with the corresponding values of the parent molecules. The thermodynamic parameters are listed in Table 8.1 and the group values of $\operatorname{HBI}(\boldsymbol{A L K O X Y})$ are listed in Table 8.2.

The ring opening of adduct IX occurs through several $\beta$-scission steps in series, see Figure 8.8. Potential energy analysis indicates that the first reaction should be ratedetermining. The reaction paths are similar for the cases of adducts X and XI, see Figure 8.9 and 8.10 , respectively. The estimations of rate constants for these $\beta$-scission process are described as follows.

V

VI

IX

X

### 8.2.2.4.1 Adduct $\mathrm{IX}=>$ Butene-1,4-dial + CHOC.HOH

There are limited or no experimental data on such kind of reactions of bicyclic species from which to estimate the corresponding kinetic factors (A and Ea). We use Transition State (TS) theory to determine the rate constants. The determination of the TS structure of the first step (see Figure 8.8) for adduct IX $\beta$-scission was carried out using the semiempirical PM3 method, and identified by the existence of one and only one imaginary frequency in the harmonic vibration normal mode analysis. The PM3 vibrational frequencies were used to determined the entropy difference ( $\Delta \mathrm{S}^{\ddagger}{ }_{298}$ ) between adduct IX and the TS, since $\Delta S^{\ddagger}{ }_{298} \approx \Delta S^{\ddagger}{ }_{298 \text {,vibration. }} 55$

From conventional transition state theory, ${ }^{17}$ the pre-exponential factor, A for a unimolecular reaction is calculated by, $A=\left(e h_{p} T / k_{b}\right) \exp \left(\Delta S^{\dagger}\right)$, where $h_{p}$ is Planck's constant, $\mathrm{k}_{\mathrm{b}}$ is the Boltzmann constant, T is the temperature and $\Delta \mathrm{S}^{\ddagger}$ is the entropy difference between the product and the TS. The PM3/UHF calculations give $\Delta \mathrm{S}^{\ddagger}{ }_{298}=1.18$ $\mathrm{cal} / \mathrm{mol}$. Therefore $\mathrm{A}=3.07 \mathrm{E} 13 \mathrm{~s}^{-1}$ at $\mathrm{T}=298 \mathrm{~K}$ for the adduct IX ring opening reaction.

The PM3 enthalpies of formation of adduct IX and the TS were used to determine the reaction barrier of the $\beta$-scission. The activation energy for the $\beta$-scission of adduct IX is calculated as:

$$
\begin{aligned}
\mathrm{Ea} & =\left[\mathrm{Hf}_{\mathrm{PM} 3}^{\mathrm{o}}(\mathrm{TS})-\mathrm{Hf}^{\mathrm{o}}{ }_{\mathrm{PM} 3}(\text { reactant })\right] \\
& =-17.42-(-25.6)=8.18 \mathrm{kcal} / \mathrm{mol} .
\end{aligned}
$$

The same procedure was applied for the ring opening reactions of adducts X and XI to obtain the corresponding A's and Ea's which are listed below.

### 8.2.2.4.2 Adduct $\mathrm{X}=>$ Butene-1,4-dial + CHOC. HOH

$\Delta \mathrm{S}^{\ddagger}{ }_{298}=0.96 \mathrm{cal} / \mathrm{mol}-\mathrm{K}, \mathrm{A}=2.75 \mathrm{El} 3 \mathrm{~s}^{-1}$,
$\mathrm{Ea}=-18.56-(-27.19)=8.63 \mathrm{kcal} / \mathrm{mol}$ (see Figure 8.9 for the potential energy diagram).

### 8.2.2.4.3 Adduct XI => 1-Hydroxy-Butene-4-al-1yl + Glyoxal

$\Delta \mathrm{S}^{\ddagger}{ }_{298}=1.41 \mathrm{cal} / \mathrm{mol}-\mathrm{K}, \mathrm{A}=3.45 \mathrm{E} 13 \mathrm{~s}^{-1}$,
$\mathrm{Ea}=-22.4-(-30.42)=8.02 \mathrm{kcal} / \mathrm{mol}$ (see Figure 8.10 for the potential energy diagram).

### 8.3 Calculations and Results for the Toluene Photooxidation System

### 8.3.1 The Chemical Activated Reactions of $\mathbf{O H}+$ Toluene

The reactions for the energized toluene- OH adduct resulting from the reaction of toluene with OH radical are parallel to those for benzene- OH adduct: dissociation back to reactants, stabilization and beta-scission to $o$-cresol +H atom, see Figure 8.11. The OH addition to the aromatic ring of toluene was presumed to occur primarily at the ortho position based on the available experimental product data. ${ }^{4,8,38}$

$$
\begin{align*}
& \mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{5}+\mathrm{OH} \Leftrightarrow\left[\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{OH}\right]^{*} \\
& {\left[\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{OH}+\mathrm{M}=>\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{OH}+\mathrm{M}\right.} \\
& {\left[\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{OH}\right]^{*}=>o \text {-Cresol }\left(\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{OH}\right)+\mathrm{H}} \tag{T2}
\end{align*}
$$

The thermodynamic properties of the toluene-OH adduct (XII, hydroxyl-1-methyl-2,4-cyclohexadien-6-yl) were estimated from its parent molecule ( $\mathrm{XII}_{+\mathrm{H}}$ ). $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}$ (XII) is estimated using bond energy $\mathrm{DH}(\mathrm{HC}--\mathrm{H})$ equal to $76.0 \mathrm{kcal} / \mathrm{mol}$ and $\mathrm{HBI}(C H D)$ was used to calculate the $\mathrm{S}^{\circ}{ }_{298}$ and $\mathrm{Cp}(\mathrm{T})$ 's of XII:
$\mathrm{S}_{\mathrm{int}}{ }^{\circ}{ }_{298}(\mathrm{XII})=\mathrm{S}_{\mathrm{int}}{ }^{\circ}{ }_{298}\left(\mathrm{XII}_{+\mathrm{H}}\right)+\Delta \mathrm{S}^{\circ}{ }_{298}($ CHD $)$
$\mathrm{Cp}(\mathrm{T})(\mathrm{XII})=\mathrm{Cp}(\mathrm{T})\left(\mathrm{XII}_{+\mathrm{H}}\right)+\Delta \mathrm{Cp}(\mathrm{T})(C H D), 300 \leq \mathrm{T} / \mathrm{K} \leq 1000$.

XII

$\mathrm{XII}_{+\mathrm{H}}$

The well depth for toluene $+\mathrm{OH} \Rightarrow$ toluene- OH adduct is calculated to be 19.6 $\mathrm{kcal} / \mathrm{mol}$ and the potential energy diagram is illustrated in Figure 8.11. The evaluation of A factors and activation energies for (T1), (-T1) and (T2) were carried out following the reaction of benzene +OH . The input data for the QRRK calculation of toluene +OH are give in Table 8.5 where the calculated apparent rate constants are also included. The Arrhenius plot for the apparent rate constants is illustrated in Figure 8.12. The calculated apparent $\mathrm{k}_{\mathrm{f}, 298}$ of toluene $+\mathrm{OH}=>$ toluene- OH adduct is $4.12 \mathrm{E} 12 \mathrm{~mol} / \mathrm{cc}-\mathrm{s}$ which is close to the experimental data, $3.85 \mathrm{E} 12 \mathrm{~mol} / \mathrm{cc}-\mathrm{s}$. ${ }^{1}$ The formation of cresol is the minor reaction path in the temperature regime lower than 500 K .

### 8.3.2 The Chemical Activated Reactions of Toluene- OH Adduct $+\mathrm{O}_{2}$

The chemical activated reactions for toluene- $\mathrm{OH}+\mathrm{O}_{2}$ are parallel to benzene- $\mathrm{OH}+\mathrm{O}_{2}$ system, see Figure 8.13 for potential energy diagram for the reaction paths.

CH3

XIII

XIV
or

XV

The entropies and heat capacities of the above radical adducts were calculated using the GA method (for their parent molecules) incorporated with HBI approach such as the calculations described in section 8.2.2.2. For instance, the entropies of adduct XIII and XIV are calculated as follows:
$\mathrm{S}_{\text {int }}{ }^{\circ}{ }_{298}(\mathrm{XIV})=\mathrm{S}_{\text {int }}{ }^{\circ}{ }_{298}\left(\mathrm{XIV}_{+\mathrm{H}}\right)+\Delta \mathrm{S}^{\circ}{ }_{298}($ CHENEA $)$
$\mathrm{S}_{\text {int }}{ }^{\circ}{ }_{298}(\mathrm{XV})=\mathrm{S}_{\text {int }}{ }^{\circ}{ }_{298}\left(\mathrm{XV}_{+\mathrm{H}}\right)+\Delta \mathrm{S}^{\circ}{ }_{298}($ CHENE $)$

The enthalpies of the above radical adducts were estimated from the GA method (for parent molecules) and the corresponding bond energies, $\mathrm{D}^{\circ}{ }_{298}(\mathrm{C}--\mathrm{H})$. The tertiary $\mathrm{C}-$ H bond energy ( $96.30 \mathrm{kcal} / \mathrm{mol}$ ) ${ }^{53}$ was used to estimate $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{XV})$ after the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{XV}_{+\mathrm{H}}\right)$ was determined as $-52.93 \mathrm{kcal} / \mathrm{mol}$ (using the GA method). Therefore $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{XV})$ is equal to $-8.7 \mathrm{kcal} / \mathrm{mol}$. The adducts XIV and XVII are allylic radicals, and
the secondary allylic $\mathrm{C}-\mathrm{H}$ bond energy $(85.6 \mathrm{kcal} / \mathrm{mol}){ }^{54}$ was used to estimate $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{XIV})$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{XVII})$ from $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{XIV}_{+\mathrm{H}}\right)$ and $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{XVII}_{+\mathrm{H}}\right)$, respectively. The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}(\mathrm{XV})$ was estimated from $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ}{ }_{298}\left(\mathrm{XV}_{+\mathrm{H}}\right)$ and secondary C--H bond energy $(98.45 \mathrm{kcal} / \mathrm{mol})$. ${ }^{53}$

### 8.3.2.1 Quantum RRK Calculation for Toluene- $\mathrm{OH}+\mathrm{O}_{2}$

The reaction system of toluene- $\mathrm{OH}+\mathrm{O}_{2}$ is similar to that of benzene- $\mathrm{OH}+\mathrm{O}_{2}$. The potential energy diagram is illustrated in Figure 8.13, and the QRRK input parameters and calculation results are given in Table 8.6. The Arrhenius plot for each reaction channel of the toluene- $\mathrm{OH}+\mathrm{O}_{2}$ reaction system is presented as Figure 8.14. Channel TB is considered to be the major pathway for the formation of $o$-cresol in the toluene photooxidation system. Bicyclic adduct XIV is the key intermediate for subsequent ring opening reactions. Channel TF has very low rate constant due to the high barrier resulting from high ring strain energy and adduct XVII is therefore excluded from further discussion.

### 8.3.3 Ring Cleavage Reactions

The three oxy radicals, XVIII, XIX and XX are formed via the addition of $\mathrm{O}_{2}$ molecule to adduct XIV, XV and XVI and the subsequent abstraction of one O atom by NO radical. The bicyclic oxy radicals further react via a series of $\beta$-scission reactions which lead to the ring cleavage and the formation of final dicarbonyl products and their precursors. The
determination of rate constants for these $\beta$-scission reactions are similar to that for adduct IX, X and XI in benzene oxidation system, see section 8.2.2.4.

### 8.4 Modeling Prediction

The kinetic modeling which contain the important initial reaction mechanisms of atmospheric oxidation of benzene and toluene are given in Table 8.7 and Table 8.8, respectively. The initial concentrations of species in modeling study are [OH]: 1.0E-8 ppm, [benzene] or [toluene]: 1 ppm and [NO]: 1 ppm . The selection of [ OH ]
concentration is based on the average $[\mathrm{OH}]$ profile in troposphere, 2.0 E 5 to 5.0 E 6 molecule $\mathrm{cm}^{-3}$. ${ }^{58}$ The first two reactions in Table 8.7 and Table 8.8 are two dummy reactions used to maintain the steady state (SS) of OH concentration, where the AA and BB are two dummy molecules.

It is important to note that in these modeling calculation:
-All reactions are elementary or treated in a way that the elementary reaction steps are properly incorporated.
-All reactions are reversible
-Reverse reaction rates are calculated from thermodynamics and microscopic reversibility principles in the numerical integration code CHEMKIN ${ }^{19}$ and thus automatically incorporated into the mechanisms.

### 8.4.1 Benzene Photooxidation

The modeling work is performed to evaluate the effects of the selected reactions to the whole reaction system. Submodel BM1 contains reactions \#1 to \#6 in Table 8.6 which are mainly the reaction system of benzene +OH plus two dummy reactions for preserving $[\mathrm{OH}]$ equal to $10^{-8} \mathrm{ppm}$. The calculated product profile of submodel BM1 is illustrated in Figure 8.15. Benzene- OH adduct reaches a steady state (SS) within 3 minutes, where the SS presents the equilibrium of forward and backward reactions of benzene $+\mathrm{OH}=$ benzene-OH. Phenol grows steadily since no further reactions included in BM1 can consume benzene-OH adduct which decomposes back to reactants and eventually decomposes to phenol +H .

Submodel BM2 includes the mechanism of BM1 plus reactions \#7 to \#18 in Table 8.7 which are the reactions following benzene- $\mathrm{OH}+\mathrm{O}_{2}$. Figure 8.16 presents the calculated product profile of submodel BM2. It is surprising to find the adduct V is the only one bicyclic adduct which can be accumulated to significant concentration while the apparent rate constants of the formation of the three bicyclic adducts, V, VI and VII, are estimated in the same order. Adduct V is the primary intermediate in this step with a concentration higher than phenol. The benzene- $\mathrm{OH}-\mathrm{O}_{2}$ adduct is in SS with concentration $\left(10^{-7} \mathrm{ppm}\right)$ one order higher than the benzene- OH adduct $\left(10^{-8} \mathrm{ppm}\right)$. The bicyclic adducts other than adduct V are of inconsiderable amount as adducts VI and VII are in SS of $10^{-12}$
 and $10^{-13} \mathrm{ppm}$, respectively. Adduct V , is therefor the only one effective bicyclic adduct which leads to ring opening products in benzene photooxidation system.

Model BM3 includes the reactions of ring cleavage. The concentration of selected species as a function of reaction time using model BM3 are illustrated in Figure 8.17. The products of ring fragments are 2-butene-1,4-dial (BDA) and glyoxal (GLY) which are of the same concentration. The subsequent reactions of phenol, BDA, and GLY with the active species in the system.

### 8.4.2 Toluene Photooxidation

The submodel TM1 which is analogous to BM2 of benzene oxidation contains the reaction systems of toluene +OH and toluene- $\mathrm{OH}+\mathrm{O}_{2}$ (reactions \#1 to \#21 in Table 8.8) without including the ring opening reactions. The product profile is illustrated in Figure

8.18. Adduct XIV
is found to be the only one effective bicyclic adduct of the following ring opening reactions. The $o$-cresol and benzaldehyde are in less concentrations than adduct XIV. The product profile of the entire mechanism listed in Table 8.8 including the ring opening reactions is illustrated as Figure 8.19.

### 8.5 Discussion

An analysis is performed to interpret the fact adduct V is the only one effective bicyclic adduct of the following ring opening reactions in benzene reaction system. The forward rate constants, concentration equilibrium constants and reverse rate constants at 298 K and 1 atm pressure for elementary reactions following benzene- $\mathrm{OH}+\mathrm{O}_{2}$ are listed in Table 8.9.

The rate constant of reaction (A) in Table 8.9 is about 5 orders of magnitude higher than those of $\mathrm{BB}, \mathrm{BC}, \mathrm{BD}$ and BE . Therefore benzene- $\mathrm{OH}-\mathrm{O}_{2}$ is the primary intermediate in the reaction sequence of benzene- $\mathrm{OH}+\mathrm{O}_{2}$. The benzene- $\mathrm{OH}-\mathrm{O}_{2}$ adduct can either dissociate back to reactants, benzene- $\mathrm{OH}+\mathrm{O}_{2}$ or to phenol $+\mathrm{HO}_{2}$ through (C1), or isomerize to bicyclic adducts through (C2), (C3) and (C4), see Table 8.9. The benzene- $\mathrm{OH}-\mathrm{O}_{2}$ adduct can also react with NO resulting an oxy radical ( $\mathrm{ROO} .+\mathrm{NO}=>$ RO. $+\mathrm{NO}_{2}$ ), but the low concentration of NO (usually $\leq 1 \mathrm{ppm}$ ) in the atmosphere makes this reaction path less important than the isomerization of benzene- $\mathrm{OH}-\mathrm{O}_{2}$ to form bicyclic adducts.

The forward reactions of (BA) and (BB) are much more thermodynamically favorable than the corresponding backward reactions. Channels (BA) and (BB) are in fact less reversible at room temperature.

The major reaction pathway of adducts V, VI and VII is the further addition to an oxygen molecule. The rate constant for addition of radicals to $\mathrm{O}_{2}$ is typically c.a. 5.0E12 $\mathrm{cm}^{3} / \mathrm{mol}-\mathrm{s}$. The reaction rates of adduct V, VI and VII addition to $\mathrm{O}_{2}$ are therefore $\leq$ $4.5 \mathrm{E} 7 \mathrm{~s}^{-1}$ with the concentration of $\mathrm{O}_{2}$ in the atmosphere, being about $9.0 \mathrm{E}-6 \mathrm{~mol} / \mathrm{cm}^{3}$ $(22 \% \mathrm{~V} / \mathrm{V})$. The backward reaction of channel $\mathrm{BE}\left(\mathrm{k}_{-\mathrm{BE}}=8.23 \mathrm{E} 8 \mathrm{~s}^{-1}\right)$ and $\mathrm{BD}\left(\mathrm{k}_{-\mathrm{BD}}=7.70 \mathrm{E} 8\right.$ $\mathrm{s}^{-1}$ ) occurs before the addition of oxygen to adducts VI and VII occurs. Adduct VI and VII therefore cannot be effective to further ring opening reactions under atmospheric condition. The backward constant of channel BC has a rather low rate constant, 8.6E-3 $\mathrm{s}^{-1}$, and thus adduct V is the effective intermediate leading to the occurrence of ring cleavage.

The situations of the toluene oxidation system are similar to benzene oxidation system. The experimental works like the smog chamber which simulates the oxidation of toluene under tropospheric conditions resulting in the product profiles: $\sim 0.25$ yield of cresols, $\sim 0.10$ yield of benzaldehyde and $\sim 0.25$ yield of the fragments of aromatic ring cleavage and 0.40 unknown products. ${ }^{30}$ Our model includes only the important initial steps of toluene photooxidation, and the results are not completely comparable. However, the features of our model present a good connection to the experimental data.

### 8.6 Summary

We have applied the Group Additivity and semiempirical Molecular Orbital methods to the determinations of thermodynamic properties and Transition State structures for the study of benzene and toluene photooxidation. These properties, along with literature experimental data on kinetics, have been utilized to determine rate constants for reactions relevant to photooxidation of aromatics species.

Quantum Rice-Ramsperger-Kassel (QRRK) calculations were performed to evaluate pressure effects and to obtain apparent rate constants of reactions from adduct formation. The data are then used to develop components of reaction mechanisms for benzene and toluene photooxidation in the atmosphere. These mechanisms are used in CHEMKIN2 ${ }^{19}$ interpreter and integrator. All reactions in the mechanisms are considered by the integrator in both forward and reverse directions via principles of Microscopic Reversibility (MR).

The equilibrium controlled by kinetic parameters which incorporate the enthalpy and entropy of reactants, reaction adducts and products at room temperature are found to play a significant role in the overall reactions. Section 8.5 interprets how the microscopic equilibrium effects the overall rates of the benzene- OH adduct $+\mathrm{O}_{2}$ reactions.

According to our initial analysis, only one effective channel will lead to ring cleavage in benzene photo-oxidation. The key bicyclic intermediate leading to ring

cleavage products, for example, in benzene oxidation system is adduct V ,
which was frequently assumed to be adduct VI,
 studies. The reason adduct V is the favored species of importance is that V is an allylic radical (i.e. resonance stabilized) with a intermediate ring strain energy (c.a. $14 \mathrm{kcal} / \mathrm{mol}$, see section 8.2.2.2.1) while other bicyclic adducts (adduct VI and adduct VII) are not allylic radicals with the similar ring strain energy or allylic (adduct VIII) with a high ring strain energy (c.a. $39 \mathrm{kcal} / \mathrm{mol}$ ).

Source of thermodynamic properties:
Molecule:
$\mathrm{CH}_{2}=\mathrm{C}=\mathrm{CH}_{2}, \mathrm{CH}_{3} \mathrm{C} \equiv \mathrm{CH}, \mathrm{CH}_{2}=\mathrm{CHCH}=\mathrm{CH}_{2}, \mathrm{HC} \equiv \mathrm{CCH}_{2} \mathrm{CH}_{3}$, (trans) $\mathrm{CH}_{2}=\mathrm{CHCH}=\mathrm{CHCH}_{3}$.
$\mathrm{CH}_{2}=\mathrm{CHCH}_{2} \mathrm{CH}=\mathrm{CH}_{2}$, ref. 41
$\mathrm{CH}_{2}=\mathrm{C}=\mathrm{CHCH}_{3}, \mathrm{CH}=\mathrm{C}=\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}, \mathrm{CH} \equiv \mathrm{CCH}\left(\mathrm{CH}_{3}\right)_{2}, \mathrm{CH} \equiv \mathrm{CCH}=\mathrm{CHCH}_{3}$, ref. 16 .
Radical:
(1) this work. MNDO/PM3 molecular orbital calculation, see text and Table 2.7.
$\mathrm{CH}_{2}=\mathrm{C}=\mathrm{C} . \mathrm{H}$ (equal to $\mathrm{C} . \mathrm{H}_{2} \mathrm{C} \equiv \mathrm{CH}$ ), $\mathrm{CH}_{2}=\mathrm{C} . \mathrm{CH}=\mathrm{CH}_{2}, \mathrm{CH}_{2}=\mathrm{CHCH}=\mathrm{CHC} . \mathrm{H}_{2}$ (equal to $\left.\mathrm{CH}_{2}=\mathrm{CHC} . \mathrm{HCH}=\mathrm{CH}_{2}\right), \mathrm{CH} \equiv \mathrm{CCH}=\mathrm{CHC} . \mathrm{H}_{2}$.
(2) Use $C=C=C J H B I$ Group values derived in this work:
$\mathrm{CH} .=\mathrm{C}=\mathrm{CHCH}_{3}$ (equal to $\mathrm{CH} \equiv \mathrm{CC} . \mathrm{HCH} 3$ ), apply $\mathrm{C}^{*} \mathrm{C}^{*} \mathrm{CJ}$ on $\mathrm{CH}_{2}=\mathrm{C}=\mathrm{CHCH}_{3}$ (data in this Table).
C. $\mathrm{H}=\mathrm{C}=\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}$ (equal to $\mathrm{CH} \equiv \mathrm{CC} .\left(\mathrm{CH}_{3}\right)_{2}$ ), apply $\mathrm{C}^{*} \mathrm{C}^{*} \mathrm{CJ}$ on $\mathrm{CH}_{2}=\mathrm{C}=\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}$ (data in this Table).

a "r" represent bond length, r12 represents the bond length of a C-C bond, where 1 and 2 are the index of atom. "a" represent a bond angle, a312 represents the angle between bond $\mathrm{C} 1-\mathrm{H} 3$ and $\mathrm{Cl} 1-\mathrm{H} 2$. "d" represents a dihedral angle, d4123 represents the dihedral angle constructed by H4-C1-C2-H3.

a "r" represent bond length. r12 represents the bond length of a C-C bond. where 1 and 2 are the index of atom. "a" represent a bond angle, a312 represents the angle between bond $\mathrm{C} 1-\mathrm{H} 3$ and $\mathrm{Cl}-\mathrm{H} 2$. "d" represents a dihedral angle, d 4123 represents the dihedral angle constructed by $\mathrm{H} 4-\mathrm{C} 1-\mathrm{C} 2-\mathrm{H} 3$.

## APPENDIX B

## FIGURES FOR SECTION I

Compare $\mathrm{C} . \mathrm{H} 2 \mathrm{CH} 3$ to CH 3 CH 3 :
lose one $\mathrm{C}-\mathrm{H}$ streching, two $\mathrm{H}-\mathrm{C}-\mathrm{H}$ bending, one $\mathrm{H}-\mathrm{C}-\mathrm{C}$ rocking, gain one C.H2 inversion, also,
the barrier of internal rotation along $\mathrm{C}-\mathrm{C}$ axis changes

## Conclusion : $\mathrm{C} . \mathrm{H} 2 \mathrm{CH} 3=\mathrm{C} 2 \mathrm{H} 6-\mathrm{v} / \mathrm{C}-\mathrm{H} /-2 \mathrm{v} / \mathrm{H}-\mathrm{C}-\mathrm{H} /$ <br> $-v / \mathrm{H}-\mathrm{C}-\mathrm{C} /+\mathrm{v} / \mathrm{inv}-\mathrm{CH} 2 /-\mathrm{ir} / \mathrm{CH}_{3}-\mathrm{CH} 3 /+\mathrm{ir} / \mathrm{CH} 2-\mathrm{CH} 3 /$

* rate constant $\mathrm{k}=\mathrm{A} \mathrm{T}^{\mathrm{n}} \exp (-\mathrm{Ea} / \mathrm{RT})$

Note:
DISSOC Apparent rate constant calculated using DISSOCIATION computor code. (Dean, A. M.. Bozzelli, J. W. and Ritter, E. R., J. Phys. (hem. 1985, 89, 4600).
For reaction (1), (2), (3), see Table 7.A.1.
QRRK Apparent rate constant calculated using CHEMAT computor code. (Dean, A. M., Bozzelli. J. W. and Ritter, E. R., Comb. Sci. and Tech. 1991, 84, 63).

For (7), (8), (9), see Table 7.A.2; for (14), (15), see Table 7.A.3; for (17), (18), see Table 7.A.4; for (20), (21), see Table 7.A. 5 .

$k_{-1} \quad$ Via $k_{1}$ and MR. $E a=\Delta H_{\text {rx }}-R_{m}$
$\mathrm{k}_{2} \quad \mathrm{~A}_{2}$ via $\mathrm{A}_{2}$ and $M R$. Ea estimated in this work.
$\mathrm{k}=\quad \mathrm{A}_{2}=1.0 \mathrm{E} 14$ evaluated from $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{CH}_{2}+\mathrm{CH}_{3}$ addition $(\mathrm{A}=2.23 \mathrm{E} 11$, ref. A13 $)$.
$\sigma, \mathrm{e} / \mathrm{k}$ Calculated from critical properties for $\mathrm{CCl}_{3} \mathrm{OH}$ (Lyderson method by Won, ref. A7)

Table 7.A. 11 Input Parameters for QRRK Calculation: $\mathrm{C}_{2} \mathrm{Cl}_{4}+\mathrm{O} \rightarrow$ Products
(Temperature $=250-2000 \mathrm{~K}$ )

108. Pardo, L., Banfelder, J. R. and Osman, R., J. Am. Chem. Soc. 1992, 114, 2382. Based on the data provided in this article, one isodesmic reaction can be set up to calculate the value of $\mathrm{D}^{\circ}\left(\mathrm{H}-\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOOH}\right)-\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{CH}_{2} \mathrm{OH}\right)$ :
C. $\mathrm{H}_{2} \mathrm{OH}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}=\mathrm{CH}_{3} \mathrm{OH}+\mathrm{CH}_{3} \mathrm{C} . \mathrm{HOH}$.

The value of $\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{HOOH}\right)-\mathrm{D}^{\circ}\left(\mathrm{H}--\mathrm{CH}_{2} \mathrm{OH}\right)$ is thus determined as -1.63 $\mathrm{kcal} / \mathrm{mol}$, based on the energies calculated at MP2/6-31G*//UHF/6-31 level of theory for the species involved in the above reaction.
