This Doctoral Dissertation is brought to you for free and open access by the Chemistry at UKnowledge. It has been accepted for inclusion in Theses and Dissertations--Chemistry by an authorized administrator of UKnowledge. For more information, please contact UKnowledge@lsv.uky.edu.

## STUDENT AGREEMENT:

I represent that my thesis or dissertation and abstract are my original work. Proper attribution has been given to all outside sources. I understand that I am solely responsible for obtaining any needed copyright permissions. I have obtained needed written permission statement(s) from the owner(s) of each third-party copyrighted matter to be included in my work, allowing electronic distribution (if such use is not permitted by the fair use doctrine) which will be submitted to UKnowledge as Additional File.

I hereby grant to The University of Kentucky and its agents the irrevocable, non-exclusive, and royalty-free license to archive and make accessible my work in whole or in part in all forms of media, now or hereafter known. I agree that the document mentioned above may be made available immediately for worldwide access unless an embargo applies.

I retain all other ownership rights to the copyright of my work. I also retain the right to use in future works (such as articles or books) all or part of my work. I understand that I am free to register the copyright to my work.

## REVIEW, APPROVAL AND ACCEPTANCE

The document mentioned above has been reviewed and accepted by the student's advisor, on behalf of the advisory committee, and by the Director of Graduate Studies (DGS), on behalf of the program; we verify that this is the final, approved version of the student's thesis including all changes required by the advisory committee. The undersigned agree to abide by the statements above.

# ABSTRACT OF DISSERTATION 

## FERROCENE-FUSED DERIVATIVES OF POLYACENES, TROPONES AND THIEPINS

This research project is concentrated on tuning the properties of small organic molecules, namely polyacenes, tropones and thiepins, by incorporating redox-active transition metal centers $\pi$-bonded to terminal cyclopentadienyl ligands. Organometallicfused acenequinones, tropones, thiepins and cyclopentadiene-capped polyacenes were synthesized and characterized. This work was divided into three parts: first, the synthesis of ferrocene-fused acenequinones, cyclopentadiene-capped acenequinones and their subsequent aromatization to polyacenes; second, the synthesis of ferrocene-fused tropones, thiotropones and tropone oxime; and third, the synthesis of ferrocene-fused thiepins.

Ferrocene-fused quinones are the precursors to our target complexes. Our synthetic route to ferrocenequinones involved two-fold aldol condensation between 1,2diformylferrocene and naphthalene-1,4-diol or anthracene-1,4-diol, and four-fold condensation between 1,2-diformylferrocene and 1,4-cyclohexanedione. Reduction of ferrocene-fused quinones with borane in THF resulted in ferrocene-fused dihydroacenes. Attempts to reduce ferrocene-fused acenequinones with sodium dithionite led to metalfree cyclopentadiene- (Cp-) capped acenequinones. Cp-capped acenequinones were aromatized to bis(triisopropylsilyl)ethynyl polyacenes by using lithium (triisopropylsilyl)acetylide (TIPSC $\equiv \mathrm{CLi}$ ) with subsequent dehydroxylation by stannous chloride. The compounds were characterized by using spectroscopic methods and X-ray crystallography. Further, the electronic properties of these compounds were studied by using cyclic voltammetry and UV-visible spectroscopy. Cyclic voltammetry showed oxidation potentials of Cp-capped TIPS-tetracene and bis-Cp-capped TIPS-anthracene as 0.49 V and 0.61 V , respectively (vs. ferrocene/ferrocenium). The electrochemical band gaps were 2.15 eV and 2.58 eV , respectively. Organic thin-film transistor device performance of Cp-capped polyacenes was studied using solution deposition bottomcontact, bottom-gate (BCBG) device architecture and the resulting performance parameters are described herein.

Similarly, we are also interested in potential applications of metallocene-fused tropones and derivatives as organic electronic materials. Condensation of 1,2diformylferrocene with acetone or 1,3-diphenylacetone in the presence of KOH resulted in the ferrocene-fused tropone ( $\eta^{5}-2,4$-cyclopentadien-1-yl)[(1,2,3,3a,8a- $\eta$ )-1,6-dihydro-6-oxo-1-azulenyl]iron ( $1, \mathrm{R}=\mathrm{H}, \mathrm{E}=\mathrm{O}$ ) and its 5,7-diphenyl derivative $(1, \mathrm{R}=\mathrm{Ph}, \mathrm{E}=$ O ) as previously reported by Tirouflet. The use of piperidine as base resulted in Michael addition of piperidine to one of the carbon-carbon double bonds of the tropones. Lawesson's reagent converted the ferrocene-fused tropones to either a thiotropone $(\mathbf{1}, \mathrm{R}=$ $\mathrm{H}, \mathrm{E}=\mathrm{S}$ ) or a detached 5,7-diphenylazulenethiol (2). Reaction of the ferrocene-fused thiotropone with hydroxylamine gave the corresponding oxime ( $1, \mathrm{R}=\mathrm{H}, \mathrm{E}=\mathrm{NOH}$ ). Products were characterized by using spectroscopic methods and X-ray crystallography. Their electronic properties were studied by using cyclic voltammetry and UV-visible spectroscopy.

The third project involved the two-fold aldol condensation of 1,2diformylferrocene with dimethylthioglycolate $S$-oxide in the presence of freshly distilled triethylamine, which gave mono- and di-dehydrated products. Deoxygenation of the ferrocene-fused thiepin S-oxide with 2-chloro-1,3,2-benzodioxaphosphole in the presence of pyridine resulted in the corresponding thiepin. The ester groups of the thiepin and thiepin S-oxide were hydrolyzed under basic conditions to give carboxylic acids, which were converted into acid chlorides using oxalyl chloride. Attempts to decarboxylate the thiepin and thiepin S-oxide diacids resulted in decomposition.

KEYWORDS: ferrocene, aldol condensation, organometallic, acenequinone, tropone, thiepin

## ACKNOWLEDGEMENTS

I am grateful to many people for their guidance, time, effort and patience in helping to further my scientific aspirations. I first and foremost would like to thank wholeheartedly my advisor, Professor John P. Selegue for his constant guidance, motivation, constructive criticism, dedication and commitment to scientific research. I am very grateful for his tremendous effort, time and patience in training me how to be an independent researcher.

I would like to express my sincere thanks to my advisory committee members, Professors Arthur Cammers, David Atwood, Bruce J. Hinds, and Douglass Kalika for their support, constructive criticism and helpful ideas throughout my Ph.D. studies. I would like to thank professor H Peter Spielmann for serving as the external examiner during my final defense.

I am thankful to Dr. Sean Parkin for his help with X-ray crystallography. I would also like to thank Mr. John Layton for his time and energy spent in acquiring NMR data and Dr. Jack Goodman for mass spectra services. I would also like to express my thanks to Mr. Art Sebesta (electronics) and Mr. J. Babbitt (glassware) for their time and effort in maintaining and keeping the instrument in workable condition. Without their prompt support, my research would not have gone smoothly.

I am grateful to Prof. John E. Anthony for allowing me to work in his lab and to use the cyclic voltammeter and UV spectrometer independently. I would like to thank his graduate student Dr. Matthew J. Bruzek for teaching me how to use electronic and optical instruments. I would also like to thank Professor Aram Amassion and Muhammad Rizwan Khan Niazi from King Abdullah University of Science and Technology, Saudi Arabia for providing the OFET studies of our compounds.

I am thankful for all my former and current group members Uttam, Rituraj, Mahendra, Deepshikha, Surya and Ilya for their friendliness, support and help in the lab, sharing their ideas and skills and also for creating an excellent working environment. I would like to extend my sincere thanks to my loving friends for their endless help.

I would like to express my deepest gratitude to my parents, Madan and Kamala Maharjan, my husband, Ishwor Maharjan and sisters and brother for their support in all rough times. Without their love, supervision and encouragement, I could not be who I am today. Also, I am very thankful to my husband's family for their support and understanding.

## Chapter 1 Organic Semiconductors

Inorganic semiconductors such as silicon ( Si ) and germanium ( Ge ) have dominated applications in the area of light-emitting diodes (LEDs), thin-film transistors (TFTs) and photovoltaic cells for the past few decades. However, recent contributions from several research groups in the field of organic semiconductor materials has enabled the use of organic molecules in optoelectronic applications, including organic lightemitting diodes (OLEDs), organic field-effect transistors (OFETs), organic photovoltaic cells, ${ }^{1 a-l c}$ sensors, ${ }^{2}$ flat-panel displays ${ }^{3}$ and radio-frequency identification tags (RF-IDs). ${ }^{4}$ Organic semiconductors are of interest due to their ease of purification and large-scale, more flexible, lower temperature solution processing and lower cost of manufacture. ${ }^{5}$ The ideal candidate should be stable under ambient conditions, suitable for solution processing, and possess high charge mobility.

Two important classes of organic semiconductors are conjugated polymers and linearly fused aromatic rings (polyacenes). These molecules are used for the chargetransport layer in organic electronic devices due to their extended $\pi$-conjugation, which lowers the energy gap between the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO). Acenes have well-defined molecular weights, highly ordered crystalline structures and exhibit high charge carrier mobility. Polymers, on the other hand, suffer from undefined molecular weights and fewer purification techniques. These limitations affect the electronic properties of polymers. ${ }^{6}$

Unlike inorganic semiconductors, both polymers and acenes ${ }^{6,7}$ can be processed by solution-phase fabrication methods such as inkjet printing, spin-casting, drop-casting and blade-coating, allowing future technological devices to be smaller, thinner and more
flexible as well as lowering the manufacturing cost of electronics. These advantages of organic conjugated small molecules may satisfy the increasing demand for cheaper, widearea coverage, flexible devices that can be processed at lower substrate temperature than conventional silicon- and germanium-based semiconductors. ${ }^{8}$

Acenes have disadvantages such as poor solubility in common organic solvents and instability toward atmospheric oxygen, moisture and light. Many of these obstacles have been circumvented by functionalizing the acenes. ${ }^{6}$ The environmental stability of organic semiconductors is the most important aspect for commercialization. Environmental sensitivity of these materials can be overcome by operating devices under inert conditions; but this could shrink the cost-savings of moving to organic semiconductor materials from inorganic semiconductors. Therefore, the application of organic semiconductors in the market still suffers from two major issues, life span and performance.

Thin-film transistors (TFTs) are the logic units for modern day microelectronic devices. In the Si and Ge semiconductors, the atoms are bonded closely with strong covalent interactions ( $100-400 \mathrm{~kJ} / \mathrm{mol})^{9}$ and form highly ordered three-dimensional crystal lattice structures with better atomic orbital overlap than organic semiconductors, which causes charge carriers to transport in highly delocalized, band-like mechanisms. ${ }^{10}$ While in organic semiconductors, namely acenes and heteroacenes, organic molecules are held together by weak van der Waals interactions (<5 kJ/mol), $\pi-\pi$ intermolecular ( $0-50$ $\mathrm{kJ} / \mathrm{mol}$ ), and hydrogen bonding ( $10-65 \mathrm{~kJ} / \mathrm{mol}$ ). ${ }^{9}$ Therefore, the atomic orbital overlap in organic semiconductor materials is weak, which results in poor charge-carrier transport.

Organic thin-film transistors (OTFTs) are also known as organic field-effect transistors (OFETs). Transistors can act as switches and amplifiers with the current flow between the source and drain electrodes controlled by an applied electric field to the gate electrode. OTFT devices consist of three major components called dielectric, semiconductor and three electrodes (gate, source and drain). The source and drain electrodes are commonly gold ( Au ); however other metals such as $\mathrm{Ag}, \mathrm{Pt}, \mathrm{Pd}, \mathrm{Al}, \mathrm{Ca}, \mathrm{Mg}$ and polymers such as PEDOT:PSS and poly(aniline) ${ }^{11}$ have been used, depending on the nature of organic molecules (p- or n-types). The gate electrode can be a metal or a conducting polymer, but highly doped silicon is often used. Inorganic insulators such as $\mathrm{SiO}_{2}, \mathrm{Al}_{2} \mathrm{O}_{3}, \mathrm{Si}_{3} \mathrm{~N}_{4},{ }^{11} \mathrm{HfO}_{2},{ }^{12}$ and polymer insulators such as poly(methyl methacrylate), (PMMA), poly(4-vinylphenol) (PVP) and polyvinyl alcohol (PVA) ${ }^{13,14}$ have been commonly used as the dielectric layer.

The semiconducting layer is either vacuum-deposited or solution-phase fabricated by spin-coating, drop-coating or inkjet printing. Depending on how organic molecules are deposited relative to one another, two common device configurations are used in OFETs: one is bottom-contact, bottom-gate and the second is top-contact, bottom-gate. Although top-contact, bottom-gate device configuration gives better device performance ${ }^{8,15}$ because it has low contact resistance due to the large area for charge injection from the electrode to semiconductor, bottom-contact, bottom-gate device configuration is often preferred because develop metal electrodes on the top contact can damage the underlying organic semiconducting layer. ${ }^{16}$

The distance between source and drain electrodes is called channel length, denoted by $L$. The width of source and drain electrodes is called channel width, denoted
by $W$. The voltage applied between source and gate electrodes, gate voltage $\left(V_{\mathrm{g}}\right)$ results in the accumulation of charge carriers at the dielectric-semiconductor interface. The voltage applied between source and drain electrodes, source-drain voltage $\left(V_{\mathrm{ds}}\right)$, results in the conduction of charge carriers in the accumulation layer, and this is known as the on state of the device. Ideally, when no $V_{\mathrm{g}}$ is applied, the conductance of the semiconducting layer should be zero because there is little to no current flow between the electrodes. Therefore, the device enters the off state. If the voltage applied to the gate electrode is enough to overcome the threshold voltage $\left(V_{\mathrm{Th}}\right)$, drain current $\left(I_{\mathrm{d}}\right)$ can be measured. If the voltage applied to the gate electrode is not enough to overcome $V_{\mathrm{Th}}$, the current measured is the leakage current ( $I_{\text {Leakage }}$ ) resulting from charge carrier tunneling through the insulating dielectric. ${ }^{17}$

Figure 1.1 Schematic diagram of an OTFT. ${ }^{18}$
An OTFT's performance can be characterized by plotting drain current versus drain voltage at various gate voltages. At a low source-drain voltage $\left(V_{\mathrm{ds}} \ll V_{\mathrm{g}}\right)$ the current flowing through the device is directly proportional to applied voltage $\left(V_{\mathrm{ds}}\right)$ and is known as linear regime (Figure 1.2). The current ( $I_{\mathrm{d}}$ ) flowing through the channel is given by

$$
\begin{align*}
& I_{\mathrm{d}}=(W / L) \mu_{\mathrm{lin}} C_{\mathrm{i}}\left(V_{\mathrm{g}}-V_{\mathrm{Th}}\right) V_{\mathrm{ds}}  \tag{1}\\
& \text { where } W=\text { channel width, } \\
& L=\text { channel length } \\
& C_{\mathrm{i}}=\text { capacitance of the insulator } \\
& \mu=\text { charge carrier mobility } \\
& V_{\mathrm{g}}=\text { gate voltage } \\
& V_{\mathrm{Th}}=\text { threshold voltage } \\
& V_{\mathrm{ds}}=\text { drain voltage }
\end{align*}
$$

As the applied $V_{\mathrm{ds}}$ increases, the device deviates from ohmic behavior. With further increase in voltage, the current flowing through the channel reaches a constant value as the device enters saturated regime (Figure 1.2).

The current flowing through the channel is given by equation 2 .

$$
\begin{align*}
& I_{\mathrm{d}}=(W / 2 L) \mu_{\mathrm{sat}} C_{\mathrm{i}}\left(V_{\mathrm{g}}-V_{\mathrm{Th}}\right)  \tag{2}\\
& V_{\mathrm{d}}=\sqrt{ }\left\{(W / 2 L) \mu_{\mathrm{sat}} C_{\mathrm{i}}\right\}\left(V_{\mathrm{g}}-V_{\mathrm{Th}}\right) \tag{3}
\end{align*}
$$

Using equations (1) and (2), charge-carrier mobility can be calculated in the linear and saturated regimes. The mobility calculated from the linear and saturation methods may not be the same. The difference is a property of contact effects since the mobility is dependent on the gate-source bias that is related to the carrier density in the accumulation layer.

Another method to characterize the output of OTFTs is to plot both the square root of drain current $\left(\sqrt{ } I_{\mathrm{d}}\right)$ and $\log \left(I_{\mathrm{d}}\right)$ versus $V_{\mathrm{g}}$. Equation 3 implies that the charge carrier mobility of the device in the saturation regime can be obtained from the slope of the plot
of $\sqrt{ } I_{\mathrm{d}}$ versus $V_{\mathrm{gs}}$ and the $x$-intercept gives the $V_{\mathrm{Th}}$ of the device. The plot of $\log \left(I_{\mathrm{d}}\right)$ versus $V_{\mathrm{g}}$ gives the on/off current ratio.

Gate Voltage (V)
b

Gate Voltage (V)
c

Figure 1.2 a) Output of OFET, b) $\sqrt{ } I_{\mathrm{d}}$ and $\log \left(I_{\mathrm{d}}\right)$ vs. $V_{\mathrm{g}}$ in the linear regime, c) $\sqrt{ } I_{\mathrm{d}}$ and $\log \left(I_{\mathrm{d}}\right)$ vs. $V \mathrm{~g}$ in the saturation regime ${ }^{11}$

The performance of an OFET is determined by the following parameters.
a) Charge carrier mobility ( $\mu$ ): A measure of the drift velocity of a charge (electron or hole) per unit of applied electric field. Mobility should be greater than $0.5 \mathrm{~cm}^{2} /(\mathrm{V}$ s) for commercial application. ${ }^{6}$
b) On/off current ratio ( $I_{\mathrm{on} / \mathrm{off}}$ ): The ratio of current flowing between source and drain electrode in the on state and the off state of the device. For real world application, on/off current ratio should be greater than $10^{5}$.
c) Threshold voltage $\left(V_{\mathrm{Th}}\right)$ : The gate voltage at which a conducting channel is formed in the semiconducting layer between the source and drain electrodes. $V_{\mathrm{Th}}$ should be close to zero for potential application. ${ }^{6}$

Based on the nature of charge carriers formed in the conducting channel of the device, organic semiconductors are classified into two types known as n-type and p-type.

In OFETs, positive gate voltage is required to turn on an n-type device, while negative gate voltage is required to turn on a p-type device. ${ }^{15}$ Organic semiconductor materials that are able to conduct both electrons and holes depending on the sign of the gate bias are categorized as ambipolar materials (Chart 1.1). Most organic semiconductors are $\pi$ -electron-rich species, which have a higher tendency to lose an electron to form the more stable radical cation. Most of the organic semiconductor materials reported in the literature are p-type. However, the addition of electron-withdrawing groups such as cyano, fluoro and nitro can convert p-type materials into n-type materials. Since n-type semiconductors have an electron deficiency, these materials tend to gain electrons to form a more stable radical anion. For example, complete fluorination of p-type pentacene converts it into a n-type organic semiconductor, perfluoropentacene, with an electron mobility of $0.22 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s}) .{ }^{19}$

n-type Organic Semiconductors

Ambipolar Semiconductors
Chart 1.1 Examples of p-type, n-type and ambipolar organic semiconductors
Polycyclic aromatic hydrocarbons (acenes), the most studied small organic semiconductors, can be synthesized to a high degree of purity with highly ordered crystallinity. ${ }^{7}$ Acenes possess relatively high charge carrier mobilities, high on/off current ratio and low threshold voltage in OFETs, which are the required features of semiconductors. The vapor-deposited thin film of pentacene, a benchmark material, has shown hole carrier mobility greater than $3 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s})$ in a OTFT. ${ }^{20}$ However, some acenes exhibit poor solubility in common organic solvents and undergo decomposition in the presence of air and light. Acenes typically undergo decomposition either through photoinduced endoperoxide formation or through "butterfly" dimerization (Figure 1.3) of the
aromatic rings. Pentacene undergoes degradation by forming a symmetric butterfly dimer in light and endoperoxide formation in the presence of oxygen. ${ }^{6,7}$

a

b

c

Figure 1.3 a) Herringbone packing, b) an endoperoxide, c) butterfly dimer ${ }^{21}$
To overcome the solubility issues and to take advantage of solution processing techniques (spin- and drop-casting), several research groups synthesized soluble adducts as pentacene precursors (Chart 1.2). The solubility of the pentacene adduct precursor in common organic solvent allows drop-casting of thin films of those materials, which are then converted into pentacene films by UV radiation followed by annealing at high temperature $\left(150-200{ }^{\circ} \mathrm{C}\right)$ under an inert atmosphere. A thin film of pentacene prepared by this method produced reasonable charge carrier mobilities of $0.89 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s}) .{ }^{19,22,23,24,25}$

$\mathrm{X}=\mathrm{Cl}, \mathrm{Br}$

Chart 1.2 Soluble pentacene adducts
Another way to improve the solubility of acenes in organic solvents is to introduce solubilizing alkyls ${ }^{26}$ or aryls ${ }^{27,28}$ groups on the acene core. Wudl et al. reported the synthesis of methyl-substituted pentacene at the terminal rings to improve the solubility, stability and electronic properties of pentacene. Methyl substitution has shown a significant improvement in solubility and a decrease in oxidation potential versus unsubstituted pentacene, which leads to improving charge injection in electronic devices and shows hole mobility as high as $0.3 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s}), I_{\mathrm{on}} / I_{\mathrm{off}}$ of $6 \times 10^{3}$ from thermally deposited film; and methyl-substituted pentacene also leads to herringbone arrangement identical to the parent pentacene. ${ }^{24}$

Functionalization of acenes with solubilizing groups not only increases their solubility but also improves their stability and intermolecular interaction in crystal packing. Anthony's group developed a methodology to functionalize the acene core at the
peri-positions with trialkylsilylethynyl groups. The size of trialkylsilylethynyl group not only enhances the solubility and stability of acenes but also improves the $\pi$ interaction between molecules in the solid state. The functionalization of pentacene at the central aromatic ring by triisopropylsilylethynyl (TIPS) groups resulted in two-dimensional (2D) $\pi-\pi$ stacking in the solid state with an interplanar spacing of $3.36 \AA$, enabling the use of solution processing techniques for making thin films for electronic devices. A study of a drop-cast bis(triisopropylsilylethynyl)pentacene film OFET has shown a mobility of 1.8 $\mathrm{cm}^{2} /(\mathrm{V} \mathrm{s})$ and $I_{\text {on }} / I_{\text {off }}$ of $10^{7 .}{ }^{6}$ When the triethylsilylethynyl (TES) group was used to functionalize the pentacene, it exhibited one dimensional (1-D) $\pi$ stacking with a maximum mobility of $1 \times 10^{-4} \mathrm{~cm}^{2} /\left(\mathrm{V}\right.$ s). ${ }^{6}$ Among the functionalized pentacene derivatives, in general 2-D $\pi$ stacking arrangement in the solid state has shown the highest charge carrier mobility.

After revising the effect of size of trialkylsilylalkynyl side groups on crystal packing for linear acenes, Anthony's group designed a roadmap for achieving 2-D $\pi$ stacking for linear acenes. When the diameter of the spherical substituent (silyl derivative) is close to half that of the acene backbone, it results into 2-D $\pi$ stacking. When the diameter of the substituent is less or greater than half, it results in 1-D $\pi$ stacking. Similarly, when the diameter of the substituent is much greater than half of the acene, it results in herringbone stacking. Therefore, the size of trialkylsilylethynyl side groups plays a vital role for tuning electronic behavior of the molecule in the solid state.

Figure 1.4 Arrangement of Pentacene derivatives in the solid state: a) onedimensional triethylsilylethynylpentacene; b) two-dimensional $\pi$-stacking in triisopropylsilylethynylpentacene; c) herringbone in

$$
\text { tris(trimethylsilyl)silylethynylpentacene }{ }^{6}
$$

Moreover, it is possible to improve the stability of acenes by adding bulky substituents, which hinder Diels-Alder reactions between a dienophile (multiple bonds of side group of one acene) and diene (central reactive aromatic ring of another acene). ${ }^{6}$ To functionalize acenes through extension of the conjugation length in order to reduce bandgap and increase $\pi$-overlap, and through the improvement of charge injection by the modification of the HOMO energy level, Anthony's group has extended the acene backbone all the way to nonacene. ${ }^{29}$

Another strategy for improving the stability of functionalized pentacene is the partial halogenation of molecules and addition of electron-withdrawing cyano-groups that lower the HOMO energy level below that of the parent TIPS-pentacene. ${ }^{30}$ Moreover, another approach to enhance the stability of acene molecules is to introduce heteroatoms to the acene core. ${ }^{31,32}$ Katz and co-workers synthesized anthradithiophene (ADT) in two steps as an alternative to pentacene. They reported the synthesis and device studies of vacuum-deposited thin films of alkyl derivatives of ADT and found mobilities as high as
$0.15 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s}) .{ }^{33}$ Heteroacenes are of interest for electronic materials because their high HOMO energies lead to high resistance to dimerization and oxygen degradation. ${ }^{34}$

Chart 1.3 Acenes and heteroacenes with electron-withdrawing groups
Similar to the approach used for pentacene functionalization, Anthony's group utilized the trialkylsilylethynyl group at the peri position of anthradithiophene to improve stability, solubility and crystal arrangement of this material. The modification at the central ring of anthradithiophene with triethylsilylethynyl group resulted in isomeric mixtures of bis(triethylsilylethynyl) anthradithiophene (TES-ADT) and crystal arrangement showed 2-D $\pi$ - interaction with a lower interplanar distance of $3.25 \AA$ as compared to TIPS-pentacene. Device study of a drop-cast film of TES-ADT showed mobility of $1 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s})$ and on-off current ratio of $10^{7} \cdot{ }^{35}$ Even though TES-ADT has a high oxidation potential ( 0.91 vs. SCE) and large HOMO-LUMO energy gap, this material did not show a significant improvement in its photostability. ${ }^{6}$

Bao and coworkers reported the synthesis of two monothiophene acene derivatives, namely tetraceno[2,3-b]thiophene, and anthra[2,3-b]thiophene (Chart 1.4), and observed the mobilities of those materials on $\mathrm{OTS} / \mathrm{SiO}_{2} / \mathrm{Si}$. Tetraceno[2,3b]thiophene has shown mobility as high as $0.47 \mathrm{~cm}^{2} /(\mathrm{V}$ s), whereas anthra[2,3$b]$ thiophene has a mobility of $0.1 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s}) .{ }^{36}$ Furthermore, Bao and coworkers modified the molecular structure of asymmetric linear heteroacenes by introducing trialkylsilylethynyl side groups to examine their impact on the $\pi$ stacking and charge carrier mobilities. A field-effect transistor made from a vacuum-deposited thin film of bis(triisopropylsilylethynyl)tetracene[2,3-b]thiophene exhibited mobility as high as 1.25 $\mathrm{cm}^{2} /(\mathrm{V}$ s), while vacuum-deposited TIPS-pentacene exhibited significantly lower mobility of $0.4 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s}) .{ }^{6}$ Moreover, Neckers et al. functionalized TIPS-tetraceno[2,3$b$ ]thiophenes at the 6,11 and TIPS-pentacene at the 5,14 positions with methoxy groups to design the highly soluble and more photostable acenes. The enhanced photostability of these materials may be due to the methoxy groups hindering the approach of oxygen $\left(\mathrm{O}_{2}\right){ }^{37,38}$

$\mathrm{n}=1,2$

Chart 1.4 Asymmetric linear unsubstituted and trialkylsilylalkynyl substituted heteroacenes derivatives

Several research groups used different substituents to functionalize the acenes core namely alkyl, aryl and trialkylsilylethynyl. Yip et al. used a platinum ethynyl with different auxiliary ligands (Figure 1.5) to functionalize the pentacene core in order to tune emission energy and also studied the effect of metal coordination on electronic and optical properties, and packing arrangement of the complexes in the solid state. ${ }^{39,40}$

Figure 1.5 Platinum complex of ethynyl substituted acenes
Organometallic semiconductors may offer interesting characteristics that combine the physical and electronic properties of all-organic semiconducting materials with the physical, electronic, optical and catalytic properties inherent to organometallic complexes. ${ }^{41}$ Organometallic groups can undergo oxidation and reduction processes that can be tuned by the choice of metal and ancillary ligand. If one portion of the organometallic polymer is oxidized or reduced, it can significantly impact the electrochemical properties of the polymer. ${ }^{42,43}$ Furthermore, if the oxidation potential of metal is sufficiently matched to the reduction potential of the receiving ligand, there is an efficient conduction of electrons from a metal donor to an organic ligand. Electron communication between a metal center and an organic ligand can be used to design novel electroactive organometallic conductors. ${ }^{44,45,46}$ Organometallic conductors may display environmental stability as well as unique redox properties due to the presence of a metal center in their molecules, which may act as a switch by changing its oxidation state. The
electronic properties of these materials can be tuned by altering the ligands attached to the transition metal center. ${ }^{38}$

### 1.1 Organometallic Complexes

Cyclopentadienyl and benzannulated cyclopentadienyl such as indenyl (Ind) and fluorenyl (Flu) are important ligands in organometallic chemistry. After the discovery of ferrocene, ${ }^{47}$ investigations of the coordination chemistry of polycyclic aromatic compounds such as indenyl and fluorenyl intensified because of the application of those complexes in catalysts for olefin polymerization. ${ }^{54-56,48}$ The higher reactivity of indenyl complexes than that of cyclopentadienyl complexes ${ }^{49}$ is attributed to the ability of the indenyl ring to slip into $\eta^{3}$ bonding to $\mathrm{C} 1-\mathrm{C} 3$, aromatizing the $\mathrm{C} 4-\mathrm{C} 9$ ring. ${ }^{50}$ This $\eta^{5}-\eta^{3}$ haptotropic slip, termed the indenyl ligand effect by Basolo and Rerek, ${ }^{51}$ opens a coordination site on the metal center, which is particularly useful for binding an additional two-electron ligand. ${ }^{52}$

Figure 1.6 Numbering scheme of the indenyl ring

Figure $1.7 \eta^{5}$ to $\eta^{3}$ haptotropic slip of the indenyl ${ }^{53}$
In 1954, Pauson and Wilkinson prepared bis(indenyl)iron(II) $\left[\mathrm{Fe}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}\right]$, by reacting indenyllithium with ferric chloride. ${ }^{54}$ In 1964, King and Bisnette synthesized cyclopentadienylindenyliron(II), $\left[\mathrm{Fe}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)\right]$, by reacting sodium indenide, sodium cyclopentadienide and ferrous chloride. ${ }^{55}$ Westcott et al. later reported the molecular structures of $\left[\mathrm{Fe}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}\right], \quad\left[\mathrm{Co}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}\right]$ and $\left[\mathrm{Ni}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}\right]$, demonstrating the unsymmetrical bonding modes of the five-membered ring of the indenyl group to metal. The slip parameter $(\Delta \mathrm{M}-\mathrm{C})$ is defined as the difference in the average bond lengths of metal to carbon atoms $\mathrm{C} 1, \mathrm{C} 2$, and C 3 and metal to the adjacent carbon atoms C8 and C9. The slip parameter of bis(indenyl)iron(II), $(\Delta \mathrm{Fe}-\mathrm{C})$ is $0.0495 \AA$. This value is not large enough to consider the indenyl group as significantly less than $\eta^{5}$ as in $\eta^{3}\left[\mathrm{Ni}\left(\eta-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}\right]\left(\left(\Delta_{\mathrm{Ni}-\mathrm{C}}=0.44 \AA\right),{ }^{50}\right.$ leading to a true $\eta^{5}$ coordination of a metal center in $\left[\mathrm{Fe}\left(\eta-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}\right]$.

Recently, Crisp et al. synthesized bis(2-trimethylsilylindenyl)manganese(II), 1,3bis(trimethylsilylindenyl)manganese(II) and 1,3-bis(isopropylindenyl)manganese(II) complexes (Chart 1.5) with $\Delta_{\mathrm{Mn}-\mathrm{C}}$ slip parameters of $0.14 \AA$ and $0.12 \AA$ respectively, ${ }^{56}$ larger than that found in bis(indenyl)iron(II).

Chart 1.5 Representative indenyl and benz $[f]$ indenyl complexes of transition metals
The replacement of cyclopentadienyl by benz[ $f$ ]indenyl in homogeneous group 4 Ziegler-Natta polymerization catalysts has received much interest due to the ability of an annulated benzo ring to improve both stereocontrol and catalytic turnover. Bradley et al. prepared sterically hindered indenyl ligands, which can reversibly stabilize the Zr (II) center by toggling between $\eta^{5}$ and $\eta^{6}$ coordination modes. ${ }^{57}$ Similarly, Kim and Foster et al. studied the catalytic activities of benz[f]indenyl complexes of group IV metals for the polymerization of ethylene to high molecular weight linear polymer. ${ }^{58,59}$ Goncalves et al. synthesized mixed-ring indenyl complexes of molybdenum and studied their electrochemical properties. ${ }^{60}$

Fluorenyl can be considered either as a benzo-substituted cyclopentadienyl ligand or as a $\mathrm{CH}^{-}$-bridged biphenyl. ${ }^{61,62}$ The main problem of these fluorenyl complexes is their limited solubility low stability in donor solvents. This low stability may be due to the weak bond interaction between metal and carbon, which increases the lability of ligands and allows solvent coordination with the loss of ligands. ${ }^{62}$ Alkylation on the rings of fluorenyl complexes shows a significant improvement in their solubilities. ${ }^{63}$

Figure 1.8 Haptotropic rearrangement of fluorenyl complexes
In 1965, Samuel and Setton synthesized bis(fluorenyl)dichlorozirconium(IV), $\left[\mathrm{ZrCl}_{2}\left(\mathrm{C}_{13} \mathrm{H}_{9}\right)_{2}\right]^{64}$, which was structurally characterized by Kowala and coworkers in 1974. ${ }^{65}$ In 1970 King and Efraty synthesized the first pentahapto-fluorenyl complex, $\left[\mathrm{Mn}(\mathrm{CO})_{3}\left(\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{9}\right)\right],{ }^{66}$ which was structurally characterized by Bottomley in 2002. ${ }^{67}$ Fluorenyl complexes of alkaline earth and rare earth metals have also been synthesized (Chart 1.6). ${ }^{61}$ In 1992 Schleyer and coworkers reported the first structurally characterized $\left[\mathrm{Ba}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{C}_{13} \mathrm{H}_{9}\right)_{2}\right]$ by reacting two equivalents of fluorene with barium in liquid ammonia at $-80{ }^{\circ} \mathrm{C}$ with a high yield. ${ }^{68}$ Moreover, fluorenyl complexes of a rare earth metal, $\left[\mathrm{Yb}(\mathrm{THF})_{2}\left(\mathrm{C}_{13} \mathrm{H}_{9}\right)_{2}\right]$ and $\left[\mathrm{Yb}(\mathrm{DME})\left(\mathrm{C}_{13} \mathrm{H}_{9}\right)_{2}\right]$, have also been synthesized from the metathesis approach and substitution method. ${ }^{61}$ Several fluorenyl complexes of zirconium and hafnium with a hydrocarbon ${ }^{69}$ or silicon ${ }^{70,71}$ tether between two fluorenyl groups or a
fluorenyl and a cyclopentadienyl ligand have enhanced stability as well as the steric rigidity required for the regioregular catalysis of olefin polymerization. ${ }^{72}$

Chart 1.6 Some fluorenyl complexes of metals
In 1977, Johnson and Treichel observed an unexpected ring-slippage in an attempt to prepare fluorenyl complex of iron, $\left[\mathrm{Fe}\left(\eta^{5}-\mathrm{Cp}\right)\left(\eta^{5}-\mathrm{C}_{13} \mathrm{H}_{10}\right)\right]$, where the metal was coordinated to a benzene ring instead of the Cp ring, with the formation of zwitterionic complex (Figure 1.8). This may be due to weak coordination of $\pi$ extended Cp-type
ligand leading to ring slippage. ${ }^{73}$ In 1994 Novikova et al. prepared fluorene complexes of iron, $\left[\left(\eta^{6}-\mathrm{C}_{13} \mathrm{H}_{10}\right) \mathrm{Fe}\left(\eta^{5}-\mathrm{Cp}^{*}\right)\right] \mathrm{PF}_{6}$ and $\left[\left(\eta^{6}-9-\mathrm{CH}_{3}-\mathrm{C}_{13} \mathrm{H}_{10}\right) \mathrm{Fe}\left(\eta^{5-} \mathrm{Cp}^{*}\right)\right] \mathrm{PF}_{6}$, by the reaction of $\mathrm{Cp} * \mathrm{Fe}(\mathrm{CO})_{2} \mathrm{Br}$ with fluorene and 9 -methylfluorene. They also observed ring slippage when $\left[\mathrm{Fe}\left(\eta^{5-} \mathrm{Cp}^{*}\right)\left(\eta^{6}-9-\mathrm{CH}_{3}-\mathrm{C}_{13} \mathrm{H}_{10}\right)\right]$ was heated in nonane at $150{ }^{\circ} \mathrm{C}$ with the formation of $\left[\mathrm{Fe}\left(\eta^{5-} \mathrm{Cp}^{*}\right)\left(\eta^{5}-9-\mathrm{CH}_{3}-\mathrm{C}_{13} \mathrm{H}_{10}\right)\right] .{ }^{74}$ Similar results were obtained by the O'Hare group during the metathesis of ferrocene with $\mathrm{Flu}{ }^{*} \mathrm{H}$ in the presence of $\mathrm{AlCl}_{3}$ and Al powder. ${ }^{62}$

Figure 1.9 Ring slippage of iron center from $\eta^{5}-\mathrm{Cp}$ to $\eta^{6}$-arene
In 1979, Katz and Slusarek synthesized $\pi$-extended iron complexes, dicyclopenta $[a, h]$ naphthalene and dicyclopenta $[c, g]$ phenanthrene. ${ }^{75}$ Further, Katz and Sudhakar synthesized $\pi$-conjugated iron complex with heptacyclic ligand (Chart 1.7) . ${ }^{76}$

b

c

## Chart $1.7 \pi$-Conjugated iron complexes

Further annulations of benzene rings to fluorene leads to more extended $\pi$ systems. The extended $\pi$-systems of these ligands may give interesting physical properties which are important for organometallic novel material to use in the field of optoelectronic application similar to benzannulated aromatic compounds. ${ }^{77}$ Beckhaus et al. reported a titanium complex with tetrabenzo[a,c,g,i]fluorene (Chart 1.8) and examined its application in the syndiospecific polymerization of styrene after activation with MAO. ${ }^{78}$ The Thiel group prepared the first transition-metal complexes of the dibenzo $[c, g]$ fluorenyl anion (Dbf ) (2 and $\mathbf{4}$ of Chart 1.8). A ligand, dibenzo $[c, g]$ fluorenyl anion, can be considered as an analogue of the cyclopentadienyl anion $\left(\mathrm{Cp}^{-}\right)$. Thus, the negative charge on Dbf can stabilize a transition metal center as efficiently as cyclopentadienyl. This might be due to localization of a negative charge on the cyclopentadienyl moiety which leads to more covalent metal-ligand bond than in fluorenyl complexes. ${ }^{79,80}$ Recently, the Toganoh group reported a double-decker ferrocene-type complex of N -fused porphyrin and compared its electronic structure with those of hypothetical $\pi$ extended ferrocene derivatives to study their similarity. ${ }^{81}$

1

4

Chart $1.8 \pi$-Extended complexes of transition metals
Although the indenyl iron complexes $\left[\mathrm{Fe}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)\right]$ and $\left[\mathrm{Fe}\left(\eta^{5}-\right.\right.$ $\left.\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}$ ] were well characterized, there is no report of benz $[f]$ indenyl or annulated benzo ring complexes of iron(II). This might be due to the weak interaction of a $\pi$ extended aromatic backbone with an electron-rich iron center. Our group has a long-term interest in exploring the coordination chemistry of benzene annulated complexes of iron and examines the electronic properties of these complexes.

### 1.2 Overall Objectives of the Dissertation

The two-fold aldol condensation between dialdehyde and 1,4dihydroxynaphthalene or 1,2-dihydroxyanthracene and four-fold aldol condensation between a 1,2-dialdehyde and 1,4-cyclohexanedione ${ }^{82}$ have been used extensively in synthesizing organic acenequinones. The immediate objective of this dissertation is to
start with 1,2-diformylferrocene to extend those synthetic approaches to $\eta^{5}$ -cyclopentadienyl-fused polycyclic quinone complexes with carbonyl groups at different positions of polycyclic backbone (A, Chart 1.9). Once we design the chemistry of Cpcapped quinone complexes, aromatization of the ligand can result in extension of $\pi$ conjugation to give new metallocene-fused polyacene complexes (B, Chart 1.9). These complexes may offer extra control of solubility, HOMO-LUMO gap, color, redox properties and solid-state packing, and utility in new electronic devices based on organometallic materials.

Similarly, the detachment of a polycyclic backbone from a metal center offers Cpcapped acenequinones. The functionalization of the resultant quinones with (trialkylsilyl)ethynyl groups gives Cp-capped substituted polyacenes (C, Chart 1.9). Then we investigate these complexes' structure, solid-state packing, redox and optical properties and their OTFT device performance to examine whether these complexes can fulfill the fundamental requirements of potential candidates of semiconducting materials for commercial optoelectronic applications.

## Chapter 2 Synthesis, Characterization and Reactivity of Ferrocene-Terminated Polyacenes

### 2.1 Introduction

Ferrocene is one of the most important and intensely studied robust organometallic compounds. It is the benchmark material for preparation of organometallic molecules and polymers because of its solubility in common organic solvents, availability, low cost, high stability and readily accessible reversible redox chemistry. ${ }^{83}$ These advantages provide a tremendous stimulus for researchers to continue investigation as well as employment in diverse applications. Ferrocenes, due to high electron densities on their cyclopentadienyl rings, are well known nucleophiles that undergo electrophilic substitution reactions such as sulfonation, halogenation, FriedelCrafts acylation and alkylation, metalation, arylation, formylation and aminomethylation more readily than benzene. ${ }^{84}$

Investigation of organometallic polymers has intensified in recent years, especially in light of their important electrical, optical and catalytic properties. Several synthetic methods for ferrocene-containing polymers have been reported including ringopening metathesis polymerization, polycondensation and electropolymerization. ${ }^{85}$ The well-studied redox reactions of ferrocene are often used as indicators in electrochemical measurements. ${ }^{86}$ Ferrocene exhibits a fast and reversible one-electron transfer on gold and other electrodes, making ferrocene a good model for studying the electron transport phenomenon. Christopher's group utilized these advantages to functionalize silica nanoparticles with ferrocene, which offered a new material with a capacity of redox
charge storage up to $5 \times 10^{7} \mathrm{C} / \mathrm{m}^{3}$ in the dry phase and $6 \times 10^{5} \mathrm{C} / \mathrm{m}^{3}$ in the concentrated slurries. ${ }^{87}$

To meet our target, we started with commercially available ferrocene to get the precursor 1,2-diformylferrocene. The experimental procedure for 1,2-diformylferrocene is well known. The conventional route of making 1,2-diacylcyclopentadiene ${ }^{88}$ cannot be extended to 1,2-diformylcyclopentadiene because of the lability of formyl chloride. Goetgheluck et al. ${ }^{89}$ and Malfait et al. ${ }^{90}$ reported that ortho-lithiation of $\mathrm{N}, \mathrm{N}$ dimethylaminomethylferrocene with $n$-BuLi, followed by formylation with DMF, results in $\mathrm{N}, \mathrm{N}$-dimethylaminomethylferrocene-carboxaldehyde, which on further oxidization with a mild oxidizing agent (activated manganese dioxide) gives 1,2-diformylferrocene. Marr et al. ${ }^{91}$ reported that ortho-lithiation of $\mathrm{N}, \mathrm{N}$-dimethylaminomethylferrocene with $n$ BuLi and formylation with paraformaldehyde results in 1-hydroxymethyl-2(dimethylaminomethylferrocene), which on reacting with methyl iodide gives Methanaminium,1-[2-(hydroxymethyl)ferrocenyl]- $N, N, N$-trimethyl-iodide. As the process is continued, further refluxing with the aqueous solution of potassium hydroxide leads to 1,2-bis(hydroxymethyl)ferrocene, and then oxidation with activated manganese dioxide results in 1,2-diformylferrocene.

Three classic organic reactions, Friedel-Crafts acylation, aldol condensation and the Cava reaction, are well known for preparing quinones, precursors of polycyclic aromatic hydrocarbons (acenes). Our long-term goal is to extend these reactions into the organometallic arena. Our group was mainly oriented in Friedel-Crafts acylation and aldol condensation. The acyl group being an electron-withdrawing group deactivates the cyclopentadienyl ring after first acylation, preventing the second acylation. To overcome
this problem, one of our group members applied Friedel-Crafts acylation between organometallic 1,2-dicarboxylic anhydride and diacyl chlorides with organic aromatic molecules (benzene, toluene, o-xylene, p-dimethoxybenzene) to synthesize several acenequinone complexes. ${ }^{92}$

The second route employed to prepare organometallic acenes is aldol condensation. Chart 2.1 shows some of our initial progress in synthesis of organometallic acenes.

E

Chart 2.1 Some progress in organometallic acenes

### 2.2 Experimental

Reactions are carried out using standard Schlenk techniques under nitrogen. Solvents including ethyl ether, benzene, tetrahydrofuran (THF), hexane and toluene were dried over sodium benzophenone ketyl and distilled under $\mathrm{N}_{2}$ before use. Dichloromethane and acetonitrile were dried and distilled over calcium hydride. $\mathrm{CDCl}_{3}$, $\mathrm{C}_{6} \mathrm{D}_{6}, \mathrm{DMSO}_{\mathrm{d}}$, acetone- $\mathrm{d}_{6}$ (Cambridge Isotopes), sodium, sodium dithionite (J.T. Baker), $\mathrm{N}, \mathrm{N}, \mathrm{N}$ ', N -tetramethylmethylenediamine, butyllithium (2.5 M in hexane), $\mathrm{N}, \mathrm{N}$ dimethylformamide, 1,4-cyclohexanedione, naphthoquinone, 1 M borane solution in THF, aluminum chloride, trifluoroacetic anhydride (Aldrich), activated manganese dioxide (Acros), 1,4-dihydroxyanthraquinone (Alfa Aesar), sodium hydroxide (Fisher), potassium hydroxide, sodium borohydride (EMD), and mossy zinc (E.H. Sargent and Co.) were used without further purification. 1,4-Dihydroxynaphthalene and 1,4anthracenediol were synthesized following the procedure reported by Oatis et al. ${ }^{93}$ and Chen et al. ${ }^{94}$ Triisopropylsilylacetylene was used as purchased from GFS chemicals. Organic phases were dried using either anhydrous sodium sulfate or anhydrous magnesium sulfate (Mallinckrodt). Flash chromatography was performed using $60 \AA$ pore size, 230-400 mesh silica gel (Sorbent Technologies). ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Varian Gemini- 400 spectrometer at ca. $25^{\circ} \mathrm{C}$ and were referenced to residual solvent peaks. Infrared spectra were recorded on an ATI-Mattson Galaxy ${ }^{\text {TM }}$ Series 5000 FTIR15 spectrometer. Mass spectra were acquired by the University of Kentucky Mass Spectrometry Facility. Electron ionization (EI) mass spectra were recorded at 70 eV on a Thermo Finnigan Polaris Q (quadrupole ion trap). Samples were introduced via a heatable direct insertion probe. Melting points were taken in open
capillary tubes on a Thomas-Hoover or Electrothermal Mel-Temp melting point apparatus and were uncorrected. X-ray diffraction data were collected at 90 K on either a Nonius KappaCCD diffractometer or a Bruker-Nonius X8 Proteum diffractometer. Crystal indexing and data processing were performed with either DENZO-SMN (KappaCCD) $)^{95}$ or Bruker APEX2 (X8 Proteum). The structures were solved and refined by using SHELXL-97. ${ }^{96}$ UV-vis spectral analyses were performed on a Shimadzu UV2501 PC. Electrochemical data were collected on a BAS CV-50 W voltammetric analyzer.

Synthesis of N,N-dimethylaminomethylferrocene (1). Phosphoric acid (43.2 g, 25. $6 \mathrm{~mL}, 0.44 \mathrm{~mol})$ and glacial acetic acid $(400 \mathrm{~mL})$ were mixed in a 1 L three-necked round-bottom flask equipped with a magnetic stir bar, septum cap, water condenser and nitrogen inlet. The solution was cooled in an ice bath. Then $\mathrm{N}, \mathrm{N}, \mathrm{N}^{\prime}, \mathrm{N}^{\prime}-$ bis(dimethylamino)methane ( $43.2 \mathrm{~g}, 58.4 \mathrm{~mL}, 0.42 \mathrm{~mol}$ ) was added dropwise via a syringe with continuous stirring. After the complete addition of amine, ferrocene ( 46.4 g , 0.25 mol ) was added. The mixture was warmed to room temperature and slowly heated in an oil bath to $100{ }^{\circ} \mathrm{C}$ for 5 h . The dark amber solution was cooled to room temperature. The solution was diluted with 500 mL of water. Unreacted ferrocene was removed by extracting the solution with ethyl ether $(3 \times 300 \mathrm{~mL})$. The aqueous phase separated from the organic phase and was cooled in ice water. NaOH ( $200 \mathrm{~g}, 5.00 \mathrm{~mol}$ ) was added slowly to make the solution alkaline. The amine was separated from the alkaline solution as oil with some black tar. The mixture was extracted with $3 \times 500 \mathrm{~mL}$ of ethyl ether. The ether solution was washed with water $(3 \times 100 \mathrm{~mL})$ and dried over anhydrous sodium sulfate. ${ }^{97}$ The solution was filtered through filter paper and evaporated under reduced
pressure to give a dark red liquid ( $39.0 \mathrm{~g}, 64.2 \%$ ). ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}$ ): $\delta$ $2.01\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{CH}_{3}\right), 3.25\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CH}_{2}\right), 4.09(\mathrm{t}, 2 \mathrm{H}, \mathrm{CHCCH}), 4.04(\mathrm{t}, 2 \mathrm{H}, \mathrm{CHCHCH})$, 4.09 ( $\mathrm{s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}$ ).

Synthesis of N,N-dimethylaminomethyl-2-formylferrocene (2). An oven-dried 250 mL Schlenk flask equipped with a magnetic stir bar, nitrogen inlet and septum cap was cooled under $\mathrm{N}_{2}$. N,N-Dimethylaminomethylferrocene ( $2.00 \mathrm{~g}, 8.22 \mathrm{mmol}$ ) was transferred through a syringe into a flask. Ethyl ether $(80 \mathrm{~mL})$ was added through a cannula. The solution was cooled with a dry ice/isopropanol slurry for $10 \mathrm{~min} . n-\mathrm{BuLi}$ ( $2.5 \mathrm{M}, 4.9 \mathrm{~mL}, 1.5$ equiv) was added dropwise. After the complete addition of $n$-BuLi, the reaction flask was transferred to an ice bath and stirred for 5 h at $0^{\circ} \mathrm{C} . \mathrm{DMF}(1.3 \mathrm{~mL})$ was added at $0^{\circ} \mathrm{C}$ and the reaction mixture was brought to room temperature and stirred for 3 h . The reaction was quenched slowly with water. The organic phase was separated from the aqueous phase and extracted with ethyl ether $(3 \times 15 \mathrm{~mL})$. The combined organic phase was washed with brine $(2 \times 20 \mathrm{~mL})$. The organic phase was dried with anhydrous magnesium sulfate and the solvent rotary evaporated. The crude product was purified by chromatography on a silica column with hexane:ethyl ether:triethylamine (6:3:1) as an eluent to give a red-brown, liquid product ( $1.25 \mathrm{~g}, 56.1 \%$ ). ${ }^{1} \mathbf{H}$ NMR ( $\mathbf{4 0 0}$ $\left.\mathbf{M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 2.18\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{CH}_{3}\right), 3.25\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CH}_{2}\right), 4.08\left(\mathrm{~d}, 2 \mathrm{H},{ }^{3} \mathrm{~J}=3.6 \mathrm{~Hz}\right.$, CHCHCH), 4.09 ( $\mathrm{s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}$ ), $4.14\left(\mathrm{t}, 1 \mathrm{H},{ }^{3} \mathrm{~J}=3.6 \mathrm{~Hz} \mathrm{CHCHCH}\right.$ ), 10.07 ( $\mathrm{s}, 1 \mathrm{H}$, CHO). IR (ATR, $\mathbf{c m}^{-1}$ ): 1671 (CHO). The compound was fully characterized by Goetgheluck et al. ${ }^{89}$

Synthesis of $\mathbf{1 , 2}$-diformylferrocene (3). In a 200 mL Schlenk flask, N,N-dimethylaminomethyl-2-formylferrocene $(1.00 \mathrm{~g}, 3.96 \mathrm{mmol})$ was dissolved in toluene
( 50 mL ) under $\mathrm{N}_{2}$. Active manganese dioxide ( $6.41 \mathrm{~g}, 20$ equiv) was added. The slurry was allowed to reflux for 2 h and then cooled to room temperature. The manganese dioxide was removed by vacuum filtration on Celite 545 , and the solvent was evaporated under reduced pressure. The crude product was chromatographed on silica with hexane:ethyl ether (1:1) as an eluent to give a dark red solid ( $450 \mathrm{mg}, 50.4 \%$ ). ${ }^{\mathbf{1}} \mathbf{H}$ NMR (400 MHz, CDCl $\mathbf{3}_{\mathbf{~}, ~ \mathbf{p p m}): ~}^{\delta} 4.39\left(\mathrm{~s}, 5 \mathrm{H}_{\mathrm{H}} \mathrm{C}_{5} H_{5}\right), 4.92\left(\mathrm{t}, 1 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}, \mathrm{CHCHCH}\right), 5.2$ (d, $\left.2 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}, \mathrm{CHCHCH}\right), 10.36(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CHO})$. IR (ATR cm$\left.{ }^{-1}\right): 1664(\mathrm{CHO})$. Mp: 111-113 ${ }^{\circ} \mathrm{C}\left(\right.$ Lit. $\left.112{ }^{\circ} \mathrm{C}\right)$. The compound was fully characterized by Malfait et al. ${ }^{90}$

Synthesis of 1-(3-carboxypropionyl)ferrocene (4). In a 500 mL Schlenk flask, ferrocene ( $16 \mathrm{~g}, 86 \mathrm{mmol}$ ) and succinic anhydride ( $4.3 \mathrm{~g}, 43 \mathrm{mmol}$ ) were dissolved in 125 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ under $\mathrm{N}_{2}$. Anhydrous $\mathrm{AlCl}_{3}(11.5 \mathrm{~g}, 86.0 \mathrm{mmol})$ was dissolved in 125 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The solution of ferrocene and succinic anhydride was added dropwise from a dropping funnel to the $\mathrm{AlCl}_{3}$ solution within 50 min . The purple solution was stirred to room temperature for 7 h . The solution was acidified with $50 \% \mathrm{HCl}$ to $\mathrm{pH} 3-4$. The organic phase was separated from the solution. The aqueous solution was further extracted with 20 mL aliquots of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ until the extract was colorless. The organic solution was reduced from 1 L to 600 mL and extracted with $\mathrm{NaOH}(2 \mathrm{M}, 3 \times 250 \mathrm{~mL})$. The solution was cooled to $5^{\circ} \mathrm{C}$ and $50 \%$ phosphoric acid was added dropwise until the precipitation was complete. The solution was filtered and the orange, viscous solid was purified by hot water filtration. The solid was dried under vacuum to give $8.1 \mathrm{~g}(66 \%)$ of 4. ${ }^{1} \mathbf{H}$ NMR ( 400 MHz , acetone-d, ppm): $\delta 2.62-2.66\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CCH}_{2} \mathrm{CH}_{2}\right), 3.08-3.11$ (m, $\left.2 \mathrm{H}, \mathrm{CCH}_{2} \mathrm{CH}_{2}\right), 4.28\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}\right), 4.53\left(\mathrm{t}, 2 \mathrm{H},{ }^{3} \mathrm{~J}=1.6 \mathrm{~Hz}, \mathrm{CHCHCH}\right), 4.83(\mathrm{t}, 2$ $\left.\mathrm{H},{ }^{3} \mathrm{~J}=1.6 \mathrm{~Hz}, \mathrm{CHCHCH}\right)$. IR (ATR, $\mathbf{c m}^{-1}$ ): 2596-2916 (br, -COOH), 1714, 1655 (CO).

Mp: $164-166{ }^{\circ} \mathrm{C}$ (lit. $166.5-167.5^{\circ} \mathrm{C}$ ). The product was characterized by Rinehart et al. ${ }^{98}$

Synthesis of 1-(3-carboxypropyl)ferrocene (5). In a 100 mL round-bottom flask, zinc ( $6.0 \mathrm{~g}, 90 \mathrm{mmol}$ ), mercuric chloride $(0.60 \mathrm{~g}, 2.2 \mathrm{mmol})$, water ( 10 mL ) and conc. $\mathrm{HCl}(0.30 \mathrm{~mL})$ were added. The solution was shaken manually for 5 min followed by stirring for 5 more min. ${ }^{99}$ The solution was decanted and zinc was washed with water. This obtained zinc was put in a 200 mL Schlenk flask equipped with nitrogen inlet, and $\mathrm{H}_{2} \mathrm{O} \quad(3.8 \mathrm{~mL})$, Conc. $\mathrm{HCl}(8.8 \mathrm{~mL})$, toluene $(20 \mathrm{~mL})$ and 1-(3carboxypropionyl)ferrocene ( $4.0 \mathrm{~g}, 14 \mathrm{mmol}$ ) were added serially. The resultant solution was heated at $90^{\circ} \mathrm{C}$ for 9 h , cooled to room temperature and diluted with water ( 20 mL ). The organic phase was separated and the aqueous layer was extracted with ethyl ether (2 $\times 10 \mathrm{~mL})$. The combined organic phase was washed with water $(2 \times 10 \mathrm{~mL})$ and dried with anhydrous $\mathrm{MgSO}_{4}$. Rotary evaporation of the solvent gave a yellow crude product. The crude product was purified by silica column chromatography with petroleum ether:ethyl acetate (8:2) to yield a yellow solid (3.26 g, 85.7\%). ${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}(\mathbf{4 0 0} \mathbf{~ M H z}$, acetone-d $\mathbf{d}_{6}$, ppm): $\delta 1.79-1.84\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 2.29-2.41\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right)$, $4.04\left(\mathrm{t}, 2 \mathrm{H},{ }^{3} \mathrm{~J}=1.6 \mathrm{~Hz}, \mathrm{CHCCH}\right), 4.09\left(\mathrm{t}, 2 \mathrm{H},{ }^{3} \mathrm{~J}=1.6 \mathrm{~Hz}, \mathrm{CHCHCH}\right), 4.11(\mathrm{~s}, 5 \mathrm{H}$, $\mathrm{C}_{5} \mathrm{H}_{5}$ ). IR (ATR cm ${ }^{\mathbf{- 1}}$ ): 3095-2595 (br, - COOH ), 1705 (CO). Mp: $115^{\circ} \mathrm{C}$ (lit. 115-116 $\left.{ }^{\circ} \mathrm{C}\right) .{ }^{100}$

Synthesis of $\boldsymbol{\alpha}$-keto-1,2-tetramethyleneferrocene (6). A solution of 5 (3.00 g, 11.0 mmol ) in $100 \mathrm{~mL} \mathrm{CH} \mathrm{Cl}_{2}$ was added dropwise to a solution of trifluoroacetic anhydride ( $13.2 \mathrm{mmol}, 1.93 \mathrm{~mL}$ ) in $100 \mathrm{~mL} \mathrm{CH}_{2} \mathrm{Cl}_{2}$ at $0{ }^{\circ} \mathrm{C}$. The solution was stirred at this temperature for an additional 5 h and poured into water ( 50 mL ) saturated with
$\mathrm{NaHCO}_{3}$. The organic layer was separated and the aqueous phase was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \times 20 \mathrm{~mL})$. The combined organic phase was washed with water $(2 \times 30 \mathrm{~mL})$ and dried with anhydrous $\mathrm{MgSO}_{4}$. After the removal of solvent under reduced pressure, the residue was chromatographed on silica with petroleum ether:dichloromethane (5:95) to yield a dark red solid ( $2.58 \mathrm{~g}, 92.1 \%$ ) ${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}, \mathbf{p p m}\right): \delta 2.05-$ $2.66\left(\mathrm{~m}, 6 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 4.16\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} \mathrm{H}_{5}\right), 4.45(\mathrm{~d}, 2 \mathrm{H}, \mathrm{CHCHCH}), 4.80(\mathrm{~s}, 1 \mathrm{H}$, CHCHCH). IR (ATR, cm ${ }^{\mathbf{1}}$ ): 2837, 2887, $2938\left(\mathrm{sp}^{3} \mathrm{C}-\mathrm{H}\right), 1662$ (CO). Mp: $80^{\circ} \mathrm{C}$ (lit. $\left.85-85.5^{\circ} \mathrm{C}\right) .{ }^{101}$

Synthesis of ferroceno[b]benzoquinone (7). In a 200 mL Schlenk flask, $\mathrm{MnO}_{2}$ ( $3.42 \mathrm{~g}, 30.0$ equiv) was added to $\mathbf{6}(500 \mathrm{mg}, 1.97 \mathrm{mmol}$ ) in chloroform ( 30 mL ). The slurry was refluxed for 9 h with additional $\mathrm{MnO}_{2}(3.42 \mathrm{~g})$ added after 3 and 6 h . The solution was allowed to cool to room temperature and filtered through a thin pad of Celite 545. The removal of the solvent gave a dark purple solid ( $250 \mathrm{mg}, 43.9 \%$ ). ${ }^{\mathbf{1}} \mathbf{H}$ NMR (400 $\left.\mathbf{M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 4.30\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}\right), 5.09\left(\mathrm{t}, 1 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}, \mathrm{CHCHCH}\right), 5.37(\mathrm{~d}$, $\left.2 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}, \mathrm{C} H \mathrm{CHCH}\right), 6.64(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CCHCH}) .{ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}\left(\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}\right.$ ppm): $\delta 70.41$ (CC, ipso), $72.80(\mathrm{CHCHCH}), 74.09\left(C_{5} \mathrm{H}_{5}\right), 76.16$ (CHCHCH), 139.71 $(\mathrm{CCHCH}), 190.59(\mathrm{CO})$. IR (ATR cm$\left.{ }^{\mathbf{- 1}}\right): 1650(\mathrm{CO}) . \mathbf{M S}(\mathbf{E I}): \mathrm{m} / \mathrm{z} 266\left(\mathrm{M}^{+}\right) . \mathrm{Mp}$ : $\left(146-148{ }^{\circ} \mathrm{C}\right)$. The compound was characterized by X-ray diffraction.

Synthesis of ferrocene-fused-1,4-cyclohexanedione (8): Compound 7 (100 mg, 0.38 mmol ) was added into a solution of sodium dithionite ( $276 \mathrm{mg}, 1.59 \mathrm{mmol}$ ) in $p$ dioxane ( 3 mL ) and nitrogen-bubbled water ( 3 mL ) under nitrogen. The reaction mixture was stirred at room temperature for 4 h , more sodium dithionite $(151 \mathrm{mg})$ was added, the reaction mixture was stirred for an additional 4 h and then poured into 5 mL water. ${ }^{94}$ The
solution was extracted with ethyl ether $(4 \times 15 \mathrm{~mL})$. The combined organic phase was dried with anhydrous $\mathrm{MgSO}_{4}$. After the removal of solvent under reduced pressure, the residue was chromatographed on silica with ethyl ether:hexane (3:1) to yield an orange solid (51.4 mg, 50.5\%). ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\mathbf{4 0 0} \mathbf{~ M H z , ~} \mathbf{C D C l}_{3}, \mathbf{p p m}$ ): $\delta 2.77-2.84(\mathrm{~m}, 2 \mathrm{H}$, $\left.\mathrm{CCH}_{2} \mathrm{CH}_{2}\right), 2.99-3.07\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CCH}_{2} \mathrm{CH}_{2}\right), 4.27\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}\right), 4.86\left(\mathrm{t}, 1 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}\right.$, CHCHCH,$), 5.18\left(\mathrm{~d}, 2 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}, \mathrm{C} H \mathrm{CHCH}\right) .{ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}\left(\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}\right.$ ppm): $\delta 71.02\left(\mathrm{CCH}_{2} \mathrm{CH}_{2}\right), 72.49\left(C_{5} \mathrm{H}_{5}\right), 72.58(\mathrm{CHCHCH}), 75.66(\mathrm{CHCHCH}), 78.89$ (CC, ipso), 201 (CO). IR (ATR, $\mathbf{c m}^{\mathbf{- 1}}$ ): 2850, 2921, $2956\left(\mathrm{sp}^{3} \mathrm{C}-\mathrm{H}\right), 1671$ (CO). The compound was recrystallized by slow evaporation of dichloromethane solution in a stream of hexane-saturated $\mathrm{N}_{2}$ through a cannula and analyzed by single X-ray crystal diffraction.

Synthesis of ferrocene-fused anthracenequinone (9): In a 25 mL two-necked round-bottom flask with a magnetic stir bar, phthalaldehyde ( $20.0 \mathrm{mg}, 0.07 \mathrm{mmol}$ ) was dissolved in absolute ethanol ( 2 mL ). Compound $\mathbf{8}$ ( $9.01 \mathrm{mg}, 0.07 \mathrm{mmol}$ ) was added, followed by $15 \% \mathrm{KOH}$ ( 1 drop). The solution was allowed to stir overnight at room temperature. The ethanol was evaporated to get a crude product, which was purified by silica column chromatography with ethyl ether:hexane (1:1) to yield a reddish purple solid (16.0 mg, 62.5\%). ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\mathbf{4 0 0} \mathbf{~ M H z , ~} \mathbf{C D C l}_{3}$, ppm): $\delta 4.17\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}\right), 5.12$ (t, 1 H, $\left.{ }^{3} J=2.4 \mathrm{~Hz}, \mathrm{CHCHCH}\right), 5.52\left(\mathrm{~d}, 2 \mathrm{H},{ }^{3} J=2.4 \mathrm{~Hz}, \mathrm{CHCHCH}\right), 7.65-7.67(\mathrm{~m}, 2 \mathrm{H}$, CCHCH), 8.05-8.07 (m, $2 \mathrm{H}, \mathrm{CCHCH}$ ), 8.77 ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{CCHC}$ ). ${ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$ NMR ( $\mathbf{1 0 0} \mathbf{~ M H z}$, $\left.\mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 72.8(\mathrm{CHCHCH}), 73.5(\mathrm{CHCHCH}), 76.9\left(C_{5} \mathrm{H}_{5}\right), 79.1(C C$, ipso), 128.6, 129.6, 130.2, 131.8, 135.0 (Ar), 188.5 (CO). IR (ATR, cm ${ }^{-1}$ ): 1658 (CO). MS (EI): m/z $366\left(\mathrm{M}^{+}\right)$. Mp: $240-260{ }^{\circ} \mathrm{C}(\mathrm{dec})$.

Synthesis of bis(ferrocene-fused) naphthoquinone (10): In a 125 mL Schlenk flask with a magnetic stir bar, 1,2-diformylferrocene ( $400 \mathrm{mg}, 1.65 \mathrm{mmol}$ ) was dissolved in absolute ethanol ( 3 mL ). Compound $\mathbf{8}(443 \mathrm{mg}, 1.65 \mathrm{mmol})$ was added, followed by $15 \% \mathrm{KOH}(0.10 \mathrm{~mL})$. The solution was allowed to stir overnight at room temperature. The solution was filtered through a frit and washed with cold ethyl ether ( 100 mL ). The purple solid was dried under vacuum, yielding 624 mg (79.5\%) of a ca. $1: 1$ syn:anti isomer mixture. Analytically pure product was obtained by recrystallization from slow evaporation of dichloromethane solution in a stream of hexane-saturated $\mathrm{N}_{2}$ through a cannula. ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $400 \mathbf{~ M H z}, \mathbf{C D C l}_{3}$, $\mathbf{p p m}$ ) $\delta 3.89,\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}\right), 3.92\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}\right)$, $4.13\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}\right), 4.14\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}\right), 4.58(2 \mathrm{H}, \mathrm{Cp}), 5.05(2 \mathrm{H}, \mathrm{Cp}), 5.28(4 \mathrm{H}, \mathrm{Cp})$, 5.45 ( $4 \mathrm{H}, \mathrm{Cp}$ ), 8.76 (s, $2 \mathrm{H}, \mathrm{CCHC}$ ), 8.77 (s, $2 \mathrm{H}, \mathrm{CCHC}$ ). ${ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{1} \mathbf{H}\right\} \mathbf{N M R}(\mathbf{1 0 0} \mathbf{~ M H z}$, $\mathbf{C D C l}_{3}$, ppm): $\delta 66.15(\mathrm{Cp}), 66.20(\mathrm{Cp}), 69.38(\mathrm{Cp}), 69.68(\mathrm{Cp}), 72.13(\mathrm{Cp}), 72.31(\mathrm{Cp})$, $73.16(\mathrm{Cp}), 73.34(\mathrm{Cp}), 75.80(\mathrm{Cp}), 76.42(\mathrm{Cp}), 76.49(\mathrm{Cp}), 79.47(\mathrm{Cp}), 79.79(\mathrm{Cp})$, $86.55(\mathrm{Cp}), 86.78$ (Cp), 129.45, 129.58, 134.49, 134.68 (Ar), 187.49, 187.87 (CO). The compound was characterized by an X-ray diffraction study.

Synthesis of 5,10-dihydroanthra[2,3-b:6,7-b]ferrocene (14). In a 100 mL Schlenk flask with a magnetic stir bar, anthra[2,3-b:6,7-b]ferrocene-5,10-dione (200 mg, 0.55 mmol ) was dissolved in THF ( 20 mL ) under $\mathrm{N}_{2}$. The solution was cooled to $0{ }^{\circ} \mathrm{C}$ in an ice bath. Borane-THF solution ( $1.00 \mathrm{M}, 4.37 \mathrm{~mL}, 4.37 \mathrm{mmol}$ ) was added dropwise. The solution was warmed to room temperature and stirred for 8 h . The solution was quenched with methanol $(10 \mathrm{~mL})$. The solvent was evaporated and the crude product was chromatographed on alumina with hexane:dichloromethane (3:2). The red fraction was collected and removal of the solvent gave a pink solid ( $84.0 \mathrm{mg}, 45.5 \%$ ). ${ }^{\mathbf{1}} \mathbf{H}$ NMR (400 $\left.\mathbf{M H z} \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 3.70\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}\right), 3.98\left(\mathrm{~s}, 4 \mathrm{H}, \mathrm{CCH}_{2} \mathrm{C}\right), 3.98(\mathrm{~s}, 1 \mathrm{H}$, CHCHCH), 4.83 (s, 2 H,CHCHCH), 7.42 (m, $2 \mathrm{H}, \mathrm{CCHCH}$ ), 7.72 (s, $2 \mathrm{H}, \mathrm{CCHC}$ ), 7.77 $(\mathrm{m}, 2 \mathrm{H}, \mathbf{C C H C H}) .{ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$ NMR (100 MHz, $\left.\mathbf{C D C l}_{\mathbf{3}}, \mathbf{p p m}\right): \delta 38.28\left(\mathrm{CCH}_{2} \mathrm{C}\right), 61.31$ $(C H C H C H), 68.37\left(C_{5} \mathrm{H}_{5}\right), 69.84(\mathrm{CHCHCH}), 87.62(\mathrm{CC}$, ipso $), 124.83(\mathrm{CCHCH})$, $125.44(\mathrm{CCHCH}), 127.43(\mathrm{CCHC}), 132.69\left(\mathrm{CH}_{2} \mathrm{CCH}\right), 136.68\left(\mathrm{CHCCH}_{2}\right)$. IR (ATR, $\mathbf{c m}^{\mathbf{- 1}}$ ): 2931 ( $\mathrm{sp}^{3} \mathrm{C}-\mathrm{H}$ ), $3089\left(\mathrm{sp}^{2} \mathrm{C}-\mathrm{H}\right) . \mathbf{M p}:>200^{\circ} \mathrm{C} . \mathbf{M S}(\mathbf{E I}): \mathrm{m} / \mathrm{z} 338\left(\mathrm{M}^{+}\right)$.

Synthesis of 5,11-dihydroanthra[2,3-b:6,7-b]diferrocene (15). In a 100 mL Schlenk flask with a magnetic stir bar, anthra[2,3-b:6,7-b]diferrocene-5,11-dione (100
$\mathrm{mg}, 0.19 \mathrm{mmol}$ ) was dissolved in THF ( 10 mL ) under $\mathrm{N}_{2}$. The solution was cooled to 0 ${ }^{\circ} \mathrm{C}$ in an ice bath. Borane-THF solution ( $1.00 \mathrm{M}, 0.57 \mathrm{~mL}, 0.57 \mathrm{mmol}$ ) was added dropwise. The solution was warmed to room temperature and stirred for 1 h . The temperature was slowly raised to $50^{\circ} \mathrm{C}$ using an oil bath and stirred for 5 h . The solution was allowed to cool at room temperature and an additional 1 mL of borane-THF solution was added dropwise. The temperature of the resulting solution was raised slowly to $50^{\circ} \mathrm{C}$ and stirred for 2 h . The initial purple solution changed to a reddish color. The solution was cooled to room temperature and quenched with methanol ( 10 mL ). The solvent was evaporated under reduced pressure and the crude product was purified by chromatography on silica with hexane:dichloromethane (3:2) as an eluent. The red fraction was collected and removal of the solvent gave a pink solid ( $40.0 \mathrm{mg}, 42.4 \%$ ), which is a $1: 1$ mixture of syn:anti isomers. ${ }^{1} \mathrm{H} \mathbf{N M R}\left(\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 3.65$, $3.69\left(\mathrm{~s}, 10 \mathrm{H}, \mathrm{C}_{5} H_{5}\right), 3.73\left(\mathrm{~s}, 8 \mathrm{H}, \mathrm{CCH}_{2} \mathrm{C}\right), 3.95-3.96(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CHCHCH}), 4.82(\mathrm{br}, 4$ H, CHCHCH), 7.35 ( $\mathrm{s}, 4 \mathrm{H}, \mathrm{CCHC}$ ), 7.38 ( $\mathrm{s}, 4 \mathrm{H}, \mathrm{CCHC})$. Synthesis of 5,12-dihydronaphthacene[2,3-b]ferrocene (16). In a 200 mL Schlenk flask, naphthacene[2,3-b]ferrocene-5,12-dione ( $100 \mathrm{mg}, 0.24 \mathrm{mmol}$ ) was dissolved in THF ( 20 mL ). The solution was cooled at $0{ }^{\circ} \mathrm{C}$ for 10 minutes. Borane in THF ( $1.0 \mathrm{M}, 0.96 \mathrm{mmol}, 0.96 \mathrm{~mL}$ ) was added to the solution dropwise. After the complete addition of reagent, the ice bath was removed and the solution was allowed to stir at room temperature for 8 h . The reaction mixture was quenched by 10 mL of methanol. The solvent was removed by rotary evaporation. The obtained crude product was purified by alumina column chromatography and eluted with
hexane:dichloromethane (3:2). The first reddish-pink fraction was collected, and the solvent was removed under reduced pressure and dried under a vacuum to give a pink solid (27.0 mg, 40.0\%). ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\mathbf{4 0 0} \mathbf{~ M H z , ~} \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{p p m}$ ): $\delta 3.69\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} \mathrm{H}_{5}\right), 3.80(\mathrm{~s}$, $\left.4 \mathrm{H}, \mathrm{CCH}_{2} \mathrm{C}\right), 3.91\left(\mathrm{t}, 1 \mathrm{H},{ }^{3} J=2.4 \mathrm{~Hz}, \mathrm{CHCHCH}\right), 4.79\left(\mathrm{~d}, 2 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}\right.$, $\mathrm{CHCHCH}), 7.29-7.32$ (m, $2 \mathrm{H}, \mathrm{CCHCH}$ ), 7.33 ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{CCHC}$ ), 7.52 ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{CCHC}$ ), 7.68-7.71 (m, $2 \mathbf{H}, \mathrm{CCHCH}) .{ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}\left(\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{p p m}\right): 38.63\left(\mathrm{CCH}_{2} \mathrm{C}\right)$, $61.87(\mathrm{CHCHCH}), 70.10\left(C_{5} \mathrm{H}_{5}\right), 88.88(C \mathrm{HCHCH}), 88.29(C C$, ipso $), 125.40,125.60$,
 ( $\left.\mathrm{sp}^{3} \mathrm{C}-\mathrm{H}\right) . \mathrm{Mp}:>250^{\circ} \mathrm{C}$. MS (EI): m/z $388\left(\mathrm{M}^{+}\right)$.

Synthesis of 1H-cyclopenta[b]anthracene-5,10-dione (17). An oven-dried 200 mL Schlenk flask was cooled under nitrogen. Anthra[2,3-b:6,7-b]ferrocene-5,11-dione (11) $(300 \mathrm{mg}, 0.82 \mathrm{mmol})$ was dissolved in THF $(40 \mathrm{~mL})$. A saturated solution of sodium dithionite in $\mathrm{N}_{2}$-purged water ( 40 mL ) was added and stirred overnight, monitored by thin-layer chromatography. There was no conversion of starting material to product, so the reaction mixture was refluxed 5 h . The organic phase was separated and the aqueous layer was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \times 30 \mathrm{~mL})$. The combined organic phase was dried with anhydrous magnesium sulfate and the solvent was removed in vacuum. The crude product was purified on silica chromatography with hexane:dichloromethane (1:1) as an eluent to collect a yellow fraction. The solvent was evaporated under reduced pressure, and the residue dried under a vacuum. The product was further triturated with pentane and dried to give a yellow solid (119 mg, 49.0\%). ${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta$ $3.59\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CCH}_{2} \mathrm{CH}\right), 6.87-6.88\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CHCH}\right), 7.04-7.06\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CHCH}\right)$, 7.75-7.78 (m, $2 \mathrm{H}, \mathrm{CCHCH}), 8.28-8.31$ (m, $2 \mathrm{H}, \mathrm{CCHCH}$ ), 8.37 (s, $2 \mathrm{H}, \mathrm{CCHC}$ ).
${ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$ NMR ( $\left.\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 40.11\left(\mathrm{CCH}_{2} \mathrm{CH}\right), 139.95\left(\mathrm{CH}_{2} \mathrm{CHCH}\right)$, $134.02\left(\mathrm{CH}_{2} \mathrm{CHCH}\right), 119.66,122.50(\mathrm{CCHC}), 127.34,127.36(\mathrm{CCHCH}), 130.40$ $(\mathrm{COCCH}), 132.30,134.15(\mathrm{CCHCH}), 133.25,133.92\left((\mathrm{CHCCO}), 149.76\left(\mathrm{CH}_{2} \mathrm{CCH}\right)\right.$, $150.84(\mathrm{CHCCH}), 183.81,183.94(\mathrm{CO})$. IR (ATR cm$\left.{ }^{\mathbf{- 1}}\right): 1672(\mathrm{C}=\mathrm{O}) . \mathbf{M S}(\mathbf{E I}): \mathrm{m} / \mathrm{z}$ $246\left(\mathrm{M}^{+}\right)$. The compound was fully characterized by X-ray crystallography.

Synthesis of 1H,9H-dicyclopenta[b,i]anthracene-5,11-dione (18). In a 250 mL sidearm round-bottom flask with a magnetic stir bar, $12(150 \mathrm{mg}, 0.29 \mathrm{mmol})$ was dissolved in 20 mL of THF. A saturated solution of sodium dithionite in $\mathrm{N}_{2}$-purged distilled water ( 30 mL ) was added and stirred overnight. TLC indicated the presence of starting material, so the reaction mixture was refluxed for 7 h . The organic phase was separated and the aqueous layer was extracted with dichloromethane $(2 \times 20 \mathrm{~mL})$. The combined organic phase was dried with anhydrous $\mathrm{MgSO}_{4}$ and the solvent was removed under reduced pressure. The crude product was purified by silica chromatography with hexane: $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (1:1). The solvent was evaporated under reduced pressure and dried under a vacuum. The product was further triturated with pentane and dried to give a yellow solid ( $35 \mathrm{mg}, 42 \%$ ). ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\mathbf{4 0 0} \mathbf{~ M H z , ~} \mathbf{C D C l}_{\mathbf{3}}, \mathbf{p p m}$ ): $\delta 3.59\left(\mathrm{~s}, 4 \mathrm{H}, \mathrm{CCH} \mathrm{CH}_{2}\right), 6.85-$ 6.87 (m, 2 H, CH 2 CHCH ), $7.04-7.05\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CHCH}\right), 8.29(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CCHC}), 8.37(\mathrm{~s}$, $2 \mathrm{H}, \mathrm{CCHC}) .{ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}\left(\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}, \mathbf{p p m}\right): \delta 40.08\left(\mathrm{CHCH}_{2} \mathrm{C}\right), 119.56$, 119.61, 122.41, 122.43 (CCHC), 131.10, 131.20, 133.40, 133.55 (СНССО), 132.30, $132.33\left(\left(\mathrm{CH}_{2} \mathrm{CHCH}\right), 139.66,139.72(\mathrm{CH} 2 \mathrm{CHCH}), 149.42,149.58,150.53,150.65\right.$ (CHCCH), $192.66(C O)$. IR (ATR, $\left.\mathbf{c m}^{\mathbf{- 1}}\right): 1664(\mathrm{C}=\mathrm{O}) . \mathbf{M S}(\mathbf{E I}): \mathrm{m} / \mathrm{z} 284\left(\mathrm{M}^{+}\right)$.

Synthesis of 1H-cyclopenta[2,3-b]naphthacene-5,12-dione (19). An oven-dried 200 mL Schlenk flask was cooled under $\mathrm{N}_{2}$. Naphthacene[2,3-b]ferrocene-5,12-dione
( $100 \mathrm{mg}, 0.24 \mathrm{mmol}$ ) was dissolved in THF ( 20 mL ). A saturated solution of sodium dithionite in $\mathrm{N}_{2}$-purged distilled water ( 20 mL ) was added and stirred overnight. TLC showed remaining starting material, so the solution was refluxed for 7 h . The color of the solution changed from purple to brownish yellow. The organic phase was separated and the aqueous layer was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \times 25 \mathrm{~mL})$. The combined organic phase was dried with anhydrous magnesium sulfate and the solvent was removed in vacuum. The evaporation of the solvent under reduced pressure gave a crude product, which was purified by silica column chromatography with hexane: $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (1:1) as eluent. The solvent was evaporated under reduced pressure and the residue dried under vacuum. The product was further triturated with pentane and dried to give a yellow solid ( 37.0 mg , $52.1 \%$ ). ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}$ ): $\delta 3.61$ (s, $2 \mathrm{H}, \mathrm{CCH}_{2} \mathrm{CH}$ ), $6.87-6.89(\mathrm{~m}, 1$ $\left.\mathrm{H}, \mathrm{CH}_{2} \mathrm{CHCH}\right), 7.06-7.07\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CHCH}\right) 7.65-7.67(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CCHCH}), 8.07-8.09$ ( $\mathrm{m}, 2 \mathrm{H}, \mathrm{CCHCH}$ ), 8.36 ( $\mathrm{s}, 1 \mathrm{H}, \mathrm{CCHC}), 8.45$ ( $\mathrm{s}, 1 \mathrm{H}, \mathrm{CCHC}), 8.83$ ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{CCHC})$. ${ }^{13} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$ NMR (100 MHz, $\left.\mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 40.08\left(\mathrm{CCH}_{2} \mathrm{CH}\right), 119.86,122.73$ (CCHC), 129.49, 129.52, 132.31(remaining Ar), 129.61, 130.22 (CHCCH), 130.29, 130.31 $(\mathrm{CCHC}), \quad 131.89, \quad 134.22(\mathrm{COCCH}), \quad 135.30\left(\mathrm{CH}_{2} \mathrm{CCH}\right), \quad 135.39\left(\mathrm{CH}_{2} \mathrm{CHCH}\right)$, $140.02\left((\mathrm{CHCCO}), 149.84\left(\mathrm{CH}_{2} \mathrm{CCH}\right), 150.91(\mathrm{CHCCH}), 183.62,183.74(\mathrm{CO})\right.$. IR (ATR $\left.\mathbf{c m}^{\mathbf{- 1}}\right): 1666(\mathrm{C}=\mathrm{O})$. MS (EI): m/z $296\left(\mathrm{M}^{+}\right)$. Finally, the compound was characterized by an X-ray crystal structure.

## Synthesis of 1H-cyclopenta-5,10-bis(triisopropylsilylethynyl)anthracene (20).

$n$ - $\mathrm{BuLi}(2.5 \mathrm{M}, 0.82 \mathrm{~mL}, 2.1 \mathrm{mmol})$ was added dropwise to hexane ( 10 mL ) and triisopropylsilylethyne ( $0.51 \mathrm{~mL}, 2.3 \mathrm{mmol}$ ) in an oven-dried 250 mL Schlenk flask cooled under $\mathrm{N}_{2}$, and the mixture was stirred for 1 h . THF ( 2 mL ) and additional hexane
$(20 \mathrm{~mL})$ were added into the reaction mixture, followed by addition of 1 H cyclopenta $[b]$ anthracene- 5,10 -dione $(100 \mathrm{mg}, 0.41 \mathrm{mmol})$, then the mixture was stirred overnight. The reaction was quenched with $1 \mathrm{~mL} \mathrm{H} \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{SnCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}(510 \mathrm{mg}, 2.26$ $\mathrm{mmol})$ solution in $10 \% \mathrm{HCl}(1 \mathrm{~mL})$ was added. The mixture was heated to $40^{\circ} \mathrm{C}$ for 8 h , and then cooled to room temperature. After the addition of 30 mL of water, the organic layer was separated and the aqueous layer was extracted with hexane $(3 \times 30 \mathrm{~mL})$. The combined organic phase was dried over anhydrous $\mathrm{MgSO}_{4}$. The volume of the solution was reduced to one-third of its original volume and poured onto a thick pad of silica. The product was eluted with distilled hexane. The removal of the solvent under reduced pressure yielded a yellow gummy product $119 \mathrm{mg}(50.0 \%)$. Recrystallization was carried out using acetone and yielded $71.8 \mathrm{mg}(30.2 \%)$ of $\mathbf{2 0} .{ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}\right.$, ppm): $\delta 1.25-1.26(\mathrm{~m}, 42 \mathrm{H}, i-\mathrm{Pr}), 3.63\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CCH}_{2} \mathrm{CH}\right), 6.71-6.72(\mathrm{~m}, 1 \mathrm{H}$, $\left.\mathrm{CH}_{2} \mathrm{CHCH}\right), 7.00-7.02\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CHCH}\right), 7.54-7.56(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CCHCH}), 8.59-8.61$ (m, $2 \mathrm{H}, \mathrm{CCHCH}$ ), 8.53 ( $\mathrm{s}, 1 \mathrm{H}, \mathrm{CCHC}$ ), 8.65 ( $\mathrm{s}, 1 \mathrm{H}, \mathrm{CCHC}) .{ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}(\mathbf{1 0 0}$ $\left.\mathbf{M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 11.79(\mathrm{CH}, i-\mathrm{Pr}), 19.12\left(\mathrm{CH}_{3}, i-\mathrm{Pr}\right), 59.75\left(\mathrm{CCH}_{2} \mathrm{CH}\right), 104.10$, 104.15, 104.26, 104.52 (CCSi), 118.51, 121.39 (CCHC), 127.37, 127.27 (CCC), 126.56, $126.87(\mathrm{CCHCH}), 129.05,129.93(\mathrm{CCHCH}), 132.09,132.29(\mathrm{CCCH}), 131.75,132.65$ $(\mathrm{CCHC}), 132.79,137.53(\mathrm{CHCC}), 136.49\left(\mathrm{CH}_{2} \mathrm{CHCH}\right), 142.86\left(\mathrm{CH}_{2} \mathrm{CCH}\right), 145.23$ $\left((\mathrm{CHCCH}), 150.25\left(\mathrm{CH}_{2} \mathrm{CHCH}\right)\right)$. IR (ATR cm$\left.{ }^{-1}\right): 3060\left(\mathrm{sp}^{2} \mathrm{C}-\mathrm{H}\right), 2944,2865\left(\mathrm{sp}^{3}\right.$ $\mathrm{C}-\mathrm{H}), 2145(\mathrm{C} \equiv \mathrm{C})$. MS (EI): m/z 576( $\mathrm{M}^{+}$). The X-ray crystal structure was highly disordered, so it was unable to be refined.

## Synthesis of 1H,9H-dicyclopenta-5,11-bis(triisopropylsilylethynyl)anthracene

(21). Hexane ( 20 mL ) and triisopropylsilylethyne $(0.59 \mathrm{~mL}, 2.6 \mathrm{mmol})$ were added to an
oven-dried 250 mL Schlenk flask equipped with a magnetic stir bar and cooled under $\mathrm{N}_{2}$. $n-\operatorname{BuLi}(2.5 \mathrm{M}, 0.98 \mathrm{~mL}, 2.5 \mathrm{mmol})$ was added dropwise and the mixture was stirred for 1 h . Hexane ( 40 mL ), THF ( 2 mL ) and $1 \mathrm{H}, 9 \mathrm{H}$-dicyclopenta $[b, i]$ anthracene-5,11-dione ( $100 \mathrm{mg}, 0.35 \mathrm{mmol}$ ) were added separately and the mixture was stirred overnight. The reaction was quenched with $1 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{SnCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}(397 \mathrm{mg}, 1.76 \mathrm{mmol})$ in $10 \%$ aqueous $\mathrm{HCl}(1 \mathrm{~mL})$, and the solution was heated for 2 h at $60^{\circ} \mathrm{C}$, and then cooled to room temperature. After the addition of $30 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}$, the organic phase was separated and aqueous phase was extracted with hexane $(3 \times 20 \mathrm{~mL})$. The combined organic phase was dried over anhydrous $\mathrm{MgSO}_{4}$ and filtered. The filtrate was evaporated under reduced pressure to reduce volume to one-third of its original volume and poured onto a thick pad of silica, then eluted with distilled hexane. The solvent was removed to yield 50.0 mg (23.0\%) of product and recrystallized from acetone yielded 34.3 mg ( $15.8 \%$ ). The compound was characterized by X-ray diffraction. ${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}, \mathbf{p p m}\right): \delta$ 1.27-1.28 (m, $42 \mathrm{H}, i-\mathrm{Pr}), 3.63\left(\mathrm{~s}, 4 \mathrm{H}, \mathrm{CCH}_{2} \mathrm{CH}\right), 6.69-6.71$ (m, $2 \mathrm{H}, \mathrm{CCHCH}$ ), 7.017.02 ( $\mathrm{m}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CHCH}$ ), 8.53 ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{CCHC}$ ), 8.64 ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{CCHC}$ ). ${ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$ NMR ( $\left.\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 11.84\left(\mathrm{CH}_{3, \mathrm{i}} \mathrm{i} \mathrm{Pr}\right), 19.14(\mathrm{CH}, i-\mathrm{Pr}), 38.47\left(\mathrm{CCH}_{2} \mathrm{CH}\right), 103.82$ (CCSi), 104.68 (CCSi), 117.63, 117.74, 121.24, 121.34 (CCHC), 118.20 (CCC), 131.17, 131.37 ( CHCHC ), 132.20, $132.40\left(\mathrm{CH}_{2} \mathrm{CHCH}\right), 132.69,137.14,137.18$ (CHCC), 142.31 142.48, 144.72, $144.86(\mathrm{CHCCH}) . \mathbf{M p}: 210{ }^{\circ} \mathrm{C}(\mathrm{dec})$. IR (ATR cm$\left.{ }^{-1}\right): 3037\left(\mathrm{sp}^{2} \mathrm{C}-\mathrm{H}\right)$, 2961, 2941, 2866 ( $\left.\mathrm{sp}^{3} \mathrm{C}-\mathrm{H}\right), 2130(\mathrm{C} \equiv \mathrm{C})$. Analysis Calc. for: C, 82.02; H, 8.85. Found: C, 79.62; H, 8.98.

Synthesis of 1H-cyclopenta-5,12-bis(triisopropylsilylethynyl)naphthacene (22). Hexane ( 10 mL ) and triisopropylsilylethyne ( $0.42 \mathrm{~mL}, 1.9 \mathrm{mmol}$ ) were added to an
oven-dried 250 mL Schlenk flask cooled under $\mathrm{N}_{2}$, followed by the dropwise addition of $n-\operatorname{BuLi}(2.5 \mathrm{M}, 0.68 \mathrm{~mL}, 1.7 \mathrm{mmol})$. The mixture was stirred for 1 h . Hexane ( 20 mL ), THF ( 2 mL ) and 1H-cyclopenta[2,3-b]naphthacene-5,12-dione ( $100 \mathrm{mg}, 0.34 \mathrm{mmol}$ ) were added separately to the mixture. The reaction mixture was stirred overnight. The reaction was quenched with $\mathrm{H}_{2} \mathrm{O}(1 \mathrm{~mL})$ and $\mathrm{SnCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}(420 \mathrm{mg}, 1.86 \mathrm{mmol})$ in $10 \%$ aqueous $\mathrm{HCl}(1 \mathrm{~mL})$, and the solution was heated at $40{ }^{\circ} \mathrm{C}$ for 8 h , and then cooled to room temperature. After the addition of $25 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}$, the organic phase was separated and aqueous phase was extracted with hexane $(3 \times 20 \mathrm{~mL})$. The combined organic phase was dried over anhydrous $\mathrm{MgSO}_{4}$ and filtered. The filtrate was evaporated under reduced pressure to reduce volume to one-third of its original volume and loaded onto a thick pad of silica. The product was eluted with hexane, then the solvent was reduced to yield 123 $\mathrm{mg}(59.0 \%)$ and recrystallized from acetone yielded $105 \mathrm{mg}(50.4 \%) .{ }^{\mathbf{1}} \mathbf{H}$ NMR (400 $\left.\mathbf{M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 1.31-1.32(\mathrm{~m}, 42 \mathrm{H}, i-\mathrm{Pr}), 3.66\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CCH}_{2} \mathrm{CH}\right), 6.71-6.73(\mathrm{~m}$, $\left.1 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CHCH}\right), 7.00-7.01$ (m, $\left.1 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CHCH}\right), 7.43$ (m, $2 \mathrm{H}, \mathrm{CHCHCH}$ ), 7.99 (m, 2 $\mathrm{H}, \mathrm{CHCHCH}), 8.51(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CCHC}), 8.62(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CCHC}), 9.27(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CCHC}) .{ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$ NMR (100 MHz, $\left.\mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 11.87(\mathrm{CH}, \mathrm{i}-\mathrm{Pr}), 19.18\left(\mathrm{CH}_{3}, \mathrm{i}-\mathrm{Pr}\right), 38.38\left(\mathrm{CCH}_{2} \mathrm{CH}\right)$, 104.62, 104.72, 105.21, 105.50 (CCSi), 117.63, 118.27 (CCC), 118.27, 121.34 (CCHC), 128.80, $128.80(\mathrm{CCHC}), 132.23,132.69(\mathrm{CCCH}), 132.04,132.17(\mathrm{CHCCH}) 133.56$ $\left(\mathrm{CH}_{2} \mathrm{CHCH}\right), 137.83,137.84(\mathrm{CHCC}), 142.75\left(\mathrm{CH}_{2} \mathrm{CHCH}\right) 145.30\left(\mathrm{CH}_{2} \mathrm{CCH}\right), 163.30$ $(\mathrm{CHCCH}), 130.37,130.19,126.29,126.16$ (remaining Ar). ### 2.3 Results and discussion

2.3.1 Synthesis. A goal in our research is to synthesize organometallic acenes. 1,2-Disubstituted metallocene is a precursor to prepare our target complexes. In order to synthesize the target complexes, the synthetic pathway was started with the following reaction scheme.

Scheme 2.1 Synthesis of 1,2-diformylferrocene
The reaction pathway involves the conversion of ferrocene to $\mathrm{N}, \mathrm{N}-$ dimethylaminomethylferrocene by following the protocol developed by Lednicer and Hauser. ${ }^{97} \mathrm{~N}, \mathrm{~N}$-dimethylaminomethylferrocene (1) was prepared in $64.2 \%$ yield by reacting ferrocene with $\mathrm{N}, \mathrm{N}, \mathrm{N}, \mathrm{N}$-tetramethylmethylenediamine under acidic conditions at $100{ }^{\circ} \mathrm{C}$ for 5 h . There are several approaches to prepare 1,2-diformyl ferrocene as described above. Among them, we used a procedure developed by the Brocard group. ${ }^{89,90}$ On treating 1 with $n$ - BuLi , it forms an ortho-lithiation complex, which on treatment with dimethylformamide forms N,N-dimethylaminomethyl-2-formylferrocene (2). Oxidation of $\mathbf{2}$ with activated $\mathrm{MnO}_{2}$ yields 1,2-diformylferrocene (3), the precursor of our project. Unfortunately, we were unable to reproduce the reported $71 \%$ yield for conversion of $\mathbf{1}$ to $\mathbf{2},{ }^{116}$ even with freshly dried solvent and oven-dried glassware cooled under nitrogen. The highest percentage of 2 we obtained under these conditions was $56 \%$, but we typically
recovered around $50 \%$ of starting material (1). In order to circumvent this issue, we attempted an alternative route to 1,2 -diformylferrocene (Scheme 2.2 ) that avoids the lithiation step.

Scheme 2.2 Attempted synthetic route to 1,2-diformylferrocene
Following the reported procedure by Rinehart, ${ }^{98}$ 1-(3-carboxypropionyl)ferrocene $(\mathbf{4}, 66 \%)$ was prepared by the Friedel-Crafts acylation between ferrocene and succinic anhydride in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature. The keto group was reduced to methylene under the Clemmensen reduction to give desired acid (5, 85.7\%). ${ }^{99}$ Compound $\mathbf{5}$ was reacted with trifluoroacetic acid to prepare $\alpha$-keto-1,2-tetramethylene ferrocene ( $\mathbf{6}$, $92.1 \%) .{ }^{102}$

Oxidation of 6 to 1,2-ferrocenedicarboxylic acid has not been achieved so far. Sotirious et al. reported aromatic 1,2-dicarboxylic acid prepared via oxidative cleavage of cyclic ketones fused to aromatic hydrocarbons using potassium superoxide in aprotic media in the presence of 18 -crown-6-ether. ${ }^{103}$ Oxidation of $\mathbf{6}$ under Sotirious' conditions resulted in intractable mixtures. Further, oxidation of acetylferrocene to
ferrocenecarboxylic acid is well known. ${ }^{104,105,}$ Several attempts were carried out to oxidize ferrocenedicarboxylic acid using reagents such as $\mathrm{Br}_{2} / \mathrm{NaOH}, \mathrm{I}_{2} / \mathrm{NaOH}$, and reaction with bleach solution resulted in a decomposition.

Ferrocenedicarboxylic acid is the precursor to get the 1,2-diformylferrocene in two steps. The first step is the reduction of dicarboxylic acid to diol followed by oxidation to yield 1,2-diformylferrocene. We did not succeed in preparing 1,2ferrocenedicarboxylic acid from 6. Then, compound 6 was reacted with excess active manganese dioxide under reflux for 8 h to prepare ferrocene-fused-benzoquinone (7). The purple, gummy compound 7 was solidified by triturating with pentane under liquid $\mathrm{N}_{2}$. The compound was characterized by ${ }^{1} \mathrm{H}$ NMR, ${ }^{13} \mathrm{C}$ NMR, IR and X-ray diffraction. IR shows a peak at $1650 \mathrm{~cm}^{-1}$ indicating the presence of a carbonyl group. Compound 7 was already reported by the Hill group, ${ }^{101}$ but it had not been structurally characterized.

Scheme 2.3 Synthesis of ferrocenebenzoquinone and ferrocene-fused cyclohexanedione

As our goal is to synthesize the ferrocenedicarboxylic acid, we attempted to oxidize ferrocene[b]benzoquinone (7) with the bleach solution in the dark at $50{ }^{\circ} \mathrm{C}$ for 6 h , with the addition of fresh bleach every 2 h resulted in decomposition. Compound 7 can be used to prepare acene analogous quinones under Cava conditions. An attempt to
prepare analogous acenequinones by the reaction of 7 with $\alpha, \alpha, \alpha^{\prime}, \alpha^{\prime}$-tetrachloro- $o$-xylene under Cava conditions resulted in decomposition. However, reduction of ferrocene[b]benzoquinone (7) with sodium dithionite at room temperature for 7 h resulted in ferrocene-fused cyclohexanedione (8). Compound $\mathbf{8}$ is the stable form of the corresponding hydroquinone (enol tautomer). The dione is kinetically stable at room temperature but converts into phenolic form rapidly in presence of base. ${ }^{106}$ The product was purified by chromatography on silica and crystallized by partial evaporation of ethyl ether solution in a stream of hexane-saturated $\mathrm{N}_{2}$. The compound was characterized by a single X-ray crystal structure.

Compound 8 was reacted with phthalaldehyde, which underwent two-fold condensation in a base catalyst to give compound 9 . The quinone complex designed by this protocol has carbonyl groups at $\alpha$ - to cyclopentadienyl ring. Compound 9 had already been synthesized by one of our group members from the Friedel-Crafts acylation of ferrocene with 2-carbomethoxynaphthaloyl chloride in the presence of anhydrous $\mathrm{AlCl}_{3}$ followed by the hydrolysis of an ester group, reduction of a carbonyl group, cyclization in presence of trifluoroacetic anhydride and oxidation of a cyclized product. The synthetic approach I have used to prepare $\mathbf{9}$ is not good as compared to one used by my former group member in termed of overall yield ( $7.38 \%$ vs. $44.7 \%$ ) and number of reaction steps. The compound was characterized fully including a crystal structure. ${ }^{107}$ Further, compound $\mathbf{8}$ was condensed with 1,2-diformylferrocene overnight at room temperature, which gave bimetallic acenequinone (10) (79.5\%) with an equal mixture of two isomers (syn and anti). We were not able to separate the isomers chromatographically.

Scheme 2.4 Synthesis of ferrocene-fused $\alpha$-carbonyl quinones

Scheme 2.5 Synthesis of ferrocene-fused quinones
Aldol condensations of 1,2-diformyl ferrocene were carried out following the literature procedure. The homologous backbone mononuclear quinones, $\mathbf{1 1}$ and $\mathbf{1 3}$ were prepared in $78.8 \%$ and $81.5 \%$ yields by reacting 1,2-diformylferocene with 1,4 dihydroxynaphthalene or with 1,4-anthracenediol in the presence of KOH. Similarly, a binuclear acenequinone, anthra-diferrocenedione, was synthesized by four-fold aldol condensation of 1,2-diformylferrocene with 1,4-cyclohexanedione in a 2:1 ratio in absolute ethanol under basic conditions, which resulted in a syn/anti isomeric mixture in 70 \% combined yield. The purification of these mono- and bimetallic acenequinones involves simple frit filtration of the reaction mixture, washing the purple solid with cold ethyl ether until the filtrate is colorless, and dried under vacuum. We were unable to separate the isomers by column chromatography. ${ }^{1}$ H NMR spectral integration shows a
ca. 1:1 ratio of syn and anti isomers. These deep blue, solid quinone complexes have a carbonyl group at $\gamma$-position with respect to cyclopentadienyl ring. They are stable in the solid state whereas standing in dichloromethane solution or chromatography on silica results in protolytic cleavage of the quinone ligand from the metal

The reaction of quinone complexes (11, $\mathbf{1 2}$ and $\mathbf{1 3}$ ) with borane in THF reduced the carbonyl groups to methylenes (14, 45.5\%; 15, $42.4 \%$ combined yield and 16, $40.0 \%$ ). Again, we were unable to separate syn and anti isomers of $\mathbf{1 5}$ by column chromatography. An attempt to aromatize Cp-capped dihydroacenes (14, 15, and 16) using 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) ${ }^{108}$ in benzene resulted in mostly decomposed products. The decomposed product was dissolved in ethyl ether. The ether layer was separated and reduced under rotary evaporation to give the yellow-green, gummy material. The purification of the gummy material on silica column chromatography eluted a yellowish green first band in 1:1 hexane: ethyl ether and evaporation of solvent gave a yellowish green viscous solid. ${ }^{1} \mathrm{H}$ NMR of that solid indicates the presence of multiple components.

Scheme 2.6 Reduction of ferrocene-fused quinones with borane

Scheme 2.7 Attempt to aromatize ferrocene-fused dihydroanthracenes
The reduction of acenequinones (11, $\mathbf{1 2}$ and $\mathbf{1 3}$ ) using saturated aqueous solution of sodium dithionite in THF under reflux gave demetalated acenequinones in reasonably
good yield (17, 49.0\%; 18, $42.0 \%$ combined yield and 19, 52.1\%). Compounds 11, 12 and $\mathbf{1 3}$ exhibit significant indenyl effect as a result when reducing reagent attacks on iron underwent ligand substitution reaction and resulted in demetalation to give Cp-capped acenequinones. In contrast, our attempt to demetalate compounds $\mathbf{9}$ and $\mathbf{1 0}$ under same reaction conditions resulted in recovery of starting material even after 55 h reaction at THF reflux temperature. We noticed the decomposition of starting material with longer reaction time. An infrared absorption around $1664-1672 \mathrm{~cm}^{-1}$ implies the presence of carbonyl groups in 17-19. Attempts to improve the demetalation by treating complex $\mathbf{1 3}$ with aqueous potassium cyanide gave 19 in only $15 \%$ yield. Similar demetalation reactions on complex $\mathbf{1 3}$ by protolysis with $10 \%$ nitric acid or by reductive cleavage with zinc amalgam resulted only $\sim 10 \%$ yield of 19 . Surprisingly, sodium dithionite is the most effective demetalation reagent.

Niebel et. al reported the synthesis of tetraketo-substituted dicyclopentanaphthalene ( $\mathbf{2}$ of Chart 2.2) by the reaction of naphthalene-tetracarboxylic dianhydrides with ethyl(triphenylphosphoranylidene)acetate in high percent yield. ${ }^{109}$ The same group synthesized dianion of octacyanotetramethylene-substituted dicyclopentanaphthalene ( $\mathbf{3}$ of Chart 2.2) by refluxing tetraketo-substituted dicyclopentanaphthalene with a large excess of malononitrile in water in the presence of sodium acetate under argon atmosphere in $75 \%$ yield, and investigation of electronic properties showed reversible redox behavior. ${ }^{110}$ Makino and coworker have investigated some theoretical calculations to examine the aromaticity and magnetotropicity of dicyclopenta-fused polyacenes and reported that dianions of dicyclopenta-fused Polyacenes (4 of Chart 2.2) have more aromatic character than their respective neutral
acenes. ${ }^{111}$ Therefore, dicyclopenta-fused polyacene derivatives are valuable precursors for the synthesis of molecular and polymeric advanced materials.

Chart 2.2 Dicyclopenta-fused Polyacene derivatives

Scheme 2.8 Reduction of ferrocene-fused quinones with sodium dithionite

Since we were not able to aromatize ferrocene-fused acenequinones to ferrocenefused polyacenes, an alternative is to aromatize the Cp-capped acenequinones. Nucleophilic addition to the quinone carbonyls followed by dehydroxylation with $\mathrm{SnCl}_{2}$ in acidic conditions is a classic method of converting acenequinones to acenes. ${ }^{6}$ Following the procedure established by Anthony's group, Cp-capped acenequinones (17, 18 and 19) were reacted with triisopropylsilylacetylene $/ n-\mathrm{BuLi}$ in hexane, followed by dehydroxylation with $\mathrm{SnCl}_{2},{ }^{21}$ which gave Cp-capped bis(triisopropylsilylethynyl)acenes $\mathbf{( 2 0}, 50 \%, \mathbf{2 1}, 23 \%$ and $\mathbf{2 2}, 59 \%)$. To the best of our knowledge, we are the first to detach mono- and bis(cyclopentadiene)fused acenequinones from iron and to aromatize the free acenequinones as Cp-capped bis(triisopropylsilylethynyl)acenes. Bis(Cp-capped-triisopropylsilylethynyl)- anthracene is closely similar to Anthony's bis(triethylsilylethynyl)anthradithiophene both structurally and electronically. ${ }^{6}$

2.3.2 Spectroscopy. The compounds synthesized previously were characterized by comparison of their ${ }^{1} \mathrm{H}$ NMR spectra, IR spectra and melting points with reported data. All new compounds were fully characterized by spectroscopic methods including ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR, IR and mass spectroscopy. The ${ }^{1} \mathrm{H}$ NMR resonances of the unsubstituted cyclopentadienyl ring of $\mathbf{1 - 1 6}$ in ${ }^{1} \mathrm{H}$ NMR lie in the range of 3.69 to 4.30
ppm depending on compounds' structures with the characteristic singlet. Similarly, proton resonances of substituted cyclopentadienyls of 2-3, and 7-16 display a characteristic doublet and triplet with an integration of a $2: 1$ ratio showing the symmetry of the ligand. The resonance of inner protons $(\mathrm{CHCHCH})$ generally display in the range of 3.91 to 4.92 ppm , whereas those of outer protons $(\mathrm{CHCHCH})$ lie between 4.08 to 5.43 ppm.

The ${ }^{1} \mathrm{H}$ NMR spectra of ferrocene-fused dihydroacenes ( $\mathbf{1 4}, \mathbf{1 5}$ and $\mathbf{1 6}$ ) show a singlet methylene proton in the range of 3.73 to $3.98 \mathrm{ppm}^{\mathrm{p}} \mathrm{CDCl}_{3}$ solvent. Similarly, the ${ }^{1} \mathrm{H}$ NMR resonances of cyclopentadiene-capped acenequinones display a characteristic singlet peak of a methylene group around $3.59-3.61 \mathrm{ppm}$. The aromatization of iron-free acenequinones to corresponding bis(triisopropylsilylethynyl) polyacenes shows the methylene proton in the range of 3.63 to 3.66 ppm in the ${ }^{1} \mathrm{H}$ NMR. The ${ }^{13} \mathrm{C}$ NMR spectra of compounds $\mathbf{7 - 1 3}$ and $\mathbf{1 7 - 1 9}$ show the characteristic peaks of carbonyl carbon in the range of 182 to 193 ppm . The ${ }^{13} \mathrm{C}$ NMR spectra of $\mathbf{1 0}, \mathbf{1 1}, \mathbf{1 2}, \mathbf{1 3}$ and $\mathbf{1 4}$ show the upfield shift of signals for ipso carbons ( $\mathrm{C} 8, \mathrm{C} 9$ in Figure 1.6) in the range of 87 to 90 ppm . Similar chemical shifts were observed by the Marder group for ipso carbons in the ${ }^{13} \mathrm{C}$ NMR of $\left[\mathrm{Fe}\left(\eta-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}\right]$ and $\left[\mathrm{Co}\left(\eta-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}\right]^{+}$, which they considered as indicative of $\eta^{5}$-coordination. ${ }^{53}$

The ${ }^{1} \mathrm{H}$ NMR of compound $\mathbf{1 2}$ indicates the presence of isomers with two peaks for unsubstituted cyclopentadienyl ligands $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)$ at 3.90 and 3.96 ppm and arene protons at 8.92 and 8.94 ppm. Similarly, ${ }^{1} \mathrm{H}$ NMR of compound $\mathbf{1 5}$ also displays the two peaks for $\mathrm{C}_{5} \mathrm{H}_{5}$ at 3.65 and 3.69 ppm and arene protons at 7.35 and 7.38 ppm , which confirms the presence of isomers. Furthermore, the ${ }^{1} \mathrm{H}$ NMR of compound $\mathbf{1 8}$ shows presence of
arene proton peaks at 8.37 and 8.29 ppm , and compound 21 shows the evidence of isomers with a tiny splitting of the peak at 8.53 ppm . In addition, the ${ }^{13} \mathrm{C}$ NMR of $\mathbf{1 2}, \mathbf{1 5}$, 18 and 21 shows strong evidence for the presence of isomer with the significant number of carbon peaks. The IR spectra of complexes show characteristic carbonyl stretching frequencies in the region of 1650 to $1672 \mathrm{~cm}^{-1}$. IR absorption frequencies of complexes are shown in Table (2.2). Mass spectra of all compounds show characteristic peaks corresponding to molecular ion.

2.3.3 Structure. The growth of crystals was conducted at ambient temperature unless otherwise mentioned. The structures of $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}\left(\mathrm{COCH}_{2}\right)\right\}\right]$ (7), $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}\left(\mathrm{COCH}_{2}\right)_{2}\right\}\right] \quad$ (8), $\quad \mathrm{Cis}-\left[\mathrm{Fe}_{2}(\mathrm{Cp})_{2}\left\{\mu-\left(\eta^{5}: \eta^{5}\right)-\left(\mathrm{C}_{5} \mathrm{H}_{3} \mathrm{COCCH}\right)\right\}_{2}\right] \quad$ (10), $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}(\mathrm{CHCCOCCHCH})_{2}\right\}\right] \quad$ (11), $\quad \operatorname{Cis}-\left[\mathrm{Fe}_{2}(\mathrm{Cp})_{2}\left\{\mu-\left(\eta^{5}: \eta^{5}\right)-\right.\right.$ $\left.\left.\left(\mathrm{C}_{5} \mathrm{H}_{3} \mathrm{CHCCOCCH}\right)_{2}\right\}\right] \quad$ (12), $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}(\mathrm{CHCCOCCHCCHCH})_{2}\right\}\right] \quad$ (13), $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}\left(\mathrm{CHCCH}_{2} \mathrm{CCHCH}\right)_{2}\right\}\right] \quad$ (14), $\quad\left[\mathrm{C}_{5} \mathrm{H}_{4}(\mathrm{CHCCOCCHCH})_{2}\right] \quad$ (17), $\left[\left(\mathrm{C}_{5} \mathrm{H}_{4}\right)_{2}(\mathrm{CHCCOCCH})_{2}\right] \quad(\mathbf{1 8}), \quad\left[\mathrm{C}_{5} \mathrm{H}_{4}(\mathrm{CHCCOCCHCCHCH})_{2}\right] \quad$ (19), $\left[\left(\mathrm{C}_{5} \mathrm{H}_{4}\right)_{2}(\mathrm{CHCCCCH})_{2}\left\{\mathrm{C} \equiv \mathrm{CSi}(i-\mathrm{Pr})_{3}\right\}_{2}\right] \quad$ (21), and $\quad\left[\left(\mathrm{C}_{5} \mathrm{H}_{4}\right)\right.$ $\left.(\mathrm{CHCCCCHCCHCH})_{2}\right)\left\{\left(\mathrm{C} \equiv \mathrm{CSi}(i-\mathrm{Pr})_{3}\right\}_{2}\right]$ (22) were determined by X-ray crystallography. Single crystals of $7, \mathbf{1 3}$, and $\mathbf{1 8}$, were grown by slow evaporation of dichloromethane under nitrogen while crystal 19 was grown by slow evaporation of ethyl ether from its saturated solution, and 21 and 22 were grown by slow evaporation of acetone. Similarly, single crystals of $\mathbf{8}$ and $\mathbf{1 0}$ were grown from evaporation of dichloromethane solution in a stream of hexane-saturated $\mathrm{N}_{2}$ through a cannula. Thermal ellipsoid plots of the molecular structures of $7, \mathbf{8}, \mathbf{1 0}, \mathbf{1 1}, \mathbf{1 2}, \mathbf{1 3}, \mathbf{1 4}, \mathbf{1 7}, \mathbf{1 8}, \mathbf{1 9}, 21$ and $\mathbf{2 2}$ are shown in Figures $\mathbf{2 . 3}$ to $\mathbf{2 . 1 4}$ with the atom numbering scheme. The crystal structure and refinement data for these compound can be found in Tables 2.3-2.7 as shown below.

The iron complexes $\mathbf{7 , 8} \mathbf{8} \mathbf{1 0}, \mathbf{1 1}, \mathbf{1 2}, \mathbf{1 3}$ and $\mathbf{1 4}$ indicate eclipsed conformation of the two cyclopentadienyl rings similar to typical ferrocene geometry. The average ironcyclopentadienyl centroid distances (substituted, unsubstituted) are 7 [1.645(5) Å, $1.662(5) \AA], \mathbf{8}[1.644(2) \AA, 1.658(2) \AA], \mathbf{1 0}[\mathrm{Fe} 11.640(3) \AA, 1.653(3) \AA, \mathrm{Fe} 21.666(3) \AA$, $1.659(3) \AA$ A $], \mathbf{1 1}[1.670(2) \AA, 1.657(2) \AA$ ] $], \mathbf{1 2}[\mathrm{Fe} 11.666(7) \AA, 1.654(8) \AA, \mathrm{Fe} 21.655(7)$
$\AA, 1.649(8) \AA], \mathbf{1 3}[1.673(2) \AA, 1.656(2) \AA], \mathbf{1 4}[1.669(2) \AA, 1.642(3) \AA]$. The average bond distance between the metal center to ipso carbons and to the remaining three carbon atoms of the substituted cyclopentadienyl ring are $7[\mathrm{Fe} 2.034(5) \AA, 2.055(5) \AA, 10[\mathrm{Fe} 1$ $2.018(3) \AA, 2.054(3) \AA, \mathrm{Fe} 22.088(3) \AA, 2.053(3) \AA], 11[2.093(2) \AA, 2.045(2) \AA], 12$ $[\mathrm{Fe} 12.070(7) \AA, 2.040(7) \AA, \mathrm{Fe} 22.072(7) \AA, 2.054(7) \AA], \mathbf{1 3}[2.092(2) \AA, 2.055(2) \AA]$, and $\mathbf{1 4}[2.092(5) \AA, 2.045(5) \AA]$. The average bond distance between the iron center to ipso carbons ( C 4 and C 5 ) in complex 7 and Fe 1 to ipso carbons ( C 1 and C 5 ) in $\mathbf{1 0}$ is shorter than the bond to the remaining three carbon atoms of the substituted cyclopentadienyl ring. The ring slippage parameter $\Delta_{\mathrm{Fe}-\mathrm{C}}$ has a value of $0.021 \AA$ (7) and $0.034 \AA(\mathbf{1 0})$. This shift is opposite to that found as a common feature in indenyl complexes. Similar behaviors have been observed by the Bernardivelli group in the structure of $\left[\mathrm{Cr}(\mathrm{CO})_{3}\left(\eta^{6}-5,8\right.\right.$-naphthoquinone $\left.)\right]$ with $\Delta_{\mathrm{Cr}-\mathrm{C}}$ value of $0.044 \AA .{ }^{112}$ The $\mathrm{C}-\mathrm{C}$ bond distances in the substituted cyclopentadienyl ring are in the range of 1.413 to 1.447 A․

The quinone moiety in complex 7 is slightly tilted toward the iron center. The interplanar angle between the quinone and the Cp plane is $6.22^{\circ}$. The bending is prominent at the carbonyl carbon, which is also supported by the torsional angle of C 1 -C5-C4-C9 $\left(-174.3^{\circ}\right)$ and C3-C4-C5-C6 $\left(177.8^{\circ}\right)$. The carbonyl groups in $\mathbf{8}$ are coplanar with the Cp ring; however, the structure is twisted at carbons C 8 and C 9 with a torsional angle (C6-C7-C8-C9) of 42.2(3) ${ }^{\circ}$.

The characteristic feature of indenyl complexes 11, 12, $\mathbf{1 3}$ and $\mathbf{1 4}$ is that the ipso carbon atoms in the substituted cyclopentadienyl ring are slightly away from the iron center, demonstrating their weaker interaction towards iron than the remaining three
carbon atoms. In contrast to ferrocene, these complexes display a gradual increase in the degree of slip-fold distortion from $\eta^{5}$ toward $\eta^{3}$ coordination, which involves slippage of the iron from ipso carbons. The ease of ring slippage for indenyl vs. cyclopentadienyl ligands may be due to the rehybridization of the indenyl $\pi$-system, which involves an increase in the aromatic character of the benzene ring. This results in a disruption of the aromatic character in the five-membered ring. Hence, cyclopentadienyl ligand requires a high energy process for ring slippage from $\eta^{5}$ to $\eta^{3}$ coordination ${ }^{113-114}$

To be a true $\eta^{3}$ complex, slip parameter ( $\Delta_{M-C}$ ) should be $0.69-0.79 \AA$ as reported for an iridium complex $\left[\operatorname{Ir}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{3}\left(\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}\right)\right] .{ }^{50}$ The slip parameter $\left(\Delta_{\mathrm{Fe}-\mathrm{C}}\right)$ is 0.048 (11), $0.03 \mathrm{Fe} 1,0.018 \mathrm{Fe} 2(\mathbf{1 2 )}, 0.037$ (13) and 0.047 (14). These values correspond to bis(indenyl)ferrocene $\left(\Delta_{\mathrm{Fe}-\mathrm{C}}=0.049\right)$ indicating that the Cp of these complexes have true $\eta^{5}$ coordination with the iron center. The true $\eta^{5}$ coordination of these complexes is also supported by carbon peaks of ipso carbons in the solution ${ }^{13} \mathrm{C}$ NMR, which lie in the range of 87 to 90 ppm ; for $\eta^{3}$-complexes, ipso carbons shifts are in the range $130-160$ ppm. Moreover, the slip-fold distortion of these indenyl complexes can be explained in terms of their hinge angle (HA) and fold angle (FA). The hinge angle (HA) is an angle between the planes (C5, C6, C7) and (C5, C4, C8 C7), and the fold angle (FA) is an angle between the planes (C5, C6, C7) and the rest of the plane of a complex as shown in Figure 2.6. The hinge angle represents bending at [C5, C7] and the fold angle represents bending at [C4, C8]. The calculated HA and FA is $2.29^{\circ}$, $8.48^{\circ}(\mathbf{1 1})$, $\mathrm{Fe} 1.67^{\circ}, 2.70^{\circ}$ and $\mathrm{Fe} 23.55^{\circ}(\mathbf{1 2}), 4.68^{\circ}, 2.75^{\circ}(\mathbf{1 3})$ and $2.16^{\circ}, 3.41^{\circ}(\mathbf{1 4})$. The hinge angles of these complexes are close to the HA of $\left[\mathrm{Fe}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}\right]$, which is $2.6^{\circ}$, whereas the fold angles are slightly larger than the FA of $\left[\mathrm{Fe}\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right)_{2}\right]$ equal to $1.6^{\circ}$. Even though crystal
structures exhibit minimal indenyl effect, these values correspond to nearly undistorted $\eta^{5}$-coordination of a ligand, consistent with the solution ${ }^{13} \mathrm{CNMR}$ data. All $\mathrm{C}-\mathrm{C}$ bonds of substituted Cp in 11, 12, $\mathbf{1 3}$ and $\mathbf{1 4}$ are ranging from 1.420-1.428(4) $\AA, 1.406-1.462(10)$ $\AA, 1.423-1.453(3) \AA$ and $1.420-1.437(4) \AA$, respectively.

The mononuclear quinone complex, $\mathbf{1 3}$ exhibits coplanarity of quinone groups with the Cp ring. Figures 2.1 and 2.2 show the packing of ferrocene-fused and cyclopentadiene-capped quinone complexes along the $a$-axis. Ferrocene-fusedtetracenequinone (13) shows sandwich herringbone arrangement. The ferrocenyl groups of two molecules in $\mathbf{1 3}$ are oriented on the opposite face of the plane, thereby avoiding steric interactions. In both the crystal packing, the two quinone complexes are arranged in anti-parallel orientation with an intermolecular arene-arene distance of $3.36 \AA(\mathbf{1 3})$ and $3.46 \AA$ (19) between two of the closest molecules. The solid-state packing of $\mathbf{1 3}$ shows the interaction of electron-rich aromatic ring of one molecule with the electron deficient carbonyl group of neighboring molecules and 19 exhibits the interaction of allyl portion of Cp of one molecule with the quinone of another neighboring molecule.

Figure 2.1 Packing of ferrocene-fused-quinone 13 on their lattice along $a$-axis

Figure 2.2 Packing of Cp-capped quinone 19 along a-axis
A crystal structure of borane-reduced ferrocene-dihydroanthracene (14) displays a strong folding of the dihydroacene ligand at the methylene carbon atoms with a bent angle of $44.8^{\circ}$ at the reduced ring. The bond distances between carbon and oxygen lie between the range of 10 [1,228(3) $\AA-1.233(3) \AA], \mathbf{1 1}[1.227(3) \AA-1.229(3) \AA], \mathbf{1 2}$ $[1.219(7) \AA-1.226(7) \AA], \mathbf{1 3}[1.226(3) \AA-1.225(3) \AA], \mathbf{1 7}[1.2247(17) \AA-1.2240(18) \AA]$, $18[1.230(2) \AA]$ and $19[1.225(2) \AA]$. Molecular structure of 17 is disordered crystallographically and oriented randomly. Molecular structure of $\mathbf{1 9}$ shows slight thermal ellipsoid elongation at C6, which might be due to slight disorder of the fivemembered ring. The $\mathrm{C}=\mathrm{C}$ bond length in the five-membered ring system of demetalated complexes (17, 18 and 19) ranges from $[1.324(16) \AA$ to 1.414 (10) $\AA]$, which lies between the $\mathrm{C}=\mathrm{C}$ bond length for an alkene and benzene. The interplanar angle between the planes C12C13C14 of complex (17), C6C5C4 (18), C4C5C6 (19) and C6C7C8 (21) and the rest of the molecules is $2.15^{\circ}, 1.11^{\circ}, 2.79^{\circ}$ and $1.03^{\circ}$. Cp-capped TIPS-derivatives 21 and 22 pack with significant two-dimensional $\pi$-overlap and $\pi$-face separation of 3.41 $\AA$ and $3.40 \AA$ (vs. $3.43 \AA$ in TIPS-pentacene).

2.4 Electrochemistry. Cyclic voltammetry was used to ascertain the HOMO and LUMO energy levels of the new Cp-capped acenes. This technique involves application of forward and reverse linear potential scans to a working electrode immersed in a solution of the redox-active analyte and a supporting electrolyte. If the material has accessible oxidation, an anodic wave develops in the forward positive scan, and a corresponding cathodic wave can observed in the reverse scan.

The voltammetric instrument consists of a three-electrode electrochemical cell. At a platinum button working electrode, potential is varied linearly with time. A platinum wire counter electrode conducts current via the electrolyte solution to the working electrode. A silver wire serves as a pseudoreference electrode. Ferrocene/ferrocenium $\left(\mathrm{Fc}_{\mathrm{c}} / \mathrm{Fc}^{+}\right)$, a stable redox couple that is soluble in common organic solvents and whose potential is independent of the solvent, ${ }^{115}$ is used as an internal standard. $\mathrm{Fc} / \mathrm{Fc}^{+}$is estimated to be around 4.8 eV against vacuum. ${ }^{116} \mathrm{HOMO}$ and LUMO energies of compounds are determined by using their first oxidation and first reduction potentials with respect to $\mathrm{Fc} / \mathrm{Fc}^{+}$.

Cyclic voltammetry measures how current (mA) changes as the potential (V) of the working electrode is varied in a supporting electrolyte solution. In a redox reaction, the oxidation potential $\left(E_{\mathrm{oxd}}\right)$ is a measurement of the ionization potential or HOMO of a compound, and reduction potential $\left(E_{\mathrm{red}}\right)$ is a measurement of the electron affinity or LUMO of a compound.

Cyclic voltammetry of bis(Cp-capped) TIPS-anthracene (21) and Cp-capped TIPS-tetracene (22) was run in $0.1 \mathrm{M} \mathrm{Bu}_{4} \mathrm{NPF}_{6} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$ under nitrogen at scan rate of 100 $\mathrm{mV} \cdot \mathrm{sec}^{-1}$. The half-wave potentials of each oxidation $\left(E_{1 / 2, \mathrm{ox}}^{0}\right)$ and reduction $\left(E_{1 / 2, \text { red }}^{0}\right)$
wave were calculated by averaging the corresponding anodic ( $E_{\mathrm{pa}}$ ) and cathodic ( $E_{\mathrm{pc}}$ ) peak potentials. The cyclic voltammograms for compounds (20), (21) and (22) are shown in Figure (2.16-2.20). The electrochemical data are summarized in Table 2.20.

Figure 2.16 Cyclic voltammogram of $\mathbf{2 0}$ showing oxidation vs. $\mathrm{Fc} / \mathrm{Fc}^{+}$in 0.1 M $\mathrm{Bu}_{4} \mathrm{NPF}_{6} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$ at scan rate $100 \mathrm{mV} \cdot \mathrm{sec}^{-1}$

Table 2.23 Electrochemical and spectroscopic data for compounds 21 and 22

| Compound | $E_{\text {HOMO }^{\text {a }}}$ | $E_{\text {LUMO }}{ }^{\text {b }}$ | $E_{\mathrm{g}, \mathrm{EC}}$ | $\lambda_{\max }$ abs | $E_{\mathrm{g}, \text { opt }}{ }^{\mathrm{e}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathbf{2 0}$ | -5.48 | - | - | 468 | 2.65 |
| $\mathbf{2 1}$ | -5.41 | -2.82 | 2.58 | 494 | 2.51 |
| $\mathbf{2 2}$ | -0.29 | -3.14 | 2.15 | 599 | 2.07 |

${ }^{\mathrm{a}} \mathrm{HOMO}=-\left[4.8-\left(E_{\mathrm{ox}}-\mathrm{Fc} / \mathrm{Fc}^{+}\right)\right], E_{\mathrm{ox}}$ calculated using cyclic voltammetry (oxidation).
${ }^{\mathrm{b}} \mathrm{LUMO}=-\left[4.8-\left(E_{\text {red }}-\mathrm{Fc} / \mathrm{Fc}^{+}\right)\right], E_{\text {red }}$ calculated using cyclic voltammetry (reduction).
${ }^{\mathrm{C}} E_{\mathrm{g}}{ }^{\text {ec }}$ Electrochemical band gap obtained from difference between LUMO and HOMO values.
${ }^{\mathrm{d}} \pi_{\text {max }}$ obtained from the absorption edges of film (prepared by drop cast using $2 \%$ by weight solution of compound in chlorobenzene).
${ }^{\mathrm{e}} E_{\mathrm{g}}{ }^{\text {opt }}$ Optical band gap estimated from the absorption edge of the film.

UV-vis absorption spectra for compounds 20, 21 and 22 were recorded in dichloromethane solution and as a solid film prepared by solution-casting $2 \%$ by weight solution in chlorobenzene ( $\mathbf{2 1}$ and 22). Absorption spectra are plotted as wavelength vs. absorbance in Figure 2.21.

Figure 2.21 UV-vis absorbance spectra of $\mathbf{2 0}$ (green), 21 (blue) and 22 (red) in dichloromethane

Figure 2.22 UV-vis absorbance spectrum of 21 (blue) and 22 (red) in solid
The UV-vis spectra of $\mathbf{2 1}$ and $\mathbf{2 2}$ show a blue shift in absorption compared to TIPS-pentacene $(644 \mathrm{~nm})$, TIPS-anthradithiophene $(555 \mathrm{~nm})^{21}$ and 5,12-bis(triisopropylsilylethynyl)tetraceno[2,3-b]thiophene $\left(\sim 600 \mathrm{~nm}\right.$ in THF) ${ }^{35}$ indicating that an extended $\pi$ conjugation system contributes a vital role in absorbance. The oxidation $\left(0.61 \mathrm{~V}\right.$ vs. $\left.\mathrm{Fc} / \mathrm{Fc}^{+}\right)$and reduction $\left(-1.98 \mathrm{~V}\right.$ vs. $\left.\mathrm{Fc}^{+} / \mathrm{Fc}\right)$ of 21 reveals an electrochemical HOMO-LUMO gap ( 2.58 eV ) that complements the gap obtained from the absorption edge of the optical spectrum [2.51 eV (494 nm)]. Similarly, the oxidation ( 0.49 V vs. $\mathrm{Fc} / \mathrm{Fc}^{+}$) and reduction ( -1.66 V ) of 22 reveal an electrochemical HOMO-LUMO gap $(2.15 \mathrm{eV})$ that complements the gap derived from the absorption edge of the optical spectrum [2.07 eV (599 nm)]. The absorption spectra of $\mathbf{2 1}$ and $\mathbf{2 2}$ show that the fusion of an additional aromatic ring leads to a further $\sim 100 \mathrm{~nm}$ red shift in absorption, which is similar to the absorption spectra data reported by Payne et al. for higher acenes (hexacene
and heptacene). ${ }^{117}$ We calculated the optical energy gap for compounds 21 and 22 in solution as 2.62 eV (473 nm) and $2.23 \mathrm{eV}(557 \mathrm{~nm})$.

Table 2.24 Ionization potential of 21 and 22

${ }^{\text {a }}$ In chlorobenzene. Thin films of sample were prepared by solution-casting using different concentration by weight and slow evaporation of solvent in air. Samples were stored under nitrogen before measurement.

The ionization potentials (IP) of 21 and 22 were studied in three different locations of thin film. The IP for compound 21 matches well with the HOMO energy ( 5.41 eV ) obtained from cyclic voltammetry, whereas the IP of compound $\mathbf{2 2}$ is slightly larger than the HOMO energy level $(5.29 \mathrm{eV})$ obtained from cyclic voltammetry. The large IP variation observed for compound $\mathbf{2 2}$ in the different location is possibly due to inhomogeneity of crystalline films or instability in air.

### 2.5 Cyclopentadiene-capped TIPS-Acenes Device Study

The main target of this entire research is to study charge-carrier mobility of the synthesized compounds. After the structural and electrochemical properties were studied, device performance of the reported Cp-capped TIPS-acenes was investigated by Aram Amassian and Muhammad Rizwan Khan Niazi of King Abdullah University of Science and Technology, Saudi Arabia. They used bottom-contact, bottom-gate (BCBG) device architecture to obtain OTFT device performance, with gold source and drain electrodes and $\mathrm{SiO}_{2}$ as a dielectric layer. Bottom contacts (Au electrodes) were deposited by thermal evaporation using shadow masks with channel length of $50 \mu \mathrm{~m}$ and channel width of $1000 \mu \mathrm{~m}(W / L 20)$. The images shown in the Figure 2.5 . 1 show the thermal deposition of thin film by blade coating at $70^{\circ} \mathrm{C}$ with a shearing speed of $1.5 \mathrm{~mm} / \mathrm{sec}$. The films of organic semiconductor materials are deposited with blade coating at different blade speeds to optimize the processing condition as shown in Figure 2.23.

Figure 2.23 Images of thin films deposited by thermal deposition at $70^{\circ} \mathrm{C}$ with a shearing speed $1.5 \mathrm{~mm} / \mathrm{sec}$ top [bis(Cp-capped) TIPS-anthracene] and bottom [Cpcapped TIPS-tetracene]

Figure 2.24 Different shearing speed to optimize the processing condition (left), $\sqrt{ } I$ and $\log I$ vs. gate voltage (middle) and output of device study (right)
Figure 2.24 shows that the thin films of compounds $\mathbf{2 1}$ and $\mathbf{2 2}$ show better device performance at $1.5 \mathrm{~mm} / \mathrm{sec}$ blade speed. These films gave a mobility of $0.03 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s})$ (21) and $0.02 \mathrm{~cm}^{2} /\left(\mathrm{V} \mathrm{s)}\right.$ (22) with $I_{\text {on }} / I_{\text {off }}$ of $10^{6}$ and $10^{4}$, respectively. Compounds 21 and $\mathbf{2 2}$ have moderate mobility from solution-deposited film. These mobilities are not good enough to consider 21 and 22 as potential candidates for device applications. In order to be useful for commercial application, a material should have mobility greater than 0.5 $\mathrm{cm}^{2} /(\mathrm{V} \mathrm{s})$ and on/off current ratio greater than $10^{5}$. TES-ADT, analogous to 21, shows mobility as high as of $1.0 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s})$ and on/off current ratio of $10^{7}$ from drop-cast films. ${ }^{6}$ Similarly, TIPS-tetraceno[2,3-b]thiophene exhibits a mobility as high as $1.25 \mathrm{~cm}^{2} /(\mathrm{V}$ s) from vacuum-deposited film. ${ }^{37}$ The performance of these materials is likely due to the
close $\pi$-stacked interaction in the crystal. Moreover, the ability to form high-quality films is essential for better device performance.

### 2.6 Summary

1,2-Diformylferrocene is the key precursor for the synthesis of mononuclear and binuclear quinone complexes of iron with carbonyl groups either at $\alpha$ or $\gamma$ position with respect to cyclopentadienyl ring. 1,2-Diformylferrocene was prepared in moderate yield $(50.4 \%) .{ }^{89,90}$ Following the idea supported by the work of Rinehart group, ferrocene was reacted with succinic anhydride in the presence of anhydrous $\mathrm{AlCl}_{3}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, reduction of carbonyl group under Clemmensen reduction conditions and cyclized in the presence of trifluoroacetic anhydride to give $\mathbf{6}(92.1 \%)$. Oxidation of $\mathbf{6}$ with activated manganese dioxide gave 7 (44\%). Ferrocenebenzoquinone (7) was reduced to ferrocene-fused-1,4cyclohexanedione ( $\mathbf{8}, 41 \%$ ) with sodium dithionite. A series of ferroceneacenequinones was synthesized by aldol condensation. Aldol condensation between $\mathbf{8}$ and phthalaldehyde gave 9 (62.5\%) and condensation between 1,2-diformylferrocene and naphthalene-1,2-diol or anthracene-1,2-diol gave 11 (78.8\%) and 13 (81.5\%).The carbonyl groups in $\mathbf{9}$ and $\mathbf{1 1}$ are located at the $\alpha$ and $\gamma$ position respectively with respect to the Cp ring.

Similarly, aldol condensation between 1,2-diformylferrocene and ferrocene-fused-1,4-cyclohexanedione (8) or 1,4-cyclohexanedione resulted in an inseparable isomer mixture (syn/anti) of binuclear quinone complexes (10, 79.5\% and 12, $69.6 \%$ combined). These quinones appear at very close $R_{\mathrm{f}}$ values by TLC in various combinations of hexane, ethyl ether and dichloromethane and could not be separated by chromatography. The ferrocene-fused quinones are deep blue and stable in the solid state at room temperature. However, solutions of complexes 11, 12 and $\mathbf{1 3}$ change from blue to yellow
on contact with silica, and the characterization of yellow compounds indicate the detachment of iron from the organic quinone ligand. This might be due to the indenyl effect, which is also supported by their single X-ray crystal data.

Organometallic acenequinones are not the final product of our research. Therefore, the carbonyl groups of quinones 11, $\mathbf{1 2}$ (mixture), and $\mathbf{1 3}$ were reduced to methylenes with borane in THF (excess), leading to light pink dihydroacenes. Attempts to dehydrogenate the dihydroacenes with DDQ resulted in decomposition. Using saturated aqueous sodium dithionite is the next logical step to reduce acenequinones to hydroquinones. Attempted reduction of organometallic acenequinones (11, 12 and 13) to organometallic hydroquinones by using aqueous sodium dithionite gave the demetalated acenequinones as the main product (17, 49\%, 18, $42 \%$ combined and $\mathbf{1 9}, 52 \%$ ). Nucleophilic addition of triisopropylsilylethynyllithium to the quinone carbonyls followed by dehydroxylation with aqueous $\mathrm{SnCl}_{2}$ gave the desired Cp - and bis(Cp)capped triisopropylsilylethynylacenes (20,50\%, $\mathbf{2 1} 23 \%$ combined and 22, 59\%) . After purification of compounds by chromatography, 21 and 22 were recrystallized from acetone to yield orange and dark purple needles, respectively, which are suitable for single X-ray diffraction. Analysis revealed that these molecules packing with twodimensional $\pi$-stacking similar to the packing nature of TIPS-pentacene and TESanthracene. The interplanar arene-arene distances are $3.41 \AA$ (21) and $3.40 \AA$ (22). Both compounds are highly soluble in common organic solvents and thus easily processible.

The electrochemistry of Cp-capped acenes 21 and 22 was investigated. Cyclic voltammetry shows oxidation and reduction potentials for 21 and 22 at $0.61 \mathrm{~V},-1.98 \mathrm{~V}$ and $0.49 \mathrm{~V},-1.66 \mathrm{~V}$, respectively, versus $\mathrm{Fc} / \mathrm{Fc}^{+}$, corresponding to estimated HOMO and

LUMO energy levels of $-5.41 \mathrm{eV},-2.82 \mathrm{eV},-5.29 \mathrm{eV}$ and -3.14 eV , respectively. The electrochemical HOMO level energy of -5.41 eV for compound 21 agrees well with the IP determined from Photoelectron Spectroscopy in Air (PESA). UV-vis absorption spectra of compound 21 and 22 were recorded in dichloromethane solution and in a solid film deposited from dichlorobenzene solution. The UV absorption maxima in dichloromethane solution of $\mathbf{2 1}$ and $\mathbf{2 2}$ are 462 nm 545 nm respectively. A greater 90100 nm bathochromic shift in absorption of TES-ADT and TIPS-pentacene as compared to Cp-capped TIPS-acenes is attributed to the extended $\pi$-conjugation. The electrochemical HOMO-LUMO gaps of $\mathbf{2 1}$ and $\mathbf{2 2}$ are 2.58 eV and 2.15 eV , respectively, which are close to the optically determined HOMO-LUMO gaps in solid films of $\mathbf{2 1}$ ( 2.51 eV at 494 nm ) and 22 ( 2.07 eV at 599 nm ). The OTFT study using bottom-contactbottom gate (BCBG) device architecture from solution-deposited film shows relatively poor device performance with the hole mobility of $0.03 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s}), I_{\text {on }} / I_{\text {off }}$ of $10^{6}$ for 21 and $0.02 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s}), I_{\text {on }} / I_{\text {off }}$ of $10^{4}$ for 22.

In general, we made a series of mononuclear and binuclear organometallic acenequinones with carbonyl groups positioned at either $\alpha$ or $\gamma$ position with respect to cyclopentadienyl ring using aldol condensation. Organometallic acenequinones are potential precursors for organometallic acenes. Ferrocene-fused acenequinones (11, 12 and 13) exhibit a significant indenyl effect, which makes it possible to release the cyclopentadiene-capped acenequinones from the metal centers. The Cp-capped acenequinones were aromatized by the nucleophilic addition of lithium triisopropylsilylethynyl to carbonyl, followed by dehydroxylation with $\mathrm{SnCl}_{2}$ in acidic conditions. The resultant Cp-capped TIPS acenes are highly soluble in common organic
solvents. The electrochemical and optical properties of Cp-capped TIPS acenes that are essential for organic semiconductor candidate were measured using cyclic voltammetry and UV-vis spectroscopy. The OFET performance of $\mathbf{2 1}$ and $\mathbf{2 2}$ shows hole mobilities of $0.03 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s})$ and $0.02 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s})$ respectively using a blade coating. These mobilities are comparable to the hole mobilities of thiophene analogues, TIPS anthracenedithiophene $\left(0.05 \mathrm{~cm}^{2} /(\mathrm{V} \text { s) solution deposited })^{6}\right.$ and TIPS tetracene[2,3$b]$ thiophene (average $0.028 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s})$ solution deposited) ${ }^{37}$.

## Chapter 3 Synthesis and Characterization of Ferrocene-Fused Tropones, Thiotropones and Oxime Derivatives

### 3.1 Introduction

The first nonlinear optical phenomenon was observed in inorganic crystalline materials, lithium niobate, gallium arsenide ( GaAs ), indium antimonide ( InSb ) and potassium dihydrogen phosphate (KDP), whose refractive index changed with an applied electric field. The study of nonlinear effects increased after the invention of lasers in 1960, followed by the observation of second-harmonic generation (SHG) in quartz by Franken et al. ${ }^{118,119,120} 3$, 4-Benzopyrene is the first organic material in which SHG was observed in 1965. ${ }^{121}$ Further, SHG was explored in another organic crystal (hexamethylenetetramine) by Heilmer et al. in the same year. ${ }^{122}$ Organic and polymeric nonlinear optical (NLO) materials have been a subject of intense investigation over the last three decades due to potential applications in electro-optic devices for telecommunication, optical computing and optical information processing. ${ }^{3}$

NLO materials possess high first-order hyperpolarizabilities and give rise to large second-order effects. ${ }^{123}$ The basic requirements for a molecule to exhibit nonlinear optical properties are polarizability, asymmetric charge distribution and acentric crystal packing. Inorganic materials have a high dielectric constant, which can perturb the incoming electric field in optoelectronic applications. ${ }^{2}$ Organic materials have a number of advantages over inorganic materials for NLO application. The distribution of $\pi$-electrons plays the dominant role in defining dielectric constant and refractive indexes. Organic materials have fast response time and the ease of modification of organic structures makes it possible to synthesize appropriate molecules and to tune the properties for
electro-optic applications. ${ }^{124}$ Molecules with $\pi$-donor and $\pi$-acceptor interactions are promising candidates to fulfill the requirement of NLO materials. ${ }^{125}$ Push-pull compounds where donor and acceptor end groups interact through a $\pi$-conjugated system can give large quadratic hyperpolarizabilities. Many recently reported NLO materials utilize new heterocyclic chromophores, such as tricyanofuran, as acceptor moieties. ${ }^{126}$

Chart 3.1 Nonlinear optical organic materials
Metallocenes are similar to organic molecules in that they can possess large NLO responses, a fast response time and ease of synthesis and fabrication. Organometallic
complexes allow greater flexibility for the design of nonlinear optical polarizabilities. The oxidation state of transition metals can be changed, which changes the number of $d$ electrons involved and allows for the study of the differences between diamagnetic and paramagnetic complexes, ligand environment and a geometrical pattern of complexes. ${ }^{124}$ These properties eventually allow tuning of NLO responses.

Organometallic and coordination compounds allow exploration of new variables for the engineering of nonlinear optical hyperpolarizabilities. These compounds can have metal-to-ligand and ligand-to-metal charge transfer bands in the UV-visible region. One can change the transition-metal element, oxidation state and the number of $d$ electrons to examine the difference between diamagnetic and paramagnetic complexes and the effect of new coordination pattern. Complexes containing metal chromophores are intensely colored and the strength of the optical absorption band is also associated with large optical nonlinearities. Ligand environments and oxidation states can be adjusted to make the metal center of an organometallic complex electron rich or electron poor. Hence, the metal center may act as a strong donor or a strong acceptor. ${ }^{127}$

Green et al. reported that (Z)-[1-ferrocenyl-2-(4-nitrophenyl)ethylene] shows SHG efficiency 62 times that of urea. ${ }^{128}$ A salt of the form ( $E$ )-[1-ferrocenyl-2-(N-methylpyridinium-4-yl)ethylene] iodide has the largest efficiency, roughly 220 times that of urea, and the related nitrate salt has a SHG efficiency of 110 times that of urea. ${ }^{129}$ Moreover, series of push-pull ferrocene and ruthenocene polyenic derivatives have been synthesized by Alain et al. in order to achieve enhanced quadratic optical nonlinearity. ${ }^{130}$

Chart 3.2 Organometallic NLO materials
Fulvenes (1) and heptafulvenes (2) (shown in Chart 3.3) are nonalternate, conjugated cyclic hydrocarbons with a strong double-bond fixation. The specific conjugated structure and the nonbenzenoid aromatic character of the seven-membered ring systems results in interesting excited-state structures. Unlike other systems of similar size, these compounds are colored. ${ }^{131}$ For example, azulene, ( $\mathbf{3}$ of Chart 3.3), a nonbenzenoid aromatic compound, is blue, whereas naphthalene, an isomer of azulene, is colorless. ${ }^{132}$ Seven-membered nonbenzenoid aromatic compounds (heptafulvenes) have a low energy electronic transition $\left(\pi-\pi^{*}\right)$. Large changes of the dipole moment upon excitation enhance the electronic properties of these compounds as compared to typical aromatic systems. ${ }^{13}$ The extension of the $\pi$-electron conjugation or the substitution of sulfur for the exocyclic oxygen atom may significantly decrease the optical gap of these compounds without increasing the overall size of the molecule. ${ }^{133,134} 8,8$ Dicyanophenylheptafulvene derivatives (4 of Chart 3.3) are highly colored and have attracted attention as chromophores for pigmentary and electronic applications. ${ }^{135}$

2

3

4

Chart 3.3 Fulvene and heptafulvene derivatives
Cycloheptatrienones, also known as tropones, are stable non-benzenoid aromatic compounds characterized by large dipole moments. Tropone might be represented as a hybrid between 1a and 1b as shown in Figure 3.1. Tropone's high dipole moment (4.3 D) and carbonyl stretch at $1582 \mathrm{~cm}^{-1}$ support the importance of the dipolar form. ${ }^{136,137,138}$ The most notable contribution of $\mathbf{1 b}$ to the chemical properties of tropone is the reduced reactivity of the carbonyl group toward common carbonyl reagents such as 2,4dinitrophenylhydrazine, hydroxylamine, hydrazine etc. ${ }^{139}$

Figure 3.1 Resonance structure of tropone
Small molecules with $\pi$-electron delocalization along the main chain are candidates for optoelectronic applications such as transistors, light-emitting diodes and organic photovoltaics. The changing morphology of connecting aromatic rings significantly affects the electronic and optical properties of compounds. ${ }^{6}$

$\mathrm{R}=\mathrm{NMe}_{2}, \mathrm{OMe}, \mathrm{H}$

Chart 3.4 Nonlinear optical materials
Several studies have been carried out by the Yuki group on conjugated oligomers and polymers containing benzotropone in the main chain for their potential application in optoelectronic devices. The introduction of benzotropone into the poly(pphenylenevinylene) (PPV) backbone improved the heat resistance of the material. ${ }^{140,141,142}$ The Swager group reported the synthesis of tropone-containing polythiophenes (Chart 3.5), which can gain aromaticity by protonation of carbonyl oxygen. Switching the tropone moiety between nonaromatic and aromatic forms in the conjugated polymer backbones may affect electronic delocalization of the conjugated polymer by conformational change. These phenomena may enable the tuning of desired properties of conjugated polymers for their optoelectronic properties. ${ }^{143}$

Chart 3.5 Tropone-containing polymers
The introduction of $\pi$-donor and $\pi$-acceptor substituents on opposite sides of $\pi$ conjugated systems such as benzene ${ }^{123,144,145}$ and thiophene ${ }^{126,26}$ promotes high second-
order hyperpolarizabilities. Similarly, when one end of nonbenzenoid chromophore of tropone is fused with a metallocene donor and the other end is functionalized with a strong acceptor group, the resultant compound demonstrates an unsymmetrical charge distribution. This is one of the most characteristic features of NLO materials. The strength of the donor and acceptor moieties can directly affect the ground and excited state dipole moments and the transition dipole moment. These properties not only change the physical properties of materials but also tune their optical properties and induce a large bathochromic shift. ${ }^{137,26}$ Chart $\mathbf{3 . 6}$ shows some of the reported tropone metal complexes.

Chart 3.6 Metal tropone complexes ${ }^{146,147}$
For a long period, our group has been exploring metallocene chemistry of 5,5fused ${ }^{148}$ and 5,6-fused ${ }^{149,150}$ ring systems. The presence of a metal can allow for control of physical properties, electronic properties, optical properties and redox potential. Therefore, we are interested in potential applications of metallocene-fused tropones (5,7fused ring system) and their derivatives as organic electronic materials.

Figure 3.2 5,5- and 5,6-fused complexes synthesized in our group

### 3.2 Experimental

All reactions were carried out using standard Schlenk techniques under nitrogen atmosphere unless otherwise noted. Solvents (Pharmco Aaper) were dried and distilled under nitrogen before use, including ethyl ether, toluene, and benzene over sodium benzophenone ketyl. Dichloromethane and acetonitrile were dried and distilled over calcium hydride. Acetone (Sigma-Aldrich) was dried in molecular selves for overnight and distilled. Chloroform was dried and distilled over $\mathrm{P}_{2} \mathrm{O}_{5} . \mathrm{CDCl}_{3}$, and $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ were purchased from Cambridge Isotopes and used without purification. Lawesson's reagent, hydroxylamine ( $50 \%$ aqueous solution) (Sigma-Aldrich), butyllithium ( 2.5 M ), N,Ndimethylformamide, activated manganese dioxide (Acros), anhydrous magnesium sulfate, sodium hydroxide (Fisher), potassium hydroxide (EMD), 1,3-diphenylacetone (Alfa Aesar), and were used without further purification. N,N,N', NTetramethylmethylenediamine, N,N-dimethylaminomethylferrocene, N,N-dimethylaminomethyl-2-formylferrocene, and 1,2-diformylferrocene were prepared using the procedure developed by Lednicer and Hauser, ${ }^{119}$ Goetgheluck et al. ${ }^{116}$ and Malfait et al. ${ }^{117}$.Organic phases were dried over anhydrous magnesium sulfate. Flash chromatography was carried out with silica gel ( 60 A pore size, 230-400 mesh) from Sorbent Technologies.
${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Varian Gemini-400 NMR spectrometer unless otherwise mentioned. Infrared spectra were recorded on an ATIMattson Galaxy ${ }^{\text {TM }}$ Series 5000 FTIR spectrometer. Electron ionization (EI) mass spectra were collected at 70 eV on a Thermo Finnigan Polaris Q (quadrupole ion trap) at the University of Kentucky Mass Spectrometry Center. Melting points were recorded
(uncorrected) on an Electrothermal Mel-Temp melting point apparatus. X-ray diffraction data were collected at 90 K on either a Nonius KappaCCD diffractometer or a BrukerNonius X8 Proteum diffractometer. The structures were solved and refined by using SHELXL-97. UV-visible spectral analyses was performed on an Agilent 8453 Diode Array Spectrophotometer and electrochemistry was performed on a CH Instruments Model 600D Series.

Synthesis of ferrocene-fused tropone (23). 1,2-Diformylferrocene ( 200 mg , 0.83 mmol ) and 3 mL of ethanol were added to an oven-dried 25 mL round bottom flask equipped with a stir bar and cooled under $\mathrm{N}_{2}$. Acetone ( $91 \mu \mathrm{~L}, 0.80 \mathrm{mmol}$ ) was added, followed by $15 \% \mathrm{KOH}(0.03 \mathrm{~mL})$. The solution was stirred at room temperature for 3 h . A dark red solution was obtained. Silica was added into a solution then evaporated the solvent and a slurry was poured onto a column of silica, and then eluted with hexane:ethyl ether (1:1). The solvent was removed under reduced pressure to yield $218 \mathrm{mg}(83.0 \%)$ of product, and recrystallized by slow diffusion of hexanesaturated $\mathrm{N}_{2}$ into its ethyl ether solution resulting in red needles. ${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}(\mathbf{4 0 0} \mathbf{~ M H z}$, $\left.\mathbf{C D C l}_{\mathbf{3}}, \mathbf{p p m}\right): \delta 4.09(\mathrm{~s}, 5 \mathrm{H}, \mathrm{H} 7), 4.38\left(\mathrm{t}, 1 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}, \mathrm{H} 6\right), 4.78\left(\mathrm{~d}, 2 \mathrm{H},{ }^{3} J=2.4\right.$ $\mathrm{Hz}, \mathrm{H} 5), 6.37\left(\mathrm{AB}, 2 \mathrm{H}, J_{\mathrm{AB}}=12 \mathrm{~Hz}, \mathrm{H} 2\right), 7.31\left(\mathrm{AB}, 2 \mathrm{H}, J_{\mathrm{AB}}=12 \mathrm{~Hz}, \mathrm{H} 3\right) .{ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$ NMR (100 MHz, CDCl $\left.{ }_{3}, \mathbf{p p m}\right): 70.62$ (C7), 71.45 (C6), 73.65 (C5), 81.77 (C4), 129.43 (C2, C9), 141.75 (C3), 190.36 (C1). IR (ATR, cm $^{\mathbf{- 1}}$ ): 1618 (C=O). MS (EI): $\mathrm{m} / \mathrm{z} 264\left(\mathrm{M}^{+}\right)$. Mp: $139{ }^{\circ} \mathrm{C}-140^{\circ} \mathrm{C}$.

Figure 3.3 Numbering scheme in ferrocene-fused tropone
Synthesis of ferrocene-fused 5,7-diphenyltropone (24a). 1,2Diformylferrocene ( $100 \mathrm{mg}, 0.41 \mathrm{mmol}$ ) and 2 mL of ethanol were added to an ovendried 25 mL round bottom flask equipped with a stir bar and cooled under $\mathrm{N}_{2}$. 1,3Diphenylacetone ( $86.9 \mathrm{mg}, 0.41 \mathrm{mmol}$ ) was added, followed by $15 \% \mathrm{KOH}(0.05 \mathrm{~mL})$. The solution was stirred at room temperature overnight. A dark red solution was obtained. Silica was added, the solvent was vacuum-evaporated and the powder was poured onto a column of silica, then eluted with hexane:ethyl ether (7:3). Solvent was removed under reduced pressure to yield $61 \mathrm{mg}(\mathbf{2 4 a}, 36 \%)$ of product and recrystallized from ethyl ether and hexane. Further, the second red band was eluted with hexane:ethyl ether (1:1) and evaporation of solvent under reduced pressure yielded a dark red solid ( $\mathbf{2 4 b}, \mathbf{3 0 \%}$ ). $\mathbf{2 4 b}$ was characterized by single X-ray crystal structure. 24a: ${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 4.11(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C} 7), 4.35\left(\mathrm{t}, 1 \mathrm{H},{ }^{3} \mathrm{~J}\right.$ $=2.4 \mathrm{~Hz}, \mathrm{C} 2), 4.79\left(\mathrm{~d}, 2 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}, \mathrm{C} 1\right), 7.07-7.39(\mathrm{~m}, 5 \mathrm{H}, \mathrm{Ph}), 7.44(\mathrm{~s}, 2 \mathrm{H}$, C4). ${ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}\left(\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}, \mathbf{p p m}\right): 70.49$ (C7), 71.47 (C2), 72.98 (C1), 81.26 (C3a), 127.17, 128.73, 139.15, 139.15 (Ph), 140.38 (C5), 141.61 (C4), 189.98 (C6). ## Synthesis of ferrocene-fused 5,7-diphenyl-8-piperidinyl-4-cyclohepten-6-

 one (25). 1,2-Diformylferrocene ( $0.05 \mathrm{~g}, 0.21 \mathrm{mmol}$ ), benzene ( 5 mL ) and 1,3diphenylacetone ( 69.6 mg 0.33 mmol ) were added to an oven-dried 125 mL Schlenk flask cooled under $\mathrm{N}_{2}$. After stirring, 1 drop of piperidine was added, and the reaction mixture was refluxed with a Dean-Stark trap for 5 h . The reaction mixture was cooled to room temperature and the volume of the solution was reduced by half under a vacuum. The remaining solution was loaded on a silica column and eluted using hexane:ethyl ether (95:5). The first red fraction was evaporated to yield a gummy product ( $30 \mathrm{mg}, 35 \%$ ). The product was triturated with pentane under liquid $\mathrm{N}_{2}$ toyield a red solid ( $13 \mathrm{mg}, 15 \%$ ). Recrystallization by slow diffusion of hexanesaturated $\mathrm{N}_{2}$ into its ethyl ether solution resulted in red needles. ${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}(\mathbf{4 0 0} \mathbf{~ M H z}$, acetone-d $\left.\mathbf{d}_{6}, \mathbf{p p m}\right): \delta 1.12-1.15\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{CH}_{2}\right.$ piperidine), $1.70-1.72\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{2}\right.$ piperidine), 2.46-2.49 (m, $4 \mathrm{H}, \mathrm{CH}_{2}$ piperidine), $3.60\left(\mathrm{~d}, 1 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}, \mathrm{H} 8\right), 4.03$ (s, $5 \mathrm{H}, \mathrm{H} 9), 4.23$ ( $\mathrm{ABC}, 1 \mathrm{H}, \mathrm{Cp}$ ), 4.27 ( $\mathrm{ABC}, 1 \mathrm{H}, \mathrm{Cp}$ ), 4.35 ( $\mathrm{ABC}, 1 \mathrm{H}, \mathrm{Cp}$ ), 4.96 $\left(\mathrm{d}, 1 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}, \mathrm{H} 7\right), 6.84-7.04(\mathrm{~m}, 10 \mathrm{H}, \mathrm{Ph}), 7.57(\mathrm{~d}, 1 \mathrm{H}, \mathrm{H} 4),{ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}$ $\left(100 \mathrm{MHz}\right.$, acetone- $\left.\mathbf{d}_{6}, \mathbf{p p m}\right): \delta 24.97\left(\mathrm{CH}_{2}\right.$ piperidine $), 27.22\left(\mathrm{CH}_{2}\right.$ piperidine $), 53.30$ $\left(\mathrm{CH}_{2}\right.$ piperidine $), 62.65,(\mathrm{C} 8), 70.20(\mathrm{Cp}), 71.34(\mathrm{C} 9), 72.43(\mathrm{Cp}), 74.38(\mathrm{Cp}), 78.01$ (Cp), $80.44(\mathrm{Cp}), 86.76$ (C7), 127.59, 127.76, 128.40, 128.75, 129.52, 131.22, 138.36, 139.85 ( Ph ), 141.41 (C4), 200.01 (C6). IR (ATR, $\mathbf{c m}^{\mathbf{- 1}}$ ): 1670 (CO). MS (EI) m/z $501\left(\mathrm{M}^{+}\right)$. Mp: $195{ }^{\circ} \mathrm{C}-206{ }^{\circ} \mathrm{C}$ (dec). The compound was fully characterized by a single X-ray crystal structure.

25

Synthesis of ferrocene-fused thiotropone (26). In an oven-dried 100 mL Schlenk equipped with a magnetic stir bar, ferrocene-fused tropone (23, $30.0 \mathrm{mg}, 0.11$ $\mathrm{mmol})$ and dried benzene $(10 \mathrm{~mL})$ were added and stirred at room temperature under $\mathrm{N}_{2}$ to dissolve. Lawesson's reagent ( $230 \mathrm{mg}, 0.57 \mathrm{mmol}$ ) was added to the solution. The solution was stirred at room temperature for 7 h . The dark green solution was
loaded onto a column of neutral alumina, then eluted with hexane:dichloromethane (3:7). The first, dark green band was collected. The solvent was evaporated under reduced pressure to yield $20.0 \mathrm{mg}(63.0 \%)$ of product. The product was recrystallized by dissolving in hot heptanes followed by cooling to $-10{ }^{\circ} \mathrm{C} . \mathbf{1}^{\mathbf{1}} \mathbf{H} \mathbf{N M R}(\mathbf{4 0 0} \mathbf{~ M H z}$, $\mathbf{C D C l}_{\mathbf{3}, \mathbf{p p m}}$ ) $\delta 4.16(\mathrm{~s}, 5 \mathrm{H}, \mathrm{H} 7), 4.43\left(\mathrm{t}, 1 \mathrm{H},{ }^{3} J=2.4 \mathrm{~Hz}, \mathrm{H} 6\right), 4.84\left(\mathrm{~d}, 2 \mathrm{H},{ }^{3} J=2.4\right.$ $\mathrm{Hz}, \mathrm{H} 5), 7.10\left(\mathrm{AB}, 2 \mathrm{H},{ }^{3} J_{\mathrm{AB}}=11.6 \mathrm{~Hz} \mathrm{H} 2\right), 7.33\left(\mathrm{AB}, 2 \mathrm{H},{ }^{3} J_{\mathrm{AB}}=11.6 \mathrm{~Hz}, \mathrm{H} 3\right)$. ${ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\}$ NMR ( $\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}, \mathbf{p p m}$ ): 70.79 (C7), 73.02 (C5), 73.67 (C6), 84.36 (C4), $136.64(\mathrm{C} 2), 138.98(\mathrm{C} 3), 217.62$ (C1). IR (ATR, $\mathbf{c m}^{\mathbf{- 1}}$ ): 1078 (C=S) MS (EI): $\mathrm{m} / \mathrm{z} 280\left(\mathrm{~m}^{+}\right) . \mathrm{Mp}: 265-370^{\circ} \mathrm{C}$ (dec).

Synthesis of ferrocene-fused tropone oxime (27). In an oven-dried 100 mL Schlenk equipped with a magnetic stir bar, ferrocene-fused thiotropone (26, 62.0 mg , $0.22 \mathrm{mmol})$ and dried, $\mathrm{N}_{2}$-purged chloroform $(5 \mathrm{~mL})$ were added and cooled to $0{ }^{\circ} \mathrm{C}$. A solution of hydroxylamine $(0.66 \mathrm{mmol}, 20.0 \mu \mathrm{~L})$ in 1 mL ethanol was added. The reaction solution was stirred at $0{ }^{\circ} \mathrm{C}$ for 5 h . A dark red solution was evaporated under reduced pressure to obtain a red solid. The solid was triturated with pentane under liquid $\mathrm{N}_{2}$ and dried under vacuum to give $52.6 \mathrm{mg}(83.0 \%)$ as a dark red solid. Red needles were obtained by slow diffusion of hexane-saturated $\mathrm{N}_{2}$ into an ethyl ether solution. The compound was fully characterized by X-ray diffraction. ${ }^{\mathbf{1}} \mathbf{H}$ NMR (400 $\left.\mathbf{M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 4.09(\mathrm{~s}, 5 \mathrm{H}, \mathrm{H} 11), 4.27(\mathrm{ABC}, 1 \mathrm{H}, \mathrm{Cp}), 4.46(\mathrm{ABC}, 1 \mathrm{H}, \mathrm{Cp})$, $4.47(\mathrm{ABC}, 1 \mathrm{H}, \mathrm{Cp}), 6.09-6.12\left(\mathrm{dd}, 1 \mathrm{H}, J_{\mathrm{dd}}=12 \mathrm{~Hz}, \mathrm{H} 2\right), 6.53\left(\mathrm{~d}, 1 \mathrm{H},{ }^{3} J=12.4 \mathrm{~Hz}\right.$, H3), 6.67(d, $\left.1 \mathrm{H},{ }^{3} \mathrm{~J}=12 \mathrm{~Hz}, \mathrm{H} 9\right), 6.79-6.83\left(\mathrm{dd}, 1 \mathrm{H}, \mathrm{J}_{\mathrm{dd}}=12 \mathrm{~Hz}, \mathrm{H} 10\right) .{ }^{13} \mathbf{C}\left\{{ }^{1} \mathbf{H}\right\}$ NMR (100 MHz, CDCl $\left.\mathbf{C l}_{\mathbf{3}}, \mathbf{p p m}\right): 70.95$ (C11), 71.03 (Cp), 72.46 (Cp), 72.79 (Cp), 80.11 (Cp), 81.79 (Cp), 113.59 (C2), 123.73 (C3), 131.86 (C9), 135.98 (C10), 156.28
(C1). IR (ATR, $\left.\mathbf{c m}^{\mathbf{- 1}}\right): 1634(\mathrm{C}=\mathrm{N}), 2936.15-3208.44(\mathrm{OH}) . \mathbf{M S}(\mathbf{E I}): \mathrm{m} / \mathrm{z} 279\left(\mathrm{M}^{+}\right)$. Mp: $150-175^{\circ} \mathrm{C}(\mathrm{dec})$.

5,7-Diphenylazulenethiol (28). 5,7-Diphenylferrocene-fused tropone (24a, $0.03 \mathrm{~g}, 0.07 \mathrm{mmol}$ ), and Lawesson's reagent ( $206 \mathrm{mg}, 0.50 \mathrm{mmol}$ ) were added to the dried $\mathrm{N}_{2}$-purged benzene ( 10 ml ). The reaction mixture was refluxed for 8 h until starting material was consumed (TLC). The reaction solution was poured onto a short column of silica and eluted with hexane:ethyl ether (9:1). The first blue band was collected and removal of the solvent under reduced pressure yielded $13.0 \mathrm{mg}(58.0 \%)$ as a dark blue solid. The product was recrystallized by slow evaporation of diethyl ether and further characterized by X-ray crystallography. ${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}\right.$, ppm): $\delta 3.88$ (s, $1 \mathrm{H}, \mathrm{SH}$ ), $7.20\left(\mathrm{~d}, 2 \mathrm{H},{ }^{3} \mathrm{~J}=3.6 \mathrm{~Hz} \mathrm{H}\right)$ ), 7.37-7.47(m, Ph), 7.75 (t, 1 $\mathrm{H},{ }^{3} \mathrm{~J}=3.6 \mathrm{~Hz} \mathrm{H} 6$, ), 8.18 (s, $2 \mathrm{H}, \mathrm{H} 3$ ). ${ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}\left(\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right):$ 119.12 (C2,), 127.76 (C4), 129.48 (C6), 134.10 (C5), 128.92, 135.89, 136.59, 136.69 (Ph), 146.02 (C3), 147.42 (C1). IR (ATR, $\mathbf{c m}^{\mathbf{- 1}}$ ): 2573.26 (SH). MS (EI): m/z 312 $\left(\mathrm{M}^{+}\right) . \mathrm{Mp}: 130.5-132{ }^{\circ} \mathrm{C}$.

28

### 3.3 Results and Discussion

3.3.1 Synthesis. Double aldol condensation of 1,2-diformylferrocene with acetone in the presence of base catalyst $(\mathrm{KOH})$ gave the ferrocene-fused tropone (23) in $83 \%$ yield as dark red needles. The appearance of AB patterns at $\delta 6.37(\mathrm{H} 2)$ and $7.31(\mathrm{H} 3)$ ppm with a coupling constant $\left(J_{\mathrm{AB}}=12 \mathrm{~Hz}\right)$ in its ${ }^{1} \mathrm{H}$ NMR and a peak at $1618 \mathrm{~cm}^{-1}$ in its IR suggest the formation of ferrocene-fused tropone (23). The carbonyl stretch of tropone appears at $1582 \mathrm{~cm}^{-1}$ in its infrared spectrum, which signifies the high polarizability between carbon and oxygen. Ferrocene-fused tropone was previously reported by Tirouflet but characterized only by the melting point. ${ }^{151}$ We characterized the compound 23 with spectroscopic, electronic and optical analysis.

Scheme 3.1 Synthesis of ferrocene-fused tropone
Condensation of 1,2-diformylferrocene with 1,3-diphenylacetone in the presence of KOH leads to the aldol condensation product (24a) and the mono-aldol product (24b) in a 1:1 ratio. Compound 24a and its methyl derivative were previously reported by Tirouflet but characterized only by melting point. We characterized both compounds by X-ray crystallography. In the presence of piperidine, the condensation of 1,2diformylferrocene and 1,3-diphenylacetone gave the Michael addition of piperidine to the
tropone $(\mathbf{2 5}, \mathbf{1 5 \%})$. The proposed mechanism of the formation of the Michael addition of piperidine to $\alpha, \beta$-unsaturated ketone is shown in Scheme 3.4.

Scheme 3.2 Synthesis of ferrocene-fused-5,7-diphenyltropone

25

Scheme 3.3 Synthesis of a piperidine adduct of tropone 24a

Scheme 3.4 Proposed mechanism for Michael addition of piperidine to tropone 24a

Several attempts to convert ferrocene-fused tropones 23 and 24a directly to oximes by reaction with hydroxylamine or hydroxylamine hydrochloride failed. Conditions ranged from $\mathrm{CHCl}_{3}$ at room temperature (no reaction) to refluxing ethanol (decomposition). These results are consistent with the low reactivity of tropone carbonyls with hydroxylamine reported by Machiguhi et al. Tropone 23 was smoothly converted to thiotropone $\mathbf{2 6}$ in $63 \%$ yield by reaction with Lawesson's reagent in anhydrous benzene at room temperature for $7 \mathrm{~h} .{ }^{152}$ Thiotropone 26, dark green in solution and dark blue as a solid, was characterized by spectroscopic analysis and single X-ray crystal analysis. The $\mathrm{C}=\mathrm{S}$ group of $\mathbf{2 6}$ showed an IR absorption at $1078 \mathrm{~cm}^{-1}$ and a ${ }^{13} \mathrm{C}$ NMR signal at 217.62 ppm.

Scheme 3.5 Synthesis of ferrocene-fused thiotropone
In contrast to tropone 23, thiotropone 26 was readily converted to tropone oxime by using hydroxylamine in anhydrous chloroform at $0{ }^{\circ} \mathrm{C}$. ${ }^{153}$ The reaction was apparent from the change of solution color from dark green to deep red over 5 h . A standard, nonchromatographic workup gave 27 as a dark red solid in $83 \%$ yield. Single crystals were obtained by slow diffusion of hexane-saturated $\mathrm{N}_{2}$ through a cannula into an ethyl ether solution.

Scheme 3.6 Synthesis of ferrocene-fused tropone oxime
The formation of ferrocene-fused oxime from ferrocene-fused thiotropone shows that nucleophilic attack on ferrocene-fused thiotropone takes place at the carbon center of a thiocarbonyl $(\mathrm{C}=\mathrm{S})$ group. Machiguchi et al. rationalized the $\mathrm{C}-2$ attack on tropone and the $\mathrm{C}-1$ attack on thiotropone in terms of frontier-orbital theory. They reported that LUMO in tropone is the $\mathrm{p} \pi$ component of $\mathrm{C}-2$ or $\mathrm{C}-7$ and whereas the LUMO of thiotropone is $\pi^{*} \mathrm{C}=\mathrm{S}$ character. Therefore, nucleophiles attack at the $\mathrm{C}-2$ or $\mathrm{C}-7$ of tropone and C-1 of thiotropone. ${ }^{154}$

Thiation of ferrocene-fused tropone 24a gave a different result. Tropone 24a did not react with Lawesson's reagent at temperatures up to $50{ }^{\circ} \mathrm{C}$. At 60 to $80{ }^{\circ} \mathrm{C}$ in benzene, 24a was converted to $\mathbf{2 8}$. The detachment of the thiated ligand from the metal may be due to harsher reaction conditions. Chromatographic workup gave $\mathbf{2 8}$ as a purpleblue solid in $45 \%$ yield. The ${ }^{1} \mathrm{H}$ NMR reveals a SH peak at $\delta 3.88 \mathrm{ppm}$.

Scheme 3.7 Synthesis of 5,7-diphenylazulenethiol
3.3.2 Spectroscopy. All new complexes were characterized with ${ }^{1} \mathrm{H}$ NMR, ${ }^{13} \mathrm{C}$ NMR, IR and mass spectroscopy. ${ }^{1} \mathrm{H}$ NMR spectra of symmetrically disubstituted 23, 24a and $\mathbf{2 6}$ display the disubstituted Cp ring as a doublet at $4.78-4.84 \mathrm{ppm}$ for the 2,4 protons and a triplet at 4.35-4.43 ppm for the 3-proton, confirming a plane of symmetry. The ${ }^{1} \mathrm{H}$ NMR spectra of the unsymmetrically disubstituted Cp ring of $\mathbf{2 4 b}, \mathbf{2 5}$ and $\mathbf{2 7}$ exhibit three pseudo-triplets. The unsubstituted Cp resonances in the ${ }^{1} \mathrm{H}$ NMR spectra of 23-27 display singlet between 4.03-4.11. ${ }^{13} \mathrm{C}$ NMR spectra of these complexes show a characteristic peak ranging from 156.03 to $217.35 \mathrm{ppm} .{ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{2 8}$ displays disubstituted Cp ring as a doublet at 7.20 ppm for the 1,3 -protons and a triplet at 7.75 ppm for the 2-proton and a characteristic singlet peak for a SH proton at 3.88 ppm . A strong IR stretching of carbonyl groups ranges from $1618 \mathrm{~cm}^{-1}$ to $1670 \mathrm{~cm}^{-1}$. The selected spectroscopic data of complexes 23-28 are shown in table 3.1

$\mathrm{E}=\mathrm{O}, \mathrm{S}, \mathrm{NOH} ; \mathrm{R}=\mathrm{H}, \mathrm{Ph}$

3.3.3 Structure. The structures of ferrocene-fused tropone and its derivatives $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}(\mathrm{CHCH})_{2} \mathrm{CO}\right\}\right]$ 23, $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}(\mathrm{CHCPh})_{2} \mathrm{CO}\right\}\right]$ 24a, $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\right.\right.$ $\left.\left.\mathrm{C}_{5} \mathrm{H}_{3}\left(\mathrm{CHCHCOCH}_{2} \mathrm{PhCHO}\right)\right\}\right]$ 24b, $\quad\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}\left(\mathrm{CHCPhCOCHPhCHC}_{5} \mathrm{H}_{11} \mathrm{~N}\right)\right\}\right]$ 25, $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}(\mathrm{CHCH})_{2} \mathrm{CS}\right\}\right] \quad$ 26, $\quad\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}(\mathrm{CHCH})_{2} \mathrm{NOH}\right\}\right] \quad 27$ and $\left[\mathrm{C}_{5} \mathrm{H}_{3}\left(\mathrm{CHCC}_{6} \mathrm{H}_{5}\right)_{2} \mathrm{CSH}\right] \mathbf{2 8}$ were determined by X-ray crystallographic methods. All the crystals except $\mathbf{2 6}$ and $\mathbf{2 8}$ were grown by slow evaporation of a concentrated diethyl ether solution in a stream of hexane-saturated $\mathrm{N}_{2}$ at room temperature, while $\mathbf{2 6}$ was grown from its saturated solution in hot heptanes by cooling to $-10^{\circ} \mathrm{C}$, and 28 was grown by slow evaporation of a concentrated diethyl ether solution at room temperature. Hydrogen
atoms were placed in geometrically calculated positions. Thermal ellipsoid plots with numbering schemes are shown in figures 3.8-3.14. The crystal structure and refinement data for compounds 23, 24a, 24b, 25, 26, 27 and 28 can be found in Tables 3.2-3.5. Bond distances and angles for 23, 24a, 24b, 25, 26, 27 and 28 can be found in Tables 3.6-3.12.

The angles between the centroids of two Cp and Fe in 23, 24a, 25, 26 and 27 are $177.99^{\circ}, 176.46^{\circ}, 176.38^{\circ}, 178.03^{\circ}$ and $178.25^{\circ}$, which are nearly linear. The average bond distances of iron to the centroids of substituted Cp and unsubstituted Cp are $\mathbf{2 3}$ $[1.657(16) \AA, 1.656(16) \AA$ ] , 24a [1.652(3) Å, 1.657(3) Å], $\mathbf{2 5}[1.642(16) \AA, 1.652(16)$ $\AA$ A], $\mathbf{2 6}[1.661(3) \AA, 1.655(3) \AA]$ and $27[1.646(16) \AA, 1.648(16) \AA]$. The average bond distances of iron to the substituted Cp and unsubstituted Cp are $23[2.055(16) \AA$, $2.052(16) \AA], \mathbf{2 4 a}[2.051(3) \AA, 2.051(3) \AA], \mathbf{2 5}[2.044(16) \AA, 2.057(16) \AA], \mathbf{2 6}[2.058(3)$ $\AA, 2.051(3) \AA]$ and $27[2.047(16) \AA, 2.046(16) \AA]$. These calculated values demonstrate that the iron center is coordinated evenly between substituted and unsubstituted cyclopentadienyl ligands. The average bond distances of iron to the substituted and unsubstituted Cp ligands of ferrocene-fused tropone derivatives are close to the calculated average bond distances of iron to two Cp ligands of ferrocene, which are 2.048 $\AA$ and $2.045 \AA .{ }^{155}$

The interplanar angles between $\mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 3-\mathrm{C} 4-\mathrm{C} 5-\mathrm{C} 6-\mathrm{C} 10$ and $\mathrm{C} 7-\mathrm{C} 8-\mathrm{C} 9$ of the molecules 23, 24a and 27 are $20.95^{\circ}, 21.94^{\circ}$ and $7.42^{\circ}$. The planarity of the cyclopentadienyl ring and seven-membered thiotropone ring in $\mathbf{2 6}$ is also supported by the chemical shift of $\mathrm{H} 3(7.33 \mathrm{ppm})$ and $\mathrm{H} 2(7.10 \mathrm{ppm})$ in the ${ }^{1} \mathrm{H}$ NMR. Moreover, it is also proved by a strong UV absorption at $408 \mathrm{~nm}\left[\epsilon=14933\left(\mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)\right]$ as compared to other ferrocene-fused tropone derivatives. The C8-O1 bond length in 23 and 24a is
$1.238(2) \AA$ and $1.230(4) \AA$ respectively, which is comparatively close to the $\mathrm{C}-\mathrm{O}$ bond length $[1.232(2) \AA]$ reported for 4,5-benzotropone, and in contrast to that in furo[3,4$d]$ tropone $[1.242(3) \AA$ A․ These values suggest that although all the tropone rings are nearly planar in tropone annulated aromatic compounds, they are deformed into a slightly boat-shaped conformation. The boat conformation in furo[3,4- $d]$ tropone is slightly shallower ${ }^{156}$ than 4,5-benzotropone, which results in slightly longer C-O bond length. ${ }^{157}$ The C8-S1 bond length in 26 is $1.675(3) \AA$, close to that in thiotropone (1.676(5) $\AA$ ) which has been reported as indicating the major contribution of polar resonance structure, and in contrast to those in 2,4,6-tri-t-butylthiobenzaldehyde (1.596 $\AA$ ) and in cyclopentadienethione ( $1.633 \AA$ ) whose $\mathrm{C}=\mathrm{S}$ is not conjugated with the benzene ring. ${ }^{158,156}$ Similarly the $\mathrm{C} 8-\mathrm{N} 1$ and $\mathrm{N} 1-\mathrm{O} 1$ bond lengths in ferrocene-fused tropone oxime are $1.309(2) \AA$ and $1.461(2) \AA$, respectively.

3.3.4 Electrochemistry. The three-electrode electrochemical cell consists of a glassy carbon button working electrode, a carbon rod counter electrode and an $\mathrm{Ag} / \mathrm{AgCl}$ reference electrode. All electrodes were connected to a potentiostat. Ferrocene/ferrocenium $\left(\mathrm{Fc} / \mathrm{Fc}^{+}\right)$, a stable redox couple that is soluble in common organic solvents and whose potential is independent of the solvent, is used as an internal standard. $\mathrm{Fc} / \mathrm{Fc}^{+}$is estimated to be around 4.8 eV against vacuum. HOMO and LUMO energies of compounds are determined by using their first oxidation and first reduction potentials with respect to $\mathrm{Fc} / \mathrm{Fc}^{+}$.

Cyclic voltammetry of ferrocene-fused tropone (23), ferrocene-fused-5,7diphenyltropone (24a) and ferrocene-fused thiotropone (26) was carried out at room temperature at scan rate $100 \mathrm{mV} \cdot \mathrm{sec}^{-1}$ in a $0.1 \mathrm{M}\left(\mathrm{Bu}_{4} \mathrm{NPF}_{6} / \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ solution as the supporting electrolyte. The half-wave potentials of each oxidation ( $E_{1 / 2, \mathrm{ox}}^{0}$ ) and reduction ( $E_{1 / 2, \text { red }}^{0}$ ) wave were calculated by averaging the corresponding anodic ( $E_{\mathrm{pa}}$ ) and cathodic $\left(E_{\mathrm{pc}}\right)$ peak potentials. The cyclic voltammograms for complexes 23, 24a and $\mathbf{2 6}$ are shown in Figures 3.11-3.13. The electrochemical data are summarized in Table 3.13.

The electrochemical data reveal that complex 23 gave a pseudo-reversible oxidation potential ( $E_{1 / 2}=0.26 \mathrm{~V}$ vs. $\left.\mathrm{Fc} / \mathrm{Fc}^{+}\right)$, indicated by the $i_{\mathrm{pa}} / \mathrm{i}_{\mathrm{pc}}$ ratio of 1.15 . Similarly, the complex 24a exhibited a reversible oxidation potential ( $E_{1 / 2}=0.19 \mathrm{~V}$ vs. $\left.\mathrm{Fc} / \mathrm{Fc}^{+}\right)$, indicated by $i_{\mathrm{pa}} / i_{\mathrm{pc}}$ of 0.95 . The peak-to-peak separation ( $E_{\mathrm{p}}=E_{\mathrm{pa}}-E_{\mathrm{pc}}$ ) is equal to 78 mV and 86 mV for complexes 23 and 24a respectively. These oxidation potentials correspond to an electrochemical HOMO energy gap of -5.06 eV (23) and -4.99 eV (24a).

Figure 3.13 shows one to fifteen scans of cyclic voltammograms of ferrocenefused thiotropone (26). The cyclic voltammogram curve on the top left is after five scans, the top right is after ten scans and the bottom is after fifteen scans. The observed electrochemical behavior shows a disappearance of the first oxidative peak at about 0.72 V and the increasing of the intensity of another oxidative peak at about 0.55 V and one reductive peak at about 0.45 V . The non-reversible feature in the cyclic voltammetry of ferrocene-fused thiotropone suggests that the oxidation of the compound is followed by a chemical reaction. A similar electrochemical behavior was reported by Blankespoor et al. in the study of electrochemical oxidation of thiourea derivatives, thioketones and 1,3-dithiolan-2-thione in anhydrous acetonitrile solution containing tetra- $n$-butylammonium perchlorate as the supporting electrolyte. They also observed two oxidative peaks and one reductive peak due to the reduction of an oxidation product in the cyclic voltammogram curve. They justified those electrochemical behaviors by the oxidative electron transfer mechanism, which involved the stepwise electron transfer oxidation of thiocarbonyl compounds to their corresponding radical cations, followed by addition to a neutral thiocarbonyl compound and one-electron oxidation of the resultant dimer radical cation. ${ }^{159}$ Based upon the reported electrochemical data of thioketone compounds, we may be observing similar types of chemical reactions as shown in Scheme 3.8.

Scheme 3.8 Oxidative electron-transfer mechanism in thiocarbonyl compound

Mouanga and Bercot have also reported the electrochemistry of thiourea in acetonitrile solution containing lithium perchlorate as the supporting electrolytes with platinum as a working electrode. They observed two reductive waves $\left(C_{I}\right.$ and $\left.C_{I I}\right)$ and one oxidative wave in the voltammogram. They noticed the peak $C_{I}$ about -250 mV vs. SCE only after the scan towards the oxidative potential. Furthermore, they mentioned that during a scan towards the anodic potential, the thiourea oxidized to its oxidized product formamidine disulfide $\left[\left(\mathrm{H}_{2} \mathrm{~N}\right)_{2}\left(\mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{C}_{2} \mathrm{~S}_{2}\right]$ and the resultant oxidized product reduced at reductive potential about -250 mV vs. SCE . Therefore they believed the peak $\mathrm{C}_{\mathrm{I}}$ at around -250 mV does not correspond to the reaction due to the reduction of thiourea; rather a reduction of the compound produced by an oxidation of thiourea. ${ }^{160}$

Figure 3.14 UV Spectra of ferrocene-fused tropone derivatives (combined) and diphenylazulenethiol

The figure 3.14 shows the UV of spectra of ferrocene-fused tropone derivatives and 5,7-diphenylazulenethiol (23, 24a, 25, 26, 27 and 28). The electronic spectrum of ferrocene-fused tropone (23) is characterized with three bands at $520 \mathrm{~nm}(2.39 \mathrm{eV}), 319$ $\mathrm{nm}(3.89 \mathrm{eV})$ and $274 \mathrm{~nm}(4.53 \mathrm{eV})$. Serrano-Andres et al. have computed the absorption spectra of a series of cyclic conjugated ketones and thioketones including tropone and
thiotropone. The computational study for tropone shows the $n-\pi^{*}$ transitions lie at 3.86 and 3.94 eV while the $\pi-\pi^{*}$ transitions appear at 4.22 eV and $4.26 \mathrm{eV} .{ }^{158}$ The calculated data suggested that the transitions observed at 3.89 eV and 4.53 eV in 23 may be due to $n-\pi^{*}$ and $\pi-\pi^{*}$ respectively. Tropone shows two characteristic bands in the UV spectrum at $230 \mathrm{~m} \mu$ and $300 \mathrm{~m} \mu .{ }^{161,162}$ The absorption band at 520 nm is due to $d-d$ transition of metal, since ferrocene has a strong absorption at $535 \mathrm{~nm} .{ }^{163}$ The absorption spectrum of ferrocene-fused 5,7-diphenyltropone (24a) shows bands at $503 \mathrm{~nm}(2.47 \mathrm{eV}), 330 \mathrm{~nm}$ ( 3.76 eV ) and $287 \mathrm{~nm}(4.32 \mathrm{eV})$ similar to 23.

The UV spectrum of ferrocene-fused thiotropone (26) displays three transitions at $585 \mathrm{~nm}(2.12 \mathrm{eV}), 408 \mathrm{~nm}(3.04 \mathrm{eV})$ and $281 \mathrm{~nm}(4.42 \mathrm{eV})$. Among those three transitions, the most intense band is located at 3.04 eV with an extinction coefficient of $14933 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. Similar behavior was observed by Serrano-Andres et al. in the theoretical study of the electronic excited state for thiotropone. The computed $\pi-\pi^{*}$ transition at 3.34 eV is the strongest band in hexane with an extinction coefficient of $151351 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. They also have reported two weak bands at 1.82 eV and 2.03 eV , and those transitions are computed as $\mathrm{n}-\pi^{*}$. Therefore, the absorption band at $585 \mathrm{~nm}(2.12$ eV ) in 26 may be the combined transitions of metal $d-d$ and $n-\pi^{*}$. The low energy electronic transition of ferrocene-fused thiotropone ( 3.04 eV ) as compared to ferrocenefused tropone ( 3.89 eV ) may be due to the larger size of the sulfur atom and longer $\mathrm{C}=\mathrm{S}$ bond in thiotropone. Ferrocene-fused oxime tropone exhibits three electronic transitions at $482 \mathrm{~nm}(2.57 \mathrm{eV}), 318 \mathrm{~nm}(3.92 \mathrm{eV})$ and $272 \mathrm{~nm}(4.56 \mathrm{eV}) .7$,9-Diphenylazulenethiol shows the strongest $\pi-\pi^{*}$ transition at $320 \mathrm{~nm}(3.88 \mathrm{eV})$ with an extinction coefficient of $32383 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$.

### 3.4 Summary

1,2-Diformylferrocene is the starting material for the synthesis of unsubstituted and substituted ferrocene-fused tropones. The starting material was prepared following the literature reported protocol. ${ }^{116,117,119}$ The reaction of 1,2-diformylferrocene with acetone at room temperature in absolute ethanol under $\mathrm{N}_{2}$ in presence of KOH gave ferrocene-fused tropone (23) in good yield (83\%). Further, the reaction of 1,2diformylferrocene with 1,3-diphenylacetone under similar reaction conditions overnight yielded a 1:1 ratio of the desired compound (24a) and mono-aldol condensed product (24b). The presence of an aldehyde peak in the ${ }^{1} \mathrm{H}$ NMR confirmed the compound $\mathbf{2 4 b}$. Finally, compound 24b was verified by an X-ray crystal analysis. To improve the reaction yield, we attempted the reaction of 1,2-diformylferrocene with 1,3diphenylacetone in piperidine gave 25, a piperidine adduct of tropone $\mathbf{2 4}$ a in poor yield (15\%).

Attempts to convert ferrocene-fused tropones $\mathbf{2 3}$ and 24a directly to oximes by reaction with hydroxylamine or hydroxylamine hydrochloride in $\mathrm{CHCl}_{3}$ at room temperature and in ethanol at refluxing temperature resulted in decomposition. The reaction of ferrocene-fused tropone with Lawesson's reagent in dry benzene at room temperature for 7 h gave a moderate yield of a dark blue ferrocene-fused thiotropone (63\%). The ferrocene-fused tropone oxime (27) was prepared by reacting 26 with hydroxylamine in chloroform at $0{ }^{\circ} \mathrm{C}$ for 5 h gave in good yield (83\%). Refluxing the ferrocene-fused 5,7-diphenyltropone with Lawesson's reagent in dried benzene for 7 h gave a blue, demetalated product, 7,9-diphenylazulenethiol (45\%).

All the complexes were characterized by X-ray crystallography. The interplanar angle between $\mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 3-\mathrm{C} 4-\mathrm{C} 5-\mathrm{C} 6-\mathrm{C} 10$ and $\mathrm{C} 7-\mathrm{C} 8-\mathrm{C} 9$ of the ferrocene-fused thiotropone is $2.14^{\circ}$, which shows almost planar, and the planarity of the molecule is also supported by the ${ }^{1} \mathrm{H}$ NMR data and UV absorption. Cyclic voltammetry of $\mathbf{2 3}$ and 24a shows an oxidation potentials at 0.26 V and 0.19 V respectively, versus $\mathrm{Fc} / \mathrm{Fc}^{+}$, corresponding to estimated HOMO and LUMO energy levels of $-5.06 \mathrm{eV},-4.99 \mathrm{eV}$ respectively. UV-vis absorption spectra for compounds 23, 24a, 26, 27 and 28 were recorded in the dichloromethane solution, and the UV absorption spectrum reveals that ferrocene-fused thiotropone shifts about 80 nm more towards the visible region as compared to other derivatives. The most intense absorption observed in the ferrocenefused thiotropone lies at $3.34 \mathrm{eV}(409 \mathrm{~nm})$ with an extinction coefficient of $14933 \mathrm{Mol}^{-1}$ $\mathrm{cm}^{-1}$. The planarity of compound 26 was supported by the downfield shift of signals H6 (7.33 ppm) and H 7 ( 7.10 ppm ), and a strong UV absorption at blue region as compared to other tropone derivatives (23 and 27).

In summary, we have synthesized unsubstituted and phenyl substituted ferrocenefused tropone using aldol condensation. The reaction of 23 and 24a with Lawesson's reagent resulted in ferrocene-fused thiotropone and 5,7-diphenylazulenethiol. Furthermore, the reaction of $\mathbf{2 6}$ with hydroxylamine gave the corresponding oxime. Compound 26 has an interesting color in solid form as compared to the other derivatives. All the ferrocene-fused tropone derivatives were characterized by a single X-ray crystal structure. The oxidation potential of $\mathbf{2 3}$ and 24a were measured by cyclic voltammetry. The UV-vis spectrum of ferrocene-fused tropone derivatives was recorded. Among those derivatives, 26 showed an interesting absorption towards the visible region ( $\lambda_{\max } 409 \mathrm{~nm}$ )
and exhibits a high dipole moment. This result suggested that 26 has extended conjugations, which is also supported by the downfield shift of protons at C2 and C3 (shown in Figure 3.3). Therefore, compound 26 may be considered as a potential candidate for optoelectronic application.

## Chapter 4 Synthesis and Characterization of Ferrocene-Fused Thiepin Derivatives 4.1 Conducting polymers

Conducting polymers are extended, $\pi$-conjugated polymers, also known as synthetic metals, which possess electronic (conductive, magnetic, optical) properties of metals and acquire high conductivity due to incorporation of a small concentration of dopants into the matrix of the initial extended $\pi$-conjugated polymer. ${ }^{164}$ The new era of conducting polymers began with the discovery in 1977 by Heeger et al. that polyacetylene exhibits a 12 -fold increase in its conductivity upon oxidative doping ( $\mathrm{I}_{2}$, $\mathrm{Br}_{2}$ and $\left.\mathrm{Cl}_{2}\right) .{ }^{165}$ The light weight, easy processability, low fabrication costs and corrosion resistance of organic polymers have led to the replacement of inorganic materials in electronic applications. ${ }^{166}$ This class of materials has attracted great attention and rapidly become a subject of considerable interest for both materials chemists and industrial researchers. ${ }^{167}$

The potential applications of conducting polymers in chemical and biological sensors are another reason for the intensive development of these materials. ${ }^{168}$ Conducting polymers offer a wide range of applications including field-effect transistors, light-emitting diodes, photovoltaics, nonlinear optic devices and batteries. ${ }^{169}$ Polyacetylene and other linear-backbone polymers (polypyrrole, polyaniline) may display favorable electronic properties. However, these materials have limited use practically due to poor environmental stability. ${ }^{170}$

One important class of organic conducting polymers is polyheterocycles. Polythiophenes and polypyrroles have been the most extensively studied due to their possibilities of structural modification, ease of formation by either chemical or
electrochemical polymerization techniques ${ }^{171}$ and their stability in air and moisture greater than polyacetylenes. The heteroatoms (sulfur and nitrogen) tend to stabilize the positive charges in the $p$-doped state. Heterocyclic conducting polymers, in particular polythiophenes, are stable to oxygen and moisture in both their doped and undoped states at ambient temperature. ${ }^{172,173}$

Figure 4.1 Conjugated conductive polymers
Polythiophene is synthesized by anodic or chemical polymerization of pure thiophene or oligothiophene, and by metal-catalyzed cross-coupling of the thienyl Grignard reagent shown in $\mathbf{2}$ of Figure 4.2. Electrochemically synthesized polythiophene ( $\mathbf{1}$ of Figure 4.2) is a tough, blue-black film, whereas chemically synthesized polythiophene is crystalline with definite number-average molecular weight. Their poor solubility in organic solvents makes chemically synthesized polythiophene difficult to purify and process into films. ${ }^{174,175}$ However, these issues can be circumvented by introducing alkyl chains or other solubilizing organic groups.

1

2

Figure 4.2 Synthesis of polythiophene. 1. Electrochemical polymerization.
2. Chemical polymerization to polythiophene

3-Substituted thiophenes are asymmetric monomers, which results in three possible couplings when two monomers are linked at 2- and 5-positions (Figure 4.3); i.e., 2,2' (head-to-head, HH), 2,5' (head-to-tail, HT) and 5,5' (tail-to-tail, TT). Regioregular functionalized polythiophene exhibits more highly ordered polymer, thereby decreasing band gap and increasing the conductivity as compared to regiorandom analogous. ${ }^{176}$

HH

HT

TT

Figure 4.3 Regioisomeric coupling patterns in poly(alkylthiophene)s
Another goal of chemists is to prepare polymers with small band gaps and intrinsic high conductivities. Considering these parameters, Wudl and coworkers prepared poly(benzo[3,4-c]thiophene), also known as poly(isothianaphthene) or PITN, which exhibits a band gap approximately 1 eV lower than polythiophene ( $\sim 2 \mathrm{eV}$ ). The
increased conductivity of PITN may be due to the resonance contribution from the quinoid canonical form (b of Figure 4.4), which increases the aromaticity of phenyl ring. ${ }^{174}$ Analogous organometallic heterocycles could potentially add a new dimension to the optoelectronic polymers. Brédas and coworkers reported that for conjugated polymers based on aromatic rings, the band gap decreases as the quinoidal character of the backbone increases, possibly due to the nearly equal bond lengths along the polyene backbone. ${ }^{177}$

c
a
b

Figure 4.4 Resonance forms of PITN
PITN shows some non-classical thiophene character (c of Figure 4.4), with a tetravalent sulfur. ${ }^{174}$ Thieno[3,4-c]thiophene is a typical non-classical thiophene. The first stable non-classical thiophene was tetraphenylthieno[3,4-c]thiophene (1 of Chart 4.1), synthesized by Cava and Husbands. ${ }^{178}$ Other stable derivatives of nonclassical thiophene have been synthesized as shown below in Chart 4.1 ( $\mathbf{2}$ and 3). ${ }^{179,180}$ The stability of nonclassical thiophenes is enhanced by introducing bulky and electron-accepting substituents. Chart 4.1 shows a few examples of stable non-classical thiophenes.

1

2

3

Chart 4.1 Few examples of non-classical thiophenes
The discovery of PITN has attracted researchers to prepare polymers incorporating a fused ring with a wide variety of structural variation. Chart 4.2 shows some examples of fused-ring polythiophenes. ${ }^{175,176,181}$

Chart 4.2 Fused-ring polythiophenes
Kim and coworkers prepared thieno[3,2-b]thiophene-substituted benzo[1,2-b:4,5$b^{\prime}$ ]dithiophene ( $\mathbf{1}$ of Figure 4.5), which has an optical band gap of 1.55 eV , as a promising building block for semiconducting polymers in high-performance organic solar cells. ${ }^{182}$ Similarly, Zhou et al. synthesized D-A copolymer (PBTT-TBDTT) 2 of Figure 4.5 , which has a narrow optical band gap around 1.45 eV and shows broader absorption
range from 300-850 nm. Designing materials with the combination of an electron-rich donor (D) unit and an electron-deficient acceptor (A) unit is a powerful strategy in the preparation of small-band-gap $\pi$-conjugated polymers. ${ }^{183}$

1

2

Figure 4.5 Thienyl group substituted donor-acceptor copolymer
Incorporating transition metals into conducting polymers may add several advantages including environmental stability, solubility in organic solvents and unique redox properties. ${ }^{41}$ There are several other examples of organometallic $\pi$-complexes with thiophene ligands. In 1958 , E.O Fisher prepared tricarbonyl[(2,3,4,5- $\eta$ )-thiophene$\kappa S]$ chromium ( $\mathbf{1}$ of Chart 4.3). ${ }^{184}$ Further, E.O Fisher et al. utilized benzo[b]thiophene as a ligand for tricarbonylchromium complex where the chromium is bonded to sixmembered ring ( $\mathbf{2}$ of Figure 4.8). ${ }^{185}$ In 1992, Loft and coworkers synthesized trialkylsilyl substituted thiophenetricarbonylchromium(0) (3 of Chart 4.3). ${ }^{186}$

1

2

3

Chart 4.3 Thiophene-based chromium complexes
The Selegue group has a long-term interest in the structural and electronic properties of materials based on $\eta^{5}$-cyclopentadienyl-fused heterocycles (Chart 4.4). Selegue and Swarat synthesized $\left[\operatorname{Cr}(\right.$ benzo $[3,4-c]$ thiophene $\left.)(\mathrm{CO})_{3}\right](\mathbf{1})$ from the reaction of benzo[3,4-c]thiophene with photolytically generated $\left[\mathrm{Cr}(\mathrm{thf})(\mathrm{CO})_{5}\right]$ at room temperature. A crystal structure showed that tricarbonylchromium is $\eta^{6}$-bonded to the arene ring of the ligand. ${ }^{149}$ Selegue and Wallace prepared the pyridazine complexes of ruthenium (2) via two methodologies. One method involves the reaction of $\left[R u\left\{\eta^{5}\right.\right.$ $\left.\left.\mathrm{C}_{5} \mathrm{H}_{3}\left(\mathrm{CO}_{2} \mathrm{Ph}\right)_{2}\right\}\left(\mathrm{Cp}^{*}\right)\right]$ with hydrazine monohydrate; and the second method involves the generation of thallium pyridazine salt by deprotonation of cyclopenta [d]pyridazine with thallium ethoxide followed by treatment with $\left[\mathrm{Ru}\left(\mu_{3}-\mathrm{Cl}\right)\left(\mathrm{Cp}^{*}\right)\right]_{4}$ to prepare pyridazine complexes. ${ }^{150}$

Moreover, several other derivatives of cyclopentadienyl-fused heterocycles have been synthesized in Selegue's group. Selegue and coworkers prepared $\eta^{5}$ cyclopenta $[c]$ thienyl complexes of manganese via two methodologies. The first method involves the lithiation of 1,3-disubstituted-cyclopent[c]thiophene followed by treatment with $\mathrm{Me}_{3} \mathrm{SnCl}$, which in turn reacts with $\left[\mathrm{MnBr}(\mathrm{CO})_{5}\right]$ to give $\mathbf{3}$ of Chart 4.4. The second method involves the complexation of 1,2-diacylcyclopentadienyl ligand, followed by ring closure using either Lawesson's reagent or $\mathrm{P}_{4} \mathrm{~S}_{10} / \mathrm{NaHCO}_{3}$ in $\mathrm{CS}_{2} .{ }^{148}$ Further, Tice 182
expanded the work to synthesize a number of halogen-substituted derivatives of cyclopenta[c]thienyl complexes of manganese employing the appropriate acid chlorides. ${ }^{152}$

Thiepins, conjugated seven-membered ring system with a thioether group, are another important class of heterocycles. Including one lone pair of electrons from the sulfur atom, a thiepin can be considered an $8 \pi$-electron heteroannulene, antiaromatic according to Hückel's rule. ${ }^{187}$ Parent thiepin is thermally unstable, possibly due to the valence isomerization of thiepin to the corresponding benzene sulfide followed by irreversible loss of sulfur to form benzene. ${ }^{188}$ However, bulky substituents at both the 2 and 7 positions of thiepins increase their stability because steric repulsion disfavors formation of the thianorcaradiene intermediate (Figure 4.6). ${ }^{187}$

Intermediate

Figure 4.6 Sulfur extrusion from thiepin
There are several reported examples of benzannulated thiepins. Traynelis et al. prepared thermally unstable benzo[b]thiepin from the reaction of 2,4-dichloro-2,3-dihydro-1-benzothiepin with potassium tert-butoxide ${ }^{189},{ }^{190}$ The same group reported mono- and di-halo substituted benzo[b]thiepin, which are more stable than parent benzo[b]thiepin. ${ }^{189}$ Further, Traynelis and Love prepared the seven-membered heterocycle, benzo[b]thiepin 1,1-dioxide. ${ }^{191}$ Benzo[b]thiepin (1 of Chart 4.5, $\mathrm{X}=\mathrm{S}$ ) and benzo[b]thiepin 1,1-dioxide ( $\mathbf{1}$ of Chart 4.5, $\mathrm{X}=\mathrm{SO}_{2}$ ) are well characterized by single X ray crystal analysis by Yasuoka et al. ${ }^{192,193}$ Benzo[b]thiepin 1-oxide (1 of Chart 4.5, X $=$ SO) has not been prepared. However, a highly substituted benzo[ $b$ ]thiepin 1-oxide ( 6 of Chart 4.5, $\mathrm{X}=\mathrm{SO}$ ) has been synthesized. These molecules are thermally less stable than the corresponding benzo[b]thiepin. ${ }^{194}$ Recently, Swager and Song synthesized thiopheneannulated thiepins (7 of Chart 4.5), which can be polymerized electrochemically to give thiepin-containing electroactive polymers. ${ }^{187}$

Chart 4.5 Derivatives of thiepins and benzannulated thiepins
Benzo[d]thiepin diacid (1a of Figure 4.7) undergoes extrusion of sulfur much more readily than its naphthalene homologue (2a of Figure 4.7). This may be due to the extra energy required to convert two benzene rings into quinoid form in naphthalene thiepin diacid (2b of Figure 4.7) during sulfur extrusion, while in benzo[d]thiepin, sulfur extrusion requires conversion of a benzene ring into quinoid form as shown in Figure 4.7 (1b). This result suggests that if there is a sufficiently great energy difference between the
ground state of the heterocycle and the benzene sulfide, it might be easier to prepare a simple thiepin. ${ }^{195,196}$

Figure 4.7 Benzo[ $d]$ thiepin-diacid and corresponding benzene sulfur
Considering these parameters, Schlessinger and Ponticello prepared a thermally stable, unsubstituted thieno[3,4- $d$ ]thiepin. The great stability of thieno[3,4- $d$ ]thiepin may be due to charge-separated species $\mathbf{b}$ and $\mathbf{c}$ of Figure 4.8. They have also reported that sulfur extrusion might require a high-energy process due to the tetravalent sulfur atom present in the quinoid position of the benzene sulfide intermediate $\mathbf{d}$ of Figure 4.8. ${ }^{197}$

Recently Cai et al. prepared new $\pi$-conjugated molecules with thiepin-fused heteroacenes for the development of high-performance p-type optoelectronic materials
and found that thin films of those molecules possess relatively high hole-carrier mobility. ${ }^{198}$ Thiepin-containing derivatives have not only potential application in optoelectronic devices but also display potent biological activities (prostaglandin antagonist, antiestrogenic effect). Therefore Shirani and Janosik synthesized dibenzothiophene $[b, f]$ thiepins. ${ }^{199}$

$\mathrm{R}=\mathrm{CH}_{3}, \mathrm{C}_{6} \mathrm{H}_{13}$
Figure $4.9 \pi$-conjugated thiepin-fused heteroacenes
Labile thiepins cannot only be stabilized by the addition of benz- or thiopheneannulations and steric effects but also by transition-metal complexation. The ability of transition metals to stabilize reactive species allowed researchers to isolate kinetically unstable conjugated molecules such as cyclobutadiene, ${ }^{200,201,202}$ pentalene, ${ }^{203}$ and norcaradiene. ${ }^{204}$ Similarly, Nishino et al. took the advantage of a transition-metal complexation strategy to stabilize a thermally labile parent thiepin and prepared the iron tricarbonyl thiepin. This is the first transition metal complex of a thiepin (Chart 4.6). ${ }^{205,188}$ Herein, we are preparing ferrocene-fused thiepins, which may allow us to design new organometallic conducting polymers.

Chart 4.6 Examples of transition metal complexes
Borepins are unsaturated seven-membered heterocyclic compounds with six carbon atoms and one boron atom as a heteroatom. Tovar and coworkers have been synthesized new boron-containing polyacenes for the past few years. The incorporation of boron atoms into $\pi$-conjugated polycyclic materials has emerged a useful strategy to develop new optoelectronic materials with unique optical properties that result from vacant p-orbital of the boron center. ${ }^{206,207}$ Borepin derivatives show well-behaved cathodic electrochemistry at the boron centers. Thus these materials are useful for n-type materials. ${ }^{208}$ The Tovar group has been utilized the strong Lewis acidity of tricoordinate boron to enhance the electronic delocalization along the $\pi$-conjugated system relative to benzo-fused analogues. ${ }^{209}$ Recently same group has prepared air- and moisture-stable dithienoborepins (2 and $\mathbf{3}$ of Chart 4.7). ${ }^{210}$

### 4.2 Experimental

Chapter 2 lists the general condition for all experiments. Thiodiglycolic acid, $m$ chloroperoxybenzoic acid, oxalyl chloride, 4-dimethylaminopyridine, quinoline, silver carbonate, Pyridine, triethylamine (Aldrich), copper powder (Fisher), 2-chloro-1,3,2benzodioxaphosphole and 1-Hydroxypyridine-2(1H)-thione sodium salt (Alfa Aesar), pyridine and triethylamine were freshly distilled before used. 1-Hydroxypyridine-2(1H)thione sodium salt was received as a $40 \%$ solution in water. The water was removed under reduced pressure, the resulting yellow solid was dissolved in ethanol and hexane was added slowly to give a white powder. ${ }^{211}$ Dimethylthiodiglycoate was prepared from esterification of thiodiglycolic acid in MeOH under acidic conditions (conc. $\mathrm{H}_{2} \mathrm{SO}_{4}$ ). Dimethylthiodiglycolate sulfoxide ${ }^{212}\left(\left(\mathrm{CH}_{3} \mathrm{OCOCH}_{2}\right)_{2} \mathrm{SO}\right)$ and copper phthalocyanine ${ }^{213}$ were prepared according to the literature procedures.

Synthesis of $\mathbf{C}_{\mathbf{1 8}} \mathbf{H}_{\mathbf{1 6}} \mathrm{FeO}_{5} \mathrm{~S}$ (29a) and $\mathrm{C}_{\mathbf{1 8}} \mathbf{H}_{\mathbf{1 8}} \mathrm{FeO}_{6} \mathrm{~S}$ (29b). To an oven-dried 125 mL Schlenk flask cooled under $\mathrm{N}_{2}, 5 \mathrm{~mL}$ dried methanol, dimethylthiodiglycolate sulfoxide $(0.19 \mathrm{~g}, 0.99 \mathrm{mmol})$, then 0.1 mL of freshly distilled $\mathrm{Et}_{3} \mathrm{~N}$ were added. After stirring at room temperature for 90 min , a solution of 1,2-diformylferrocene ( 200 mg , 0.83 mmol ) in 3 mL methanol was added dropwise, and the reaction mixture was stirred for 16 h . Then the original volume of reaction mixture was reduced by half under vacuum and poured into a column of silica. The column was flushed with hexane:ethyl ether (1:1). Pure ethyl ether eluted a purple band containing 29b, then ethyl ether:dichloromethane (3:1) eluted a dark red band containing 29a. The evaporation of the solvent from both collected fractions gave gummy solids, which were triturated with pentane and dried under vacuum to yield red (29a) and purple (29b) solids in a ratio of

2:1 (29a $40 \%$ and 29b $22 \%) .29 a:{ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\left.\mathbf{4 0 0} \mathbf{~ M H z , ~} \mathbf{C D C l}_{\mathbf{3}}, \mathbf{p p m}\right): \delta 3.89(\mathrm{~s}, 6 \mathrm{H}$, H9), $4.29(\mathrm{~s}, 5 \mathrm{H}, \mathrm{H} 7), 4.84\left(\mathrm{t}, 1 \mathrm{H},{ }^{3} J=2.8 \mathrm{~Hz}, \mathrm{H} 6\right), 5.20\left(\mathrm{~d}, 2 \mathrm{H},{ }^{3} J=2.4 \mathrm{~Hz}, \mathrm{H} 5\right), 8.30$ (s, $2 \mathrm{H}, \mathrm{H} 3$ ). ${ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}\left(\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{\mathbf{3}}, \mathbf{p p m}\right): 53.08$ (C9), 72.13 (C7), 76.64 (C6), 78.25 (C5), 78.96 (C4), 147.20 (C3), $164.50(\mathrm{C} 8)$. Figure 4.10 Ferrocene-fused dimethyl ester thiepin S-oxide with numbering Synthesis of $\mathbf{C}_{\mathbf{1 8}} \mathbf{H}_{\mathbf{1 6}} \mathbf{F e O}_{4} \mathbf{S}$ (30). Compound 29a ( $0.10 \mathrm{~g}, 0.25 \mathrm{mmol}$ ) and pyridine ( $0.30 \mathrm{mmol}, 22 \mu \mathrm{~L}$ ) were dissolved in dry benzene ( 5 mL ) in a 100 mL Schlenk flask purged with $\mathrm{N}_{2}$. The resulting solution was cooled in an ice bath. To the stirring reaction mixture, 2-chloro-1,3,2-benzodioxaphospole ( $0.11 \mathrm{~g}, 0.62 \mathrm{mmol}$ ) was added
slowly. The reaction mixture was warmed to room temperature and stirred for 3 h . Aqueous sodium hydroxide ( $2 \mathrm{M}, 3 \mathrm{~mL}$ ) was added and the benzene layer was washed again with sodium hydroxide ( $2 \mathrm{M}, 5 \mathrm{~mL}$ ) solution, followed by one water wash. The benzene layer was dried with anhydrous magnesium sulfate; and the solvent was removed to yield the crude product. The product was dissolved in a minimum amount of dichloromethane, loaded onto a silica gel column and eluted using ethyl ether:hexane (1:1). The first red band was collected, and the solvent was removed to yield a dark red solid ( $78 \mathrm{mg}, 81 \%$ ) that was recrystallized by slow diffusion of hexane-saturated $\mathrm{N}_{2}$ into its ethyl ether solution through a cannula. ${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): \delta 3.79$ (s, $6 \mathrm{H}, \mathrm{H} 9), 4.28(\mathrm{~s}, 5 \mathrm{H}, \mathrm{H} 7), 4.66\left(\mathrm{t}, 1 \mathrm{H},{ }^{3} J=2.4 \mathrm{~Hz}, \mathrm{H} 6\right), 4.70\left(\mathrm{~d}, 2 \mathrm{H},{ }^{3} J=2.4 \mathrm{~Hz}, \mathrm{H} 5\right)$, 7.72 (s, $2 \mathbf{H}, \mathrm{H} 3$ ). ${ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}\left(\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}, \mathbf{p p m}\right): 53.22$ (C9), 72.19 (C7), 74.17 (C6), 78.05 (C5), 78.05 (C4), 119.40 (C2), 143.09 (C3), 165.45 (C8). IR (ATR, $\left.\mathbf{c m}^{\mathbf{- 1}}\right): 1700(\mathrm{C}=\mathrm{O})$.

Synthesis of $\mathbf{C}_{\mathbf{1 6}} \mathbf{H}_{\mathbf{1 2}} \mathbf{F e O} \mathbf{5} \mathbf{S}$ (31). In a 100 mL Schlenk flask, KOH (84 mg, 1.5 mmol ) was added to a stirred solution of 29a ( $200 \mathrm{mg}, 0.50 \mathrm{mmol}$ ) in 3 mL methanol under $\mathrm{N}_{2}$. The reaction mixture was refluxed for 3 h , cooled to room temperature and quenched with water ( 4 mL ). The layers were separated and the aqueous layer was washed with ethyl ether $(3 \times 5 \mathrm{~mL})$ and acidified to pH 2 with conc. HCl . The aqueous layer was extracted with dichloromethane $(4 \times 10 \mathrm{~mL})$, the solvent was removed and the residue was triturated with ethyl ether to give a red solid ( $88 \mathrm{mg}, 47 \%$ ). ${ }^{\mathbf{1}} \mathbf{H}$ NMR (400 MHz, acetone-d $\mathbf{d}_{6}, \mathbf{p p m}$ ): $\delta 4.41$ (s, $5 \mathrm{H}, \mathrm{H} 7$ ), $4.97\left(\mathrm{t}, 1 \mathrm{H},{ }^{3} \mathrm{~J}=2.4 \mathrm{~Hz}, \mathrm{H} 6\right), 5.41$ (d, 2 H , $\left.{ }^{3} J=2.4 \mathrm{~Hz}, \mathrm{H} 5\right), 8.37(\mathrm{~s}, 2 \mathrm{H}, \mathrm{H} 3) \cdot{ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}\left(\mathbf{1 0 0} \mathbf{~ M H z}\right.$, acetone-d $\left.\mathbf{d}_{\mathbf{6}}, \mathbf{p p m}\right): 72.86$
(C7), 77.06 (C6), 78.76 (C5), 80.21 (C4), 131.34(C2), 147.52 (C3), 165.29 (C8). IR (ATR, cm ${ }^{-1}$ ): $1151(\mathrm{~S}=\mathrm{O}), 1700(\mathrm{C}=\mathrm{O}), 2856-3106(\mathrm{COOH})$.

Synthesis of $\mathbf{C}_{\mathbf{1 6}} \mathbf{H}_{\mathbf{1 2}} \mathbf{F e O}_{\mathbf{4}} \mathbf{S}$ (32). In a 100 mL Schlenk flask, NaOH ( $23 \mathrm{mg}, 0.60$ $\mathrm{mmol})$ in 1 mL methanol was added to a stirred solution of $\mathbf{3 0}(50 \mathrm{mg}, 0.10 \mathrm{mmol})$ in 5 ml dichloromethane and allowed to reflux for 12 h under $\mathrm{N}_{2}$. The reaction mixture was cooled to room temperature and quenched with water ( 4 mL ). The layers were separated and the aqueous layer was washed with ethyl ether $(3 \times 5 \mathrm{~mL})$ and acidified to pH 2 with 6 M HCl . The dark red precipitate was collected on a medium-porosity glass frit, washed with water $(20 \mathrm{~mL})$ and hexane $(10 \mathrm{~mL})$, and dried in a vacuum overnight to give dark red powder $32(30 \mathrm{mg}, 65 \%) .{ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\mathbf{4 0 0} \mathbf{~ M H z}$, acetone-d ${ }_{\mathbf{6}}$, ppm): $\delta 4.38(\mathrm{~s}, 5 \mathrm{H}$, H7), 4.85 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{H} 5$ and H 6 merge), 7.72 (s, $2 \mathrm{H}, \mathrm{H} 3$ ). ${ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}(\mathbf{1 0 0} \mathbf{~ M H z}$, acetone- $\left.\mathbf{d}_{6}, \mathbf{p p m}\right): 72.84$ (C7), 74.86 (C6), 77.85 (C5), 78.62 (C4), 120.77 (C2), 142.52 (C3), $165.90(\mathrm{C} 8)$. IR (ATR, $\left.\mathbf{c m}^{\mathbf{- 1}}\right): 1700(\mathrm{C}=\mathrm{O}), 2947-3100(\mathrm{COOH})$.

Synthesis of $\mathbf{C}_{\mathbf{1 6}} \mathbf{H}_{\mathbf{1 0}} \mathbf{C l}_{\mathbf{2}} \mathrm{FeO}_{\mathbf{2}} \mathbf{S}$ (33). In a 100 mL Schlenk flask, oxalyl chloride $(48 \mu \mathrm{~L} 0.60 \mathrm{mmol}$,$) and anhydrous DMF (5 \mu \mathrm{~L})$ were added to a stirred suspension of 32 $(50 \mathrm{mg}, 0.1 \mathrm{mmol})$ in anhydrous benzene $(10 \mathrm{~mL})$ under $\mathrm{N}_{2}$. The reaction mixture was stirred at room temperature for 5 h . The solvent was removed to yield $\mathbf{3 3}(42 \mathrm{mg}, 75 \%)$. An analytical sample was obtained by slow diffusion of hexane-saturated $\mathrm{N}_{2}$ into its ethyl ether solution through a cannula. ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\mathbf{4 0 0} \mathbf{~ M H z , ~} \mathbf{C D C l}_{\mathbf{3}}, \mathbf{p p m}$ ): $\delta 4.41(\mathrm{~s}, 5 \mathrm{H}, \mathrm{H} 7$ ), 5.06 (s, $1 \mathrm{H}, \mathrm{H} 6$ ), 5.07 ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{H} 5$ ), 8.29 ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{H} 3$ ). ${ }^{\mathbf{1 3}} \mathbf{C}\left\{{ }^{\mathbf{1}} \mathbf{H}\right\} \mathbf{N M R}\left(\mathbf{1 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}\right.$, ppm): 73.14 (C7), 76.93 (C6), 77.55 (C5), 79.35 (C4), 120.71 (C2), 153.17 (C3), 164.59 (C8). IR (ATR, $\mathbf{c m}^{\mathbf{- 1}}$ ): $1700(\mathrm{C}=\mathrm{O})$.

### 4.3 Results and Discussion

4.3.1 Synthesis. The two-fold Knoevenagel reaction of 1,2-diformylferrocene and dimethylthioglycolate sulfoxide in the presence of freshly distilled triethylamine, by slight modification of the procedure developed by Borai et al., ${ }^{214}$ gave mono- and didehydrated products 29b and 29a in a ratio of 1:2. In order to eliminate mono-dehydrated product 29b, the reaction was carried out with 16 h stirring at room temperature followed by 6 h at $60^{\circ} \mathrm{C}$. The progress of the reaction was monitored by TLC until there was no change in the reaction mixture. The compounds 29a and 29b were typically obtained in pure form by column chromatography on silica, followed by recrystallization by slow diffusion of hexane-saturated $\mathrm{N}_{2}$ into their dichloromethane solutions through a cannula. Compound 29a was a dark red solid, whereas 29b was a dark purple solid. Byproduct 29b was characterized by ${ }^{1} \mathrm{H}$ NMR, which shows an unsymmetrical pattern of substituted Cp protons in a ratio of 1:1:1. Further, the compound was characterized by IR, which shows the presence of an -OH group at $3378 \mathrm{~cm}^{-1}$ along with two carbonyl stretches at 1720 and $1743 \mathrm{~cm}^{-1}$. This also proves that $\mathbf{2 9 b}$ is an asymmetric compound.

Scheme 4.1 Synthesis of ferrocene-fused 5,7-dimethylester thiepin S-oxide
Following the procedure for the deoxygenation of 1,3-dibenzalthiophthalan 2oxide, ${ }^{215}$ ferrocene-fused 5,7-dimethylester thiepin S-oxide (29a) was reacted with 2-
chloro-1,3,2-benzodioxaphosphole to form ferrocene-fused 5,7-dimethylester thiepin (30) in good yield ( $81 \%$ ). The absence of an $\mathrm{S}=\mathrm{O}$ peak in its IR spectrum indicates the formation of deoxygenated product (30). An analytically pure compound was obtained by slow diffusion of hexane-saturated $\mathrm{N}_{2}$ into its ethyl ether solution.

Scheme 4.2 Synthesis of ferrocene-fused 5,7-dimethylester thiepin
The saponification of 29a was carried out by using KOH in refluxing methanol for 3 h to give thiepin S-oxide diacid 31 ( $47 \%$ ). ${ }^{107}$ The saponification of 30 was accomplished by using NaOH in refluxing dichloromethane/methanol for 12 h to yield thiepin diacid $32(65 \%) .{ }^{107}$ The conversion of esters to carboxylic acids was confirmed by IR spectra, which displayed a broad COOH stretch from 2626 to $3106 \mathrm{~cm}^{-1}$.

Scheme 4.3 Saponification of diesters

Scheme 4.4 Attempted decarboxylation of $\mathbf{3 1}$ and $\mathbf{3 2}$

Scheme 4.5 Attempted synthesis of ferrocene-fused thiepin (34)
Multiple attempts to decarboxylate diacids $\mathbf{3 1}$ and $\mathbf{3 2}$ ended in failure. Reactions with silver acetate/acetic acid in DMSO according to Larrosa, ${ }^{216}$ with copper powder in quinoline at $75{ }^{\circ} \mathrm{C}^{217}$ and with copper(II) phthalocyanine in $\mathrm{H}_{2} \mathrm{O} /$ ethyl ether at $40{ }^{\circ} \mathrm{C}^{218}$ all resulted in decomposition.

The Barton reductive decarboxylation is a powerful method for converting difficult carboxylic acids to alkanes. We attempted to decarboxylate diacid 32 by employing the procedure of Eun et al. ${ }^{211}$ Thiepin diacid (32) reacted with oxalyl chloride in the presence of catalytic DMF to give thiepin diacyl chloride (33) in good yield (75\%). Subsequent reaction of $\mathbf{3 3}$ with 1-hydroxypyridine-2(1H)-thione sodium salt in chloroform also resulted in decomposition. Based upon literature reports, ${ }^{189,190}$ benzannulated thiepins are thermally labile and readily undergo extrusion of sulfur to give naphthalenes. We may be observing similar chemical behavior in our system, with extrusion of sulfur from the unsubstituted ferrocene-fused thiepin $\mathbf{3 4}$ resulting in formation of $\left(\eta^{5}\right.$-cyclopentadienyl)( $\eta^{5}$-indenyl)iron (35), which decomposed under the reaction conditions. It may be possible to trap compound 35 in situ, but we made no attempt to do so.
4.3.2 Spectroscopy. New compounds were fully characterized by spectroscopic methods, including ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR, and IR. The substituted cyclopentadienyl ( Cp ) resonances in the ${ }^{1} \mathrm{H}$ NMR spectra of ferrocene-fused thiepin derivatives 29a and $\mathbf{3 0} \mathbf{- 3 3}$ display a characteristic doublet and triplet with an integration of a $2: 1$ ratio. The resonances for the outer protons (H5 in Figure 4.10) range from 4.70 to 5.20 ppm . The resonances for the inner protons (H6 in Figure 4.10) generally range from 4.66 to 5.06 ppm. The ${ }^{1} \mathrm{H}$ NMR singlet of unsubstituted cyclopentadienyl (H7 in Figure 4.10) lies between 4.28 and 4.41 ppm . The formation of byproduct 29b was indicated in the ${ }^{1} \mathrm{H}$ NMR by the ABC pattern from 4.68 to 5.21 ppm for the substituted $\mathrm{Cp}(\mathrm{H} 4, \mathrm{H} 5$ and H 6 in Figure 4.10), indicating the unsymmetrical nature of the ligand. The proton peak at 3.79 ppm in ${ }^{1} \mathrm{H}$ NMR and an OH stretch at $3373 \mathrm{~cm}^{-1}$ in IR indicate the presence of a
hydroxyl group in 29b, a mono-dehydrated product of a double Knoevenagel reaction. The methyl ester protons for compounds 29a, 29b and 30-33 range between 3.79 and 3.89 ppm .

The ${ }^{13} \mathrm{C}$ NMR of 29b shows a resonance of unsubstituted Cp carbon at 70.84 ppm, whereas for the complexes 29a and $\mathbf{3 0} \mathbf{- 3 3}$ it ranges between 72.13 to 73.14 ppm . The Cp carbon resonances for the ferrocene-fused thiepin derivatives 29a and $\mathbf{3 0}-\mathbf{3 3}$ consist of a set of three resonances attributed to the inner position (74.86-77.06 ppm, C6), the outer positions ( 77.55 to $78.76 \mathrm{ppm}, \mathrm{C} 5$ ) and the ipso positions ( 78.62 to 80.21 ppm, C4) as shown in Figure 4.10. The ester carbonyl carbon resonances of 29a, 29b, 30, and carboxylic acid carbonyl carbon resonances of $\mathbf{3 1}$ and $\mathbf{3 2}$ display between 164.50 and 169.32 ppm , typical of organic carbonyls. The IR spectra of 29a, $\mathbf{3 0}$ and $\mathbf{3 3}$ display carbonyl stretching between 1700 and $1720 \mathrm{~cm}^{-1}$ typical of $\alpha, \beta$ unsaturated organic ester compounds, and the IR spectra of $\mathbf{3 1}$ and $\mathbf{3 2}$ exhibit very broad COOH absorbances from 2856 to $3106 \mathrm{~cm}^{-1}$. Table 4.1 shows some selected ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR and IR data for compounds 29a, 29b and 30-33.

Solvent: $\mathrm{a}=\mathrm{CDCl}_{3}, \mathrm{~b}=$ acetone- $\mathrm{d}_{6}$
4.3.3 Structure. Single crystals of 29a, 29b and 33 were grown by slow evaporation of dichloromethane solutions with a stream of hexane-saturated $\mathrm{N}_{2}$ through a cannula; a single crystal of $\mathbf{3 0}$ was grown by slow evaporation of ethyl ether solution by the diffusion of hexane-saturated $\mathrm{N}_{2}$ through a cannula. The structures of $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\right.\right.$ $\left.\left.\mathrm{C}_{5} \mathrm{H}_{3}(\mathrm{CHCCOOMe})_{2} \mathrm{SO}\right\}\right]$ (29a), $\left[\mathrm{Fe}\left\{(\mathrm{Cp}) \eta^{5}-\right.\right.$ $\left.\left.\mathrm{C}_{5} \mathrm{H}_{3}(\mathrm{CHCCOOMeCHOHCHCOOMeSO})\right\}\right]$ (29b), $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}(\mathrm{CHCCOOMe})_{2} \mathrm{~S}\right\}\right]$ (30), $\left[\mathrm{Fe}(\mathrm{Cp})\left\{\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{3}(\mathrm{CHCCOCl})_{2} \mathrm{~S}\right\}\right]$ (33) were determined by X-ray crystallographic methods. Thermal ellipsoid plots with numbering schemes are shown in Figures 4.11 to 4.14. The crystal structure and refinement data for compounds $\mathbf{2 9} \mathbf{a}, \mathbf{2 9 b}, \mathbf{3 0}$ and $\mathbf{3 3}$ can be found in Tables 4.2 to 4.3. Bond distances and angles for 29a, 29b, $\mathbf{3 0}$ and $\mathbf{3 3}$ can be found in Tables 4.4 to 4.7.

The ferrocene complexes 29a, 29b, 30 and 33 show the typical ferrocene geometry. The average bond distances of metal to substituted Cp are 2.048(3) $\AA$ for 29a, $2.048(2) \AA$ for 29b, $2.046(3) \AA$ for $\mathbf{3 0}$ and 2.046(3) $\AA$ for 33. Similarly, the average bond distances of metal to unsubstituted Cp are 2.050(3) $\AA$ for 29a, 2.052(3) $\AA$ for 29b, $2.056(3) \AA$ for 30 and 2.060 (3) $\AA$ for 33. The average bond distances of iron to the centroids of substituted Cp and unsubstituted Cp are 29a [1.646(3) $\AA, 1.657(3) \AA$ ], 29b $[1.646(2) \AA, 1.655(2) \AA], \mathbf{3 0}[1.644(3) \AA, 1.664(3) \AA]$, and $33[1.718(3) \AA, 1.667(3) \AA]$.

The SO groups of complexes $\mathbf{2 9} \mathbf{a}$ and $\mathbf{2 9 b}$ are exo with respect to the iron center. The ester groups are positioned in the least-squares plane of Cp and the seven-membered ring. The molecular structure of $\mathbf{2 9 b}$ shows that the ester on C 7 is exo and the hydroxy on C8 is endo to the iron center. The endo orientation of the hydroxy group and the mutually cis orientation of the hydrogen atom on C7 may explain the failure of the $\mathrm{C} 7-\mathrm{C} 8$ bond to
dehydrate under basic (E2) conditions.. The interplanar angle between C4-C3-C2-C1-C5-C9 and C12-C8-S1 of complex $\mathbf{3 0}$ is $7.12^{\circ}$. The sulfur-oxygen bond distances of 29a and 29b are $1.495(2) \AA$ and $1.5008(19) \AA$, which are close to the $S=O$ bond distance $\left[(1.431(3) \AA\right.$ and $1.436(3) \AA]$ in benzo[b]thiepin 1,1-dioxide. ${ }^{193}$

### 4.4 Summary

Two-fold Knoevenagel reaction of 1,2-diformylferrocene with dimethylthioglycolate sulfoxide in the presence of triethylamine resulted in ferrocenefused 5,7-dimethylester thiepin S-oxide along with the mono-dehydrated byproduct 29b with a ratio of $2: 1$. The formation of mono-dehydrated product $\mathbf{2 9 b}$ was indicated by the ABC pattern of substituted $C p$ in ${ }^{1} H$ NMR. 29b was fully characterized with a single $X$ ray crystal structure. The analysis of the molecular structure of 29b showed that the hydroxyl and hydrogen groups were oriented endo with respect to the iron center. The molecular structure of 29a and 29b displayed that the SO groups were directed exo with respect to the iron center.

To study the reactivity of ferrocene-fused thiepin S-oxide and ferrocene-fused thiepin in the further reaction steps, ferrocene-fused 5,7-dimethylester thiepin (30,81\%) was synthesized via deoxygenation of ferrocene-fused 5,7-dimethylester thiepin S-oxide with 2-chloro-1,3,2-benzodioxaphosphole in the presence of pyridine. Saponification of the resulting ferrocene-fused 5,7-dimethylester thiepin was carried out by using a methanolic solution of NaOH in dichloromethane at reflux temperature of dichloromethane for 12 h to yield ferrocene-fused 5,7-dicarboxylic acid thiepin (32). The diester complex of ferrocene-fused thiepin S-oxide (29a) was hydrolyzed to the corresponding dicarboxylic acid (47\%) using KOH in methanol for 3 h at reflux temperature.

Attempts to decarboxylate complexes $\mathbf{3 1}$ and $\mathbf{3 2}$ using copper powder in quinoline, $\mathrm{AgCO}_{3} / \mathrm{AcOH}$ in DMSO and copper(II) phthalocyanine in $\mathrm{H}_{2} \mathrm{O}$ /ethyl ether
resulted in decomposition. The Barton reductive decarboxylation of $\mathbf{3 2}$ by conversion to its acid chloride followed by reaction with 1-hydroxypyridine-2(1H)-thione sodium salt also resulted in decomposition. We have been unable to find suitable reaction conditions for the decarboxylation of $\mathbf{3 1}$ or $\mathbf{3 2}$.

In summary, ferrocene-fused 5,7-dimethylester thiepin S-oxide was synthesized using a two-fold Knoevenagel reaction. Deoxygenation of 29a with 2-chloro-1,3,2benzodioxaphosphole resulted in corresponding thiepin (30). The saponification of 29a and $\mathbf{3 0}$ resulted in diacids $\mathbf{3 1}$ and $\mathbf{3 2}$. Attempts to decarboxylate $\mathbf{3 1}$ and $\mathbf{3 2}$ under different reaction conditions were unsuccessful. Ferrocene-fused 5,7-disubstituted thiepin derivatives are dark red solid. Organometallic thiepins are not common in chemistry literature. The first transition metal complex of thiepin, benzo[b]thiepin(tricarbonyl)iron was reported by Nishino et.al in $1988 .{ }^{205}$ Organometallic thiepin 29a is more stable than the heavily substituted benzo[b]thiepin S-oxide (6 of Chart 4.5). We can explore the electrochemical polymerization of $\mathbf{3 0}$ and the resultant compound may be a potential candidate for organometallic semiconducting material.

## Chapter 5 Conclusions and Future Directions

Chapter 2 focused upon the synthesis of mononuclear and binuclear organometallic acenequinones by using a classic organic reaction that has served well for making organic acenes (aldol condensation). The key precursor in the preparation of organometallic acenes is 1,2-diformylferrocene, which was prepared by using a welloptimized literature procedure. Cp-capped acenequinones were synthesized from organometallic acenequinones by demetalation with saturated, aqueous sodium dithionite in THF. The resultant acenequinones were aromatized into corresponding TIPS acenes using a classic method of converting acenequinones to useful acenes. We have studied their structural and physical properties, including oxidation and reduction processes. Cp capped TIPS acenes ( $\mathbf{2 1}$ and $\mathbf{2 2}$ ) exhibit a 2-D brickwork structure in single crystals. The HOMO energy level and the important HOMO-LUMO gap of Cp-capped TIPS acenes were measured using cyclic voltammetry. The optical energy gap of Cp-capped TIPS acenes was calculated from UV-vis spectra. Finally, we have investigated the OFET performance of 21 and 22 and observed hole mobilities of $0.03 \mathrm{~cm}^{2} /(\mathrm{V} \mathrm{s})$ and 0.02 $\mathrm{cm}^{2} /(\mathrm{V} \mathrm{s})$, respectively.Continuing research will further explore synthetic approaches to prepare extended benzannulated organometallic acenequinones and corresponding organometallic acenes, and investigate their structural and physical properties including important parameters for organometallic semiconducting materials.

Scheme 5.1 Synthesis of extended $\pi$-conjugated organometallic acenequinones
Chapter 3 demonstrated the synthetic approaches to prepare unsubstituted and phenyl-substituted ferrocene-fused tropones by using two-fold aldol condensation. We have synthesized ferrocene-fused thiotropone and a detached 5,7-diphenylazulenethiol by reacting 23 and 24 a with Lawesson's reagent. Furthermore, the reaction of 26 with hydroxylamine resulted in ferrocene-fused tropone oxime. Tropones 23 and 24a have HOMO energy levels of -5.06 eV and -4.99 eV measured by cyclic voltammetry. The UV-vis spectra of all the tropone derivatives were recorded. Among those derivatives, ferrocene-fused thiotropone has unique physical (color) and optical properties (visible region absorption). Continuing research will study the electrochemical properties of ferrocene-fused thiotropones and investigate synthetic routes to prepare ferrocene-fused dicyanoheptafulvene.

Scheme 5.2 Synthesis of ferrocene-fused dicyanoheptafulvene
Chapter 4 focused on the synthesis of ferrocene-fused 5,7-disubstituted thiepins and thiepin S-oxides. We have been unable to find suitable reaction conditions for the decarboxylation of $\mathbf{3 1}$ or $\mathbf{3 2}$ to prepare an unsubstituted ferrocene-fused thiepin or thiepin S-oxide. Future research will examine the physical properties, including oxidation processes and UV absorption of the synthesized ferrocene-fused 5,7-disubstituted thiepin and thiepin S-oxide derivatives. Moreover, the electrochemical polymerization of ferrocene-fused 5,7-dimethylester thiepin may be explored in continuing research. In addition, synthetic approaches to ferrocene-fused 5,7-diphenylthiepin and ferrocenefused 5,7-dicyanothiepin will be examined.

## Vita

Bidhya L. Maharjan was born in Kathmandu, Nepal. She enrolled at Tri-Chandra College, Kathmandu Nepal, where she majored in Chemistry/Biology and graduated with a B. Sc in 2001. She attended Tribhuvan University, Kathmandu Nepal and graduated in 2003 with a Master Degree in Chemistry. She enrolled in the graduate program at the University of Kentucky in January 2007 and joined the research group of Dr. John P. Selegue in May 2009. She is a member of the Kentucky Academy of Science, American Chemical Society and its Organic and Organometallic Divisions.

## Awards

- First position in the Kentucky Academy of Sciences for oral presentation, University of Morehead, November 2013
- Outstanding Teaching Assistant Award, Department of Chemistry, University of Kentucky, May 2013

## TEACHING EXPERIENCE

- 2010-2015: Teaching Assistant for Organic Chemistry lab courses. University of Kentucky, Lexington. (CHE 233 \& 231)
- 2009-2010: Teaching Assistant for General Chemistry lab courses, University of Kentucky, Lexington. (CHE 111 \& 113)
- 2005-2007: Assistant Lecturer of Chemistry: Organic Chemistry lab, Department of Chemistry, Tribhuvan University, Nepal

## PROFESSIONAL AFFILIATION

- American Chemical Society
- Kentucky Academy of Science
- Nepal Chemical Society

## CONFERENCE ORAL PRESENTATIONS

- 2014: American Chemical Society National Meeting, Dallas, TX: Synthetic Approaches to Ferrocene-Fused Tropones, Thiotropones and Tropone Oximes
- 2013: American Chemical Society National Meeting, New Orleans, LA: Synthetic Approaches to Cyclopentadiene-Capped Acenes \& Their Iron Complexes
- 2013: Kentucky Academy of Science Annual Meeting, Morehead, KY: Synthetic Approaches to Cyclopentadiene-Capped Acenes \& Their Iron Complexes

## CONFERENCE POSTER PRESENTATIONS

- 2015: Naff Symposium on Chemistry and Molecular Biology metals and Proteins, University of Kentucky, Lexington, KY: Synthesis and Characterization of Ferrocene-Fused Tropones, Thiotropones and Tropone Oximes
- 2012: Naff Symposium on Chemistry and Molecular Biology metals and Proteins, University of Kentucky, Lexington, KY: Synthetic Approaches to Cyclopentadiene-Capped Acenes \& Their Iron Complexes
