ACKNOWLEDGEMENTS

An expression of sincere appreciation is extended to Carla Crossfield and Louise Hensley for their significant contributions to the completion of this research report. Without their assistance in summarizing, analyzing, and preparing the report, it would have been difficult to meet the deadline requirement.

INTRODUCTION

An annual highway safety program is prepared each year for the state of Kentucky in order to comply with Section 402, Title 23 of the United States Code. This program includes the identification, programming, budgeting, and evaluation of safety projects with the objective of reducing the number and severity of traffic accidents. This is the fifth in a series of annual reports that have been included as the problem identification portion of Kentucky's Annual Highway Safety Plan (1, 2, 3, 4).

In the past, the approach to problem identification has been to identify problem areas in the 18 highway safety program areas (standards). While the search for problems in each of these standard areas will continue, certain program areas have been identified for emphasis. Currently, those areas include 1) Alcohol and 2) Occupant Protection.

To identify problems in these "program emphasis" areas as well as any of the other "highway standard" areas, 12 problem identification areas were investigated:

1. County Accident Statistics,
2. City Accident Statistics,
3. Alcohol- and Drug-Related Accidents,
4. Occupant Protection,
5. Speed-Related Accidents and 55 mph National Maximum Speed Limit,
6. Pedestrian Accidents,
7. Bicycle Accidents,
8. Motorcycle Accidents,
9. School Bus Accidents,
10. Vehicle Defects,
11. General Trend Analysis, and
12. Accidents by Police Reporting Agency.

The "Records Analysis for Problem Identification and Definition (RAPID)" computer software package was used for analyses. Except where noted otherwise, all accident analyses were for a 5-year period (1978-1982).

In this report, problems that have contributed to the number and severity of traffic accidents were identified. Problem areas associated with any of the "highway standard" areas were

investigated, with the "program emphasis" areas receiving particular attention. Recommendations were made for programs that could serve as countermeasures for the highway safety problems which were identified. Recommendations were also made for studies with the objectives of developing and evaluating such programs.

PROBLEM AREAS INVESTIGATED

COUNTY ACCIDENT STATISTICS

As in previous problem identification reports, average accident rates were calculated for each county (Table 1). Vehicle-miles travelled was the exposure measure used in the accident rate analyses. These rates were used to identify the counties, by population category, having the highest accident rates. The rates were also used, together with other statistics, in analyses of other problem identification areas.

Rates, in terms of accidents per 100 million vehicle-miles, were calculated for the categories of total accidents, fatal accidents, and injury-or-fatal accidents. Vehicle-miles-travelled data were for a 5-year period (1978-1982). To assist in the analysis of county accident statistics, county populations in descending order were tabulated and presented in Table 2. Miles travelled in 1981 and 1982 were determined from the statewide mileage tape and added to the 1978-1980 total presented in a previous report (4). This figure represents total miles driven in each county. It was obtained by adding the known miles driven on the state-maintained highway system and the estimated miles driven on the remaining streets and highways.

Average and critical accident rates were calculated for each county population category (Table 3). The critical accident rate was calculated using the following formula:

$$A_c = A_a + K(\text{SQRT}(A_a/m)) + 1/(2m) \text{ in}$$

which A_c = critical rate,
 A_a = average rate,
 K = constant related to level of statistical significance selected

(for $P=0.995$, $K=2.576$),
SQRT = square root, and
 m = annual mileage driven
per county.

Critical rates (in terms of accidents per 100 million vehicle-miles) were calculated for total accidents, fatal accidents, and injury-or-fatal accidents. The numbers of counties having rates above critical in each population category were determined. The total number was 40 for total accidents, 24 for injury-or-fatal accidents, and one for fatal accidents.

Presented in Table 4 are numbers of accidents and accident rates for all counties grouped by population category. It should be noted that population categories have been changed since the last report (4). A more balanced number of counties within each category results. Counties within each population category are listed in order of descending accident rate with the critical rates identified. Those counties having the highest rates in each of the population groups were Carroll, Lewis, Mason, Franklin, and Campbell. The four highest accident rates in the state were in counties in the group with populations over 50,000. They were Campbell, Kenton, Fayette, and Jefferson counties. Because of the use of a 5-year

data base, counties identified as having critical accident rates in Table 4 should represent relatively long-term accident problems.

An alternative to using total accidents is to exclude property-damage-only accidents and use only injury-or-fatal accidents. All counties, by population category, having injury-or-fatal accident rates at or above critical are given in Table 5. Counties having the highest rates for their population categories were Trigg, Magoffin, Marion, Henderson, and Campbell. Presented in Table 6 are fatal accident rates for counties listed by population category. Only Pike County had a fatal accident rate that was determined to be critical.

A summary of the other miscellaneous accident data used in the problem identification process is presented by county in Table 7. This table includes number of accidents by county by year; percent change in the 1982 accident total from the previous 4-year average; percentages of accidents involving alcohol, drugs, and speeding; percentage of fatal accidents; percentage of injury-or-fatal accidents; and percentage of drivers using safety equipment.

TABLE 1. ACCIDENT RATES BY COUNTY (1978 - 1982 DATA)

COUNTY	TOTAL NUMBER OF ACCIDENTS	POPULATION	VEHICLE MILES (100 MILLION)	ACCIDENTS PER 100 MILLION			NUMBER OF LICENSED DRIVERS	NUMBER OF REGISTERED VEHICLES	NUMBER OF FATAL ACCIDENTS	ACCIDENTS PER 100 MILLION VEHICLE MILES	NUMBER OF FATAL OR INJURY ACCIDENTS	FATAL AND INJURY ACCIDENTS PER 100 MILLION VEHICLE MILES
				VEHICLE MILES	VEHICLE MILES	VEHICLE MILES

CITY ACCIDENT STATISTICS

Accident statistics were analyzed for cities using 1978 through 1982 accident data. The primary group of cities included in the analysis were those having a population over 2,500 that were incorporated and had a police agency. Incorporated cities were eliminated if they did not have a police agency even though they were listed in the 1980 census. This analysis of city accident statistics is different from that of previous years because some cities in Jefferson County, such as St. Matthews, Jeffersontown, and Shively, were included separately from Louisville because of a desire to analyze accidents for each police reporting agency. Therefore, only the Louisville city area was included with a population of 298,451 as compared to a metropolitan area population of 490,095 used in last year's problem identification report (4).

Presented in Table 8 is a summary of detailed accident statistics for cities having populations more than 2,500 that are incorporated and have police agencies. Included in this table were 110 cities. Rates were calculated in terms of accidents per 1,000 population, because the total number of vehicle-miles traveled in each city was not known. Rates were calculated for all accidents as well as

fatal, pedestrian, bicycle, and motorcycle accidents. The percentages of accidents involving speeding and alcohol also were determined. As supplemental information, accident statistics for all cities listed in the 1980 census were summarized in Table 9. Included for 369 cities were population, number of accidents, and accident rate.

Average and critical accident rates by population category were calculated and are shown in Table 10. Only those cities having populations more than 2,500 that were incorporated and had a police agency were included. Critical fatal accident rates were not tabulated because no cities were found to have rates that exceeded the critical rate. Total accident rates for cities by population category are listed in Table 11. They are tabulated in order of descending accident rates and critical rates are identified. A total of 27 cities were identified as having total accident rates above critical. Louisville, Bowling Green, Florence, Maysville, and Pikeville had the highest rates in their respective population ranges. Fatal accident rates, by city and population category, are listed in Table 12. They also are tabulated in order of descending fatal accident rates and there were no cities with rates above critical.

TABLE 8. ACCIDENT DATA FOR CITIES WITH POPULATION OVER 2,500 (INCORPORATED CITIES WITH POLICE AGENCIES)

CITY	POPULATION	NUMBER OF ACCIDENTS PER 1,000 (1978-1982)	ANNUAL ACCIDENTS PER 1,000 POPULATION	NUMBER OF FATAL ACCIDENTS (1978-1982)	ANNUAL FATAL ACCIDENTS PER 10,000 POPULATION	NUMBER OF PEDESTRIAN ACCIDENTS (1978-1982)	ANNUAL PEDESTRIAN ACCIDENTS PER 10,000 POPULATION	NUMBER OF BICYCLE-RELATED MOTOR VEHICLE ACCIDENTS (1978-1982)	ANNUAL BICYCLE-RELATED ACCIDENTS PER 10,000 POPULATION	NUMBER OF MOTORCYCLE ACCIDENTS (1978-1982)	ANNUAL MOTORCYCLE ACCIDENTS PER 10,000 POPULATION	PERCENT OF ACCIDENTS INVOLVING SPEEDING	PERCENT OF ACCIDENTS INVOLVING ALCOHOL

ALCOHOL- AND DRUG-RELATED ACCIDENTS

Alcohol- and drug-related accidents continue to be one of the highest priority problem identification areas and considerable emphasis is being placed on programs to impact the problems. Over the past 10 years, the number of highway deaths involving alcohol nationwide has averaged approximately 25,000 per year. Economic losses due to drunk driving are also staggering. A conservative estimate of the total economic cost of drunk driving is between five and six billion dollars per year. In Kentucky, the number of alcohol-related accidents has averaged slightly over 10,000 each of the past five years. Alcohol-related fatal accidents have averaged 193 during the past five years. When the costs of a fatality and an injury are considered, the estimated annual cost of alcohol-related accidents in Kentucky is \$86 million.

The effectiveness of alcohol enforcement programs has had varied results over a period of years in various parts of the country. In Kentucky, several enforcement programs are currently in progress and it is too early to determine their effectiveness, except for the Lexington Traffic Alcohol Program. Preliminary results from the program of increased enforcement in Lexington show a significant reduction (29.7 percent) in alcohol-related accidents during the enforcement hours of the program. In addition, the number of DUI arrests increased from 929 in the year before to 4,427 during the first year of the program. Of those arrested, 95 percent have been convicted of DUI. Public acceptance of the program has been very good. Results from a survey of registered vehicle owners show 78 percent felt the program reduced their chances of involvement in an alcohol-related accident and 85 percent favored increased enforcement as a means of reducing drunk driving. Overall, the program has been determined to be one of the most successful of its type ever undertaken. Implementation of enforcement programs similar to the Lexington project could have major impact on the drunk-driving accident problem.

To identify alcohol-related accident problem areas, percentages of accidents involving alcohol were summarized for counties and cities as shown in Tables 13 and 14, respectively. In Table 13, number and percentage of accidents involving alcohol were listed by county population group in order of descending percentages. Counties in each population category having the highest percentage of accidents involving alcohol are Menifee, Bath, Meade, Nelson, and Madison. Table 14 is a summary of number and percentage of accidents involving alcohol for cities. For each population category, cities having the highest percentages of accidents involving alcohol are Lexington, Covington, Fort Thomas, Dayton, and Vine Grove.

Additional analyses were performed to show number and rate of convictions by county (Table 15). Rates are in terms of convictions per 1,000 licensed drivers and convictions per alcohol-related accident. Those same rates are presented in Table 16 with counties grouped by population ranges and rates listed in order of descending percentages. Counties in each population group having the lowest rates of alcohol convictions per 1,000 licensed drivers were Owen, Magoffin, Knott, Graves, and Pike. Counties having the lowest rates of alcohol convictions per alcohol-related accident were Trimble, Magoffin, Knott, Perry, and Pike. Counties having low rates for either convictions per 1,000 licensed driver or convictions per alcohol-related accident may be candidates for increased enforcement or other special programs. Data in Table 15 show there was a 31.2 percent increase, statewide, in the number of alcohol convictions in 1982 when compared to 1981. The largest increase occurred in Fayette County, apparently as a result of the Traffic Alcohol Program, which was started in May 1982.

In many cases, it has been determined that a drunk-driving offense may be reduced to a charge of reckless driving. That occurs when a person is arrested for drunk driving because of erratic driving behavior and field sobriety or BAC tests fail to confirm the drunk-driving charge. In addition, the severity of the penalty

for drunk driving has influenced many police officers to reduce the drunk-driving charge to reckless driving. Similarly, the judicial system has been at fault in many cases. For these reasons, it was determined that a summary of reckless driving convictions would be beneficial. Presented in Table 17 are numbers of reckless driving convictions and the rate of convictions per 1,000 licensed drivers for each county. Data in Table 17 show there was a 24.4 percent reduction in reckless driving convictions when 1982 data were compared with data of the previous 4 years.

Even though drugs were listed as a contributing factor in a relatively small

percentage of all accidents, there has been a general upward trend in those types of accidents during the 1978-1982 study period. Presented in Table 18 are percentages of accidents involving drugs by county and population category. Within each population category, counties having the highest percentages of drug-related accidents were Lee, Martin, Rowan, Boone, and Kenton. Another summary was prepared to show percentages of accidents involving drugs by city population categories (Table 19). Within each population category, cities having the highest percentages of drug-related accidents were Lexington, Covington, Georgetown, Independence, and Beaver Dam.

OCCUPANT PROTECTION

The percentage of drivers or passengers involved in traffic accidents who wore safety belts is listed by county in Table 7. Drivers of passenger cars were used in the analysis so comparisons could be made to observational surveys being conducted across the state. These percentages are listed in descending order by county population category in Table 20. The rates varied from a high of 9.1 percent in Fayette County to a low of 0.5 percent in Estill and Adair counties. Counties having the greatest potential for intensive promotion campaigns are identified. Those counties were selected on the basis of their safety belt usage, accident rate, and location in the state. ~~Counties having low usage rates and high accident rates were identified. Also, an effort was made to select counties so they would be distributed in the various state police posts across the state. A total of 26 counties was identified.~~

The variance of safety belt usage by year from 1978 through 1982 is given in Table 21 along with the relationship between county population and safety belt usage. The percentage using safety belts decreased from 1978 to 1980 and then increased slightly in 1981 and 1982. However, it did not increase to the levels of 1978 and 1979. Those usage percentages for accident-involved drivers agree well with the 4.2 percent usage determined from a 1982 observational survey (5). This table also shows the large increase in usage for counties having over 50,000 population.

Safety belts are recognized as an effective method of reducing accident severity. This is confirmed by data presented in Table 22. This table shows that, when a driver of a motor vehicle is wearing a safety belt at the time of an accident, the chances of being fatally injured is reduced by 77 percent. Also, the chance of receiving an incapacitating injury is reduced by 46 percent and the chance of receiving a non-incapacitating injury is reduced by 17 percent. The reduction for the less severe injury is less. Safety belts will greatly decrease the possibility of injury in accidents

involving large deceleration forces, but some injury or complaint of soreness or discomfort will exist. In fact, the category of "possible injury" involving a complaint of pain without visible signs of injury increased from 4.56 percent for drivers not wearing safety belts to 4.81 for drivers wearing safety belts.

There has been a gradual increase in the percentage of drivers sustaining given injuries over the past few years (Table 23). For example, the percentage of incapacitating injuries for drivers not wearing a safety belt has increased from 1.96 percent in 1978 to 2.49 percent in 1982. For drivers wearing safety belts, the percentage increased from 0.94 percent in 1978 to 1.50 percent in 1982. That may be related to the high number of small cars on the highways.

Potential savings associated with increased safety belt usage were estimated and are shown in Table 24. This table lists the annual potential dollar savings in the event all drivers wore safety belts. The total numbers of drivers sustaining either a fatal, incapacitating, or non-incapacitating injury for the years 1978 through 1982 were determined. Percentages listed in Table 22 for drivers using safety belts provided estimates of the number of drivers who would have sustained the given injury in the event all drivers used safety equipment. Annual reductions for the various injuries were calculated. The 1981 National Safety Council costs for injuries resulting from motor-vehicle accidents were used to compute an annual potential savings of 97.6 million dollars in the event all drivers in Kentucky wore a safety belt. A potential dollar savings in accident costs of about one million dollars may result for each one percent increase in safety belt usage by drivers in Kentucky.

A summary of usage and effectiveness of child safety seats for children under the age of four who were involved in traffic accidents is given in Table 25. Data are for 1978 through 1982. Age categories in the RAPID accident file governed the age category that was used. Most children three years of age or younger would be placed in a child

restraint rather than a seatbelt or harness. However, many were coded as wearing a safety belt, so the categories of restraint used were 1) none, 2) safety belt or harness, 3) child safety seat, and 4) any restraint.

Of the 65 fatalities occurring during the study period, only five involved use of a restraint. Also, of 470 incapacitating injuries, only 19 involved use of a restraint. However, since the reported usage of restraints for those involved in accidents is low, a better measure of effectiveness would be the percentage sustaining a specific injury. This analysis revealed the percentage of fatalities was lowest for children who were in a child safety seat. This percentage was slightly higher for the "safety belt or other" category compared to the "none" category.

The larger sample size of severe (incapacitating) injuries should provide more reliable results. It was determined that the percentage of restrained children receiving a severe injury was about one-third that for unrestrained children. The percentage of restrained children receiving a non-incapacitating injury was also substantially lower than that for unrestrained children. The comparison of

incapacitating and non-incapacitating injuries did not indicate an advantage of child restraints over a safety belt or harness. However, the percent ejected was lowest for the child safety seat.

An analysis of injury by seat position indicated rear-seat restraints as being more effective. Of the five fatalities involving restrained children, the children were sitting in the middle-front-seat position.

An analysis of the percentage of children in restraints revealed the percentage was highest for rear-seat locations. A comparison of percent usage by year indicated usage has increased substantially. That is in contrast to a slight decline in total seatbelt usage from 1978 to 1982. Increased usage of child restraints may be partly attributed to a law that became effective in July 1982. That law required the use of child safety seats for children 40 inches in height or less. A survey of child safety seat usage was conducted in 1982 before the new law became effective and it was determined that 15.4 percent of affected children used a restraint (5). That compares well with the percentage determined in this analysis.

SPEED-RELATED ACCIDENTS AND 55 NATIONAL MAXIMUM SPEED LIMIT

Speed has been observed to be one of the most common contributing factors in total accidents and fatal accidents. However, the number of speed-related accidents has decreased gradually for the 1978 through 1982 study period, as has total accidents. Speed-related fatal accidents have remained about the same over the 5-year period. As a means of addressing the subject, accidents involving unsafe speeds were summarized by county and population category in Table 26. When arranged in order of decreasing percentages of speed-related accidents, those counties having the highest percentages in each population category were Wolfe, Leslie, Knott, Letcher, and Pike. There appears to be a concentration of counties having a high percentage of speed-related accidents in the southeastern section of the state. A similar summary of accidents involving unsafe speeds for cities was prepared and is presented in Table 27. Those cities having the highest percentages in each population category were Louisville, Hopkinsville, Radcliff, Independence, and Jenkins.

In addition to accident analysis, the other major area of analysis for unsafe speed was speeding convictions. Areas having large percentages of accidents involving speeding and low conviction rates are candidates for increased enforcement. Table 28 presents a summary of speeding convictions by county. Numbers of speeding convictions, speeding convictions per 1,000 licensed drivers, and speeding convictions per speed-related accident are included. Statewide, the number of speeding convictions in 1982 was 27.8 percent lower than the annual average from 1978 through 1981. To assist in identifying areas having the potential for increased enforcement, Table 29 was prepared with speeding conviction rates listed in descending order by county population categories. Within each population category, those counties having the lowest speeding conviction rates per 1,000 licensed driver are Menifee, Monroe, Knott, Letcher, and Pike. Counties having

the lowest rates of speeding convictions per speed-related accidents are Menifee, Morgan, Knott, Letcher, and Pike.

The relationship between speeds and accident rates was investigated in an earlier study (6). Accident rates were observed to increase as speeds increased. The relationship was more pronounced for wet-surface accidents. It was concluded that continuation of the 55-mph speed limit on all rural highways would be advisable.

The percentage of vehicles exceeding the 55-mph speed limit has been monitored and reported by the Kentucky Department of Highways on a quarterly basis since 1978. A summary of data for the fiscal year ending September 30, 1982, is given in Table 30. That summary shows 429,279 vehicles were monitored at 50 locations. The percentage of vehicles exceeding 55 mph on all roads was 36.4 percent. The average speed was highest on sections of rural interstate and lowest on urban arterials. Only 10 percent of the vehicles were exceeding the 55-mph limit on urban arterials as compared to 70 percent on sections of rural interstate.

Another summary was prepared to show overall compliance with the 55-mph speed limit from 1979 through 1982 (Table 31). When considering statewide totals, the percentage of vehicles exceeding 55 mph in 1982 (36.4 percent) increased as compared to the three previous years (an average of 29.3 percent). On urban interstates, the increase in 1982 was even more significant. However, on rural interstates, the percent exceeding 55 mph was considerably less than the previous three-year average. It should be noted that, beginning July 1982, some significant changes occurred in data collection requirements that may have affected the reported speed data. The primary difference was a change from monitoring the speed of the first vehicle in a queue to monitoring all vehicles in the traffic stream. In addition, the change from radar meters to automatic speed monitoring equipment has enabled data collection to include 1,200 hours measurement in 1982 as compared to 162 hours in 1981. The number of vehicles

measured has also increased tremendously, from 24,397 in 1981 to 429,279 in 1982. Because the automatic speed monitoring equipment measures data only within five-mile-per-hour ranges, the precise speed

cannot be determined. Therefore, speed data reported for 1982 is a weighted average for the various speed ranges and may be expected to fall somewhere in a five-mile-per-hour range.

GENERAL ACCIDENT STATISTICS

Several types of general statistics were developed for use in analyses of specific problem areas. Included were accident trends over a five-year period, a summary of accidents by police reporting agency, and several types of statistics for accidents involving pedestrians, bicycles, motorcycles, and school buses.

Accident Trend Analysis

An analysis of accident trends over the five-year period is summarized in Table 32. The change in 1982 accidents was compared to an average of the preceeding four years (1978-1981). There was a substantial reduction in total accidents, as well as fatalities and injuries, when comparing 1982 to the previous four years.

There was a total of 677,541 accidents in the five-year period, of which 3,808 were fatal and 139,479 were injury accidents. Those accidents resulted in 4,287 fatalities and 211,200 injuries. Using 1981 National Safety Council motor-vehicle cost estimates yields an average annual cost of 576 million dollars for motor-vehicle accidents in Kentucky for the period 1978 through 1982.

A listing of numbers of accidents reported by various police agencies is presented in Table 33. For each agency listed, the numbers of accidents reported for 1978 through 1982 are listed. An average per year for 1978 through 1981 is listed, as well as the percent change of the 1982 total from that average. Agencies are listed in descending order of the three-year average and only the 130 agencies having the highest number of accidents are listed. Those 130 agencies account for 95 percent of the total accidents reported in Kentucky. The highest number of accidents was reported by the Kentucky State Police, followed by the Louisville Police Department, the Jefferson County Police Department, and the Lexington-Fayette County Police Department.

There was a substantial decrease in number of reported accidents for 1980 through 1982 when compared to 1978 and 1979. There was a 12.2 percent decrease

in total reported accidents in 1982 compared to the average for 1978 through 1981. Also, of the 130 agencies listed in Table 33, 96 (72 percent) showed a decrease in accidents in 1981 compared to the 1978 through 1980 average. There were some large changes in reported accidents that may be attributed to changes in reporting responsibility.

Analysis of contributing factors (human, vehicular, and roadway) presented in Table 34 also was used in problem identification. The percentage of accidents in which a factor was listed as a contributing factor was summarized for various accident types. Included are total accidents, fatal accidents, and accidents involving pedestrians, bicycles, motorcycles, and school buses.

Presented in Table 35 are additional general statistics compiled by county for accidents involving pedestrians, bicycles, motorcycles, and school buses. Included were numbers of accidents and average annual accidents per 10,000 population. Another table was prepared summarizing accident severity for various accident types. Included in Table 36 are percentages of fatal and injury accidents for all accidents and for accidents involving pedestrians, bicycles, motorcycles, and school buses.

Pedestrian Accidents

A summary of pedestrian accident statistics by county and population category is presented in Table 37. Included are numbers of accidents and annual accident rates per 10,000 population. From the listing of accident rates in descending order, the following counties had the highest rates in each population category: Ballard, Caldwell, Bourbon, Henderson, and Kenton. A similar analysis was performed for pedestrian accidents by city and population category. Results are summarized in Table 38 and the following cities had the highest rates in their respective population categories: Louisville, Newport, Somerset, Mt. Sterling, and London.

As previously noted, accident-contributing factors were summarized for several vehicle types in Table 34. The

most common human factors associated with pedestrian accidents were driver inattention, failure to yield right of way, unsafe speed, and alcohol. The most common vehicular contributing factor was defective brakes, and the most common roadway factors were view obstruction and slippery surface.

Results previously presented in Table 36 indicate pedestrian accidents tended to be severe. Almost seven percent resulted in fatalities and 89 percent resulted in injuries. For all accidents, only one-half percent were fatal accidents and 21 percent were injury accidents. Pedestrian accidents have shown a general decrease (Table 32).

Bicycle Accidents

Numbers and rates of motor-vehicle accidents involving bicycles are listed in Table 39. Counties were grouped by population category and the counties having the highest accident rate in each category are Ballard, Caldwell, Marion, Henderson, and Kenton. A similar summary was prepared for cities and the results are presented in Table 40. Cities having the highest rate of bicycle-related accidents are Louisville, Owensboro, Shively, Bellevue, and Ludlow.

The most common human factors contributing to motor-vehicle accidents involving bicycles were driver inattention and failure to yield right of way (Table 34). Those were the most common contributing factors of any type. Among vehicular factors, defective brakes were the most common problem, while obstructed view was the most frequently listed roadway contributing factor.

Bicycle accidents also tended to be severe, as shown in Table 36. Over 80 percent of the motor-vehicle accidents involving bicycles resulted in injuries and 1.2 percent resulted in fatalities. The number of bicycle accidents has remained relatively constant for the 1978-1981 period with a five percent decrease in 1982 (Table 32).

Motorcycle Accidents

County and city statistics for accidents involving motorcycles are

presented in Tables 41 and 42, respectively. For each population category, counties having the highest rates for motorcycle accidents per 10,000 population were Carroll, Garrard, Meade, Boone, and McCracken (Table 41). From Table 42, those cities having the highest rates in each population category were Louisville, Bowling Green, Radcliff, Williamsburg, and Carrollton.

Additional information on motorcycle accidents may be obtained from Table 34, which lists contributing factors, and Table 36, which contains severity data. The most frequently listed factors contributing to motorcycle accidents were failure to yield right of way, driver inattention, and unsafe speed. The principal vehicular factors were tire failure and defective brakes. Slippery surface and obstruction of view were the major roadway contributing factors. Motorcycle accidents tended to be severe, with almost three percent resulting in fatalities and 73 percent resulting in injuries. Motorcycle accidents have remained at a level of about 1,800 per year over the five-year period, with a slight decrease in 1982 as compared to the four previous years.

School Bus Accidents

School bus accident statistics were summarized for counties and cities and the results are presented in Tables 43 and 44. Table 43 lists numbers and rates of school bus accidents, by county and population category. Counties having the highest rates in each population category are Robertson, Grant, Union, Clark, and Fayette. A similar summary was prepared for cities by population categories, as shown in Table 44. Those cities having the highest rates in each population category are Louisville, Hopkinsville, Nicholasville, Independence, and London.

As with all accidents, the leading human factors contributing to school bus accidents were driver inattention and failure to yield right of way (Table 34). The leading vehicular factor was defective brakes and the most frequently occurring roadway factors were slippery surface and view obstruction.

School bus accidents tended not to be severe, as shown in Table 36. Only 15 percent of the accidents resulted in injuries, while less than one-half percent resulted in fatalities. From the trend analysis presented in Table 32, school bus accidents have varied significantly over the five-year period. When comparing 1982 with the previous four-year average, the number of school bus accidents decreased by almost 11 percent.

Vehicle Defects

The requirement for an annual vehicle inspection was repealed in 1978. A summary of the involvement of vehicle defects in accidents before and after repeal of that law is given in Table 45. The percent of accidents involving a vehicle defect was 5.86 percent before repeal of the vehicle inspection law. The

percent increased to 7.09 in the first 19 months after repeal of the law and was about 7.5 percent for 1981 and 1982.

Applying the "before" percentage of accidents involving a vehicle defect (5.86 percent) to the 1981 and 1982 data provides an estimate of increase in the number of "vehicle defect" related accidents that may be attributed to repeal of the vehicle inspection law. Applying this "before" percentage yielded 2,058 fewer accidents in 1981 and 1,979 fewer accidents in 1982, or an average of about 2,000 accidents. The average cost of an accident in 1981 and 1982 was about \$4,400 using 1981 National Safety Council figures. Therefore, 2,000 additional accidents would result in 8.8 million dollars in accident costs that could be partially attributed to repeal of the vehicle inspection law.

TABLE 32. ACCIDENT TREND ANALYSIS

ACCIDENT STATISTIC	NUMBER IN GIVEN YEAR				4-YEAR AVERAGE 1978-81	1982	1982 PERCENT CHANGE
	1978	1979	1980	1981			
Total Accidents	152,303	147,247	128,130	125,116	138,199	124,745	-9.7

TABLE 45. ACCIDENTS INVOLVING VEHICLE DEFECT BEFORE
AND AFTER REPEAL OF VEHICLE INSPECTION LAW

TIME PERIOD	TOTAL NUMBER OF ACCIDENTS	NUMBER OF ACCIDENTS INVOLVING VEHICLE DEFECTS	PERCENT OF ALL ACCIDENTS INVOLVING VEHICLE DEFECT
October 1976 -May 1978 (20 Months Before Repeal of Law)	246,500	14,440	5.86
June 1978 -December 1979 (19 Months After Repeal of Law)	233,155	16,527	7.09
January 1980 - December 1980	124,503	9,176	7.37
January 1981 - December 1981	121,810	9,196	7.55
January 1982 - December 1982	121,080	9,074	7.49

RECOMMENDATIONS

ALCOHOL- AND DRUG-RELATED ACCIDENTS

1. Alcohol is second to unsafe speed as a contributing factor in fatal accidents and is the fifth most common contributing factor to all accidents. The number of alcohol-related accidents has remained relatively unchanged over the five-year period even though the total number of accidents has decreased significantly during the same time period.

As part of the analysis, percentages of alcohol-related accidents were tabulated for counties and cities. In addition, alcohol conviction rates were tabulated by county. Those counties having high percentages of alcohol-related accidents and low alcohol conviction rates were identified as potential locations where increased enforcement may be beneficial. Counties that had high accident locations as well as 250 or more alcohol-related accidents during the five-year analysis period were judged potential counties for the increased alcohol-related enforcement program. Those counties are listed below by State Police Post:

Post Number	Counties
1	McCracken, Marshall
2	Christian, Muhlenburg
3	Warren
4	Hardin, Nelson, Meade
5	Oldham
6	Kenton, Boone
9	Pike
10	Harlan
12	Fayette
13	Perry
14	Carter
15	Marion
16	Union

2. An analysis was performed for cities similar to that for counties. However, alcohol conviction rates were not available for cities and consideration was given to conviction rates for counties within which a city was located. Again, the criterion of 250 or more alcohol-related accidents within a five-year period were applied. Cities where a

program of increased alcohol enforcement is recommended are:

1. Lexington
2. Bowling Green
3. Paducah
4. Covington
5. Radcliff
6. Shively

3. Drug-related accidents continue to be a problem in some parts of the state. From the analysis of counties and cities, only a few locations have a sufficient number and/or rate of drug-related accidents to warrant a special enforcement program. It is recommended that consideration be given to a special enforcement program in Lexington because it has the highest number of drug-related accidents. Covington has the highest rate of drug-related accidents and it should be targeted for a drug-related enforcement program.

OCCUPANT PROTECTION

1. The large potential for reduction in injury and accident costs associated with increased use of safety belts warrants programs having the objective of increasing safety belt usage. Safety belt programs such as those described by the National Highway Traffic Safety Administration (NHTSA) should be implemented, with the objectives of increasing awareness of risks of traffic accidents, increasing understanding of benefits of safety belt usage, and providing assistance to organizations willing to promote safety belt usage. This should be implemented on a statewide level. Counties that are candidates for more intensive promotion campaigns were identified in Table 20. A list of those counties, by State Police Post, follows:

Post Number	Counties
1	Calloway, McCracken
2	Caldwell, Hopkins
3	Allen, Warren, Barren
4	Nelson
5	Owen
6	Harrison, Kenton
7	Estill, Jessamine, Clark

8 Mason, Montgomery
 9 Pike
 10 Bell
 11 Wayne, Pulaski
 12 Anderson, Franklin
 13 Perry
 14 Carter
 15 Marion, Taylor
 16 Henderson, Daviess

2. A current study involves a survey of the use of child safety seats after implementation of the mandatory usage law became effective in July 1982. That survey also includes observation of safety belt usage of drivers. In the next year, the Kentucky General Assembly will meet and modifications to the current child safety seat law could be enacted. Also, intensive programs having the objective of increasing safety belt usage will be implemented. To maintain up-to-date usage statistics and to determine the effect of new or modified laws or promotional campaigns, an updated observational study should be conducted in 1984.

3. The age at which a child may safely be placed in a safety belt rather than a child safety seat has not been determined. While accident statistics (Table 25) indicate a difference in accident severity may exist between child safety seats and safety belts, a more detailed investigation is needed. An analysis should be conducted through use of a report supplement to be completed by investigating officers when a child in a restraint is involved in an accident.

4. More detailed information should be obtained for accidents in which a driver or passenger wearing a safety belt is either fatally or severely injured. A report supplement should be developed for use when an occupant wearing a safety belt receives a fatal or incapacitating injury.

5. A mandatory safety belt usage law for all drivers would provide the greatest potential for increasing safety belt usage but might be difficult to enact. However, a law requiring drivers of certain types of vehicles, such as school buses and emergency vehicles, to wear seatbelts might have a possibility of being enacted. While such a law would only affect a

limited number of drivers, it would serve to publicize the need for wearing safety belts and it could have an effect on overall usage rates. A survey of public opinion on various types of safety-belt legislation would provide valuable input to the General Assembly.

SPEED-RELATED ACCIDENTS

1. Unsafe speed continues to be the primary contributing factor in fatal accidents and the fourth most frequent contributing factor in all accidents. Problems were identified for counties and cities by determining the percentages of speed-related accidents. In addition, speeding conviction rates were tabulated by county. Those counties having high percentages of speed-related accidents and low conviction rates were identified as possibilities for increased enforcement. Locations meeting the criteria for accidents and convictions also had to have at least 250 speed-related accidents during the five-year study period. Following is a list of counties (tabulated by State Police Post) recommended for programs of increased speed enforcement:

Post Number	Counties
1	Marshall, McCracken
2	Christian, Muhlenberg
3	Warren
4	Hardin, Nelson, Meade
5	Oldham, Henry
6	Grant
7	Madison
8	Rowan, Morgan
9	Pike, Floyd, Martin
10	Harlan
11	Laurel, Clay
12	Shelby
13	Letcher, Perry, Knott, Breathitt, Leslie
14	Carter
15	Marion
16	Ohio

It should be noted that all counties in Post 13 were identified.

2. By analyzing speed-related accident rates for cities and applying the criterion of at least 250 accidents during

the five-year period, the following cities were recommended for additional programs of speed enforcement:

1. Louisville
2. Covington
3. Bowling Green
4. Hopkinsville
5. Florence

VEHICLE DEFECTS

The percentage of accidents involving vehicle defects has increased since repeal of the vehicle inspection law. It may be concluded that repeal of that law resulted in additional accidents involving vehicle defects. However, before that conclusion can be reached, a detailed study of defects involved should be conducted. There is a need for such a study to determine whether the defects that have contributed to accidents since repeal of the vehicle inspection law were of the type that might have been detected under the previous inspection program. That study could also reveal types of inspection necessary to detect defects contributing to accidents.

PEDESTRIANS

Accidents involving pedestrians were the most severe of the types investigated. The accident rate analyses identified the Newport and Covington area in northern Kentucky as a particular problem area when compared to other cities in the state (Table 38). A study to determine factors contributing to this problem with recommendations for improved traffic control measures or increased police

enforcement or driver and pedestrian education programs is warranted.
