#### INTRODUCTION

Usage of restraint systems has been shown to be an effective method of reducing accident severity; however. actual usage has remained low (1). An 1980 Kentucky accident analysis of statistics showed. for children under the age of four who were involved in traffic accidents, only about nine percent were coded as using restraint systems (2). Usage of seatbelts was even lower, with five percent of drivers involved in traffic accidents coded **8**5 using seatbelts.

In an attempt to increase child restraint usage, a law was enacted by the 1982 Kentucky Legislature requiring use of child restraints for children forty inches or less in height. A copy of the law is presented in Appendix A. An important modification was made to the law as originally proposed. This was the elimination of any penalty, other than a warning, for violation of the law.

To evaluate effectiveness of the law, a survey of child restraint usage had to be completed before the law became effective on July 15, 1982. One objective of this study was to determine statewide child restraint usage as well as usage rates in various areas of the state. objective was todetermine Another statistics relating to improper usage. This involved identifying the restraint used and determining whether it was used properly. Also, as part of the survey, seatbelt usage of drivers was noted.

#### PROCEDURE

### IDENTIFICATION OF AVAILABLE RESTRAINTS

All personnel involved in the survey had to become acquainted with each common restraint, noting its usage requirements and method of installation. Literature pertaining to available child restraints was reviewed (3, 4, 5). Letters were sent to all major manufacturers of domestically available child restraints requesting describing theirliterature various restraints. Almost all manufacturers supplied this information, and several sent samples of their restraints. These samples were installed in a vehicle by

data collectors to become familar with proper installation procedures. Other restraint types were borrowed from local sources, and some were examined at local department stores. Photographs were taken of all restraint types.

A list of various child restraints examined while preparing for this study is given in Table 1. The manufacturer and seat name are given, as well as a description of the type of protection afforded and the age range for which the restraint is to be used. Photographs of several restraints are in Appendix E. Usage requirements for each restraint had to be known to determine whether the restraint was used properly. For example, if a tether was required but not used, the restraint would be classified 88 improperly used. As part of the training process, a quiz was developed dealing with characteristics of various restraints. This quiz was administered to all data collectors.

#### DEVELOPMENT OF SAMPLING PLAN

A sampling plan was developed to assure a statistically valid sample for cities of various sizes distributed across the state. The sample size was determined so that the relative error of the observed proportion (percent using child restraints) would be within acceptable bounds with a given probability. The required sample size was determined using the following formula (6):

$$n = (X)(1 - p)/((d^2)(p))$$
(1)

in which n = sample size, X = cumulative Chi-square distribution for a given probability and one degree of freedom.

- d = bound on the relative error of the proportion, and,
- p = true or assumed proportion.

A probability of 0.95 was assumed. The sample size needed would vary as a function of the proportion of children using child restraints and the required bound on the relative error. For a proportion between 10 and 15 percent and a

10 percent upper bound on relative error, the required sample size varies from 2,176 to 3,456. For a proportion of 15 percent and a 5 percent upper bound on relative error, the required sample size increased substantially to 8,704. The assumption was made that the observed proportion would not be much lower than 15 percent. For a sample size of 5,000, this would yield a 6.6 percent upper bound on relative error. For a proportion of 15 percent, the resulting range would be from 14 to 16 percent. A goal was established to obtain a total sample of 5,000 children in the survey.

The sample had to be distributed across the state and be representative of a range of populations to account for social and economic factors. The sample was distributed based on county population categories. From the 1980 census, the number of children under five years old in each county was used to distribute the sample. This was theyoungest age category available. The sample size needed for each population category. as well as the survey counties and cities selected, are given in Table 2. Counties were selected so that a distribution across the state would be obtained. The largest city in each selected county was chosen for data collection. City 298,451 populations varied fromin Louisville to 3,967 in Carrollton.

## DEVELOPMENT OF DATA COLLECTION PLAN

A review of data collection procedures used by other researchers was performed 11). (7, 8, 9, 10, Most used an observation technique, some used driver interviews, and some used a combination of both. After testing and revisions, the data collection form shown in Figure 1 was developed for use in this study. The procedure involved collecting the data by observation without interviews. This allowed data to be collected much more quickly than with interviews, and it was discovered through testing that observers were able to gather all necessary data through observation. This procedure allowed data to be collected by one A total of four person. observers collected all data, which minimized requirements. training Substantial

training was still necessary to acquaint data collectors with the various restraints and their proper usage.

of explanation An information collected is given in Figure 2. The data sheet was divided into three sections. General information described when and where the data were collected. The section pertaining to cars containing children under four included basic information concerning type of restraint used and, if a child restraint was used, the brand used and whether it was used properly. During data collection, some unknown brands of car seats were observed. Often, the child sat in the seat with an armrest in front but with no provision for harnessing the child to the seat. In such instances, the child was classified as using a child restraint, but usage was classified as improper, with the reason being that the restraint was not a type approved by the National Highway Traffic Safety Administration.

It should be noted thatchild restraint usage was obtained for children under four years of age. Kentucky's law requires the use of child restraints for chidren 40 inches in height or less. Since no interviews were conducted, a judgment concerning age or height had to be made, and the decision was made to use four years of age as the cutoff. Children were further classified as being less than one year old or from one to three years old. In this report, children less than one year of age will be referred to as "infants", and children from one to three years of age will be termed "toddlers".

Information was also obtained for the driver of any vehicle containing a child under four years of age. This information consisted of the driver's age category, sex, and restraint usage. The third section of the data sheet contained similar information for drivers of other vehicles. Seatbelt usage was obtained for drivers of those vehicles when it did not interfere with child restraint data collection.

A set of general instructions was developed to assist data collectors. The methodology used was taken primarily from a paper that described guidelines for state surveys of seatbelt and child restraint usage (10). That procedure had been used in nationwide surveys, and use of that procedure would allow a more valid comparison between data collected in Kentucky and that collected elsewhere in the country.

The general instructions follow:

1. Data will be collected by observation. Data collectors should attempt to be as inconspicuous as possible and avoid conversation, if possible. A message stating "TRAFFIC SURVEY" will be placed on the backs of all clipboards. Data collectors will wear or carry identification and will carry handouts to give to individuals who ask questions.

2. Sites will be selected in cities listed in the survey plan. It is anticipated that most data will be collected at traffic signals and stop signs, probably near shopping centers and other locations where children will most likely be present.

3. For data taken at an intersection, observers will stand on the curb or at the edge of the roadway and observe stopped cars in the near lane. They should not attempt to include moving cars. Only passenger cars and station wagons are to be included. Trucks, vans, or vehicles used for commercial purposes, such as taxicabs, should not be included.

4. All data should be collected during daylight hours at various times throughout the day.

5. Priority will be given to any car containing a child under four years old. Driver restraint information for other cars will be collected in available intervals.

6. Observers shall use their best judgment in estimating age. However, they will not guess on restraint usage. If restraint usage cannot be determined, it should be left blank.

7. Proper or improper usage, along with the reason for improper usage, should be determined whenever possible, even if the type of child restraint cannot be determined.

8. If feasible at traffic signals, data collection will begin with the second vehicle in the queue. However, where the first vehicle obviously had to stop for the signal or where the traffic volume is light, the first vehicle may be included.

#### DATA ANALYSIS

The child restraint data were entered into a computer file using the format and codes shown in Figures 3 and 4, respectively. This allowed summaries and cross-tabulations to be performed rapidly for any of the recorded data. Restraint usage data for drivers of vehicles not containing children under four were summarized manually.

### RESULTS

#### USAGE RATES

A summary of statewide usage of child restraints is given in Table 3. A total sample of 5,000 children was obtained with a distribution in the various county populations as given in Table 2. All data were collected prior to the effective date of the mandatory child restraint law. Statewide, the data showed that 14.4 percent of children under four years of age were in child restraints. However, only 44 percent of those children were placed in an approved restraint in a proper manner. Therefore, only 6.3 percent of the children were properly restrained with child restraints. An additional one percent of the children were in seatbelts or harnesses. Therefore, 15.4 percent of the children were restrained in some manner.

Using Equation 1 with a sample size (n) of 5,000, a probability of 0.95, and a proportion (p) of 14.4 percent yielded a bound on the relative error of the proportion (d) of 6.8 percent. When applied to the observed proportion (14.4 percent), this yielded an absolute error of 1.0 percent. Therefore, confidence limits of statewide child restraint usage were 13.4 to 15.4 percent.

relationship between The county population category and child restraint usage is shown in Table 3. Highest restraint usage was in the most heavily populated counties; lowest usage was in populated counties. the least The child percentage of restraints used properly showed no relationship to The percentage population. using seatbelts or harnesses showed the same

The usage of child restraints in the 19 survey cities is given in Table 4. As expected, restraint usage was highest in the largest cities. This was in agreement with the findings of previous studies. The percentage using child restraints ranged from 29.8 percent in Lexington to 6.3 percent in Carrollton. The percentage using restraints properly showed no relationship to city size and varied from 20 percent in Madisonville to 64 percent in Carrollton. The percentage using seatbelts or harnesses was highest in Covington, followed by Lexington. Several of the smaller cities had no children observed wearing seatbelts or harnesses.

Several other factors were found to be related to child restraint usage, as shown in Table 5. As the number of children in a car increased, child restraint usage decreased. Restraint usage was almost three times higher for infants (30.6 percent) than for toddlers (11.4 percent). Usage was also much higher for children in the rear seat. There was a strong relationship between the restraint usage of the driver and that of the child. Almost 70 percent of children were by a child restraint or restrained seatbelt when the driver was also using a restraint. This compared to only about a 12 percent restraint usage for children when the driver was not restrained. Child restraint usage was also related to driver age and sex, with usage being higher for female drivers and lower for older drivers.

Some of those factors were also related to proper usage. Proper usage was higher for infants than for toddlers. Proper usage was also higher for children travelling with restrained drivers. Driver age was also a factor, with very low proper usage for older drivers.

The seating positions of unrestrained children are summarized in Table 6. The majority of children were classified into the "other" category. This position primarily involved standing on the seat or sitting on the front edge of the seat. About 18 percent were sitting in someone's lap. Only about 25 percent were seated in a normal manner. SUMMARY BY TYPE OF RESTRAINT

Usage of various types of child restraints is summarized in Table 7. Data are presented for all children, for infants only, and for toddlers only. For each restraint type, the number observed is given as well as the percentage stated previously, properly used. As observers were trained toidentify specific restraints and their proper usage. Information regarding type and usage was obtained for a high percentage of restraints.

Overall, the Strolee Wee Care was the most frequently observed child restraint; the Bobby-Mac Champion or Deluxe II was second, and the Kantwet One-Step was third. The Bobby-Mac Champion and Deluxe II were difficult to distinguish from each other and were classified together. A large number of Century seats were observed, but in most instances, the model was not determined. The Cosco/Peterson Safe-T-Seat and the Child Love Seat were also observed frequently. Considering only infants, the Bobby-Mac Champion or Deluxe II, Questor Dyn-O-Mite, and Strolee Wee Care were the most frequently observed. Ranking of restraints for toddlers was very similar to that for all children.

The percentage properly used showed that proper usage varied substantially by type of restraint. Of the major restraints, Strolee and Bobby-Mac had lower proper-usage percentages, and Questor, Century, and Cosco/Peterson had higher proper-usage percentages.

A summary of the types of improper usage is given in Table 8. The major overall improper usage was failure to tether the restraint as required. This was also the major problem for toddlers. For infants, the major problem involved facing the infant forward rather than in the required backward position. Some children judged to be less than one year of age were large enough to be placed in the forward-facing position. This meant that improper usage for an infant could involve failure to tether or failure to use a shield. Not harnessing the child into the restraint was also a problem, especially for toddlers. Another major problem for toddlers was failure to use

the shield required by some restraints. Unapproved types of restraints were observed in 90 instances (12.5 percent of all restraints). Such restraints usually consisted of a seat with an armrest but no provision to harness the child to the seat. These unapproved restraints were used more for toddlers than for infants.

The most frequent improper usages for the common child restraints are given in Table 9. The most prevalent problem was failure to tether the Strolee and Child Love Seat restraints. The other major problem was failure to use the shield with the Bobby-Mac Champion or Deluxe II in the forward-facing toddler position. Other improper usages involved not harnessing the child into the restraint, facing an infant in a forward-facing position, and failure to secure the restraint to the car.

DRIVER RESTRAINT USAGE RATES

A summary of driver restraint usage rates for the survey cities is given in Table 10. Data were obtained for over 31,000 drivers. The summary is divided into categories based on the number of licensed drivers in the county. As with child restraints, driver restraint usage was highest in the large cities. Usage was highest in Lexington and Covington and lowest in Lawrenceburg.

A statewide rate was obtained by weighting the overall percent usage for each category by the percentage of the total driving population in that category. Using that procedure, a statewide driver restraint usage rate of 4.2 percent was determined.

Using Equation 1 with a sample size (n) of 31,143, a probability of 0.95, and a proportion (p) of 4.2 percent yielded a bound on the relative error of the proportion (d) of 5.3 percent. When applied to the observed proportion (4.2 percent), this yielded an absolute error of 0.2 percent. Therefore, confidence limits of statewide driver restraint usage were 4.0 to 4.4 percent.

The variation in driver restraint usage rates as a function of driver age and sex was also investigated (Table 11). Although no substantial differences were noted, drivers in the middle age category had higher rates than either younger or older drivers. Males had a slightly higher usage rate than females. The highest rate was for males in the middle age category, while the lowest rate was for older females.

### SUMMARY

1. A statewide child restraint usage rate of 14.4 percent was obtained, with confidence limits of 13.4 to 15.4 percent.

2. Of the children observed in child restraints, only about 44 percent were in approved restraints used in a proper manner.

3. Child restraint usage was related to county and city size, with higher usage in more densely populated areas. Usage ranged from 29.8 percent in Lexington to 6.3 percent in Carrollton.

4. Several factors were found to be related to child restraint usage. For example, usage was higher for infants (under one year of age) compared to toddlers (from one to three years of age) and was much higher in cars driven by restrained drivers.

5. Only one-fourth of unrestrained children were observed to be seated in a normal manner. A majority were standing on the seat, sitting on the front edge of the seat, or sitting on an adult's lap.

6. A few brands of child restraints were very popular. The Strolee Wee Care was the most frequently observed child restraint. Other common restraints included Bobby-Mac Champion or Deluxe II, Kantwet One-Step, various models of Century and Cosco/Peterson seats, Questor Dyn-O-Mite, and Child Love Seat.

7. Proper usage varied substantially by type of restraint. Of the major restraints, Strolee and Bobby-Mac had lower proper-usage percentages, while Questor, Century, and Cosco/Peterson had higher proper-usage percentages.

8. The major overall improper usage was failure to tether the restraint as required. For infants, the major problem involved facing the infant forward rather than in the required backward position.

9. A summary of improper usage for the most common restraints showed that the most prevalent problem was failure to tether the Strolee and Child Love Seat restraints. The other major problem was failure to use the shield with the Bobby-Mac Champion or Deluxe II in the forwardfacing toddler position.

10. A statewide driver restraint usage rate of 4.2 percent was determined. This rate did not vary substantially by driver age or sex.

## RECOMMENDATIONS

The finding that only a small percentage of children are being placed in child restraints indicates that efforts to increase usage are warranted. One such effort was undertaken through mandatory usage legislation enacted by the 1982 Kentucky Legislature. The effectiveness of this legislation in increasing child restraint usage should be evaluated, and possible improvements to the law should be identified.

Child restraint usage rates were determined for cities distributed throughout the state. That summary identifies locations where emphasis should be placed on publicity and enforcement concerning the new child restraint law.

Child restraint usage and the percentage of restraints properly used were much higher when the driver was using a restraint. Based upon that result, it may be assumed that an increase in either driver restraint or child restraint usage would result in a corresponding increase in the other. Upcoming campaigns having the objective of increasing either seatbelt or child restraint usage should include a reference to both. In addition, increased expenditures for promoting child restraint usage may be warranted due to potential impact on overall seatbelt usage.

A significant problem was observed with respect to improper usage of child restraints. Consequences of improper usage should be documented through indepth accident investigations. For example, the consequences of not tethering a child restraint should be documented through accident case studies.

Only 1.2 percent of toddlers were observed to be in seatbelts or harnesses.

Future promotional campaigns should stress the importance of using a seatbelt when a child outgrows his child restraint or when no child restraint is available.

## KENTUCKY'S CHILD RESTRAINT LAW

20

------

.

. . . . . . . .

#### AN ACT relating to traffic safety.

Be it enacted by the General Assembly of the Commonwealth of Kentucky:

Section 1. KRS 189.125 is amended to read as follows:

(1) No person shall sell any new passenger vehicle in this state nor shall any person make application for registering a new passenger vehicle in this state unless the front or forward seat or seats have adequate anchors or attachments secured to the floor and/or sides to the rear of the seat or seats to which seat belts may be secured.

(2) Any resident parent or legal guardian of a child, forty inches (40") in height or less, when transporting his child in a motor vehicle owned by that parent or guardian operated on the roadways, streets and highways of this state, shall have such child properly secured in a child restraint system of a type meeting federal motor vehicle safety standards.

(3) As used in this section, "child restraint system" means any device manufactured to transport children in a motor vehicle which conforms to all applicable federal motor vehicle safety standards.

(4) The term "motor vehicle" as used in subsection (2) of this Act shall not apply to recreational vehicles or trucks having a tonnage rating of more than one (1) ton.

(5) Failure to wear a child passenger restraint shall not be considered as contributory negligence, nor shall such failure to wear said passenger restraint system be admissible as evidence in the trial of any civil action.

(6) KRS 189.990 and 189.993 to the contrary notwithstanding, there shall be no penalty for the violation of this section. No peace officer shall issue a uniform citation or any other citation, other than a warning, for a violation of this section nor shall any arrest be permitted for violation of this section. 21
