Selected KGS reports published before 1999 have been scanned and converted to PDF format. Scanned documents may not retain the formatting of the original publication. In addition, color may have been added to some documents to clarify illustrations; in these cases, the color does not appear in the original printed copy of the publication. Every effort has been made to ensure the integrity of the text. KGS maps and charts are supplied either whole or in part and some are too large to be printed on most plotters. Open-file reports are reproduced from the best available copy provided by the author, and have not undergone KGS technical or editorial review.

## BACKGROUND

About 3.7 million people live in Kentucky, of which 1.9 million (52 percent) live in urban areas (roughly defined as any community with 2,500 or more people) and 1.8 million (48 percent) live in rural areas (University of Kentucky, 1993). Figure 1 summarizes sources of drinking water for Kentucky residents. About 70 percent of Kentuckians get their daily supply of water from surface-water sources - lakes and streams; about 25 percent get their water from ground-water wells; and about 5 percent get their water from other sources - springs, cisterns, ponds, or hauled water.

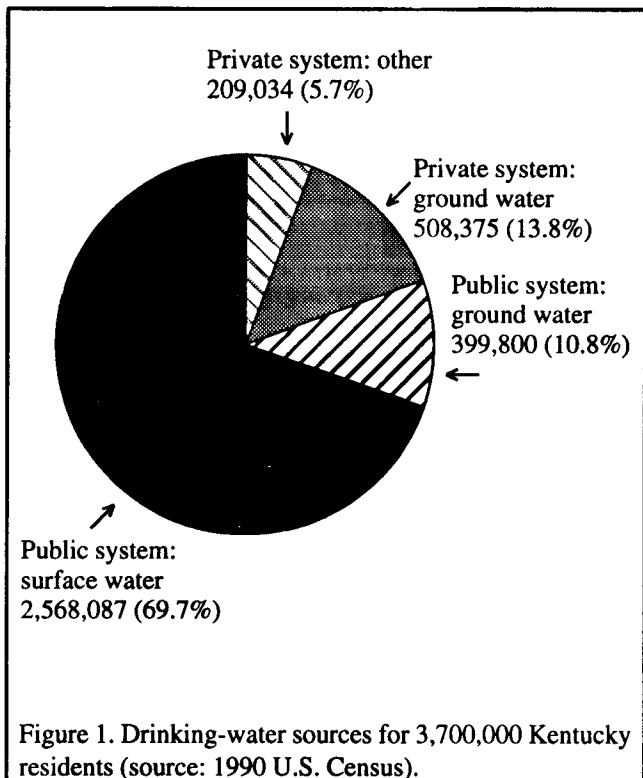

About 3 million Kentuckians (80 percent) get water from public systems. The remaining 720,000 people, or 40 percent of all rural Kentuckians, rely on private water systems. Over 200,000 private wells provide most of this water. Wells and springs also provide drinking water

for schools, restaurants, gasoline stations, livestock, and irrigation (Kentucky Department of Natural Resources and Environmental Protection, 1992).

Not all ground water is safe or pleasant to drink. In some areas, natural conditions render water unpalatable, if not hazardous to health. In other areas, human activities have contaminated ground water. Most studies of ground water have focused on areas of high vulnerability to pollution. Reports from such studies may have exaggerated the extent of ground-water contamination, adversely affecting the public's perception. In the absence of mandated routine testing for private water supplies, the information available is largely associated with testing in response to complaints. Such information is likely to be biased toward those private systems having water-quality problems. Information about "typical" private water supplies is scarce.

In general, much less is known about the quality of private water supplies than of public water supplies. Public water supplies are regulated by the Safe Drinking Water Act of 1974 to ensure that they are safe. Treatment plants utilizing surface water have more stringent testing requirements than those using ground water. Monitoring and testing by the Kentucky Division of Water provides information on the quality of drinking water for approximately 860 public water systems in Kentucky. Testing focuses on those chemical and biological constituents, such as metals and coliform bacteria, for which safe drinking water standards have been established.

Such testing is not required for private systems. The only testing requirement for private water systems is a bacteria test that must be completed when a well is initially installed (401 KAR 6:310, Section 10). Where pollutants in private water systems are found to be in excess of safe drinking-water standards, water treatment may be used to reduce concentration levels. Costs per household are very high, however, when compared to treatment costs for public systems. This high treatment cost is one of the reasons that protecting ground water from pollution is important.

At a time when surprisingly little information is available on ground-water quality, ground-water contamination has become one of the major environmental issues of the current decade, and will likely remain so into the next decade. Reliable information about water quality is necessary in order to develop plans for protecting ground water. The absence of accurate and broad perspectives on ground-water quality may lead to inappropriate and ineffective regulatory policies. Because ground water supplies a large percentage of rural drinking water and water for agricultural use in the State, rural landowners have become increasingly concerned about the quality of ground water.

## GROUND-WATER EDUCATION AND TESTING PROGRAM

The Ground Water Education and Testing Program began in the fall of 1989 through the cooperative efforts of the Kentucky Farm Bureau, Kentucky Division of Conservation, University of Kentucky Cooperative Extension Service, and Kentucky Geological Survey. A nine-county pilot program was initiated. Public meetings were held between April 16 and May 7, 1990, with 475 people attending. These local meetings were used to discuss water-quality issues, best management practices for protecting ground water, well construction, and a "Self-Help Check Guide Book" published by the American Farm Bureau. Water-sample test kits were distributed to well owners, and water-sampling procedures were discussed. Samples were later taken by well owners and submitted to the county coordinator.

A total of 888 water samples from the nine counties were collected and analyzed in the first phase of the study. The samples were tested for ammonia, nitrite-nitrogen, nitrate-nitrogen, chloride, sulfate, specific conductance (conductivity), alachlor, and triazine. All samples were chemically analyzed at the Heidelberg University Testing Laboratory in Heidelberg, Ohio. Conductivity was measured with a test probe. Alachlor and triazine were analyzed by immunoassay. Gas chromatography was also used, as a check on immunoassay results, to analyze about 10 percent of the alachlor and triazine samples in selected counties. The remaining constituents were analyzed by colorimetry. All samples were analyzed using standard methods approved by the U.S. Environmental Protection Agency.

The second phase of the well-water testing program was conducted in 37 additional counties. Public meetings and testing took place from February to April of 1991, and 2,032 water samples were tested, an average of about 55 per county, ranging from 182 samples in Perry County to 15 in Logan County.

The third phase of the program, from September to November 1991, provided 1,489 samples from 44 counties. The fourth and final phase in May and June of 1992 provided an additional 332 samples from remaining counties that expressed interest in the program. Twelve counties did not participate.

Participation in the program was voluntary and individual water test information is confidential. The success of the program resulted from the active leadership of local organizing committees consisting of and supported by local conservation districts, Soil Conservation Service district conservationists, the county Farm Bureau Organization, members of the county Cooperative Extension staff, local health departments, and other locally interested groups.

## SURVEY RESULTS

Data from the survey are summarized for: (1) the entire State, (2) each of the fifteen Area Development Districts (ADD's), and (3) each county (Fig. 2).

The survey answered four general questions: (1) What kind of well is it? (2) How is it used? (3) Where is the well in relation to crops, chemicals, livestock, waste, and other potential sources of pollution? and (4) What is the quality of the water based on ammonia, nitrite-nitrogen, nitrate-nitrogen, chloride, sulfate, conductivity (an indicator of dissolved solids), alachlor (Lasso), and triazine (atrazine, cyanazine, simazine)?

The 1990 census estimated about 207,000 domestic wells in Kentucky. Therefore, the survey sample of 4,859 wells represents about 2.3 percent of all wells. A total of 1,735 samples were tested for triazine, and 744 samples were tested for alachlor. One hundred eight of Kentucky's 120 counties are represented in the survey.

The survey represents ground-water data from wells and springs in all regions of Kentucky. Kentucky is divided into six major physiographic regions, shown in Figure 3. The Mississippi Embayment is also known as the Jackson Purchase Region, and the west-central Mississippian Plateau is also called the Pennyryle Plateau. These regions closely follow the generalized geology of Kentucky, also shown in Figure 4.

Ground-water quality is affected by the geology of an area and by human activities. Both of these factors are related to the physiographic region in which they occur. The gently sloping, fertile soils of the Jackson Purchase and Pennyryle Plateau regions produce most of Kentucky's food crops, and ground water in these areas may be affected by agricultural activities such as the mixing of chemicals near wells and the application of fertilizers. Ground water in the coal field regions of eastern and western Kentucky may

Figure 2. Locations of counties and Area Development Districts in Kentucky.

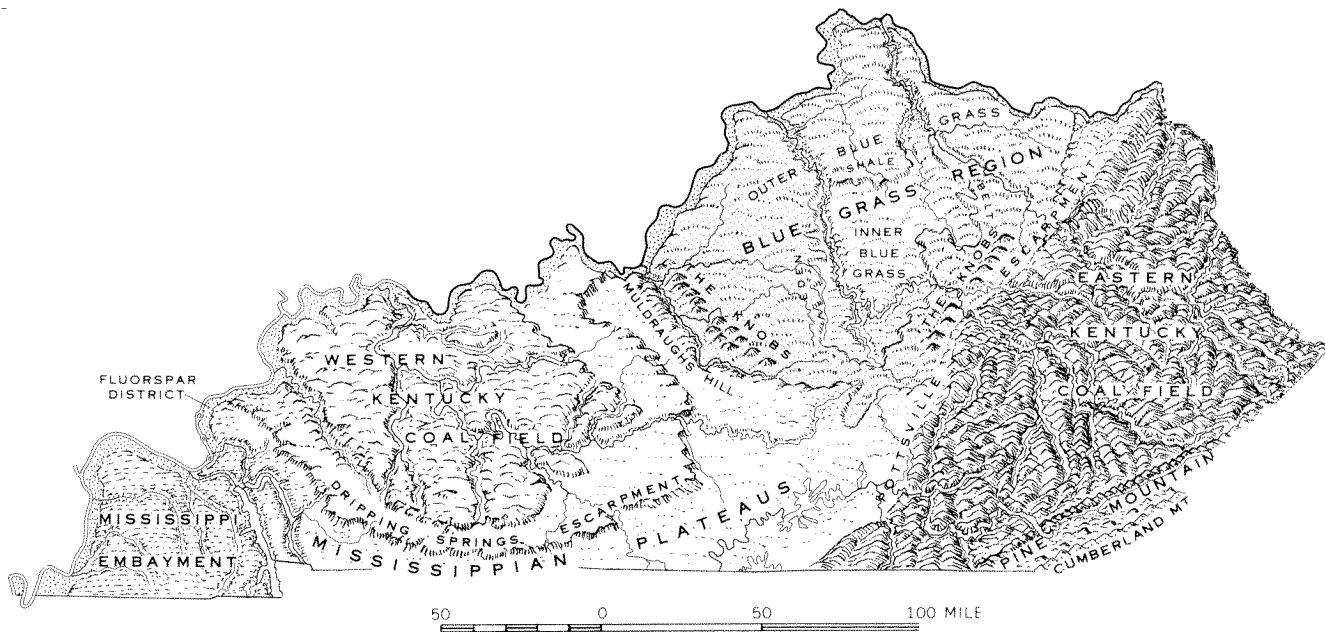

Figure 3. Physiographic regions of Kentucky.

and coal mining: for example, the oxidation products of sulfide minerals in the coals and associated strata.

Samples were taken in different seasons of the year (Table 1). A comparison of survey statistics between counties sampled during different seasons should be

made with the understanding that differences caused by seasonal effects may be present.

Preliminary data summaries for the Area Development Districts and the individual counties suggest regional differences in ground-water quality. Relation-

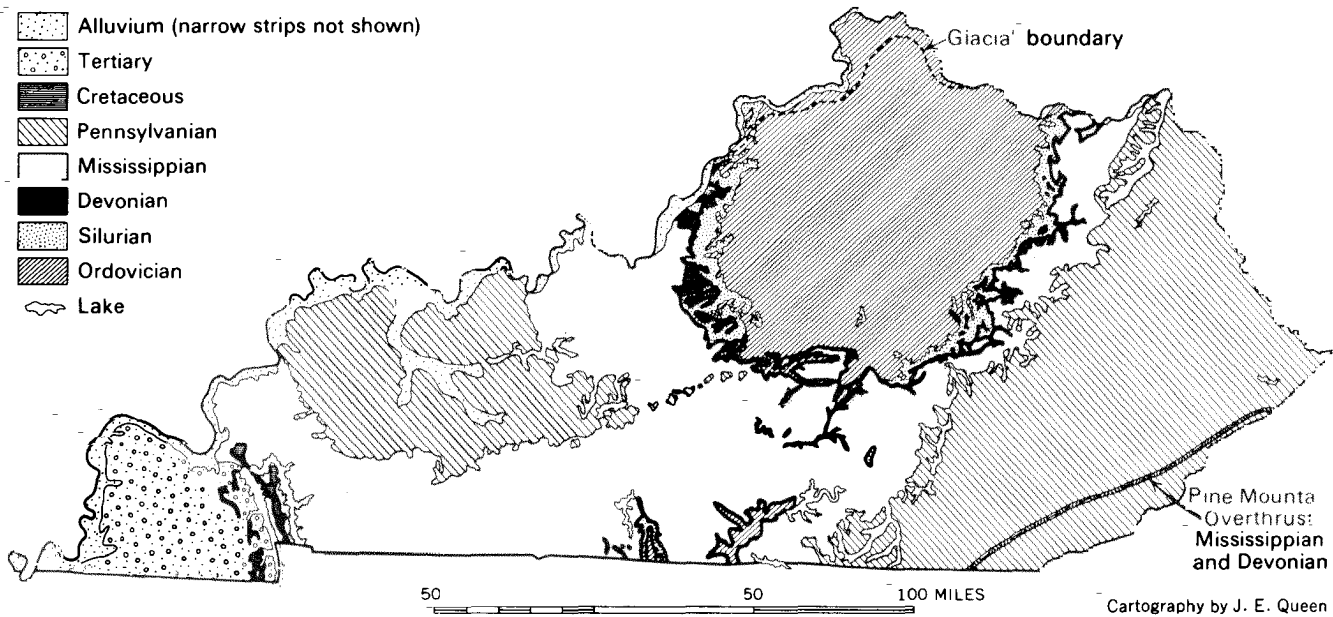

Figure 4. Generalized geologic map of Kentucky.

ships between the physical environment, human activities, types of wells, seasonal and other factors, and levels of contamination will be examined in detail in a later study.

### Statewide Summary

A summary of the Statewide testing program is shown in Table 2. About 85 percent of the sampled wells were drilled, to an average depth of about 100 feet (median depth of 90 feet). About seven out of eight wells provide household water. About one-third of the wells provide water for livestock, and about 10 percent provide for irrigation or other uses. Agricultural chemicals were mixed and diluted near 7.5 percent of the wells.

Most well owners provided information about the proximity of their wells to potential sources of pollution. Over two-thirds of the wells were within sight of crops, and almost one-half were within 200 feet of crops. Half the wells were within sight of a feedlot or livestock barn. Over half the wells were within 200 feet of a septic leach field. These responses indicate the rural setting of most of the wells.

Sample statistics of water-quality variables for all the wells are shown in Table 2. The median represents the value for which half the values are larger, and half are smaller. For example, half the samples had nitrate-nitrogen levels higher than 0.71 milligram per liter (mg/L), while half the samples had levels of nitrate-nitrogen less

than 0.71 mg/L. The fact that the median is significantly less than the average indicates that a few large values raised the average. More detail on the distribution of values is given in Table 3. For example, of all the wells sampled in the State, one out of four had nitrate-nitrogen levels greater than 2.96 mg/L (three out of four had lower levels), one out of 10 had levels greater than 6.72 mg/L, 1 out of 20 greater than 9.56 mg/L, and one out of 100 greater than 20.20 mg/L.

The Drinking Water Standards list Maximum Contaminant Levels (MCL). Those pertaining to the survey are shown in Table 4. The percentage of the samples that exceeded these levels, and the percentage that exceeded one-half these levels, are also given in Table 4. One-half of the MCL value has been suggested as a possible action level for the protection of ground water. The standards for chloride, sulfate, and conductivity (an indicator of dissolved solids) are based on taste considerations and not on health hazards.

As noted above, regional differences in the survey data are apparent and will be examined in more detail in a future study. Appendix A shows the average levels of measured variables for each county and how they compare to the rest of the State. Average ammonia levels in eastern Kentucky were high when compared to the rest of the State, for instance. Nitrate-nitrogen levels tended to be higher in the western Pennyrile counties. Actual percentile values of county averages are shown in Table 5.

### Summary by Area Development District

Area Development Districts, from a planning standpoint, and because of their reflection of regional differences, are appropriate regional units for evaluating the survey information. Survey data for the 15 ADD's are summarized in Appendix B. The graphs show how average levels of ground-water constituents in each district compare with the rest of the State. For example, average ammonia levels in the Big Sandy ADD were more than twice (237 percent) the Statewide average, and average nitrite-nitrogen levels in the KIPDA ADD were four times (405 percent) the State average.

### Summary by County

Survey data for individual counties were tabulated and average sample values were plotted on graphs to compare with regional and State values (Appendix C). For example, average triazine levels in Oldham County (seven wells) were over seven times higher than the Statewide average, and over seven times higher than the average for the KIPDA ADD. Average nitrate-nitrogen levels in the 16 wells tested in Logan County were over four times higher than the Statewide average and over three times higher than the average for the Barren River ADD, of which Logan County is a part.

**Table 4.—Maximum Contaminant Levels.**

<i>Parameter</i>	<i>Percent of Samples Exceeding</i>		
	<i>MCL</i>	<i>MCL</i>	<i>50% MCL</i>
Nitrite–Nitrogen	mg/L	0.04%	0.27%
Nitrate–Nitrogen	10 mg/L	4.6%	14.7%
Chlorides	250 mg/L	1.6%	3.4%
Sulfates	250 mg/L	2.8%	6.1%
Conductivity <sup>1</sup>	780 μsiemens	12.0%	57.2%
Alachlor	2 μg/L	0.9%	1.6%
Triazine	3 μg/L	0.3%	1.0%

<sup>1</sup> This standard is based on a total dissolved solids (TDS) concentration of 500 mg/L, assuming that TDS=0.64 X conductivity, or conductivity=500/0.64=780.

**Table 5.—Sample Quintile Values of County Averages.**

<i>Percent Less Than or Equal</i>	<i>Parameter Values</i>							
	<i>Ammonia (mg/L)</i>	<i>Nitrite Nitrogen (mg/L)</i>	<i>Nitrate Nitrogen (mg/L)</i>	<i>Chloride (mg/L)</i>	<i>Sulfate (mg/L)</i>	<i>Conductivity (μmho/cm)</i>	<i>Alachlor (μg/L)</i>	<i>Triazine (μg/L)</i>

## SUMMARY

The samples in this survey were collected by volunteers. Variance in the time of sampling, types of sampling containers, and other factors may contribute to corresponding variance in measured values. Only a small fraction of the total number of wells in the State were included in the survey. The data represent most areas of Kentucky, however, and provide a starting point for evaluating local and regional ground-water quality based on the natural environment and human activities. It is hoped that this basic summary of data will provide a better understanding of the present quality of ground water in Kentucky, and guidance for further study and the development of rational ground-water management and protection activities.

## ACKNOWLEDGMENTS

The Ground-Water Education and Testing Program succeeded through the help of many organizations and individuals who volunteered their time. Thanks must go primarily to the many well owners whose interest and participation were vital. Thanks also to the personnel of

the local Conservation Districts, county Farm Bureaus, county Cooperative Extension Services, local Health Departments, the Kentucky Department of Agriculture, the University of Kentucky, the Kentucky Geological Survey, and the Heidelberg University Testing Laboratory. The program was funded in part by the 319 Nonpoint Source Water Quality program.

For the preparation of this report, special thanks go to Meg Smath for her editorial assistance and improvements, to Bob Holladay for his usual fine drafting and graphics work, and to Phil Conrad for the cover photo.
