Lipid Binding Studies of Blood Coagulation Factor VIII C1 and C2 Domains

Rachel Blazevic, Serena Wo and P. Clint Spiegel

Department of Chemistry, Western Washington University; Bellingham, WA

Introduction

The blood coagulation protein, factor VIII (FVIII), is a necessary cofactor for factor IXa in the mammalian blood coagulation cascade. To function as a cofactor, FVIII must bind to the anionic phosphatidylserine head groups on the surface of platelets localized to the site of injury. Two domains, C1 and C2, are known to be involved in lipid binding, however the working model for platelet binding needs to be bolstered by mutational studies to identify the necessary amino acid contacts. This work uses site directed mutagenesis, metal affinity column chromatography, and enzyme-linked immunosorbent assays to directly compare the lipid binding affinities of single residue mutants of isolated FVIII C1 domain and C2 domain relative to wild type C1 domain and C2 domain. Understanding the role of both residues may further the model of FVIII lipid binding and provide the basis for development of more effective therapeutics.

Background

Figure 5. All mutants were created through site directed mutagenesis and confirmed with Sanger sequencing.²

Expressio

vector Figure 6. All proteins were purified by immobilized metal affinity gravity flow column chromatography with TALON (cobalt affinity) resin. Further purification achieved with FPLC using a S column.³

Figure 7. Binding affinity of mutant proteins to phosphatidyl serine (PS) analyzed with an enzyme-linked immunosorbent assay (ELISA).

where lipids are not bound substrate (1% BSA) (Ni-NTA•HRP), binds His-tag of protein

detection

Results

Conclusions and Future Work

- C2 Domain: R2320 does play a role in membrane binding.
- Thermodynamic stability and proper folding of human C1 and C2 mutants will be measured with circular dichroism and intrinsic tryptophan fluorescence. Proper folding will also be confirmed with pull down assays.
- Binding capacity of C1 and C2 mutants for activated platelet surfaces will be measured with enzyme-linked immunosorbent assays (ELISAs) and liposome sedimentation assays.
- Crystallize the C2 domain mutants to understand conformational changes caused by each mutation and elucidate a working model for membrane binding by the C2 domain.
