MODULATION INVARIANT BILINEAR T(1) THEOREM

ÁRPÁD BÉNYI, CIPRIAN DEMETER, ANDREA R. NAHMOD, CHRISTOPH M. THIELE,
RODOLFO H. TORRES, AND PACO VILLARROYA

ABSTRACT. We prove a T(1) theorem for bilinear singular integral operators (trilinear forms) with a one-dimensional modulation symmetry.

1. INTRODUCTION

The $T(1)$ Theorem is a criterion that gives necessary and sufficient conditions for the L^2 boundedness of non-convolution singular integral operators. It arose as a culmination of decade long efforts to understand the Cauchy integral operator on a Lipschitz graph and the related Calderón commutators. In the original statement of the theorem, proved by G. David and J.L. Journé [10], the necessary and sufficient conditions are expressed by the requirement that some properly defined functions $T(1)$ and $T^*(1)$ belong to BMO - hence the name of the theorem - together with the so called weak boundedness property. This latter condition requires the L^2 bounds when tested weakly on a restricted class of bump functions

$$|\langle T(\varphi_{x,R}), \varphi_{y,R} \rangle| \lesssim R,$$

where $\varphi_{x,R}(t) = \varphi(R^{-1}(t-x))$.

In [28], E. Stein reformulated the necessary and sufficient conditions into what he called the restricted boundedness property. This amounts to the existence of L^2 bounds when strongly tested on the same class of bump functions, that is

$$\|T(\varphi_{x,R})\|_2 \lesssim R^{1/2}$$

and likewise for T^* . Both forms of the $T(1)$ theorem will be used in this paper and further developed in a bilinear version to study certain modulation invariant bilinear singular integrals.

A basic operator in the study of the Cauchy integral on a Lipschitz graph is Calderón's first commutator. This operator can be written as a superposition of bilinear singular integral operators of the form

$$T_\alpha(f_1, f_2)(x) = \text{p.v.} \int_{\mathbb{R}} f_1(x-t) f_2(x-\alpha t) \frac{dt}{t}$$

Key words and phrases: bilinear operator, trilinear form, modulation invariant, T(1) theorem.

with parameter $\alpha \notin \{0, 1\}$, called bilinear Hilbert transforms. One of Calderón's early attempts to bound his commutator was to show the boundedness of the bilinear Hilbert transforms from $L^2 \times L^\infty$ to L^2 . However, he gave up on this approach and proved bounds on the commutator by different means [2], [3].

The bounds for the bilinear Hilbert transform conjectured by Calderón remained an open problem for more than 30 years. M. Lacey and C. Thiele proved [20],[21], that the bilinear Hilbert transforms are bounded from $L^{p_1} \times L^{p_2}$ to L^p for $1 < p_1, p_2 \leq \infty$, $p^{-1} = p_1^{-1} + p_2^{-1}$ and $2/3 < p < \infty$. Appropriate control on the growth of the constants associated with these bounds as α approaches the forbidden values $\{0, 1\}$, was established in [30]. This step was necessary in order to complete Calderón's program of estimating the commutator as superposition of bilinear Hilbert transforms. Thiele's results were strengthened to uniform bounds in some range of exponents by L. Grafakos and X. Li [19], [22].

The main feature that distinguishes the bilinear Hilbert Transform from its classical linear counterpart is the fact that the former has modulation invariance. In other words it is also invariant under translations in frequency rendering Littlewood-Paley theory which takes into account spatial translations and dilations but not oscillations, ineffective. This is also in contrast with those bilinear operators studied by Coifman and Meyer [9] where there is a preferred point in frequency and thus Littlewood-Paley theory suffices. A similar property to that of the bilinear Hilbert transform is shared by Carleson's maximal operator, which controls convergence of the Fourier series, [4]. The resolution of both problems resides in a suitable frequency decomposition that allows for the representation of these operators in an adapted wave packet frame that is itself invariant under the relevant modulations.

The natural question regarding bounds on more general bilinear singular integral operators than the bilinear Hilbert transform, where the kernel $1/t$ is replaced by more general Calderón-Zygmund kernels was first addressed by J. Gilbert and A. Nahmod [15], [16], [17]. They proved, in particular, bounds for the class of kernels $K(t)$ which are x -independent. Uniform bounds in α for these operators were then shown by C. Muscalu, T. Tao and C. Thiele [25].

The purpose of the current article is to address the case of kernels $K(x, t)$ that have both t and x dependence; this corresponds to the non-convolution case in the classical linear theory. The results we obtain, in particular Theorem 2.7, are different in nature from the bilinear or multilinear $T(1)$ theorems of M. Christ and J.L. Journé [5] and L. Grafakos and R. Torres [18] since, as we shall soon describe, we treat operators associated with far more singular kernels. The main new feature that distinguishes the operators we analyze is that they have modulation invariance in a certain direction. We seek a theory for them analogous to the one involved in the classical $T(1)$ Theorem. We will have to incorporate, however, time-frequency techniques that reflect the modulation invariance of the bilinear operators treated. Since the operators we deal with are no longer invariant under spatial translations the frequency decomposition used in the bilinear Hilbert transform situation no longer captures the oscillatory character of the

operator. Instead of a one parameter family of cubes, a new frequency decomposition is introduced and a two parameter family of boxes with varying eccentricities is needed (c.f. Section 5 for a detailed explanation). In other words the x -dependence allows for two degrees of freedom in the oscillations instead of one; which naturally adds new layers of complexity to the proof.

This paper represents a fundamental step in the understanding of bilinear singular and pseudo-differential operators lying beyond the Coifman-Meyer's class. There are many examples arising from nonlinear partial differential equations of singular multilinear multipliers that are still beyond reach. A concurrent aim of this paper is thus to introduce new frequency decompositions and further develop wave packet techniques that might become useful in the study of other multilinear operators outside the Coifman-Meyer's framework.

The work is motivated in part by typical examples of certain classes of bilinear pseudodifferential operators and their symbolic calculus as introduced by A. Bényi, A. Nahmod and R. Torres in [1]. This and other applications are presented in Sections 2.2 and 3.3.

2. THE MAIN THEOREM, APPLICATIONS, AND THE ROAD MAP OF THE PROOF

2.1. Modulation invariant bilinear $T(1)$ Theorem.

We start with a few definitions and examples that will lead us into formulating the classical (linear) $T(1)$ Theorem in its dual version and its bilinear counterpart. Throughout the whole paper we will restrict our attention to the one dimensional case.

Definition 2.1. A function $K : \mathbb{R} \times (\mathbb{R} \setminus \{0\}) \rightarrow \mathbb{R}$ is called a Calderón-Zygmund kernel if for some $0 < \delta \leq 1$ and some constant C_K we have

$$(2.1) \quad |K(x, t)| \leq C_K |t|^{-1}$$

$$(2.2) \quad |K(x, t) - K(x', t')| \leq C_K \|(x, t) - (x', t')\|^\delta |t|^{-1-\delta}$$

whenever $\|(x, t) - (x', t')\| \leq |t|/2$, where $\|\cdot\|$ denotes the euclidian norm.

Definition 2.2. A bilinear form Λ , defined on the product of Schwartz spaces

$$\Lambda : \mathcal{S}(\mathbb{R}) \times \mathcal{S}(\mathbb{R}) \rightarrow \mathbb{C}$$

is said to be associated with a standard Calderón-Zygmund kernel K if for some $\beta = (\beta_1, \beta_2)$ and for all Schwartz functions $f_1, f_2 \in \mathcal{S}(\mathbb{R})$ whose supports are disjoint¹, we

¹The requirement that the supports are disjoint is sufficient -due to (2.1)- to guarantee the convergence of the integral; it is also necessary in general, as it is easily seen by working with $K(x, t) = |t|^{-1}$.

have

$$\Lambda(f_1, f_2) = \int_{\mathbb{R}^2} f_1(x + \beta_1 t) f_2(x + \beta_2 t) K(x, t) dx dt.$$

If the form is continuous on $\mathcal{S}(\mathbb{R}) \times \mathcal{S}(\mathbb{R})$ then it will be referred to as a bilinear Calderón-Zygmund form.

The above representation of Λ is convenient for the formulation of the trilinear forms that we will study. Note, however, that the simple change of variables $x' := x + \beta_2 t$, $t' := x + \beta_1 t$ gives the more classical representation

$$(2.3) \quad \Lambda(f_1, f_2) = \int_{\mathbb{R}^2} f_1(t') f_2(x') \tilde{K}(x', t') dt' dx'$$

where

$$\tilde{K}(x, t) = \frac{1}{|\beta_1 - \beta_2|} K\left(\frac{\beta_1 x - \beta_2 t}{\beta_1 - \beta_2}, \frac{t - x}{\beta_1 - \beta_2}\right)$$

satisfies

$$|\tilde{K}(x, t)| \leq C_K |x - t|^{-1}$$

and

$$|\tilde{K}(x, t) - \tilde{K}(x', t')| \leq C_K (2 + \|\beta\|)^\delta \|(x, t) - (x', t')\|^\delta |x - t|^{-1-\delta}$$

whenever $c_\beta \|(x, t) - (x', t')\| \leq |x - t|$ and $c_\beta = 2(1 + \|\beta\|) \geq 2$.

We will use the notation $\langle \cdot | \cdot \rangle$ to denote the pairing of a distribution with a test function, which we take to be linear in both entries. We reserve the notation $\langle \cdot, \cdot \rangle$ to denote the usual Hilbert space inner product of L^2 , conjugate linear in the second entry. With this notation we can associate to Λ the linear dual operators T and T^* , continuous from $\mathcal{S}(\mathbb{R})$ to $\mathcal{S}'(\mathbb{R})$, given by

$$\Lambda(f_1, f_2) = \langle T(f_1) | f_2 \rangle = \langle T^*(f_2) | f_1 \rangle.$$

We see from (2.3) that the Schwartz kernel of T restricted away from the diagonal of \mathbb{R}^2 agrees with the function \tilde{K} , as usually stated for linear Calderón-Zygmund operators. When convenient in our computations, and without loss of generality, we will often assume this more classical representation (2.3) for Λ .

Definition 2.3. *A trilinear form Λ defined on $\mathcal{S}(\mathbb{R}) \times \mathcal{S}(\mathbb{R}) \times \mathcal{S}(\mathbb{R})$, is said to be associated with a standard Calderón-Zygmund kernel K if for some $\beta = (\beta_1, \beta_2, \beta_3)$ and for all functions $f_1, f_2, f_3 \in \mathcal{S}(\mathbb{R})$ such that the intersection of the three supports is empty, we have*

$$(2.4) \quad \Lambda(f_1, f_2, f_3) = \int_{\mathbb{R}^2} \prod_{j=1}^3 f_j(x + \beta_j t) K(x, t) dx dt.$$

If the form is continuous on $\mathcal{S}(\mathbb{R}) \times \mathcal{S}(\mathbb{R}) \times \mathcal{S}(\mathbb{R})$ then it will be referred to as a trilinear Calderón-Zygmund form.

Now the trilinear form Λ is associated to the bilinear dual operators given by

$$\Lambda(f_1, f_2, f_3) = \langle T_3(f_1, f_2) | f_3 \rangle = \langle T_1(f_2, f_3) | f_1 \rangle = \langle T_2(f_1, f_3) | f_2 \rangle,$$

but unlike the bilinear case, K is no longer the restriction of the Schwartz kernel of T_3 . In the sequel, we shall assume that $\beta_1, \beta_2, \beta_3$ are pairwise different, as otherwise the trilinear form reduces to a combination of a pointwise product and bilinear form. If needed, by a simple change of variables and appropriately modifying the constants involved in the definition of a Calderón-Zygmund kernel, we can assume β to be of unit length and perpendicular to $\alpha = (1, 1, 1)$. Let γ be a unit vector perpendicular to α and β , the sign of γ being of no importance. The condition that no two components of β are equal is equivalent to no component of γ being zero. The integral representing Λ for functions with disjoint supports satisfies the *modulation symmetry along the direction of γ* :

$$(2.5) \quad \Lambda(f_1, f_2, f_3) = \Lambda(M_{\gamma_1 \xi} f_1, M_{\gamma_2 \xi} f_2, M_{\gamma_3 \xi} f_3)$$

for all $\xi \in \mathbb{R}$. Here modulation is defined as $M_\eta f(x) = e^{2\pi i \eta x} f(x)$. Note, however, that the kernel representation does not guarantee the modulation invariance (2.5) for arbitrary triples of Schwartz functions f_1, f_2, f_3 .

Definition 2.4. *A trilinear Calderón-Zygmund form Λ associated with a standard kernel K for some β is said to have modulation symmetry in the direction γ , with γ of unit length and perpendicular to the plane generated by β and α , if (2.5) is satisfied for all functions $f_1, f_2, f_3 \in \mathcal{S}(\mathbb{R})$.*

Let us look at typical examples of these operators given in pseudodifferential form. Consider again the bilinear Hilbert transform

$$T(f_1, f_2)(x) = \text{p.v.} \int_{\mathbb{R}} f_1(x-t) f_2(x+t) \frac{dt}{t},$$

or equivalently

$$T(f_1, f_2)(x) = \int_{\mathbb{R}^2} \text{sign}(\xi - \eta) \widehat{f}_1(\xi) \widehat{f}_2(\eta) e^{2\pi i x \cdot (\xi + \eta)} d\xi d\eta.$$

More generally, one can consider operators of the form

$$T(f_1, f_2)(x) = \int_{\mathbb{R}^2} m(\xi - \eta) \widehat{f}_1(\xi) \widehat{f}_2(\eta) e^{2\pi i x \cdot (\xi + \eta)} d\xi d\eta,$$

where m is a multiplier satisfying the classical conditions

$$|m^{(n)}(u)| \leq C|u|^{-n}, \quad n \leq N.$$

Undoing the Fourier transforms of f_1, f_2 , one arrives to the kernel representation of T , namely

$$T(f_1, f_2)(x) = \text{p.v.} \int_{\mathbb{R}} f_1(x-t) f_2(x+t) K(t) dt,$$

where K is a classical CZ kernel of convolution type and $\widehat{K}(u) = m(u)$. These bilinear operators fall under the scope of the more general boundedness results stated in [15] and [24].

To introduce x -dependent kernels consider now bilinear operators of the form

$$T(f_1, f_2)(x) = \int_{\mathbb{R}^2} \sigma(x, \xi - \eta) \widehat{f}_1(\xi) \widehat{f}_2(\eta) e^{2\pi i x(\xi + \eta)} d\xi d\eta,$$

where $\sigma(x, u)$ is a symbol in the Hörmander class $S_{1,0}^0$, so that

$$|\partial_x^\mu \partial_{\xi, \eta}^\alpha \sigma(x, \xi - \eta)| \leq C_\alpha (1 + |\xi - \eta|)^{-|\alpha|}.$$

Then, undoing again the Fourier transforms, we arrive to the following integral representation of T valid at least for functions with disjoint support:

$$\begin{aligned} T(f_1, f_2)(x) &= \int_{\mathbb{R}^2} K(x, x - y) \delta(z - 2x + y) f_1(y) f_2(z) dy dz \\ &= \int_{\mathbb{R}} K(x, t) f_1(x - t) f_2(x + t) dt, \end{aligned}$$

where $K(x, x - y) = (\mathcal{F}^{-1}\sigma)(x, x - y)$ and the inverse Fourier transform is taken in the second variable. It is well-known that such a K is a Calderón-Zygmund kernel (and with $\delta = 1$). These bilinear operators give rise then to trilinear forms of the type (2.4) with $\beta = (-1, 1, 0)$.

In the previous example, the Schwartz kernel of the bilinear operator T is given by $k(x, y, z) = K(x, x - y) \delta(z - 2x + y)$ and hence it is too singular to fall under the scope of other multilinear $T(1)$ theorems in [5] and [18], which essentially apply to pseudodifferential operators of the form

$$T(f_1, f_2)(x) = \int_{\mathbb{R}^2} \sigma(x, \xi, \eta) \widehat{f}_1(\xi) \widehat{f}_2(\eta) e^{2\pi i x(\xi + \eta)} d\xi d\eta,$$

where $\sigma(x, \xi, \eta)$ satisfies the classical Coifman-Meyer estimates

$$|\partial_x^\mu \partial_{\xi, \eta}^\alpha \sigma(x, \xi, \eta)| \leq C_\alpha (1 + |\xi| + |\eta|)^{-|\alpha|},$$

so that the (restricted) Schwartz kernels satisfy

$$|\partial^\alpha k(x, y, z)| \leq C_\alpha (|x - y| + |y - z| + |z - x|)^{-(|\alpha|+1)}.$$

Definition 2.5. An L^p -normalized bump function $\phi : \mathbb{R}^m \rightarrow \mathbb{C}$ is said to be C -adapted of order N to a box $I := I_1 \times \dots \times I_m$ if

$$|\partial^\alpha \phi(x)| \leq C \prod_{m'=1}^m |I_{m'}|^{-1/p - \alpha_{m'}} \chi_I^N(x),$$

for each $0 \leq |\alpha| \leq N$.

We will use the notation

$$\chi_I(x) = \left(1 + \left\| \left(\frac{x_1 - c(I_1)}{|I_1|}, \dots, \frac{x_m - c(I_m)}{|I_m|} \right) \right\|^2 \right)^{-1/2},$$

with $c(I)$ denoting the center of the interval I . Often times we will simply call a function L^p - adapted to I (or L^p - adapted to I of some order N_0), if it is L^p - normalized and C_N - adapted of each order N (or of order N_0), for some C_N whose value will not be specified. When no L^p normalization will be mentioned for a bump, it will be implicitly understood that the normalization is taken in L^2 .

The implicit bounds hidden in the notation $a \lesssim b$ that we shall use, will be allowed to depend on the constants of adaptation and on fixed parameters like γ , δ , α or C_K . The notation $A \approx B$ will mean that $A \lesssim B$ and $B \lesssim A$.

Before we state our main result we recall the classical $T(1)$ theorem in a form useful for our purposes.

Theorem 2.6 (Linear $T(1)$ theorem). *Assume Λ is a Calderón-Zygmund form on $\mathcal{S}(\mathbb{R}) \times \mathcal{S}(\mathbb{R})$. Then Λ extends to a bounded bilinear form on $L^2(\mathbb{R}) \times L^2(\mathbb{R})$ if and only if there exists an N such that*

$$(2.6) \quad \begin{aligned} |\Lambda(\phi_I, f)| &\lesssim \|f\|_2 \\ |\Lambda(f, \phi_I)| &\lesssim \|f\|_2 \end{aligned}$$

for any interval I , any L^2 - adapted bump function ϕ_I of order N which is supported in I and any Schwartz function f . If these equivalent conditions are satisfied, then the bilinear form extends also to a bounded form on $L^p(\mathbb{R}) \times L^{p'}(\mathbb{R})$ for $1 < p < \infty$ and $1/p + 1/p' = 1$.

The condition (2.6) and its symmetric form are called the restricted boundedness conditions. In Lemma 3.1 we will see a slightly stronger result, namely that it is sufficient to test the restricted boundedness condition only for those f supported in I .

Remark 2.1. *There are a few other equivalent formulations of the $T(1)$ theorem. We just recall, as mentioned in the introduction, that the boundedness of T is also equivalent to the weak boundedness property (that is $\Lambda(\varphi_I, \varphi_I) \lesssim 1$ for all φ_I which are L^2 - adapted to I) together with the fact that some appropriately defined functions $\Lambda(1, \cdot)$, $\Lambda(\cdot, 1)$ are in BMO.*

We now state our new result for trilinear forms.

Theorem 2.7 (Main theorem). *Assume Λ is a trilinear Calderón-Zygmund form on $\mathcal{S}(\mathbb{R}) \times \mathcal{S}(\mathbb{R}) \times \mathcal{S}(\mathbb{R})$ associated with a kernel K with parameter δ , and with modulation symmetry (2.5) in the direction of γ (with $\gamma_i \neq 0$).*

Then Λ extends to a bounded form

$$|\Lambda(f_1, f_2, f_3)| \lesssim \prod_{j=1}^3 \|f_j\|_{p_j}$$

for all exponents $2 \leq p_1, p_2, p_3 \leq \infty$ with

$$\frac{1}{p_1} + \frac{1}{p_2} + \frac{1}{p_3} = 1$$

if and only if there is an² N such that the following three estimates hold for all intervals I , all L^2 - adapted functions ϕ_I and ψ_I of order N which are also supported in I , and all Schwartz functions f

$$(2.7) \quad \begin{aligned} |\Lambda(\phi_I, \psi_I, f)| &\lesssim |I|^{-1/2} \|f\|_2, \\ |\Lambda(\phi_I, f, \psi_I)| &\lesssim |I|^{-1/2} \|f\|_2, \\ |\Lambda(f, \phi_I, \psi_I)| &\lesssim |I|^{-1/2} \|f\|_2. \end{aligned}$$

Moreover, if these equivalent conditions hold, then for $\sum_j \alpha_j = 1$ the following holds: If $0 \leq \alpha_i < \min(1/2 + \delta, 1)$ for $1 \leq i \leq 3$, then

$$|\Lambda(f_1, f_2, f_3)| \lesssim \prod_{i=1}^3 \|f_i\|_{1/\alpha_i}.$$

If $\max(-\delta, -1/2) < \alpha_j < 0$ for only one index j and $0 \leq \alpha_i < \min(1/2 + \delta, 1)$ for the other two indices, then the dual operator T_j satisfies

$$\|T_j((f_i)_{i \neq j})\|_{1/(1-\alpha_j)} \lesssim \prod_{i \neq j} \|f_i\|_{1/\alpha_i}.$$

To summarize, there is an a priori estimate for the form Λ and a tuple α of reciprocals of exponents provided that $\sum_j \alpha_j = 1$ and $\max(-\delta, -1/2) < \alpha_j < \min(1/2 + \delta, 1)$ for all j . Interestingly, the range of exponents α for which the theorem guarantees boundedness is the same for each $\delta \in [\frac{1}{2}, 1]$, while the range shrinks for $\delta < \frac{1}{2}$, as δ approaches 0. We do not know if this range is optimal. Note also that for $\delta \geq 1/2$ in Theorem 2.7 we recover the same range in which the bilinear Hilbert transform is known to be bounded.

It is worthwhile noting that the necessity of condition (2.7) and its symmetric counterparts is clear, as such conditions follow from the claimed estimates applied to special test functions. We call these conditions the *(trilinear) restricted boundedness conditions*. One can see that it is also enough to test the conditions for C^∞ functions f supported in an interval containing I of length $C|I|$, where $C > 0$ is a universal constant. See Lemma 3.3 below for more details.

Note also that, formally, if Λ is a trilinear Calderón-Zygmund form satisfying the conditions of the main theorem, then

$$\Lambda(f_1, f_2, 1)$$

²As in the case of the classical $T(1)$ Theorem, the value of N is not important. Once the theorem holds for some N , it also holds for any larger value. This observation will be used repeatedly throughout the argument.

is a bilinear Calderón-Zygmund form satisfying the conditions of the classical $T(1)$ Theorem. We will make this reduction to bilinear forms rigorous in the next section. However, not every bounded bilinear Calderón-Zygmund form can be obtained this way, since for the trilinear form to be bounded more conditions need to be satisfied. We will see concrete examples in Section 7.

2.2. Applications.

Of course, the relevance of Theorem 2.7 is that it applies to operators with x -dependent kernels. We present one application to the bilinear pseudodifferential operators mentioned before.

Consider again the trilinear form

$$\begin{aligned} \Lambda(f_1, f_2, f_3) &= \int_{\mathbb{R}} T_3(f_1, f_2)(x) f_3(x) dx \\ &= \int_{\mathbb{R}^3} \sigma(x, \xi - \eta) \widehat{f}_1(\xi) \widehat{f}_2(\eta) f_3(x) e^{2\pi i x(\xi + \eta)} d\xi d\eta dx \end{aligned}$$

with σ in $S_{1,0}^0$. Note that this form has modulation symmetry in the direction $\gamma = (1, 1, -2)/\sqrt{6}$ for all triples f_1, f_2, f_3 , not just the ones with disjoint supports. To check the first of the restricted bounded conditions we may assume f is supported in CI and compute

$$\begin{aligned} |\Lambda(\phi_I, \psi_I, f)| &\lesssim \|\widehat{\phi}_I\|_{L^1} \|\widehat{\psi}_I\|_{L^1} \|f\|_{L^1} \lesssim \|\widehat{\phi}_I\|_{L^1} \|\widehat{\psi}_I\|_{L^1} |I|^{1/2} \|f\|_{L^2} \\ &\lesssim |I|^{-1/2} \|f\|_{L^2}. \end{aligned}$$

Here, we used that $\widehat{\phi}_I$ and $\widehat{\psi}_I$ are L^2 -normalized and adapted to intervals of length $|I|^{-1}$. More precisely, ϕ_I can be written as $\phi_I(x) = |I|^{-1/2} \phi_0((x - x_0)/|I|)$ where ϕ_0 is adapted to and supported in the unit interval centered at the origin. It follows easily now that

$$\|\widehat{\phi}_I\|_{L^1} = |I|^{-1/2} \|\widehat{\phi}_0\|_{L^1} \leq C |I|^{-1/2}$$

where C depends only on finitely many derivatives of ϕ_0 . The same estimate applies to ψ_I . To obtain the other restricted boundedness conditions, write

$$\Lambda(\phi_I, f, \psi_I) = \int_{\mathbb{R}} T_2(\phi_I, \psi_I)(x) f(x) dx$$

and

$$\Lambda(f, \phi_I, \psi_I) = \int_{\mathbb{R}} T_1(\phi_I, \psi_I)(x) f(x) dx.$$

It was proved by Á. Bényi, A. Nahmod and R. Torres [1], that T_1 and T_2 can be computed from σ and they admit pseudodifferential representations of the form³

$$T_2(f, g)(x) = \int_{\mathbb{R}^2} \sigma_2(x, \xi, \eta) \widehat{f}(\xi) \widehat{g}(\eta) e^{2\pi i x(\xi + \eta)} d\xi d\eta$$

³ $T_1(f, g) = T^{*1}(g, f)$ and $T_2(f, g) = T^{*2}(f, g)$ in the notation of [1].

and

$$T_1(f, g)(x) = \int_{\mathbb{R}^2} \sigma_1(x, \xi, \eta) \widehat{g}(\xi) \widehat{f}(\eta) e^{2\pi i x(\xi + \eta)} d\xi d\eta$$

where $\sigma_2(x, \xi, \eta)$ and $\sigma_1(x, \xi, \eta)$ satisfy

$$|\partial_x^\mu \partial_{\xi, \eta}^\alpha \sigma_2(x, \xi, \eta)| \lesssim (1 + |2\xi + \eta|)^{-|\alpha|}$$

and

$$|\partial_x^\mu \partial_{\xi, \eta}^\alpha \sigma_1(x, \xi, \eta)| \lesssim (1 + |\xi + 2\eta|)^{-|\alpha|}.$$

The computations done with T_3 can now be repeated with T_2 and T_1 . It follows that Λ and the T_j have the boundedness properties of Theorem 2.7 with $\delta = 1$.

Similar examples of forms can be obtained by starting with a bilinear operator T_3 given by a symbol of the form $\sigma_\theta(x, \xi, \eta) = \sigma(x, \eta - \xi \tan \theta)$ for σ in $S_{1,0}^0$ and $\theta \neq -\pi/4, 0, \pi/2$ (we make the convention $\sigma_{\pi/2}(x, \xi, \eta) = \sigma(x, \xi)$). In the three forbidden cases when $\theta = -\pi/4, 0, \pi/2$ the trilinear forms correspond again to a combination of a pointwise product and a bilinear form. See [1] for more details.

The above examples of operators appear when studying symbolic calculus properties of bilinear pseudodifferential operators. They provided some of the original motivation to look at the boundedness results presented here. We refer again to [1] for more on the subject.

There are certainly other operators to which our main theorem applies. Because of the persisting appearance of Calderón's commutators in problems involving singular integrals, a very natural operator to consider is, for example, the one associated with the trilinear form

$$p.v. \int f(x+t)g(x-t)h(x) \frac{A(x+t) - A(x)}{t^2} dt dx,$$

where A is a Lipschitz function. There are at least two ways to study this form. One possible approach⁴ is to use the main theorem after verifying the restricted boundedness conditions for appropriately modified bilinear Hilbert transform. There is, however, a simpler and more general method that applies to *antisymmetric* kernels and that we will follow using an alternative formulation of the main theorem combined with the linear theory. We postpone the application to this general class of antisymmetric kernels until after we introduce Theorem 3.10 in Section 3.2. Nevertheless, the reader familiar with other computations involving the Calderón commutators and interested only in such application may jump directly to Section 3.3, where their study in this bilinear context is presented.

2.3. Plan of the proof.

The rest of this article is structured as follows. In Section 3, after some basic reductions, we present some equivalent formulations of the main theorem. In particular, in analogy to the classical $T(1)$ theorem, we give a meaning to the functions $T_j(1, 1)$ for

⁴Suggested to some of the authors by C. Muscalu.

$j = 1, 2, 3$ (see Lemma 3.7 below) and show that the restricted boundedness conditions imply that these functions are in BMO. We also observe that the restricted boundedness conditions imply a certain weaker one (3.8), which together with the conditions $T_j(1, 1) \in \text{BMO}$ is all what will be used to prove the main theorem. Hence this set of conditions is also necessary and sufficient to obtain the bounds on the trilinear form.

In Section 4 we establish some bounds on the action of trilinear Calderón-Zygmund forms satisfying the alluded weak continuity (3.8) and some special cancellation conditions on bumps functions. These are almost orthogonality type conditions. The proof of the Theorem 2.7 then splits into two steps. First, one proves the theorem under the special cancellation condition that $T_j(1, 1) = 0$ for all j . This step is done in Sections 5 and 6. In the former the problem is reduced to a time-frequency model form, which is then estimated in the latter.

The second step in the proof of the theorem is to construct for each given BMO function b , forms Λ_j , $j = 1, 2, 3$, which are associated to Calderón-Zygmund kernels, have a given modulation symmetry, satisfy the bounds of the theorem, and are such that the corresponding dual operators satisfy $T_j(1, 1) = b$ and $T_i(1, 1) = 0$ for $i \neq j$. By analogy again with the classical T(1) Theorem, we call these special forms modulation invariant paraproducts. Then, Theorem 2.7 can be always reduced to the case with special cancellation by subtracting from the original form Λ three paraproducts with the same modulation symmetry. The paraproducts are discussed in Section 7.

3. ALTERNATIVE FORMULATIONS OF THE MAIN THEOREM AND FURTHER EXAMPLES

3.1. Some technical lemmas and the expected appearance of BMO.

We begin this discussion by a lemma that implies the strengthening of the classical Theorem 2.6 that was mentioned after the statement of the theorem. This will be used in the proof of Lemma 3.3.

From now on, for each box I in \mathbb{R}^n and each $R > 0$, RI will denote the box with the same center as I and sidelengths R times larger than those of I .

Lemma 3.1. *Assume Λ is a continuous bilinear form on $\mathcal{S}(\mathbb{R}) \times \mathcal{S}(\mathbb{R})$ that is associated with a standard Calderón-Zygmund kernel K . Assume there is an N such that the restricted boundedness condition*

$$|\Lambda(\phi_I, f)| \leq C_0 \|f\|_2$$

holds for all bump functions ϕ_I of order N adapted to and supported in I and all Schwartz functions f supported in I . Then,

$$|\Lambda(\phi_I, f)| \leq C \|f\|_2$$

(with a possibly larger constant C) also holds for all bump functions ϕ_I of order N adapted to and supported in I and all Schwartz functions f (not necessarily supported in I).

Proof. Without loss of generality, we may assume that I is centered at the origin. Also, by the continuity of Λ on $\mathcal{S}(\mathbb{R}) \times \mathcal{S}(\mathbb{R})$, it is enough to prove the conclusion for all f in \mathcal{S} with compact support. Consider first the case when ϕ_I has mean zero. Let R be a large constant chosen later depending on β . Decompose now in a smooth way $f = f_1 + f_2$, with f_1 supported in $2RI$ and f_2 supported outside RI . Since $(2R)^{-(1/2+N)}\phi_I$ is adapted to and supported in $2RI$, the hypotheses of the Lemma give then

$$|\Lambda(\phi_I, f_1)| \leq C_0(2R)^{(1/2+N)}\|f\|_2.$$

To estimate $\Lambda(\phi_I, f_2)$ we use the kernel representation with the change of variables explained in the introduction to get

$$\Lambda(\phi_I, f_2) = \int \phi_I(u)f_2(v)\tilde{K}(u, v) du dv,$$

where \tilde{K} satisfies

$$|\tilde{K}(u, v) - \tilde{K}(u', v')| \leq C_{\beta_1, \beta_2}|u - v|^{-1-\delta}\|(u, v) - (u', v')\|^\delta$$

for $c_\beta\|(u, v) - (u', v')\| < |u - v|$ and $c_\beta \geq 2$. The domain of integration is given by $|u| < |I|/2$ and $|v| > R|I|/2$, which imply that $|u - v| > (R - 1)|I|/2 > c_\beta|u|$ if R is large enough. Thus, using the mean zero of ϕ_I we can write

$$\Lambda(\phi_I, f_2) = \int \phi_I(u)f_2(v)(\tilde{K}(u, v) - \tilde{K}(0, v)) du dv$$

and obtain

$$\begin{aligned} |\Lambda(\phi_I, f_2)| &\leq C_{\beta_1, \beta_2} \int |\phi_I(u)||f_2(v)||u|^\delta|u - v|^{-(1+\delta)} du dv \\ &\leq C_{\beta_1, \beta_2}|I|^\delta \int_{|u-v|>c|I|} |\phi_I(u)||f_2(v)||u - v|^{-(1+\delta)} du dv \\ &\leq C_{\beta_1, \beta_2}|I|^\delta\|\phi_I\|_2\|f_2\|_2 \int_{|x|>c|I|} |x|^{-(1+\delta)} dx \leq C_{\beta_1, \beta_2}\|f\|_2. \end{aligned}$$

This proves

$$|\Lambda(\phi_I, f)| \leq C_1\|f\|_2$$

for an appropriate constant C_1 under the additional assumption that ϕ_I has mean zero.

To treat the general case, define $\phi_{2^j I}(x) = 2^{-j/2}\phi_I(2^{-j}x)$ for $j > 0$ and observe that $2^{-(1/2+N)}(\phi_{2^j I} - 2^{-1/2}\phi_{2^{j+1} I})$ is adapted to and supported in $2^{j+1}I$ and has mean zero. Let now $k \geq 0$ be the smallest integer such that the support of f is contained in $2^{k+1}I$, and write

$$\Lambda(\phi_I, f) = \sum_{j=0}^k 2^{-j/2}\Lambda(\phi_{2^j I} - 2^{-1/2}\phi_{2^{j+1} I}, f) + 2^{-(k+1)/2}\Lambda(\phi_{2^{k+1} I}, f).$$

In the first $k+1$ terms the bumps have mean zero, while the last term can be controlled by the hypothesis. Thus,

$$|\Lambda(\phi_I, f)| \leq (C_1 2^{1/2+N} \sum_{j=0}^k 2^{-j/2} + C_0 2^{-(k+1)/2}) \|f\|_2 \leq C \|f\|_2,$$

where C is independent of k . \square

We continue by studying the relationship between bilinear and trilinear forms. By the Schwartz kernel theorem, the trilinear form Λ can be represented by a tempered distribution in \mathbb{R}^3 , which we shall also denote by Λ , so that

$$\Lambda(\phi_1, \phi_2, \phi_3) = \Lambda(\phi_1 \otimes \phi_2 \otimes \phi_3).$$

In this way, $\Lambda(\phi)$ has a meaning for any $\phi \in \mathcal{S}(\mathbb{R}^3)$ not necessarily a tensor product.

Moreover, the modulation invariance of Λ implies that the distribution is supported on the orthogonal complement of γ . Even stronger, it is given by a two dimensional distribution Λ_* applied to the restriction $\phi|_{\gamma^\perp} : \gamma^\perp \rightarrow \mathbb{C}$ of the test function ϕ to γ^\perp . This can be seen as follows. Consider first a function f in $C_0^\infty(\mathbb{R}^3)$ and pick another function φ in $C_0^\infty(\mathbb{R}^3)$ with $\varphi \equiv 1$ on a neighborhood of the support of f . By the linearity, continuity, and modulation invariance of Λ , and writing $\xi = t\gamma + \xi^*$ with ξ^* in γ^\perp , we get

$$\begin{aligned} \Lambda(f) &= \Lambda(\varphi f) = \Lambda\left(\int \varphi(x) e^{2\pi i x \xi} \widehat{f}(\xi) d\xi\right) = \Lambda\left(\int_{\mathbb{R}} \int_{\gamma^\perp} \varphi(x) e^{2\pi i x \gamma t} e^{2\pi i x \xi^*} \widehat{f}(t\gamma + \xi^*) dt d\xi^*\right) \\ &= \int_{\mathbb{R}} \int_{\gamma^\perp} \Lambda(\varphi(x) e^{2\pi i x \gamma t} e^{2\pi i x \xi^*}) \widehat{f}(t\gamma + \xi^*) dt d\xi^* = \int_{\mathbb{R}} \int_{\gamma^\perp} \Lambda(\varphi(x) e^{2\pi i x \xi^*}) \widehat{f}(t\gamma + \xi^*) dt d\xi^* \\ &= \Lambda\left(\int_{\mathbb{R}} \int_{\gamma^\perp} \varphi(x) e^{2\pi i x \xi^*} \widehat{f}(t\gamma + \xi^*) dt d\xi^*\right) = \Lambda\left(\int_{\mathbb{R}^3} \varphi(x) e^{2\pi i x \xi} \widehat{f}(\xi) d\xi\right) = \Lambda(\varphi f_*), \end{aligned}$$

where $f_*(x) = f(x^*)$. (Note that φf_* is still in $C_0^\infty(\mathbb{R}^3)$). In particular, if two functions f_1 and f_2 in $C_0^\infty(\mathbb{R}^3)$ agree on γ^\perp , then $\Lambda(f_1 - f_2) = 0$. Also, since $C_0^\infty(\mathbb{R}^3)$ is dense in $\mathcal{S}(\mathbb{R}^3)$, a simple limiting argument shows that $\Lambda(f) = 0$ for all $f \in \mathcal{S}(\mathbb{R}^3)$ with $\text{supp } f \cap \gamma^\perp = \emptyset$ and so $\text{supp } \Lambda$ is contained in γ^\perp .

Now, let $\tilde{\psi}$ be in $C_0^\infty(\mathbb{R})$, $\tilde{\psi} \equiv 1$ in a neighborhood of zero, and define $\psi(x) = \psi(t\gamma + x^*) = \tilde{\psi}(t)$. We have already seen that for $f \in C_0^\infty(\mathbb{R}^3)$, $\Lambda(f)$ depends only on $f|_{\gamma^\perp}$ so

$$\Lambda(f) = \Lambda(\psi f) = \Lambda(\psi f_*)$$

and a limiting argument gives the same result for $f \in \mathcal{S}(\mathbb{R}^3)$. This also allows to define a distribution in $\mathcal{S}'(\gamma^\perp)$ by

$$\Lambda_*(g) = \Lambda(\psi \tilde{g})$$

for all $g \in \mathcal{S}(\gamma^\perp)$, where $\tilde{g} : \mathbb{R}^3 \rightarrow \mathbb{C}$ satisfies $\tilde{g}(t\gamma + x^*) = g(x^*)$. The definition is clearly independent of the choice of ψ and we have

$$\Lambda(f) = \Lambda_*(f|_{\gamma^\perp}).$$

Clearly, by a density argument, the kernel representation of Λ continues to hold when the test function ϕ is no longer a tensor product but still has support disjoint from the span of $(1, 1, 1)$.

Moreover,

$$\Lambda(\phi) = \int \phi(x\alpha + t\beta) K(x, t) dxdt = \int \phi(x + \beta_1 t, x + \beta_2 t, x + \beta_3 t) K(x, t) dxdt$$

and the integral is absolutely convergent as long as function ϕ just vanishes on the span of $(1, 1, 1)$, but provided that Λ satisfies a weak boundedness property (3.8) below, which is implied by the restricted boundedness conditions. To verify this, the reader may adapt to the case of trilinear forms the arguments used in, for example, [31] for bilinear ones.

There are three distinct bilinear forms that we can consider now

$$\Lambda_1(\phi_2, \phi_3) = \Lambda_*((1 \otimes \phi_2 \otimes \phi_3)|_{\gamma^\perp})$$

$$\Lambda_2(\phi_1, \phi_3) = \Lambda_*((\phi_1 \otimes 1 \otimes \phi_3)|_{\gamma^\perp})$$

$$\Lambda_3(\phi_1, \phi_2) = \Lambda_*((\phi_1 \otimes \phi_2 \otimes 1)|_{\gamma^\perp})$$

Observe that the functions on the right hand side are in $\mathcal{S}(\gamma^\perp)$, since none of the components of γ is zero. Moreover in case of disjointly supported functions ϕ_2, ϕ_3 we obtain a kernel representation for Λ_1 with the same kernel K . In fact, since $\psi(1 \otimes \phi_2 \otimes \phi_3) \in \mathcal{S}(\mathbb{R}^3)$ and obviously has the same values as $\psi(1 \otimes \phi_2 \otimes \phi_3)_*$ on γ^\perp ,

$$\begin{aligned} \Lambda_1(\phi_2, \phi_3) &= \Lambda_*((1 \otimes \phi_2 \otimes \phi_3)|_{\gamma^\perp}) = \Lambda(\psi(1 \otimes \phi_2 \otimes \phi_3)_*) = \Lambda(\psi(1 \otimes \phi_2 \otimes \phi_3)) \\ &= \int \psi(x\alpha + t\beta) \phi_2(x + \beta_2 t) \phi_3(x + \beta_3 t) K(x, t) dxdt = \int \phi_2(x + \beta_2 t) \phi_3(x + \beta_3 t) K(x, t) dxdt. \end{aligned}$$

Similarly for Λ_2 and Λ_3 .

In the sequel we will use the following notation.

Definition 3.2. For $a > 0, v \in \mathbb{R}^d$ the L^p -normalized dilation operator D_a^p and the translation operator τ_v are defined via

$$D_a^p f(x) = a^{-d/p} f(a^{-1}x), \tau_v f(x) = f(x - v),$$

for all functions f defined on \mathbb{R}^d . We will also sometimes write

$$D_a f(x) = D_a^\infty f(x) = f(a^{-1}x).$$

Lemma 3.3. The restricted boundedness conditions for Λ are equivalent to the restricted boundedness conditions for the Λ_i 's, if one is willing to have a loss in the order of the bump functions and the constants involved in defining restricted boundedness.

Proof. We assume first that Λ satisfies the restricted boundedness conditions, and prove restricted boundedness of Λ_1 (Λ_2 and Λ_3 can be done analogously). Let $\Phi : \mathbb{R} \rightarrow [0, 1]$ be smooth with

$$(3.1) \quad \begin{aligned} \Phi(x) &= 1 & |x| \leq 1 \\ \Phi(x) &= 0 & |x| \geq 2. \end{aligned}$$

It is easy to check that if f is supported in the interval I (Lemma 3.1 allows us to restrict attention to this case) then

$$(1 \otimes \phi_I \otimes f)|_{\gamma^\perp} = (\tau_{c(I)} D_{C|I|} \Phi \otimes \phi_I \otimes f)|_{\gamma^\perp},$$

where C is a sufficiently large constant depending only on γ . To obtain restricted boundedness for Λ_1 , we simply apply the restricted boundedness of Λ for the enlarged interval CI .

For the converse, we first show, as claimed in the introduction, that it is enough to show the restricted boundedness estimates for $\Lambda(\phi_I \otimes \psi_I \otimes f)$ for every C^∞ function f supported in CI , where C is a universal constant depending on γ . To see this, and without loss of generality, we may assume I centered at the origin. The region $|x + \beta_1 t| < |I|/2$ and $|x + \beta_2 t| < |I|/2$ is a parallelogram centered at the origin in the (x, t) while $|x + \beta_3 t| > C|I|/2$ is the complement of a strip along the line $x + \beta_3 t = 0$. Recall that the components of β are pairwise distinct, so if C is large enough depending only on β , then the two regions do not intersect. Decompose now in a smooth way $f = f_{CI} + (f - f_{CI})$, where f_{CI} coincides with f on CI , is zero outside $2CI$ and satisfies $\|f_{CI}\|_2 \leq 2\|f\|_2$. Note that $\phi_I \otimes \psi_I \otimes (f - f_{CI})(x\alpha + t\beta) \equiv 0$, so we must have $\Lambda(\phi_I \otimes \psi_I \otimes (f - f_{CI})) = 0$, and the claim follows.

Assume now that all the Λ_i satisfy restricted boundedness conditions of order N . For simplicity of notation also assume that I is of length $1/C$ and centered at the origin and that ϕ_I, ψ_I are bump functions adapted of order $N' \gg N$ and supported in I . Let f be a smooth function supported in CI . Let g be adapted of order N' and supported on $\{|u| < 1/(2C) < 1/2, |v| < 1/2\}$ and so that $g(u, v)\psi_I(u)f(v) = \psi_I(u)f(v)$ on the same region. Write $\tilde{\phi}(u, v) = \phi_I(-\gamma_1^{-1}(\gamma_2 u + \gamma_3 v))$ and note that $\tilde{\phi}g$ is adapted of order N' to $[-1/2, 1/2] \times [-1/2, 1/2]$. Expanding $\tilde{\phi}g$ in Fourier series on $[-1/2, 1/2] \times [-1/2, 1/2]$ we get

$$\begin{aligned} & \phi_I(x + \beta_1 t)\psi_I(x + \beta_2 t)f(x + \beta_3 t) \\ &= \tilde{\phi}(x + \beta_2 t, x + \beta_3 t)g(x + \beta_2 t, x + \beta_3 t)\psi_I(x + \beta_2 t)f(x + \beta_3 t) \\ &= \sum_{m_2, m_3} c_{m_2, m_3} \psi_I(x + \beta_2 t) e^{2\pi i m_2(x + \beta_2 t)} f(x + \beta_3 t) e^{2\pi i m_3(x + \beta_3 t)}, \end{aligned}$$

with

$$|c_{m_2, m_3}| \lesssim (1 + \max(|m_2|, |m_3|))^{-N'}.$$

Now, the function

$$(1 + |m_2|)^{-N} \psi_I(x) e^{2\pi i m_2 x}$$

is a bump function of order N adapted to the interval I . The factor $(1 + |m_2|)^{-N}$ is needed to offset the loss of powers of m_2 when taking derivatives of the exponential factor. Applying the restricted boundedness of Λ_1 proves that

$$\Lambda(\phi_I \otimes \psi_I \otimes f) = \sum_{m_2, m_3} c_{m_2, m_3} (1 + |m_2|)^N \Lambda_1((1 + |m_2|)^{-N} M_{m_2} \psi_I, M_{m_3} f) \lesssim \|f\|_2.$$

□

Assuming Theorem 2.7 is true, we have thereby seen the following corollary of Theorems 2.6 and 2.7.

Theorem 3.4. *Let Λ be a trilinear Calderón-Zygmund form with modulation symmetry in direction γ . Then Λ extends to bounded trilinear form with exponents as in Theorem 2.7 if and only if Λ_i for $i = 1, 2, 3$ are bounded in $L^2 \times L^2$.*

The lemma below will allow us to state the restricted boundedness property in a slightly more general way. We need to consider bumps which may no longer be compactly supported but are still concentrated around appropriate intervals.

Lemma 3.5. *Assume Λ is a Calderón-Zygmund trilinear form with modulation symmetry in the direction γ and that satisfies the restricted boundedness conditions of Theorem 2.7 for some N . Then for all intervals I , all L^2 -normalized bump functions $\phi_{I \times I}$ L^2 -adapted to $I \times I$ of order $N' \gg N$ and all functions $f \in \mathcal{S}(\mathbb{R})$ we have the estimate*

$$|\Lambda(\phi_{I \times I} \otimes f)| \lesssim |I|^{-1/2} \|f\|_2$$

and the symmetric inequalities.

Proof. For simplicity of notation we shall assume I is centered at the origin and of length 1. We take a lacunary decomposition related to I : let Φ be as in (3.1) and define

$$\phi_0 = (\Phi \otimes \Phi) \phi_{I \times I}$$

$$\phi_k = (\Phi_k \otimes \Phi_k - \Phi_{k-1} \otimes \Phi_{k-1}) \phi_{I \times I}$$

for $k > 0$, where $\Phi_k = D_{2^k}^\infty \Phi$. Note that the functions ϕ_k add up to $\phi_{I \times I}$, so by using the continuity of Λ in $\mathcal{S}(\mathbb{R}^3)$ we obtain

$$(3.2) \quad \Lambda(\phi_{I \times I} \otimes f) = \sum_{k \geq 0} \Lambda(\phi_k \otimes f).$$

Note also that $2^{5k} \phi_k$ is L^2 -adapted to and supported in $2^{k+2}(I \times I)$. We write

$$\phi_k(x_1, x_2) = \widetilde{\phi}_k(x_1, x_2) \Phi_k(x_1) \Phi_k(x_2)$$

where $\widetilde{\phi}_k$ means the periodization of ϕ_k from the square $2^{k+2}(I \times I)$. By performing a windowed Fourier series, we obtain

$$\phi_k(x_1, x_2) = \sum_{m_1, m_2 \in \mathbb{Z}} c_{k, m_1, m_2} \Phi_k(x_1) \Phi_k(x_2) e^{2\pi i 2^{-(k+2)}(m_1 x_1 + m_2 x_2)}$$

where the coefficients c_{k,m_1,m_2} are rapidly decaying in the sense that

$$(3.3) \quad |c_{k,m_1,m_2}| \lesssim 2^{-5k}(1 + \max(|m_1|, |m_2|))^{-2N-5}$$

Denoting by $\Phi_{k,m}(x) = \Phi_k(x)e^{2\pi i 2^{-(k+2)}mx}$ we have that the functions $|m|^{-N}2^{-k/2}\Phi_{k,m}$ are L^2 -normalized, adapted of order N and supported in $2^{k+2}I$, uniformly in m and k .

By (3.2) we have

$$\begin{aligned} |\Lambda(\phi \otimes f)| &\leq \sum_{k \geq 0} \sum_{m_1, m_2 \in \mathbb{Z}} |c_{k,m_1,m_2}| |\Lambda(\Phi_{k,m_1}, \Phi_{k,m_2}, f)| \\ &\leq \sum_{k \geq 0} \sum_{m_1, m_2 \in \mathbb{Z}} |m_1|^N |m_2|^N 2^k |c_{k,m_1,m_2}| \Lambda(|m_1|^{-N} 2^{-k/2} \Phi_{k,m_1}, |m_2|^{-N} 2^{-k/2} \Phi_{k,m_2}, f) | \end{aligned}$$

Now the estimate of the lemma follows by applying (3.3) and the restricted boundedness condition to each summand on the right hand side with interval $2^{k+2}I$. \square

We will now give a rigorous definition of $T_i(1, 1)$ as a distribution modulo constants and prove that the restricted boundedness property implies that they are elements of BMO. The approach is similar to the linear case and we will follow some of the arguments in [28]. See also [31] and [18] for similar linear and multilinear definitions. We start with the following lemma.

Lemma 3.6. *Assume that Λ is a trilinear Calderón-Zygmund form with modulation symmetry in the direction γ . Let Φ be as in (3.1). For every C_0^∞ function f with mean zero the limit*

$$(3.4) \quad L(f) = \lim_{k \rightarrow \infty} \Lambda(D_{2^k}^\infty(\Phi \otimes \Phi) \otimes f) = \lim_{k \rightarrow \infty} \langle T_3(D_{2^k}^\infty \Phi, D_{2^k}^\infty \Phi) | f \rangle$$

exists. Moreover, if $\text{supp } f \subset (-2^{k_0}, 2^{k_0})$, then for sufficiently large k (depending on k_0 and γ) we have the error bound

$$(3.5) \quad |L(f) - \Lambda(D_{2^k}^\infty(\Phi \otimes \Phi) \otimes f)| \lesssim 2^{-\delta(k-k_0)} \|f\|_{L^1}$$

where δ is the parameter in the Calderón-Zygmund property of the kernel K and the implicit constant is independent of k_0, k and f .

Proof. Assume $\text{supp } f \subset (-2^{k_0}, 2^{k_0})$. For all $j > k \gg k_0$ write

$$D_{2^j}^\infty(\Phi \otimes \Phi) - D_{2^k}^\infty(\Phi \otimes \Phi) = \sum_{l=1}^{j-k} D_{2^{l+k}}^\infty(\Phi \otimes \Phi) - D_{2^{l+k-1}}^\infty(\Phi \otimes \Phi)$$

and let $\psi_l = D_{2^{l+k}}^\infty(\Phi \otimes \Phi) - D_{2^{l+k-1}}^\infty(\Phi \otimes \Phi)$. We will estimate $|\Lambda(\psi_l \otimes f)|$ to prove that the sequence $\Lambda(D_{2^k}^\infty(\Phi \otimes \Phi) \otimes f)$ is Cauchy, as well as to estimate the error bound. Since the support of $\psi_l \otimes f$ is disjoint from the span of $(1, 1, 1)$, we can use the kernel representation of Λ

$$\Lambda(\psi_l \otimes f) = \int \psi_l(x + \beta_1 t, x + \beta_2 t) f(x + \beta_3 t) K(x, t) dx dt.$$

Similarly to what we did in Section 2.1 for bilinear forms, a simple change of variables allows us to write the above integral in the form

$$\int \psi_l(u, v) f(w) \tilde{K}(u, w) dudw$$

where $v = -\gamma_2^{-1}(\gamma_1 u + \gamma_3 w)$ and \tilde{K} satisfies the classical Calderón-Zygmund estimates

$$(3.6) \quad |\tilde{K}(u, w)| \lesssim |u - w|^{-1},$$

$$(3.7) \quad |\tilde{K}(u, w) - \tilde{K}(u', w')| \lesssim |u - w|^{-(1+\delta)} \|(u, w) - (u', w')\|^\delta$$

for $c_\beta \|(u, w) - (u', w')\| < |u - w|$.

On the support of ψ_l ,

$$2^{l+k-1} \leq \|(u, v)\| \leq 2^{l+k+1}$$

and for $w \in \text{supp } f$, $|w| < 2^{k_0}$. Note that if $|u| < (1 + |\gamma_2^{-1}\gamma_1|)^{-1} 2^{k+l-2}$ and $k \gg k_0$, then

$$\|(u, v)\| \leq |u|(1 + |\gamma_2^{-1}\gamma_1|) + |\gamma_2^{-1}\gamma_3| 2^{k_0} < 2^{k+l-1}.$$

Thus, in the integral representation of $\Lambda(\psi_l \otimes f)$ we may assume

$$2^{k+l} \lesssim |u| \leq 2^{k+l+1}.$$

Using the mean zero property of f we obtain

$$\Lambda(\psi_l \otimes f) = \int [\psi_l(u, v) \tilde{K}(u, w) - \psi_l(u, -\gamma_2^{-1}\gamma_1 u) \tilde{K}(u, 0)] f(w) dw du.$$

We now write the term in square brackets as

$$(\psi_l(u, v) - \psi_l(u, v_0)) \tilde{K}(u, w) + \psi_l(u, v_0) (\tilde{K}(u, w) - \tilde{K}(u, 0))$$

and estimate each term by its supremum norm on the domain of integration. Clearly, we have $|\psi_l| \leq 2$. As the derivative of ψ_l is $O(2^{-k-l})$, we have

$$|\psi_l(u, v) - \psi_l(u, v_0)| \lesssim 2^{-k-l} |w| \lesssim 2^{-k-l} 2^{k_0}.$$

For \tilde{K} we have from the Calderón-Zygmund estimates

$$|\tilde{K}(u, w)| \lesssim |u - w|^{-1} \lesssim (2^{k+l} - 2^{k_0})^{-1} \lesssim 2^{-k-l}$$

and

$$|\tilde{K}(u, w) - \tilde{K}(u, 0)| \lesssim |u|^{-(1+\delta)} |w|^\delta \lesssim 2^{-(k-l)(1+\delta)} 2^{k_0 \delta},$$

Hence we can estimate

$$\begin{aligned} |\Lambda(\psi_l \otimes f)| &\lesssim (2^{-2(k+l)} 2^{k_0} + 2^{-(k+l)(1+\delta)} 2^{k_0 \delta}) \int_{|u| < 2^{k+l+1}} \int |f(w)| dudw \\ &\lesssim 2^{-(k+l-k_0)\delta} \|f\|_{L^1}. \end{aligned}$$

Summing in l finishes the proof of the lemma. \square

Lemma 3.7. *Assume that Λ satisfies the restricted boundedness conditions. Then the linear functional given by (3.4) can be extended to all the Hardy space H^1 and defines an element of BMO that we will denote by $T_3(1, 1)$.*

Proof. We will show first that the functions $T_3(D_{2^k}^\infty \Phi, D_{2^k}^\infty \Phi)$ are uniformly bounded in BMO. To simplify the notation, let $\phi_k = D_{2^k}^\infty(\Phi \otimes \Phi)$, and let c_γ be a large constant (depending only on γ) whose value will become clear later. We will show that the mean oscillation of $T_3(\phi_k)$ on some arbitrary interval I is $O(1)$.

If I is an interval with $c_\gamma|I| \geq 2^k$, then by Lemma 3.5

$$\|T_3(\phi_k)\|_{L^2(I)} \leq \|T_3(\phi_k)\|_{L^2} \lesssim 2^{k/2} \lesssim |I|^{1/2},$$

which implies that the mean oscillation of $T_3(\phi_k)$ on I is $O(1)$.

Assume next that I is an interval centered at the point $c(I)$ and such that $c_\gamma|I| < 2^k$. Let M be the smallest integer so that $[-2^k, 2^k] \subseteq c_\gamma 2^M I$ and write

$$\phi_k = \sum_{l=0}^{M-1} \psi_{k,I,l},$$

where

$$\psi_{k,I,0} = (\tau_{(c(I),c(I))} D_{c_\gamma|I|}^\infty(\Phi \otimes \Phi)) \phi_k$$

and

$$\psi_{k,I,l} = (\tau_{(c(I),c(I))} D_{c_\gamma 2^{l+1}|I|}^\infty(\Phi \otimes \Phi) - \tau_{(c(I),c(I))} D_{c_\gamma 2^l|I|}^\infty(\Phi \otimes \Phi)) \phi_k.$$

By Lemma 3.5, for any function f in L^2 we can write (with a small abuse of notation)

$$\langle T_3(\phi_k)|f \rangle = \Lambda(\phi_k \otimes f) = \sum_{l=0}^{M-1} \Lambda(\psi_{k,I,l} \otimes f) = \sum_{l=0}^{M-1} \langle T_3(\psi_{k,I,l})|f \rangle$$

Since $c_\gamma|I| \leq 2^k$, $|I|^{-1}\psi_{k,I,0}$ is L^2 -adapted to $I \times I$ and we can estimate again using Lemma 3.5,

$$\|T_3(\psi_{k,I,0})\|_{L^2(I)} \lesssim |I|^{1/2},$$

which implies that the mean oscillation of $T_3(\psi_{k,I,0})$ on I is $O(1)$. In the other terms $T_3(\psi_{k,I,l})$ can be represented on I by absolutely convergent integrals which, after the usual change of coordinates, take the form

$$T_3(\psi_{k,I,l})(w) = \int \psi_{k,I,l}(u, v) \tilde{K}(u, w) du,$$

with $v = -\gamma_2^{-1}(\gamma_1 u + \gamma_3 w)$. Observing that $v - c(I) = -\gamma_2^{-1}(\gamma_1(u - c(I)) + \gamma_3(w - c(I)))$, we may proceed as in the previous lemma to verify that the above integral may be restricted to the region where

$$c'_\gamma c_\gamma 2^l |I| \leq |u - c(I)| \leq c_\gamma 2^{l+1} |I|$$

for some small constant c'_γ depending only on γ . We take now c_γ large enough so that

$$|u - c(I)| \geq \max\{10 \times 2^l, c_\beta\} |I|,$$

where c_β is associated with \tilde{K} as in Lemma 3.6.

Define $v_0 = -\gamma_2^{-1}(\gamma_1 u + \gamma_3 c(I))$ and the constant

$$C_{k,I,l} = \int \psi_{k,I,l}(u, v_0) \tilde{K}(u, c(I)) du$$

and write

$$\begin{aligned} & |T_3(\psi_{k,I,l})(w) - C_{k,I,l}| \leq \\ & \int |\psi_{k,I,l}(u, v) - \psi_{k,I,l}(u, v_0)| |\tilde{K}(u, w)| du + \int |\psi_{k,I,l}(u, v_0)| |\tilde{K}(u, w) - \tilde{K}(u, c(I))| du. \end{aligned}$$

Take now some $w \in I$. We can apply (3.7) to obtain that the second integral above is bounded (up to a multiplicative constant) by

$$\int_{|u-c(I)| > 10 \times 2^l |I|} |I|^\delta |u - c(I)|^{-(1+\delta)} du \lesssim 2^{-l\delta}.$$

To estimate the first integral note that

$$\left\| \frac{\partial \psi_{k,I,l}}{\partial v} \right\|_\infty \lesssim \frac{1}{\min(c_\gamma 2^l |I|, 2^k)}, \quad |v - v_0| \lesssim |I|, \quad |\tilde{K}(u, w)| \lesssim (2^l |I|)^{-1},$$

and the region of integration has length $O(\min(c_\gamma 2^l |I|, 2^k))$. By putting these things together, the first integral above is easily seen to be $O(2^{-l})$. This proves that the mean oscillation of $T_3(\psi_{k,I,l})$ over the interval I is $O(2^{-l\delta})$. Finally, by the triangle inequality we conclude that $\|T_3(\phi_k)\|_{BMO} \lesssim 1$.

To conclude the proof we can now use the $H^1 - BMO$ duality. In fact, since the unit ball of the dual of a Banach space is weak*-compact, we can extract a subsequence of $T_3(\phi_{k_j})$ so that $\lim_{j \rightarrow \infty} \langle T_3(\phi_{k_j}), f \rangle = \langle T_3(1, 1)|f \rangle$ for some $T_3(1, 1) \in BMO$ and all $f \in H^1$. However, the previous lemma shows that the sequence on the left converges to $L(f)$ for C^∞ functions f with compact support and mean zero. Since such functions are dense in H^1 , it follows that the continuous functional induced by $T_3(1, 1)$ on $H^1(\mathbb{R})$ extends L to all H^1 and that $T_3(1, 1)$ is the unique limit (in BMO) of the sequence $T_3(\phi_k)$. \square

The following result shows that the definition of $T_3(1, 1)$ in Lemma 3.6 is independent of the choice of function Φ in a very general sense.

Lemma 3.8. *Let f be a Schwartz function supported on $I = [-1/2, 1/2]$ and with mean zero, and $k > 0$. Then, for every L^∞ -normalized bump function ϕ adapted to the square $[-2^k, 2^k] \times [-2^k, 2^k]$ with $\phi \equiv 1$ in a neighborhood of $(0, 0)$ we have the estimate*

$$|\langle T_3(1, 1)|f \rangle - \Lambda(\phi, f)| \leq C_{\gamma, \delta'} 2^{-\delta' k} \|f\|_{L^1},$$

where we can take $\delta' = \delta$ if $\delta < 1$ and $\delta' = 1^-$ if $\delta = 1$.

Moreover, if Λ satisfies the restricted boundedness conditions then the estimate above still holds with $\|f\|_1$ replaced by $\|f\|_2$ (note $|I|^{1/2} = 1$), if the L^∞ -normalized bump function ϕ adapted to the square $[-2^k, 2^k] \times [-2^k, 2^k]$ satisfies only $\phi(0, 0) = 1$.

Proof. Let Φ be as before. Considering $\psi_k = D_{2^k}^\infty(\Phi \otimes \Phi) - \phi$, we need to prove

$$|\Lambda(\psi_k \otimes f)| \lesssim 2^{-\delta k}.$$

Let

$$\Phi_{k\pm l} = D_{2^{k\pm l+1}}^\infty(\Phi \otimes \Phi) - D_{2^{k\pm l}}^\infty(\Phi \otimes \Phi).$$

For a large k_0 and $k \gg k_0$, write

$$\psi_k = \sum_{l=0}^{\infty} \Psi_{k+l} + \sum_{l=1}^{k-k_0} \Psi_{k-l} + \tilde{\Psi}_{k_0},$$

where

$$\Psi_{k\pm l} = \Phi_{k\pm l} \psi_k = (D_{2^{k\pm l+1}}^\infty(\Phi \otimes \Phi) - D_{2^{k\pm l}}^\infty(\Phi \otimes \Phi))(D_{2^k}^\infty(\Phi \otimes \Phi) - \phi)$$

and

$$\tilde{\Psi}_{k_0} = D_{2^{k_0}}^\infty(\Phi \otimes \Phi) \psi_k.$$

We can apply the reasoning of Lemma 3.6 to $\Psi_{k\pm l}$ to write $\Lambda(\Psi_{k\pm l} \otimes f)$ as the sum of two integrals, one involving $(\nabla \Psi_{k\pm l}) \tilde{K}$ and the other involving $\Psi_{k\pm l} (\nabla \tilde{K})$, and where the integration in u takes place for $|u| \approx 2^{k\pm l}$. We then need to estimate $|\nabla \Psi_{k\pm l}|$ and $|\Psi_{k\pm l}|$ and combine them with the Calderón-Zygmund estimates on \tilde{K} (which can be applied if k_0 is chosen large enough depending only on γ).

For Ψ_{k+l} , we can use in the first integral that ψ_k is adapted to a square of side length 2^k to get

$$\begin{aligned} |\nabla \Psi_{k+l}| &\leq |\nabla \Phi_{k+l}| |\psi_k| + |\Phi_{k+l}| |\nabla \psi_k| \\ &\lesssim (2^{-(k+l)}) \|\psi_k\|_{L^\infty} + \|\Phi_{k+l}\|_{L^\infty} 2^{-k} (1 + \frac{2^{k+l}}{2^k})^{-N} \lesssim 2^{-(k+l)} \end{aligned}$$

and in the second integral we simply use that that Ψ_{k+l} is bounded. Together with the Calderón-Zygmund estimates this leads to estimates on the integrals of order $2^{-(k+l)}$ and $2^{-(k+l)\delta}$, respectively, which sum in l to the correct bound. On the other hand, since $\phi(0,0) = 1$, we can use for Ψ_{k-l} in the first integral

$$\begin{aligned} |\nabla \Psi_{k-l}| &\leq |\nabla \Phi_{k-l}| |\psi_k| + |\Phi_{k-l}| |\nabla \psi_k| \\ &\lesssim 2^{-(k-l)} 2^{-k} 2^{(k-l)} + \|\Phi_{k-l}\|_{L^\infty} 2^{-k} \lesssim 2^{-k} \end{aligned}$$

and

$$|\Psi_{k-l}| \lesssim 2^{-k} 2^{(k-l)} \lesssim 2^{-l}$$

in the second integral, which leads to estimates of the order of 2^{-k} and $2^{-k\delta} 2^{-l(1-\delta)}$, respectively. Noting that there are less than k terms in this case, we get to an estimate of the form $2^{-k\delta'}$ with δ' as in the statement.

Finally, note that the last term, $\Lambda(\tilde{\Psi}_{k_0} \otimes f)$ is zero if $\phi \equiv 1$ in a neighborhood of $(0,0)$ or otherwise it can be controlled by the restricted boundedness property since $\tilde{\Psi}_{k_0}$ is adapted to a cube of side length 2^{k_0} with a constant of the order of 2^{-k} . \square

Remark 3.1. For any fixed y and Φ as in (3.1), the function $\tau_{(y,y)}D_{2^k}^\infty(\Phi \otimes \Phi)$ is an L^∞ -normalized bump function adapted to $[-2^k, 2^k] \times [-2^k, 2^k]$ and equal to 1 in a neighborhood of the origin, for sufficiently large k . Hence we may also write

$$\Lambda(1, 1, f) = \langle T_3(1, 1) | f \rangle = \lim_{k \rightarrow \infty} \Lambda(\tau_{(y,y)}D_{2^k}^\infty(\Phi \otimes \Phi), f).$$

Moreover, an examination of the proof of Lemma 3.6, shows that if the test function f with mean zero satisfies $\text{supp } f \subset I$, then

$$|\Lambda(1, 1, f) - \Lambda(\tau_{(c(I), c(I))}D_{2^k|I|}^\infty(\Phi \otimes \Phi), f)| \lesssim 2^{-k\delta} \|f\|_{L^1},$$

for large k depending only on γ .

3.2. A $T(1)$ -type formulation of the main theorem.

We now introduce a weaker continuity property on Λ alluded to before.

Definition 3.9. We say that a trilinear form Λ satisfies the weak boundedness property if for any interval I and any ϕ that is L^2 -normalized and adapted to $I \times I \times I$ of order N ,

$$(3.8) \quad |\Lambda(\phi)| \leq C|I|^{-1/2}.$$

The restricted boundedness conditions with order $N' \gg N$ imply (3.8) of order N . This is immediate for ϕ given by a tensor product, while arguments similar to the ones used in Lemma 3.5 give the general case. We will prove Theorem 2.7 assuming only the weak boundedness property and that the distributions $T_j(1, 1)$ given by (3.4) (and its symmetric versions) are in BMO for $j = 1, 2, 3$. Since, as we already saw, all these conditions are implied by the restricted boundedness, it will follow then yet another formulation of the main theorem.

Theorem 3.10. Let Λ be a Calderón-Zygmund trilinear form with modulation symmetry in the direction of γ . Then Λ is bounded in the range of exponents of Theorem 2.7 if and only if $T_j(1, 1) \in \text{BMO}$ for each $j = 1, 2, 3$, and Λ satisfies the weak boundedness property (3.8).

While the Calderón-Zygmund condition does not distinguish between Calderón-Zygmund kernels associated with bilinear or trilinear forms, the BMO conditions constitute a real difference between distributions which are bounded bilinear forms and those which are bounded trilinear forms. For trilinear forms, there are three BMO conditions, while for bilinear forms there are only two. In the section on paraproducts we will see that the three BMO conditions are indeed independent, and we can adjust the three functions $T_j(1, 1)$ independently for each j . In particular, we can take two of these functions in BMO and a third one not in BMO and construct a distribution that provides a bounded bilinear form but not a bounded trilinear one.

We also observe the following.

Remark 3.2. *Let Λ be a trilinear Calderón-Zygmund form with modulation symmetry in the direction γ and satisfying (3.8). Then, the forms Λ_j , $j = 1, 2, 3$, satisfy the bilinear weak boundedness property of Remark 2.1 and the identities*

$$\begin{aligned}\Lambda_1(1, \cdot) &= \Lambda(1, 1, \cdot) = \Lambda_2(1, \cdot), \\ \Lambda_2(\cdot, 1) &= \Lambda(\cdot, 1, 1) = \Lambda_3(\cdot, 1), \\ \Lambda_3(1, \cdot) &= \Lambda(1, \cdot, 1) = \Lambda_1(\cdot, 1),\end{aligned}$$

hold when the terms are interpreted as tempered distributions modulo constants.

It is trivial to check the bilinear weak boundedness conditions for the Λ_j given the one for Λ . The above identities are also clear at a formal level. To verify them in a rigorous way, let f be a test function with mean zero supported in some interval I centered at the origin. For C large enough depending just on γ and for k large enough compared to $\log |I|$ we have

$$\Lambda_1(D_{2^k}\Phi, f) = \Lambda(D_{2^k}D_C\Phi, D_{2^k}\Phi, f),$$

because $1 \otimes D_{2^k}\Phi \otimes f = D_{2^k}D_C\Phi \otimes D_{2^k}\Phi \otimes f$ on γ^\perp . As $k \rightarrow \infty$ the left hand side tends to $\Lambda_1(1, f)$ while, by Lemma 3.8, the right hand side approaches $\Lambda(1, 1, f)$ since $D_C\Phi \otimes \Phi \equiv 1$ in a neighborhood of $(0, 0)$. A symmetric reasoning gives the other identities.

3.3. The bilinear Calderón commutators and the bilinear Cauchy integral on Lipschitz curves.

As we mentioned in Section 2.2, Theorem 3.10 has applications to operators with a particular antisymmetric property. Let $K(x, t)$ be a Calderón-Zygmund kernel with the property

$$(3.9) \quad K(x, t) = -K(x + t, -t).$$

This unconventionally looking antisymmetry comes from the fact that we chose the kernels to be singular at $t = 0$ and not at $x = t$, i.e. we assume in this article

$$|\partial^\alpha K(x, t)| \lesssim |t|^{-(|\alpha|+1)}$$

instead of (the equivalent after a change of variable)

$$|\partial^\alpha K(x, t)| \lesssim |x - t|^{-(|\alpha|+1)}.$$

If K satisfies (3.9), then one can always define the trilinear form

$$\begin{aligned}\Lambda(f, g, h) &= p.v. \int f(x+t)g(x-t)h(x)K(x, t) dt dx = \\ &= \frac{1}{2} \int (f(x+t)g(x-t)h(x) - f(x)g(x+2t)h(x+t)) K(x, t) dt dx,\end{aligned}$$

since the integral now is absolutely convergent. This form is also clearly modulation invariant, even for functions without disjoint support, and it is easy to see that such a form satisfies the weak boundedness property of Definition 3.9.

A change of variables gives

$$\Lambda(f, 1, h) = p.v. \int f(y)h(x)K(x, y - x) dx dy$$

and if the bilinear form with kernel

$$\tilde{K}(x, y) = K(x, y - x)$$

(which is antisymmetric in the usual way) is bounded, we immediately get (see Remark 3.2)

$$\Lambda(1, 1, \cdot) = -\Lambda(\cdot, 1, 1) \in BMO.$$

Another change of variables gives

$$\Lambda(1, g, h) = p.v. \int g(y)h(x)K(x, x - y) dx dy.$$

The last condition to be satisfied is $\Lambda(1, \cdot, 1) \in BMO$. This requires the bilinear form with kernel

$$\tilde{K}(x, y) = K(x, x - y)$$

to be bounded too.

Examples of the above are provided by *the bilinear Calderón commutators* whose associated trilinear forms are

$$(3.10) \quad p.v. \int f(x+t)g(x-t)h(x) \frac{(A(x+t) - A(x))^m}{t^{m+1}} dt dx$$

with $\|A'\|_\infty < C$.

Since

$$K(x, t) = \frac{(A(x+t) - A(x))^m}{t^{m+1}}$$

we have that the bilinear form associated to the kernel $K(x, y - x)$ is just the usual Calderón commutator,

$$p.v. \int f(y)h(x) \frac{(A(y) - A(x))^m}{(y-x)^{m+1}} dy dx;$$

while the one for $K(x, x - y)$ is

$$p.v. \int f(y)h(x) \frac{(A(2x-y) - A(x))^m}{(x-y)^{m+1}} dy dx.$$

This last bilinear form is treatable with the linear T1-Theorem in the same way the ones associated to the linear commutators are. Theorem 3.10 gives now the boundedness of the forms in (3.10).

Keeping track of the constants involved and expanding in the usual way in terms of commutators one can obtain also the boundedness of *the bilinear Cauchy integral operator*

$$(3.11) \quad C_A(f, g)(x) = p.v. \int \frac{f(x+t)g(x-t)}{t + i(A(x+t) - A(x))} dt dx,$$

at least for $\|A'\|_\infty < \epsilon$.

On the other hand, note that the kernel

$$K(x, t) = \frac{1}{t + i(A(x+t) - A(x))}$$

is also antisymmetric in the sense of (3.9), so one can try to study it directly. The function $K(x, y-x)$ is now

$$K(x, y-x) = \frac{1}{(y-x) + i(A(y) - A(x))}$$

which gives the linear Cauchy integral operator which we know is bounded even with $\|A'\|_\infty < C$. The other bilinear form to consider has kernel

$$K(x, x-y) = \frac{1}{(x-y) + i(A(2x-y) - A(x))}.$$

This should be studied using similar arguments to the ones used for the linear Cauchy integral operator to yield, invoking again Theorem 3.10, the boundedness of the bilinear operator in (3.11) for arbitrary Lipschitz function A . We leave the details to the interested reader.

4. BUMP FUNCTIONS ESTIMATES

In this section we prove some estimates on bump functions under the additional assumption of $T_j(1, 1) = 0$ (in the BMO sense) for $j = 1, 2, 3$. Recall that $T_j(1, 1)$ has been defined in Lemma 3.7. We will study the action of Λ on triples of bump functions and obtain good estimates in terms of the localization in space and frequency of the bump functions. The estimates will be obtained from a reduction to the bilinear form case, which we will discuss first. Lemma 4.3 below is a slight generalization of some almost orthogonality estimates found in the literature.

In what follows, we will write $\text{diam}(I_1, I_2)$ for the diameter $\text{diam}(I_1 \cup I_2)$ of the union of the two intervals. We will also use the fact that if $|I_1| > |I_2|$ then

$$1 + \frac{\text{diam}(I_1, I_2)}{|I_1|} \approx 1 + \frac{|c(I_1) - c(I_2)|}{|I_1|}.$$

Lemma 4.1. *Let ϕ_J and c_I be bump functions L^2 -adapted of order N to the intervals J and I . We have*

$$(4.1) \quad \int |\phi_J(x)| |c_I(x)| dx \lesssim \left(\min\left(\frac{|I|}{|J|}, \frac{|J|}{|I|}\right) \right)^{1/2} (1 + (\max(|I|, |J|)^{-1} \text{diam}(I, J))^{-N})$$

while

$$(4.2) \quad \left| \int \phi_J(x) c_I(x) dx \right| \lesssim \left(\frac{|I|}{|J|} \right)^{3/2} (1 + |J|^{-1} \text{diam}(I, J))^{-N},$$

as long as $|J| \geq |I|$ and $\int c_I(x) dx = 0$.

Note that the estimate in (4.1) only needs the size estimates on ϕ_J and c_I but not the ones on their derivatives. Similar estimates are obtained when the bumps ϕ_J are replaced by the ones obtained by the action of Calderón-Zygmund operators with certain cancellation. More precisely one has.

Lemma 4.2. *Let ϕ_J and c_I be as in the previous lemma with $N \geq 2$. Assume that Λ is a bilinear Calderón-Zygmund form associated with a kernel K with regularity parameter δ . Suppose that Λ satisfies the restricted boundedness conditions (2.6) (or equivalently that is bounded on $L^2 \times L^2$) and that the linear dual operator⁵ T has the special cancellation condition $T(1) = 0$. Then for each $0 < \delta' < \delta$,*

$$(4.3) \quad \int |T(\phi_J)(x)| |c_I(x)| dx \lesssim \left(\min\left(\frac{|I|}{|J|}, \frac{|J|}{|I|}\right) \right)^{1/2} (1 + (\max(|I|, |J|)^{-1} \text{diam}(I, J))^{-(1+\delta')},$$

provided that $\int \phi_J(x) dx = 0$, while

$$(4.4) \quad \left| \int T(\phi_J)(x) c_I(x) dx \right| \lesssim \left(\frac{|I|}{|J|} \right)^{1/2+\delta'} (1 + |J|^{-1} \text{diam}(I, J))^{-(1+\delta')}$$

if $|J| \geq |I|$, $\int \phi_J(x) dx = 0$, and $\int c_I(x) dx = 0$.

For a proof of Lemma 4.1 and Lemma 4.2 see, e.g., [23] and [14]. We have now the following generalization.

Lemma 4.3. *Assume again that Λ is a bilinear form associated with a Calderón-Zygmund kernel K with regularity parameter δ . Suppose that Λ is bounded and that the dual linear operator T has the special cancellation condition $T(1) = 0$.*

Let $|I_1| \geq |I_2|$ be intervals and let $\psi \in \mathcal{S}(\mathbb{R}^2)$ be a bump adapted to $I_1 \times I_2$ of order at least 4. Assume ψ has mean zero in the second variable, meaning

$$\int \psi(x_1, x_2) dx_2 = 0$$

for all x_1 . Then for each $0 < \delta' < \delta$,

$$(4.5) \quad |\Lambda(\psi)| \lesssim \left(\frac{|I_2|}{|I_1|} \right)^{1/2+\delta'} (1 + |I_1|^{-1} \text{diam}(I_1, I_2))^{-(1+\delta')}.$$

Proof. Let $\psi(x_1, x_2)$ be adapted to $I_1 \times I_2$ with $|I_1| \geq |I_2|$ and having mean zero in the second variable. Using wavelets, we can expand it in the first variable into a family of bumps (wavelets) $\{\phi_J\}$ which are L^2 -adapted to the dyadic intervals J and have mean zero. Furthermore, using the linearity of Λ and the fact that Λ extends to a continuous functional on $L^2(\mathbb{R}^2)$ (this being a consequence of the hypothesis and of Theorem 2.6), we obtain

$$|\Lambda(\psi)| \leq \sum_J |\Lambda(\langle \psi(\cdot, x_2), \phi_J \rangle \phi_J(x_1))| = \sum_J |\Lambda(\phi_J(x_1) c_{I_2}^J(x_2))| = \sum_J |\langle T\phi_J, c_{I_2}^J \rangle|,$$

⁵Recall that this is $\Lambda(f_1, f_2) = \int T(f_1) f_2$

where the $c_{I_2}^J$ has mean zero and is adapted to the interval I_2 but with implicit bounds depending on the relative sizes of I_2 and J that can be estimated using (4.1) and (4.2). We will use (4.3) and (4.4) to estimate $|\langle T\phi_J | c_{I_2}^J \rangle|$. We proceed as follows.

We split the sum as

$$\sum_J = \sum_{J: |J| < |I_2| \leq |I_1|} + \sum_{J: |I_2| \leq |J| \leq |I_1|} + \sum_{J: |I_2| \leq |I_1| < |J|} = \sum_A + \sum_B + \sum_C.$$

Using (4.2) and (4.3) we estimate

$$\begin{aligned} \sum_A &\lesssim \sum_{J: |J| < |I_2| \leq |I_1|} \left(\frac{|J|}{|I_2|}\right)^{1/2} \left(\frac{|J|}{|I_1|}\right)^{3/2} \left(1 + \frac{\text{diam}(J, I_2)}{|I_2|}\right)^{-1-\delta'} \left(1 + \frac{\text{diam}(J, I_1)}{|I_1|}\right)^{-1-\delta'} \\ &\lesssim \sum_{\nu: 2^{-\nu} < |I_2| \leq |I_1|} \left(\frac{2^{-\nu}}{|I_2|}\right)^{1/2} \left(\frac{2^{-\nu}}{|I_1|}\right)^{3/2} |I_2|^{1/2} |I_1|^{1/2} 2^\nu \left(\frac{|I_2|}{|I_1|}\right)^{1/2} \left(1 + \frac{\text{diam}(I_1, I_2)}{|I_1|}\right)^{-1-\delta'}, \end{aligned}$$

where we have used a discrete version of estimate (4.1) to sum on all intervals J of a fixed scale. That creates the normalization factors in the last line. Simplifying, we get

$$\sum_A \lesssim \frac{|I_2|^{1/2}}{|I_1|^{3/2}} \left(1 + \frac{\text{diam}(I_1, I_2)}{|I_1|}\right)^{-1-\delta'} \sum_{2^{-\nu} < |I_2|} 2^{-\nu} \lesssim \frac{|I_2|^{3/2}}{|I_1|^{3/2}} \left(1 + \frac{\text{diam}(I_1, I_2)}{|I_1|}\right)^{-1-\delta'},$$

which gives a better estimate than the desired one.

Similarly for \sum_B , we first use (4.1) and (4.3) and then sum at each scale to get the estimate in (4.5).

To estimate \sum_C , we use (4.1) and (4.4) and $\delta' < \delta'' < \delta$ to compute

$$\begin{aligned} \sum_C &\lesssim \sum_{J: |I_2| \leq |I_1| < |J|} \left(\frac{|I_2|}{|J|}\right)^{1/2+\delta''} \left(\frac{|I_1|}{|J|}\right)^{1/2} \left(1 + \frac{\text{diam}(J, I_2)}{|J|}\right)^{-1-\delta''} \left(1 + \frac{\text{diam}(J, I_1)}{|J|}\right)^{-1-\delta''} \\ &\lesssim \sum_{\nu: |I_2| \leq |I_1| < 2^{-\nu}} \left(\frac{|I_2|}{2^{-\nu}}\right)^{1/2+\delta''} \left(\frac{|I_1|}{2^{-\nu}}\right)^{1/2} \left(1 + \frac{\text{diam}(I_1, I_2)}{2^{-\nu}}\right)^{-1-\delta''}. \end{aligned}$$

By further splitting the above summation according to the relative size of $2^{-\nu}$ with respect to $\text{diam}(I_1, I_2)$, we get again the desired bound. \square

Next, we formulate the corresponding estimates for trilinear forms. We will use the following notation.

Definition 4.4. For an interval $\omega = (a, b)$ and a constant $c > 0$, let $\widetilde{c\omega} = (ca, cb)$ (that is the dilation of ω from the origin, not from its center which we denote by $c\omega$).

Lemma 4.5. Let Λ be a trilinear Calderón-Zygmund form associated with a kernel K with parameter δ , with modulation symmetry in the direction of γ with $\gamma_i \neq 0$, and which satisfies the weak boundedness condition (3.8). Assume also that $\Lambda(1, 1, \cdot) =$

$\Lambda(1, \cdot, 1) = \Lambda(1, 1, \cdot) = 0$. Let $k_1 = k_2 \geq k_3$ be three integers. For each $1 \leq i \leq 3$, let ω'_i be an interval of length 2^{-k_i} , and assume that $\omega'_3 \cap \frac{2^3}{\gamma_1} \omega'_1 = \emptyset$ and $\omega'_3 \cap \frac{2^3}{\gamma_2} \omega'_2 = \emptyset$.

Let I_i be an interval of length 2^{k_i} and assume $\phi \in \mathcal{S}(\mathbb{R}^3)$ is a bump function of order $2N$ adapted to $I_1 \times I_2 \times I_3$ and with Fourier transform supported in the box $\omega' := \omega'_1 \times \omega'_2 \times \omega'_3$. Then, for each $0 < \delta' < \delta$ we have

$$(4.6) \quad |\Lambda(\phi)| \lesssim |I|^{-1/2} \left(\frac{|I_3|}{|I|} \right)^{\delta'+1/2} \left(1 + \frac{\text{diam}(I_1, I_2, I_3)}{|I|} \right)^{-1-\delta'} \left(1 + \frac{|\sum_{i=1}^3 \gamma_i c(I_i)|}{|I|} \right)^{-N},$$

where we have written $\text{diam}(I_1, I_2, I_3)$ for $\text{diam}(\bigcup_{i=1}^3 I_i)$ and $|I| = |I_1| = |I_2|$.

Similar statements and estimates holds by symmetry for any permutation of the indices 1, 2, 3.

Proof. We assume without loss of generality that $\text{diam}(I_1, I_2, I_3)$ is comparable to $\text{diam}(I_2, I_3)$. This can be achieved by switching the otherwise symmetric roles of I_1 and I_2 if necessary. We write

$$\psi(x + \beta_2 t, x + \beta_3 t) = \phi(x + \beta_1 t, x + \beta_2 t, x + \beta_3 t),$$

and note that $\Lambda_1(\psi) = \Lambda(\phi)$. We plan to apply Lemma 4.3 to Λ_1 and ψ .

First observe that by hypothesis and Remark 3.2, Λ_1 is bounded and satisfies the requirements of Lemma 4.3. Second, we claim the function ψ is adapted to $I_2 \times I_3$ with constant $|I|^{-1/2} M^{-N}$, where

$$5M = 1 + |I|^{-1} \left| \sum \gamma_i c(I_i) \right|.$$

Clearly, it is enough to see this when $|I|^{-1} |\sum \gamma_i c(I_i)| \gg 1$. We truncate

$$\psi = \psi_1 + \psi_2$$

where

$$\psi_1(x_1, x_2) = \psi(x_1, x_2) \Phi_{MI_2}(x_1) \Phi_{MI_3}(x_2)$$

and the functions Φ_{MI} are the usual L^∞ -normalized functions adapted to MI .

If $(x_1, x_2) := (x + \beta_2 t, x + \beta_3 t)$ is in the support of ψ_1 , then $|x + \beta_1 t - c(I_1)|/|I| \gtrsim M$ because

$$|\gamma_1(x + \beta_1 t - c(I_1))| \geq \left| \sum_{j=1}^3 \gamma_j(x + \beta_j t - c(I_j)) \right| - 4M|I| = \left| \sum_{j=1}^3 \gamma_j c(I_j) \right| - 4M|I|.$$

By computing derivatives, the claim for ψ_1 follows easily. Let us only indicate the bound for the function itself:

$$\begin{aligned} |\psi_1(x_1, x_2)| &= |\phi(x + \beta_1 t, x + \beta_2 t, x + \beta_3 t)| \Phi_{MI_2}(x_2) \Phi_{MI_3}(x_3) \\ &\lesssim |I|^{-1/2} |I_2|^{-1/2} |I_3|^{-1/2} M^{-N} \times \\ &(1 + |I|^{-1} |x + \beta_2 t - c(I_2)|)^{-N} (1 + |I|^{-1} |x + \beta_3 t - c(I_3)|)^{-N}. \end{aligned}$$

If $(x + \beta_2 t, x + \beta_3 t)$ is in the support of ψ_2 , then either $|x + \beta_2 t - c(I_2)|/|I|$ is of order at least M or $|x + \beta_3 t - c(I_3)|/|I|$ is of order at least M , and the claim for ψ_2 is again easy to see.

Finally, it remains to show that ψ has mean zero in the second variable. Consider first the particular case when

$$\widehat{\phi}(\eta_1, \eta_2, \eta_3) = \widehat{\phi}_1(\eta_1)\widehat{\phi}_2(\eta_2)\widehat{\phi}_3(\eta_3).$$

A simple change of coordinates gives then

$$\psi(u, v) = \phi_1\left(-\frac{\gamma_2}{\gamma_1}u - \frac{\gamma_3}{\gamma_1}v\right)\phi_2(u)\phi_3(v).$$

For each u , the Fourier transform of ψ in the second variable is supported in $\omega'_3 - \frac{\gamma_3}{\gamma_1}\widetilde{\omega'_1}$. Since this interval does not contain the origin, the claim follows.

To obtain the general case expand $\widehat{\phi}$ as a series of products of the above, via windowed Fourier series. \square

Remark 4.1. Let $\langle \gamma \rangle$ be the line spanned by γ , and $\langle \gamma^{(i)} \rangle$ be the projection of the line $\langle \gamma \rangle$ onto the plane e_i^\perp . We observe that the conditions on ω' in the previous lemma are actually equivalent to

$$(4.7) \quad \omega'_1 \times \omega'_3 \cap \langle \gamma^{(2)} \rangle = \emptyset,$$

$$(4.8) \quad \omega'_2 \times \omega'_3 \cap \langle \gamma^{(1)} \rangle = \emptyset,$$

In all applications of Lemma 4.5, the box ω' will emerge in the following way. We will initially have a box $\omega := (\omega_1, \omega_2, \omega_3)$ which satisfies (4.7) and (4.8). We will then choose some appropriate vector $\xi\gamma \in \langle \gamma \rangle$ and define $\omega' := \omega - \xi\gamma$. Regardless of the choice of ξ , (4.7) and (4.8) imply for $i \in \{1, 2\}$ that $\omega'_3 \cap \widetilde{\omega'_i} = \emptyset$, since $\widetilde{\omega'_i} = \frac{\gamma_3}{\gamma_i}\omega_i - \xi\gamma_3$ and $\omega'_3 = \omega_3 - \xi\gamma_3$.

5. DECOMPOSITION OF Λ UNDER THE SPECIAL CANCELLATION CONDITIONS.

In this section we will express the form Λ as a superposition of well localized model operators. Before achieving this goal we first recall how the decomposition was performed in the particular case of the bilinear Hilbert transform, see [20]. More generally, assume $K(t)$ is an x independent Calderón-Zygmund kernel with enough decay on the derivatives of \widehat{K} , and consider a Λ which for each $f_1, f_2, f_3 \in \mathcal{S}(\mathbb{R})$ has the representation

$$\Lambda(f_1, f_2, f_3) = \text{p.v.} \int f_1(x + \beta_1 t) f_2(x + \beta_2 t) f_3(x + \beta_3 t) K(t) dx dt.$$

One first decomposes K in pieces K_k localized at frequency $\approx 2^{-k}$. Then, the modulation symmetry of Λ recommends a wave packet decomposition of the three functions, adapted to the scale of the multiplier. The geometry of the Fourier plane in conjunction with the decay in the derivatives of \widehat{K} allows then one to reduce the boundedness

of $|\Lambda(f_1, f_2, f_3)|$ to that of model operators of the form

$$\sum_{p \in \mathbf{P}} a_p |I_p|^{-1/2} |\langle f_1, \phi_{p_1} \rangle \langle f_2, \phi_{p_2} \rangle \langle f_3, \phi_{p_3} \rangle|,$$

where \mathbf{P} is the collection of all multi-tiles in phase space $p = p_1 \times p_2 \times p_3$, $p_i = I_{p_i} \times \omega_{p_i}$ with $|I_p| := |I_{p_1}| = |I_{p_2}| = |I_{p_3}|$ and ω_{p_i} pairwise disjoint for each fixed p . The ϕ_{p_i} are wave packets L^2 - adapted to the time-frequency tile p_i and $\{a_p\} \in \ell^\infty(\mathbf{P})$.

A fundamental feature of \mathbf{P} is that it is a one parameter family of multi-tiles, in that each ω_{p_i} determines uniquely the other two ω_{p_j} . Another important aspect about \mathbf{P} is the so called ‘quartile property’; namely the fact that if for two multi-tiles p and p' we have $\omega_{p_i} \cap \omega_{p'_i} \neq 0$ then we are guaranteed that $\omega_{p_j} \cap \omega_{p'_j} = 0$ for each $j \neq i$. Both of these properties follow as a consequence of the fact that the cubes $\omega_{p_1} \times \omega_{p_2} \times \omega_{p_3}$ are located at some uniform distance from the line $\langle \gamma \rangle$ and they touch the plane $(1, 1, 1)^\perp$.

In the case K depends on both x and t we proceed differently. Consider again a Calderón-Zygmund trilinear form Λ which is modulation invariant in the direction γ . We saw that we can write

$$\Lambda(f_1, f_2, f_3) = \langle K(x, t) | f_1 \otimes f_2 \otimes f_3(x\alpha + t\beta) \rangle$$

where we still denote by K a distribution in $\mathcal{S}'(\mathbb{R}^2)$, which agrees with the given kernel when $t \neq 0$. Note that the Calderón-Zygmund conditions on the kernel do not say anything about the distribution K for $t = 0$. As in the linear case, the weak boundedness property and the conditions $T_j(1, 1) \in \text{BMO}$ are needed to complete, in a certain sense, the control on the distribution K .

To study Λ we will perform a particular Whitney decomposition on the frequency domain. We want to give a heuristic motivation for it. Based on the experience with multipliers (both linear and multilinear ones), one expects that a Mihlin-type of behavior for the frequency representation of Λ should play an important role. That is, the form should be given in the frequency side by a distribution whose derivatives behave like the reciprocal of the distance to a particular singular or bad set. Typically one then performs a Whitney decomposition with respect to that set.

Applying the Fourier inversion formula to each f_j we see that, in the sense of distributions, we can represent Λ on the frequency domain as

$$(5.1) \quad \Lambda(f_1, f_2, f_3) = \langle \widehat{K}(-\alpha \cdot \xi, -\beta \cdot \xi) | \widehat{f}_1 \otimes \widehat{f}_2 \otimes \widehat{f}_3(\xi) \rangle,$$

where $\xi = (\xi_1, \xi_2, \xi_3)$. The conditions on the kernel are too weak to conclude any pointwise kind of behavior for \widehat{K} . This will substantially complicate our analysis but, intuitively, β^\perp should be a bad set for $\widehat{\Lambda}$. To further motivate the analysis to be performed, consider a very particular case of K with compact support, smooth in x , and satisfying for $t \neq 0$ the stronger conditions

$$|\partial^\alpha K(x, t)| \lesssim |t|^{-(1+|\alpha|)},$$

for all $|\alpha| \geq 0$. These conditions (together with the weak boundedness property) imply

$$(5.2) \quad |\partial_v^m \widehat{K}(u, v)| \lesssim |v|^{-m},$$

for $v \neq 0$ and $m \geq 1$. The estimates say that the derivatives $\partial_v^m \widehat{K}$ are only singular at the origin (though they still do not say anything about \widehat{K} itself). This and the representation (5.1) suggest that $\widehat{\Lambda}$ may have some singularities on β^\perp .

The representation (5.1) is not unique in the sense that it depends on β . In fact, for duality purposes and to exploit the conditions on the operators T_j , we can also write by simple changes of variables

$$\begin{aligned}\Lambda(f_1, f_2, f_3) &= \langle K_3(x, t) | f_1 \otimes f_2 \otimes f_3(x\alpha + t\beta^3) \rangle = \langle T_3(f_1, f_2) | f_3 \rangle \\ \Lambda(f_1, f_2, f_3) &= \langle K_2(x, t) | f_1 \otimes f_2 \otimes f_3(x\alpha + t\beta^2) \rangle = \langle T_2(f_1, f_3) | f_2 \rangle \\ \Lambda(f_1, f_2, f_3) &= \langle K_1(x, t) | f_1 \otimes f_2 \otimes f_3(x\alpha + t\beta^1) \rangle = \langle T_1(f_2, f_3) | f_1 \rangle,\end{aligned}$$

where the vectors β^j are still perpendicular to γ and satisfy that the component β_j^j of them is zero. The K_j are also related to K by a change of variable and still satisfy the same conditions assumed on K . In other words,

$$T_3(f_1, f_2)(x) = \int f_1(x + \beta_1^3 t) f_2(x + \beta_2^3 t) K_3(x, t) dt$$

and similarly for T_1 and T_2 .

We obtain then the three frequency representations

$$(5.3) \quad \Lambda(f_1, f_2, f_3) = \langle \widehat{K}_j(-\alpha \cdot \xi, -\beta^j \cdot \xi) | \widehat{f}_1 \otimes \widehat{f}_2 \otimes \widehat{f}_3(\xi) \rangle.$$

In each of them, away from a plane through γ defined by

$$P_j := (\beta^j)^\perp = \text{span}(e_j, \gamma),$$

the form Λ is given by a symbol whose derivatives blow up according to (5.2) when ξ approaches P_j . We use a Whitney decomposition that simultaneously resolves all of the three singular sets P_j independently of which T_j we are using. In a way, the conditions $T_j(1, 1) \in \text{BMO}$ are needed to control the behavior on the bad set

$$S := \bigcup_{i=1}^3 P_i$$

and eliminate the potential singularities of $\widehat{\Lambda}$ on it.

We see from (5.3) that, at least formally, $T_j(1, 1) = 0$ translates into

$$\langle \widehat{K}_j(-\xi_j, 0) | \widehat{f}_j(\xi_j) \rangle = 0,$$

and hence $\widehat{K}_j(u, 0) = 0$, so $\widehat{\Lambda}$ vanishes in some sense on S . We will show rigorously that we can perform our analysis in $\mathbb{R}^3 \setminus S$ in Lemma 5.3 below.

In the case of the bilinear Hilbert transform (or a kernel that is x -independent), the formula in (5.1) takes the simpler form

$$(5.4) \quad \Lambda(f_1, f_2, f_3) = \langle \delta(\alpha \cdot \xi) \widehat{K}(-\beta \cdot \xi) | \widehat{f}_1 \otimes \widehat{f}_2 \otimes \widehat{f}_3(\xi) \rangle,$$

which clearly vanishes if $\widehat{f}_1 \otimes \widehat{f}_2 \otimes \widehat{f}_3$ is supported away from α^\perp (which also contains $\langle \gamma \rangle$). We see then that $\widehat{\Lambda}$ is supported on α^\perp and hence is possibly singular only on the

line $\langle \gamma \rangle$ independently of the representation used. A one-parameter family of boxes, i.e. cubes, is then used in this case as mentioned above. In the x -dependent case, however, a two-parameter family of boxes in \mathbb{R}^3 will be used to decompose the complement of the bad set as we will now describe.

We first produce a Whitney decomposition of the frequency domain $\mathbb{R}^3 \setminus S$ into tubes as defined below. This is achieved by combining two-dimensional Whitney decompositions of each $e_j^\perp \setminus \langle \gamma^{(j)} \rangle$. In a second stage we perform wave packet decompositions of the three functions adapted to such tubes. Finally, information on the decay of the coefficients associated with various localized pieces will be provided via the almost orthogonality estimates of the previous section, combining the kernel representation with the weak boundedness condition and the cancellations $T_j(1, 1) = 0$.

Definition 5.1. *A dyadic box is a parallelepiped $\omega_1 \times \omega_2 \times \omega_3$ such that all intervals ω_i -called the sides of the box- are dyadic intervals. A tube is a dyadic box where the minimal side-length is attained by two of the sides. We also allow the maximal side to be all of \mathbb{R} . The orientation of a dyadic tube is the direction corresponding to its longest side (cubes have no orientation).*

Observe that a nonempty intersection of two dyadic tubes of possibly different orientations is again a dyadic tube.

Let $C_1 \gg 1$ be a sufficiently large constant depending on γ , whose value will not be specified. Constraints on how large C_1 should be will become apparent throughout the paper. The other important constants⁶ that will appear throughout this work are $C_2 := C_1^{1/2}$ and $C_3 := C_1^2$.

For each $j \in \{1, 2, 3\}$, we decompose the complement of the plane P_j into the collection Ω_j of minimal dyadic tubes ω such that $C_1\omega$ intersects the plane P_j . An important property that will be used repeatedly is that for each such tube we have $\frac{C_1}{3}\omega \cap \langle \gamma \rangle = \emptyset$. These tubes partition the complement of P_j , they are infinitely long in direction e_j and their projection onto the orthogonal plane to e_j defines a standard Whitney decomposition into squares of $e_j^\perp \setminus \langle \gamma^{(j)} \rangle$.

Now let Ω be the collection of all tubes which are nonempty intersections of three tubes as above, one in each of Ω_1 , Ω_2 , and Ω_3 . Then Ω partitions the complement of the bad set. Each of the tubes ω in this partition, initially defined as the intersection of three tubes, is actually determined by the intersection of two of the three tubes, one defining the two shorter sides of ω and the other one defining the long side of ω .

For each Whitney tube $\omega \in \Omega$ we consider the box 3ω , which is the box ω dilated about its center by a factor 3. By a standard argument for Whitney decompositions (e.g. applied to the Whitney decompositions of each of the three planes) these boxes have bounded overlap and two overlapping boxes have comparable side-length in each dimension. Therefore we can find a partition of unity of the complement of S

$$1_{S^c} = \sum_{\omega \in \Omega} \widehat{\phi}_\omega$$

⁶From now all occurrences of C_1 , C_2 and C_3 will refer only to this constants

where each $\widehat{\phi}_\omega$ is supported in 3ω and L^∞ -adapted to ω .

Definition 5.2. *The width of a tube is the length of each of the shorter sides, its length is the length of its longest side, and its eccentricity is the ratio between its width and length.*

Lemma 5.3. *Assume Λ is a trilinear Calderón-Zygmund form with modulation symmetry in direction γ that satisfies the weak boundedness property (3.8) and the special cancellation conditions $T_i(1, 1) = 0$ for $1 \leq i \leq 3$.*

Let $\Omega^{(k)}$ be the set of all tubes in Ω with width at least 2^{-k} . Then we have

$$(5.5) \quad \Lambda(\psi) = \lim_{k \rightarrow \infty} \sum_{\omega \in \Omega^{(k)}} \Lambda(\psi * \phi_\omega)$$

for each Schwartz function ψ with compactly supported Fourier transform.

Proof. We will assume without loss of generality that $\widehat{\psi}$ is supported into the cube $[-1, 1]^3$. For each $k \in \mathbb{Z}$ we construct a set $\widetilde{\Omega}^{(k)}$ of tubes of width 2^{-k} such that the tubes in $\Omega^{(k)} \cup \widetilde{\Omega}^{(k)}$ form a partition of \mathbb{R}^3 , their dilates by a factor of 3 have bounded overlap, and which have the property that if $3\omega \cap 3\omega' \neq \emptyset$ for some $\omega, \omega' \in \Omega^{(k)} \cup \widetilde{\Omega}^{(k)}$ then ω and ω' have comparable side-length in every dimension. To achieve this, let $\Omega_{j,k}$ be the subset of Ω_j consisting of all the tubes of width at least 2^{-k} . Define also $\widetilde{\Omega}_{j,k}$ to be the (uniquely determined) collection of tubes infinitely long in the direction e_j with width 2^{-k} such that $\Omega_{j,k} \cup \widetilde{\Omega}_{j,k}$ forms a partition of \mathbb{R}^3 .

Define now $\widetilde{\Omega}^{(k)}$ as the collection of all tubes that arise by intersecting 3 tubes, one in each of $\Omega_{1,k} \cup \widetilde{\Omega}_{1,k}$, $\Omega_{2,k} \cup \widetilde{\Omega}_{2,k}$ and $\Omega_{3,k} \cup \widetilde{\Omega}_{3,k}$, with at least one of the three tubes in some $\widetilde{\Omega}_{i,k}$. Note that $\Omega^{(k)}$ consists of all tubes that arise by intersecting 3 tubes, one in each of $\Omega_{1,k}$, $\Omega_{2,k}$ and $\Omega_{3,k}$. It is now an easy exercise to prove that $\Omega^{(k)} \cup \widetilde{\Omega}^{(k)}$ is a partition of \mathbb{R}^3 that has all the desired properties.

Using these properties and the standard process of partition of unity, we may define functions $\widehat{\phi}_\omega$ for $\omega \in \widetilde{\Omega}^{(k)}$ that are L^∞ -adapted to ω and supported in 3ω so that

$$1 = \sum_{\omega \in \Omega^{(k)}} \widehat{\phi}_\omega + \sum_{\omega \in \widetilde{\Omega}^{(k)}} \widehat{\phi}_\omega.$$

Recall that the functions ϕ_ω with $\omega \in \Omega^{(k)}$ have been defined earlier.

It is not hard to observe (see also the rank properties in section 6.1) that

$$(5.6) \quad C_3\omega \cap \langle \gamma \rangle \neq \emptyset$$

for each $\omega \in \Omega^{(k)} \cup \widetilde{\Omega}^{(k)}$. There are only finitely many tubes in

$$\Omega^{(k)} \cup \widetilde{\Omega}^{(k)}$$

which intersect the compact support of $\widehat{\psi}$, hence clearly

$$(5.7) \quad \Lambda(\psi) - \sum_{\omega \in \Omega^{(k)}} \Lambda(\psi * \phi_\omega) = \sum_{\omega \in \widetilde{\Omega}^{(k)}} \Lambda(\psi * \phi_\omega)$$

It then suffices to show that the right hand side tends to 0 as k tends to ∞ . For the rest of the proof it suffices to restrict attention to tubes that intersect the support of $\widehat{\psi}$ and to sufficiently large values of k . (In particular, we can assume $k \geq 0$)

We first estimate the contribution coming from the collection $\widetilde{\Omega}^{(k,1)}$ of tubes in $\widetilde{\Omega}^{(k)}$ whose eccentricity is 1 (the cubes). Due to (5.6) there are $O(2^k)$ tubes in $\widetilde{\Omega}^{(k,1)}$. To estimate the contribution of a tube in $\widetilde{\Omega}^{(k,1)}$ to (5.7) we use the modulation symmetry of Λ to get that $\Lambda(\psi * \phi_\omega) = \Lambda(M_{\gamma\xi}(\psi * \phi_\omega))$, where $\xi \in \mathbb{R}$ is chosen in such a way that the support of the Fourier transform of $M_{\gamma\xi}(\psi * \phi_\omega)$ lies inside the cube centered at the origin with side-length $100C_32^{-k}$. This is possible due to (5.6). It follows now easily that the Fourier transform of $M_{\gamma\xi}\phi_\omega$ is L^∞ - adapted to the cube of sidelength 2^{-k} centered at the origin. Since $k \geq 0$, the same can be said about the Fourier transform of $M_{\gamma\xi}(\psi * \phi_\omega)$. This easily implies now that $M_{\gamma\xi}(\psi * \phi_\omega)$ is L^1 - adapted to the cube of sidelength 2^k centered at the origin. Applying inequality (3.8) we obtain that

$$|\Lambda(M_{\gamma\xi}(\psi * \phi_\omega))| \lesssim 2^{-2k}.$$

Thus, the contribution of $\widetilde{\Omega}^{(k,1)}$ to (5.7) is $O(2^{-k})$.

It remains to consider the set $\widetilde{\Omega}^{(k,2)}$ of tubes $\omega \in \widetilde{\Omega}^{(k)}$ whose eccentricity $2^{-\kappa}$ is smaller than 1. Without loss of generality we can assume that the sides of ω have lengths 2^{-k} , 2^{-k} and $2^{-k+\kappa}$ in this order. It follows that ω is determined by the intersection of 3 special tubes $\omega' := \mathbb{R} \times \omega_{1,1} \times \omega_{1,2} \in \Omega_{1,k} \subset \Omega_1$, $\omega'' := \omega_{2,1} \times \mathbb{R} \times \omega_{2,2} \in \Omega_{2,k} \subset \Omega_2$ and $\omega''' := \omega_{3,1} \times \omega_{3,2} \times \mathbb{R} \in \widetilde{\Omega}_{3,k}$.

First observe that if such a tube ω produces a nonzero contribution to our sum then its sides have lengths smaller than 1. This is immediate for the smaller sides whose length is 2^{-k} . Let us now see that the same thing is true for the longer side. We observe that ω must intersect the cube $[-1, 1]^3$, which implies $(\omega_{2,1} \times \omega_{2,2}) \cap [-1, 1]^2 \neq \emptyset$. But since $\omega'' \in \Omega_2$, we know that $0 \notin 10(\omega_{2,1} \times \omega_{2,2})$. This proves $|\omega_{2,2}| \leq 1$. As a consequence, we deduce that the Fourier transform of $\psi * \phi_\omega$ is L^∞ - adapted to the tube ω .

Choose now $\xi \in \mathbb{R}$ such that $0 \in C_3(\omega - \xi\gamma)$ (this is possible due to (5.6)). Using again the modulation invariance of Λ and (5.6), we get as before that

$$|\Lambda(\psi * \phi_\omega)| = |\Lambda(M_{\xi\gamma}(\psi * \phi_\omega))|,$$

where $M_{\xi\gamma}(\psi * \phi_\omega)$ is L^1 - adapted to the box centered at the origin with side-lengths comparable to $(2^k, 2^k, 2^{-\kappa}2^k)$. Moreover, the Fourier transform of the function $M_{\xi\gamma}(\psi * \phi_\omega)$ will be supported in the box $\omega - \gamma\xi$ which is easily seen to satisfy the requirements of Lemma 4.5, once we prove that ω satisfies the requirements (4.7) and (4.8) in Remark 4.1. But this is immediate since $(\omega_{2,1} \times \omega_{2,2}) \cap \langle \gamma^{(2)} \rangle = \emptyset$ and $(\omega_{3,1} \times \omega_{3,2}) \cap \langle \gamma^{(3)} \rangle = \emptyset$.

Lemma 4.5 now gives

$$|\Lambda(M_{\xi\gamma}(\psi * \phi_\omega))| \lesssim 2^{-k/2} 2^{-\kappa(1/2+\delta')} 2^{-3k/2+\kappa/2}$$

where the factor $2^{-3k/2+\kappa/2}$ adjusts the L^2 normalization of $\psi * \phi_\omega$. Finally note that for each $\kappa \geq 0$ there are $O(2^k)$ tubes ω as above. To see this, we can further assume without loss of generality that ω is determined by ω'' and ω''' , that is $\omega = (\omega_{3,1}, \omega_{3,2}, \omega_{2,2})$. Note

first that there are $O(2^k)$ tubes $\omega''' = \omega_{3,1} \times \omega_{3,2} \times \mathbb{R}$ of width 2^{-k} which intersect $[-1, 1]^2$, since $C_1(\omega_{3,1} \times \omega_{3,2}) \cap \langle \gamma^{(3)} \rangle \neq \emptyset$. Given $\omega_{3,1}$, we know that $\omega_{2,1}$ is determined uniquely, and then $\omega_{2,2}$ is determined within finitely many choices by $\omega_{2,1}$, since $C_1(\omega_{2,1} \times \omega_{2,2}) \cap \langle \gamma^{(2)} \rangle \neq \emptyset$. Hence we can estimate

$$\sum_{\omega \in \tilde{\Omega}^{(k,2)}} |\Lambda(\psi * \phi_\omega)| \lesssim \sum_{\kappa \geq 0} 2^{-k} 2^{-\kappa \delta'},$$

which is again an acceptable contribution. \square

As we proceed with the second stage of the decomposition of Λ , we return to viewing Λ as a trilinear form on the triple product of Schwartz spaces, rather than a distribution on \mathbb{R}^3 . Thus we assume ψ in Lemma 5.5 is an elementary tensor $\psi = f_1 \otimes f_2 \otimes f_3$ of three compactly supported smooth functions. To turn ϕ_ω into a convergent sum of elementary tensors, we invoke Fourier series.

For each tube $\omega \in \Omega$ we choose functions $\widehat{\phi}_{\omega_i}$ for $i = 1, 2, 3$, L^∞ - adapted to ω_i , constant equal to 1 on $3\omega_i$ and supported on $5\omega_i$. The dilated tubes 5ω are still disjoint from the bad set S since $C_1 \gg 1$. Then

$$\widehat{\phi}_\omega(\xi) = \widehat{\phi}_\omega(\xi) \prod_{i=1}^3 \widehat{\phi}_{\omega_i}(\xi_i)$$

Applying Fourier series on 5ω gives

$$\widehat{\phi}_\omega(\xi) = \sum_{n_1, n_2, n_3 \in \mathbb{Z}} c_{\omega, n_1, n_2, n_3} \prod_{i=1}^3 \widehat{\phi}_{\omega_i}(\xi_i) e^{2\pi i n_i \xi_i / (5|\omega_i|)},$$

and note that for each M the coefficients decay as

$$|c_{\omega, n_1, n_2, n_3}| \lesssim_M (1 + \max(|n_1|, |n_2|, |n_3|))^{-M}.$$

We also note that since $\widehat{\phi}_{\omega_i}$ is L^∞ - adapted to ω_i of any order M and supported in $5\omega_i$, so is the function $M_{n_i/5|\omega_i|} \widehat{\phi}_{\omega_i}$, with a constant that is $O(n_i^M)$. These observations imply that

$$\Lambda(\psi * \phi_\omega) = \sum_{n_1, n_2, n_3 \in \mathbb{Z}} c_{\omega, n_1, n_2, n_3} \Lambda(f_1 * \tau_{n_1/5|\omega_1|} \phi_{\omega_1}, f_2 * \tau_{n_2/5|\omega_2|} \phi_{\omega_2}, f_3 * \tau_{n_3/5|\omega_3|} \phi_{\omega_3}).$$

Another immediate implication is that it suffices to bound

$$\sum_{\omega \in \Omega} |\Lambda(f_1 * \phi_{\omega_1}, f_2 * \phi_{\omega_2}, f_3 * \phi_{\omega_3})|$$

uniformly over all functions ϕ_{ω_i} such that $\widehat{\phi}_{\omega_i}$ is L^∞ - adapted of order -say- $2N$ and supported in $5\omega_i$.

By Shannon's sampling theorem, we can write for each such function $\widehat{\phi}_{\omega_i}$ and each f

$$f * \phi_{\omega_i} = \sum_{I_i} \langle f, \phi_{I_i, \omega_i} \rangle \phi_{I_i, \omega_i}$$

where I_i runs through all dyadic intervals of length $(16|\omega_i|)^{-1}$ and $M_{-c(\omega_i)}\phi_{I_i, \omega_i}$ is an L^2 -normalized bump function adapted to I_i of order $2N$ such that $\widehat{\phi}_{I_i, \omega_i}$ is supported in $8\omega_i$.

We then estimate $\Lambda(f_1, f_2, f_3)$ by

$$(5.8) \quad \sum_{\omega \in \Omega} \sum_{I_1, I_2, I_3} |\Lambda(\phi_{I_1, \omega_1}, \phi_{I_2, \omega_2}, \phi_{I_3, \omega_3})| \prod_{i=1}^3 |\langle f_i, \phi_{I_i, \omega_i} \rangle|$$

Next, observe that for each $\omega \in \Omega$ with width 2^{-k} and eccentricity $2^{-\kappa}$ and each $\delta' < \delta$

$$(5.9) \quad \begin{aligned} & |\Lambda(\phi_{I_1, \omega_1}, \phi_{I_2, \omega_2}, \phi_{I_3, \omega_3})| \\ & \lesssim 2^{-k/2} 2^{-\kappa(\delta'+1/2)} (1 + 2^{-k} \text{diam}(I_1, I_2, I_3))^{-1-\delta'} (1 + 2^{-k} |\sum \gamma_i c(I_i)|)^{-N}. \end{aligned}$$

This will follow from Lemma 4.5. Indeed, reasoning as before, we can find $\xi \in \mathbb{R}$ such that the tube $\omega - \xi\gamma$ is contained in some tube centered at the origin with width $100C_3 2^{-k}$ and eccentricity $2^{-\kappa}$. Since $|\xi\gamma_i - c(\omega_i)| = O(|\omega_i|)$ for each i , it follows that $M_{-\xi\gamma}(\phi_{I_1, \omega_1} \otimes \phi_{I_2, \omega_2} \otimes \phi_{I_3, \omega_3})$ is L^2 -adapted to the box $I_1 \times I_2 \times I_3$. The fact that ω satisfies the requirements (4.7) and (4.8) (and actually all the other symmetric 4 identities) in Remark 4.1 is immediate (see the proof of Lemma 5.3).

Using these estimates we shall restructure the sum in (5.8) and extract the main terms.

First we shall use symmetry to reduce to the case where the sum runs over all tubes

$$(5.10) \quad \omega = (\omega_1, \omega_2, \omega_3) := (\omega_{1,1} \times \omega_{1,2} \times \omega_{2,2})$$

such that $\omega_{2,2}$ is the longest side and ω is determined by intersection of the tubes $\omega' = \omega_{1,1} \times \omega_{1,2} \times \mathbb{R} \in \Omega_3$, $\omega'' = \mathbb{R} \times \omega_{2,1} \times \omega_{2,2} \in \Omega_1$ and $\omega''' = \omega_{3,1} \times \mathbb{R} \times \omega_{3,2} \in \Omega_2$.

At the expense of replacing the exponent δ in (5.9) by a slightly smaller δ' it suffices to consider only those tubes ω with a fixed eccentricity $2^{-\kappa}$ and those triples of intervals for which

$$(5.11) \quad 2^{m-1} \leq \text{diam}(I_1, I_2, I_3)/|I| \leq 2^m$$

$$(5.12) \quad 2^{m-2} \leq \text{diam}(I_2, I_3)/|I|$$

for some fixed m and prove summable bounds in κ and m . Here we use again the notation $|I| := |I_1| = |I_2|$.

Next, we shall use the rapid decay in the last factor in (5.9) to argue similarly to above that one only needs to consider those terms for which this factor is large. For fixed I_3 and I_2 we choose an interval \tilde{I}_1 satisfying (5.11) and (5.12), for which $\sum_j \gamma_j c(I_j)$ is minimal. For any other interval I_1 satisfying (5.11) and (5.12), we note

that the function $M_{-c(\omega_1)}\phi_{I_1,\omega_1}$ is adapted to \tilde{I}_1 of order N . The constant of adaption increases like $(1 + \text{dist}(c(I_1), c(\tilde{I}_1))/|I|)^N$, which is offset by the last factor in (5.9) since

$$|\gamma_1||c(I_1) - c(\tilde{I}_1)| \leq \left| \sum_j \gamma_j c(I_j) \right| + O(I).$$

Thus it suffices to consider only \tilde{I}_1 . We shall write again I_1 for \tilde{I}_1 and we shall maintain from the above discussion that we are summing over a two parameter family of intervals I_1, I_2, I_3 such that I_1 is determined by I_2 and I_3 . Likewise we may assume I_2 is determined by I_3 and I_1 . Note that we cannot do the same for I_3 , as I_3 is potentially much smaller than I_1 and I_2 and there may be many intervals I_3 (about 2^κ) which maximize the last factor in (5.9), for given I_1 and I_2 .

To summarize the above reductions, let Ω_κ^* denote all tubes as in (5.10), which have eccentricity $2^{-\kappa}$. Let $\mathcal{I}_m(\omega)$ denote the set of all triples (I_1, I_2, I_3) associated with ω as above, satisfying (5.11) and such that both I_1 and I_2 are uniquely determined by the other two intervals. Then it suffices to get uniform bounds in m and κ over all functions ϕ_{I_i,ω_i} such that $M_{-c(\omega_i)}\phi_{I_i,\omega_i}$ is L^2 - adapted I_i of order N , for the following sum

$$(5.13) \quad \sum_{\omega \in \Omega_\kappa^*} \sum_{(I_1, I_2, I_3) \in \mathcal{I}_m(\omega)} |I_1|^{-1/2} 2^{-\kappa(1/2+\delta')} 2^{-m(1+\delta')} \prod_{i=1}^3 |\langle f_i, \phi_{I_i,\omega_i} \rangle|,$$

where $\delta' < \delta$ will be chosen conveniently (see Theorem 5.5).

It will be convenient to associate with ω and (I_1, I_2, I_3) as above

- (1) For each $i = 1, 2, 3$ a dyadic interval ω_{p_i} of length $2^7|\omega_i|$ which contains the support $8\omega_i$ of the function $\widehat{\phi_{I_i,\omega_i}}$.
- (2) For each $i = 1, 2, 3$ a dyadic interval ω_{R_i} of length $2^7|\omega_3|$ which contains ω_{p_i} . Note that $\omega_{R_3} = \omega_{p_3}$.
- (3) For each $i = 1, 2, 3$ a dyadic interval I_{p_i} of length $|\omega_{p_i}|^{-1}$ which is contained in I_i .
- (4) A dyadic interval I_R of length $2^7 \times 2^m |I_1|$ which contains I_1, I_2, I_3 .

It is clear that such intervals exist. There is no deep reason we choose to modify I_i to I_{p_i} in (3), we only do that so that we have $|I_{p_i}||\omega_{p_i}| = 1$.

These intervals in general might not be standard dyadic intervals. However, we can choose them to be generalized dyadic intervals. We briefly describe this construction and refer the reader to [11] for more details. Let q be a large prime and define a generalized dyadic interval to be one of the form $[2^n k/q, 2^n(k/q + 1))$ for integers k and n . If k is restricted to a fixed residue class modulo q , the collection above forms a grid, in the sense that all intervals of fixed scale form a partition of the real line and any two intervals in the grid are either disjoint or one contains the other one.

For every interval I , there are q generalized dyadic intervals, which we call covers, of length strictly between $q|I|$ and $2q|I|$ (thus the length is a uniquely determined power of two) which contain I . More precisely, each grid except for possibly one of the q grids

contains such a cover for I . Therefore, for every collection of less than q intervals, there is one grid which contains a cover for each interval in the collection.

Using this method, for q large enough we can choose for each ω and I_1, I_2, I_3 the intervals listed above to belong to one of the q grids. We will work with $q = 11$. Since there are only 11 grids, it suffices to consider the sum (5.13) over each grid separately. For simplicity of notation we shall only discuss the standard dyadic grid, which is one of the 11 grids. Since we only use the grid properties of the dyadic intervals, our proof will easily transfer to the case of the other grids.

The above intervals determine rectangles in the phase plane: $R_i = I_R \times \omega_{R_i}$ and $p_i = I_{p_i} \times \omega_{p_i}$. We will denote by R the 3-tuple of rectangles (R_1, R_2, R_3) and will call it a multi-rectangle. Similarly, p will denote the 3-tuple of tiles (p_1, p_2, p_3) , which will be referred to as a multi-tile.

We discuss the important properties of the triples R and p other than the obvious containment properties visible in the figure below. First, by a further splitting into finitely many collections it suffices to assume that each of R_1, R_2, R_3 determines the other two. As all three rectangles have the same spatial interval I_R , it suffices to show this for the frequency intervals. This in turn follows from the fact that the frequency intervals have equal side-length and from the easy⁷ observation that

$$(5.14) \quad C_3(\omega_{R_1} \times \omega_{R_2} \times \omega_{R_3}) \cap \langle \gamma \rangle \neq 0.$$

Similarly, we can assume that ω_{p_i} determines both ω_{p_j} and ω_{p_3} , $i \neq j \in \{1, 2\}$. The fact that ω_{p_i} determines ω_{p_j} within finitely many choices follows from the fact that

$$C_1(\omega_{p_1} \times \omega_{p_2}) \cap \langle \gamma^{(3)} \rangle \neq 0,$$

a consequence of the special representation $\omega = \omega' \cap \omega''$. Note also that ω_{p_j} determines ω_{R_j} , which we have proved to determine $\omega_{R_3} = \omega_{p_3}$. We must point out however that ω_{p_3} only determines ω_{p_j} within $O(2^\kappa)$ choices.

⁷For similar results, see the rank properties in Section 6.1.

On the spatial side, we observe that the intervals I_{p_3} and I_{p_i} determine I_{p_j} , this property being reminiscent of the similar property shared by the intervals I_i . This implies that in the triple (p_1, p_2, p_3) we can assume that p_1, p_3 vary freely and determine p_2 and also that p_2, p_3 vary freely and determine p_1 . We recall for comparison the fact that in the case of x independent kernels K , each p_l , $l \in \{1, 2, 3\}$ determined uniquely the other two (See the discussion in the beginning of this section).

The area of any rectangle R_i is $A = O(2^{\kappa+m})$. If we incorporate the latest reductions, we denote by \mathbf{p} the family of all multi-tiles p as above. We will also denote by \mathbf{R} the family of all multi-rectangles⁸ R (of fixed area A) associated with triples $p \in \mathbf{p}$. For any fixed triple R , we denote by $\mathbf{p}(R)$ the set of all multi-tiles $p \in \mathbf{p}$ that are contained in R .

Finally we notice that for any given $R \in \mathbf{R}$ there are at most A^2 multi-tiles $p \in \mathbf{p}(R)$. On the other hand, any given $p \in \mathbf{p}$ determines a unique $R \in \mathbf{R}$ such that $p \in \mathbf{p}(R)$. Let us see this latter point. Given $p = (p_1, p_2, p_3)$ we know that p_3 determines ω_{R_3} which determines both ω_{R_1} and ω_{R_2} . On the other hand, both the length and the position of I_R are determined by I_{p_1} , since κ and m are known a priori.

With these notations we may rewrite (5.13) as

$$(5.15) \quad A^{-\delta'} \sum_{R \in \mathbf{R}} \sum_{p \in \mathbf{p}(R)} |I_R|^{-1} |I_{p_3}|^{1/2} \prod_{i=1}^3 |\langle f_i, \phi_{p_i} \rangle|,$$

where we can take $0 < \delta' < \delta$ as close to δ as we want. We will prove bounds for this sum that are then summable in κ and m .

For each measurable subset $E \subset \mathbb{R}$ with finite measure we define

$$X(E) = \{f : |f| \leq 1_E \text{ a.e.}\},$$

$$X_2(E) = \{f : |f| \leq |E|^{-1/2} 1_E \text{ a.e.}\}.$$

A major subset of a set E is a subset $E_0 \subset E$ such that $|E_0| \geq |E|/2$.

Definition 5.4. *Let α be an 3-tuple of real numbers and assume $\alpha_j \leq 1$ for all $j \in \{1, 2, 3\}$. A 3-sublinear form is called of type α if there is a constant C such that for each finite measure tuple $E = (E_1, E_2, E_3)$, there is an index j_0 and a major subset \tilde{E}_{j_0} of E_{j_0} such that for all tuples $f = (f_1, f_2, f_3)$ with $f_j \in X(E_j)$ for all $j \neq j_0$ and $f_{j_0} \in X(\tilde{E}_{j_0})$ we have*

$$|\Lambda(f_1, f_2, f_3)| \lesssim \prod_{j=1}^3 |E_j|^{\alpha_j}.$$

We will work with $\Lambda(f_1, f_2, f_3) = \sum_{R \in \mathbf{R}} \sum_{p \in \mathbf{p}(R)} |I_R|^{-1} |I_{p_3}|^{1/2} \prod_{i=1}^3 |\langle f_i, \phi_{p_i} \rangle|$. In the next section we will prove the following theorem.

⁸From now, we will stop indexing the dependence of various collections like \mathbf{p} and \mathbf{R} on κ and m .

Theorem 5.5. *Let $j_0 \in \{1, 2, 3\}$. For each α in the triangular region defined by*

$$\begin{aligned} \alpha_1 + \alpha_2 + \alpha_3 &= 1 \\ 1/2 < \alpha_{j_1}, \alpha_{j_2} < 1, \text{ for } j_1, j_2 \in \{1, 2, 3\} \setminus j_0 \\ \max(-\delta, -1/2) < \alpha_{j_0} < 0, \end{aligned}$$

we have that $\Lambda(f_1, f_2, f_3)$ is of type α with bound $C = O(A^{\delta''})$, for some $\delta'' < \delta$ depending only on α .

By choosing then in (5.15) $\delta' > \delta''$ we obtain that the original form Λ is also of type α in the same regions. Since the convex hull of the three triangular regions in the above theorem is the region characterized by the restrictions

$$\begin{aligned} \alpha_1 + \alpha_2 + \alpha_3 &= 1 \\ \max(-\delta, -1/2) < \alpha_j < \min(\delta + 1/2, 1), \text{ for all } j, \end{aligned}$$

Theorem 2.7 follows then by invoking multilinear interpolation as in [24], [29].

We remark that the case $A = 1$ in Theorem 5.5 corresponds to the situation when the form Λ is associated with an x independent kernel $K(t)$ (see also the discussion at the beginning of this section).

Finally, to prove Theorem 5.5 we will assume that

$$(5.16) \quad R, R' \in \mathbf{R} \text{ and } |I_R| < |I_{R'}| \text{ implies } C_3 A |I_R| \leq |I_{R'}|,$$

at the expense of considering $\log(C_3 A)$ families in scales.

6. THE BOUNDEDNESS OF THE MODEL SUMS

6.1. Rank, trees and sizes. We will prove that if C_1 is sufficiently large we have the following:

Rank properties of \mathbf{p}

Let $p \in \mathbf{p}(R)$ be a multi-tile that is associated with a tube ω as in (5.10), according to the procedure described earlier. Let $(\xi^1, \xi^2, \xi^3) \in \langle \gamma \rangle$.

- (1) (3-overlapping implies j -lacunary; tile version) If $\xi^3 \in 2\omega_{p_3}$ then for each $j \in \{1, 2\}$ we have $\xi^j \notin C_2\omega_{p_j}$ and $\xi^j \in C_3 A \omega_{p_j}$.

Proof. We will consider⁹ the case $j = 2$. Recall that $\omega \subseteq \omega'' = \mathbb{R} \times \omega_{2,1} \times \omega_{2,2}$. If $\xi^2 \in C_2\omega_{p_2}$, then this together with $\xi^3 \in 2\omega_{p_3}$ would force $\frac{C_1}{4}(\omega_{2,1} \times \omega_{2,2}) \cap \langle \gamma^{(1)} \rangle \neq \emptyset$, contradicting the construction of ω'' . On the other hand, by construction it follows that there is some $(\tilde{\xi}^2, \tilde{\xi}^3) \in \langle \gamma^{(1)} \rangle \cap C_1(\omega_{2,1} \times \omega_{2,2})$. Note that $|\tilde{\xi}^3 - \xi^3| \leq C_1|\omega_{p_3}|$. This implies $|\tilde{\xi}^2 - \xi^2| \leq \frac{1}{100}C_3|\omega_{p_3}|$. This together with the fact that $\tilde{\xi}^2 \in C_1\omega_{2,1}$, implies $\xi^2 \in C_3\omega_{2,1}$. Finally, this together with the fact that $\omega_{2,1} \subset A\omega_{p_2}$ implies $\xi^2 \in C_3A\omega_{p_2}$. \square

⁹For $j = 1$ one has to use the fact that $\omega \subset \omega''' := (\omega_{3,1}, \mathbb{R}, \omega_{3,2})$.

- (2) (*j*-overlapping implies 3-lacunary) If $\xi^j \in 2\omega_{p_j}$ for some $j \in \{1, 2\}$ then we have $\xi^3 \notin C_2\omega_{p_3}$ and $\xi^3 \in C_3\omega_{p_3}$.

Proof. A similar argument as for (1) applies here. \square

- (3) (*j*-overlapping implies *i*-lacunary) If $\xi^j \in 2\omega_{p_j}$ for some $j \in \{1, 2\}$ then for $i = 3 - j$ we have $\xi^i \notin C_2\omega_{p_i}$ and $\xi^i \in C_3\omega_{p_i}$.

Proof. If $\xi^i \in C_2\omega_{p_i}$ then this together with $\xi^j \in 2\omega_{p_j}$ forces $(\xi^1, \xi^2) \in \langle \gamma^{(3)} \rangle \cap C_2(\omega_{p_1} \times \omega_{p_2})$, contradicting the construction of ω' . On the other hand, from the construction of ω' we know that there is some $(\tilde{\xi}^1, \tilde{\xi}^2) \in \langle \gamma^{(3)} \rangle \cap C_1(\omega_{p_1} \times \omega_{p_2})$. Since $|\tilde{\xi}^j - \xi^j| \leq C_1|\omega_{p_j}|$ and $\tilde{\xi}^i \in C_1\omega_{p_i}$, it follows that $\xi^i \in C_3\omega_{p_i}$. \square

- (4) (3-overlapping implies *j*-lacunary; rectangle version) If $\xi^3 \in 2\omega_{R_3}$ then for each $j \in \{1, 2\}$ we have $\xi^j \notin C_2\omega_{R_j}$ and $\xi^j \in C_3\omega_{R_j}$.

Proof. Similar arguments apply here and for the rest of the properties. \square

- (5) (*j*-overlapping implies 3-lacunary; rectangle version) If $j \in \{1, 2\}$ and $\xi^j \in 2\omega_{R_j}$, then $\xi^3 \notin C_2\omega_{R_3}$ and $\xi^3 \in C_3\omega_{R_3}$.
- (6) (*j*-overlapping implies *i*- C_3 overlapping; rectangle version) If $i, j \in \{1, 2, 3\}$ and $\xi^j \in 2\omega_{R_j}$ then $\xi^i \in C_3\omega_{R_i}$.

Definition 6.1. Let $i \in \{1, 2, 3\}$. An *i*-tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ with top $(I_{\mathbf{T}}, \xi_{\mathbf{T}}^i)$, where $I_{\mathbf{T}}$ is a dyadic interval, is a collection $\mathbf{T} \subset \mathbf{R}$ of multi-rectangles R such that $I_R \subseteq I_{\mathbf{T}}$, together with a collection $\mathbf{p}_{\mathbf{T}} = \bigcup_{R \in \mathbf{T}} \mathbf{p}(R, \mathbf{T})$ of multi-tiles satisfying $\mathbf{p}(R, \mathbf{T}) \subseteq \mathbf{p}(R)$ and $\xi_{\mathbf{T}}^i \in 2\omega_{p_i}$ for each $R \in \mathbf{T}$ and each $p \in \mathbf{p}(R, \mathbf{T})$.

A 0-tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ with top $(I_{\mathbf{T}}, \xi_{\mathbf{T}}^0)$, where $I_{\mathbf{T}}$ is a dyadic interval, is a collection $\mathbf{T} \subset \mathbf{R}$ of multi-rectangles R such that $I_R \subseteq I_{\mathbf{T}}$, together with a collection $\mathbf{p}_{\mathbf{T}} = \bigcup_{R \in \mathbf{T}} \mathbf{p}(R, \mathbf{T})$ of multi-tiles satisfying $\mathbf{p}(R, \mathbf{T}) \subseteq \mathbf{p}(R)$ and either

(1) $\xi_{\mathbf{T}}^0 \in 2\omega_{R_1}$ for each $R \in \mathbf{T}$ and $\xi_{\mathbf{T}}^0 \notin 2\omega_{p_1}$, $\xi_{\mathbf{T}}^2 \notin 2\omega_{p_2}$ for each $p \in \mathbf{p}(R, \mathbf{T})$, where $(\xi_{\mathbf{T}}^0, \xi_{\mathbf{T}}^2) \in \langle \gamma^{(3)} \rangle$ (this will be referred to as 0¹-tree)

or

(2) $\xi_{\mathbf{T}}^0 \in 2\omega_{R_2}$ for each $R \in \mathbf{T}$ and $\xi_{\mathbf{T}}^1 \notin 2\omega_{p_1}$, $\xi_{\mathbf{T}}^0 \notin 2\omega_{p_2}$ for each $p \in \mathbf{p}(R, \mathbf{T})$, where $(\xi_{\mathbf{T}}^1, \xi_{\mathbf{T}}^0) \in \langle \gamma^{(3)} \rangle$ (this will be referred to as 0²-tree).

Given a dyadic interval I and a point $\vec{\xi} = (\xi^1, \xi^2, \xi^3) \in \langle \gamma \rangle$, define the saturation $\mathcal{S}(I, \vec{\xi})$ of the pair $(I, \vec{\xi})$ to the set of all multi-tiles which lie in the union of the maximal 1-tree with top (I, ξ^1) , the maximal 2-tree with top (I, ξ^2) , the maximal 3-tree with top (I, ξ^3) , the maximal 0¹-tree with top (I, ξ^1) and the maximal 0²-tree with top (I, ξ^2) . Note that actually

$$(6.1) \quad \mathcal{S}(I, \vec{\xi}) = \bigcup_{i=1}^3 \bigcup_{\substack{R: \xi^i \in 2\omega_{R_i} \\ I_R \subseteq I}} \mathbf{p}(R).$$

We state three easy lemmas for future reference.

Lemma 6.2. *If $\xi^l \in 2\omega_{R_l}$ for some $l \in \{1, 2, 3\}$ and $I_R \subseteq I$ then $\mathbf{p}(R) \subset \mathcal{S}(I, \vec{\xi})$.*

Lemma 6.3. *If $\xi^i \in 2\omega_{R_i}$, $I_{R'} \subsetneq I$ and $\omega_{R_j} \subsetneq \omega_{R'_j}$ for some $i, j \in \{1, 2, 3\}$ then $\mathbf{p}(R') \subset \mathcal{S}(I, \vec{\xi})$.*

Proof. We know from rank property (6) that $\xi^j \in C_3\omega_{R_j}$, and from (5.16) we deduce that $\xi^j \in 2\omega_{R'_j}$. The conclusion now follows from the previous lemma. \square

The following is an immediate consequence of the rank properties.

Lemma 6.4. *If $i \in \{0, 1, 2, 3\} \setminus \{j\}$, $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ is an i -tree with top $(I_{\mathbf{T}}, \xi_{\mathbf{T}}^i)$ and $p \in \mathbf{p}_{\mathbf{T}}$ then¹⁰ $\xi_{\mathbf{T}}^j \notin 2\omega_{p_j}$ and $\xi_{\mathbf{T}}^j \in C_3A\omega_{p_j}$.*

Remark 6.1. *Lemma 6.4 and (5.16) imply that for each $i \in \{0, 1, 2, 3\} \setminus \{j\}$, each i -tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$, each $R, R' \in \mathbf{T}$ with $|I_R| < |I_{R'}|$ and each $p \in \mathbf{p}(R, \mathbf{T})$, $p' \in \mathbf{p}(R', \mathbf{T})$ we have $\omega_{p_j} \cap \omega_{p'_j} = \emptyset$.*

For each subcollection $\mathbf{p}^*(R) \subseteq \mathbf{p}(R)$ and each $l \in \{1, 2, 3\}$ we will denote $\mathbf{p}_l^*(R) := \{p_l : p \in \mathbf{p}^*(R)\}$. For the simplicity of notation we will sometimes write \mathbf{T} instead of $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$.

Definition 6.5. *For $l \in \{1, 2, 3\}$, the tile size $\text{size}_{l,l}$ of a collection $\mathbf{p}^* \subset \mathbf{p}$ of multi-tiles with respect to a function f_l is defined as*

$$\text{size}_{l,l}(\mathbf{p}^*) := \sup_{R \in \mathbf{R}} \left(\frac{\sum_{p_l \in \mathbf{p}_l^*(R)} |\langle f_l, \phi_{p_l} \rangle|^2}{|I_R|} \right)^{1/2},$$

where $\mathbf{p}^*(R) := \mathbf{p}(R) \cap \mathbf{p}^*$.¹¹

Definition 6.6. *For $i \neq j \in \{1, 2, 3\}$ and for $j \in \{1, 2\}$ and $i = 0$, the tree size $\text{size}_{j,i}$ of a collection $\mathbf{p}^* \subset \mathbf{p}$ of multi-tiles with respect to a function¹² f_j is defined as*

$$\text{size}_{j,i}(\mathbf{p}^*) := \sup_{\mathbf{T}} \left(\frac{\sum_{R \in \mathbf{T}} \sum_{p_j \in \mathbf{p}_j(R, \mathbf{T})} |\langle f_j, \phi_{p_j} \rangle|^2}{|I_{\mathbf{T}}|} \right)^{1/2},$$

where the supremum is taken over all i -trees $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ with $\mathbf{p}_{\mathbf{T}} \subseteq \mathbf{p}^*$.

¹⁰Here $\xi_{\mathbf{T}}^j$ is the j^{th} coordinate of the vector $\vec{\xi}_{\mathbf{T}} \in \langle \gamma \rangle$ which is uniquely determined by the coordinate $\xi_{\mathbf{T}}^i$. If $i \neq 0$, then $\xi_{\mathbf{T}}^i$ is the i^{th} coordinate of this vector, while if $i = 0$, it is either the first or the second, depending on whether $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ is a 0^1 -tree or a 0^2 -tree.

¹¹While a given tile p_l may correspond to more multi-tiles p in $\mathbf{p}(R)$ or in \mathbf{p}^* , it will be counted only once in each summation.

¹²The size will not be indexed by f_j , the function with respect to which the size is measured will always be clear from the context.

We will estimate the model operator associated with each tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ by first summing in the third variable and then applying the Cauchy-Schwartz inequality in the first two variables. In doing so we recall that p_i and p_3 determine p_j uniquely

$$\begin{aligned} \Lambda_{\mathbf{T}}(f_1, f_2, f_3) &:= \sum_{R \in \mathbf{T}} |I_R|^{-1} \sum_{p \in \mathbf{p}(R, \mathbf{T})} |I_{p_3}|^{1/2} \prod_{i=1}^3 |\langle f_i, \phi_{p_i} \rangle| \\ &\leq \sum_{R \in \mathbf{T}} |I_R|^{-1} \left(\sum_{p_1 \in \mathbf{p}_1(R, \mathbf{T})} |\langle f_1, \phi_{p_1} \rangle|^2 \right)^{1/2} \left(\sum_{p_2 \in \mathbf{p}_2(R, \mathbf{T})} |\langle f_2, \phi_{p_2} \rangle|^2 \right)^{1/2} \sum_{p_3 \in \mathbf{p}_3(R, \mathbf{T})} |I_{p_3}|^{1/2} |\langle f_3, \phi_{p_3} \rangle| \\ &\leq \sum_{R \in \mathbf{T}} |I_R|^{-1/2} \left(\sum_{p_1 \in \mathbf{p}_1(R, \mathbf{T})} |\langle f_1, \phi_{p_1} \rangle|^2 \right)^{1/2} \left(\sum_{p_2 \in \mathbf{p}_2(R, \mathbf{T})} |\langle f_2, \phi_{p_2} \rangle|^2 \right)^{1/2} \left(\sum_{p_3 \in \mathbf{p}_3(R, \mathbf{T})} |\langle f_3, \phi_{p_3} \rangle|^2 \right)^{1/2} \end{aligned}$$

This estimate is refined as follows, depending on the type of tree we are dealing with.

For a 3-tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ we write

$$\begin{aligned} \Lambda_{\mathbf{T}}(f_1, f_2, f_3) &\leq |I_{\mathbf{T}}| \left(\frac{\sum_{R \in \mathbf{T}} \sum_{p_1 \in \mathbf{p}_1(R, \mathbf{T})} |\langle f_1, \phi_{p_1} \rangle|^2}{|I_{\mathbf{T}}|} \right)^{1/2} \left(\frac{\sum_{R \in \mathbf{T}} \sum_{p_2 \in \mathbf{p}_2(R, \mathbf{T})} |\langle f_2, \phi_{p_2} \rangle|^2}{|I_{\mathbf{T}}|} \right)^{1/2} \\ &\quad \times \left(\sup_{R \in \mathbf{T}} \frac{\sum_{p_3 \in \mathbf{p}_3(R, \mathbf{T})} |\langle f_3, \phi_{p_3} \rangle|^2}{|I_R|} \right)^{1/2} \\ &\leq |I_{\mathbf{T}}| \text{size}_{1,3}(\mathbf{p}_{\mathbf{T}}) \text{size}_{2,3}(\mathbf{p}_{\mathbf{T}}) \text{size}_{3,3}(\mathbf{p}_{\mathbf{T}}). \end{aligned}$$

An identical estimate shows that if $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ is a 0-tree then

$$\Lambda_{\mathbf{T}}(f_1, f_2, f_3) \leq |I_{\mathbf{T}}| \text{size}_{1,0}(\mathbf{p}_{\mathbf{T}}) \text{size}_{2,0}(\mathbf{p}_{\mathbf{T}}) \text{size}_{3,3}(\mathbf{p}_{\mathbf{T}}).$$

For an i -tree with $i \in \{1, 2\}$ we write

$$\begin{aligned} \Lambda_{\mathbf{T}}(f_1, f_2, f_3) &\leq |I_{\mathbf{T}}| \left(\frac{\sum_{R \in \mathbf{T}} \sum_{p_j \in \mathbf{p}_j(R, \mathbf{T})} |\langle f_j, \phi_{p_j} \rangle|^2}{|I_{\mathbf{T}}|} \right)^{1/2} \sup_{R \in \mathbf{T}} \left(\frac{\sum_{p_i \in \mathbf{p}_i(R, \mathbf{T})} |\langle f_i, \phi_{p_i} \rangle|^2}{|I_R|} \right)^{1/2} \\ &\quad \times \left(\frac{\sum_{R \in \mathbf{T}} \sum_{p_3 \in \mathbf{p}_3(R, \mathbf{T})} |\langle f_3, \phi_{p_3} \rangle|^2}{|I_{\mathbf{T}}|} \right)^{1/2} \\ &\leq |I_{\mathbf{T}}| \text{size}_{j,i}(\mathbf{p}_{\mathbf{T}}) \text{size}_{i,i}(\mathbf{p}_{\mathbf{T}}) \text{size}_{3,i}(\mathbf{p}_{\mathbf{T}}). \end{aligned}$$

We thus see that if a collection \mathbf{p}^* of multi-tiles is organized as a disjoint union \mathcal{F} of trees, $\mathbf{p}^* = \bigcup_{(\mathbf{T}, \mathbf{p}_{\mathbf{T}}) \in \mathcal{F}} \mathbf{p}_{\mathbf{T}}$, then

$$(6.2) \quad |\Lambda_{\mathbf{p}^*}(f_1, f_2, f_3)| \leq \left(\sum_{i=0}^3 \prod_{j=1}^3 \text{size}_{j,i}(\mathbf{p}^*) \right) \left(\sum_{\mathbf{T} \in \mathcal{F}} |I_{\mathbf{T}}| \right),$$

where for the purpose of keeping the notation symmetric we denote $\text{size}_{3,0} := \text{size}_{3,3}$.

This inequality sets up the strategy for the following sections, where we will split \mathbf{p}^* into collections which can be organized into trees, with good control over both their sizes and over the L^1 norm of the counting function of the tops of the trees.

6.2. Bessel type inequalities. For each $j \in \{1, 2, 3\}$, each $R \in \mathbf{R}$ and each $\mathbf{p}^*(R) \subseteq \mathbf{p}(R)$ we will use the notation¹³

$$T_{R, \mathbf{p}^*(R)}^j(f) = \sum_{p_j \in \mathbf{p}_j^*(R)} \langle f, \phi_{p_j} \rangle \phi_{p_j}$$

$$S_{R, \mathbf{p}^*(R)}^j(f) = \left(\sum_{p_j \in \mathbf{p}_j^*(R)} |\langle f, \phi_{p_j} \rangle|^2 \right)^{1/2}.$$

If R belongs to a tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ and $\mathbf{p}^*(R) = \mathbf{p}(R, \mathbf{T})$, then the notation $T_{R, \mathbf{T}}^j(f)$, $S_{R, \mathbf{T}}^j(f)$ will be preferred.

An immediate consequence of Lemma 4.1 is the fact that

$$(6.3) \quad \|T_{R, \mathbf{p}^*(R)}^j(f)\|_2 \approx S_{R, \mathbf{p}^*(R)}^j(f) \lesssim \|f\|_2$$

for each $f \in L^2$, each R and each $\mathbf{p}^*(R) \subseteq \mathbf{p}(R)$. Similarly, due to Remark 6.1, for each $i \in \{0, 1, 2, 3\}$, each $j \in \{1, 2, 3\} \setminus \{i\}$ and each i -tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$

$$(6.4) \quad \sum_{R \in \mathbf{T}} \|T_{R, \mathbf{T}}^j(f)\|_2 \approx \sum_{R \in \mathbf{T}} S_{R, \mathbf{T}}^j(f) \lesssim \|f\|_2.$$

Definition 6.7. (*M-separated rectangles*) We say that a family \mathbf{R}^* of rectangles $R = I_R \times \omega_R$ is *M-separated* if for any $R, R' \in \mathbf{R}^*$, $R \neq R'$, we have that $(MI_R \times \omega_R) \cap (MI_{R'} \times \omega_{R'}) = \emptyset$.

Lemma 6.8. Let \mathbf{R}^* be a finite family of pairwise disjoint rectangles. Then, for each $M \geq 1$ we can find a subfamily $\tilde{\mathbf{R}} \subset \mathbf{R}^*$ that is *M-separated* and satisfies

$$\sum_{R \in \tilde{\mathbf{R}}} |I_R| \leq 3M \sum_{R \in \mathbf{R}^*} |I_R|.$$

Proof. Fix $M \geq 1$ and define $R_M = MI_R \times \omega_R$. We select recursively rectangles $R \in \mathbf{R}^*$ with maximal $|I_R|$ and with the property that $R_M \cap R'_M = \emptyset$ for all previously selected rectangles R' . When this procedure ends, we get a family of rectangles $\tilde{\mathbf{R}} = \{R^1, \dots, R^n\} \subset \mathbf{R}^*$. We now define

$$\mathbf{R}^i = \{R \in \mathbf{R}^* : R_M \cap R_M^i \neq \emptyset, R_M \cap R_M^k = \emptyset \text{ for } k < i\}.$$

Then it is clear that $\tilde{\mathbf{R}}$ is *M-separated* and that

$$\mathbf{R}^* = \bigcup_{i=1}^n \mathbf{R}^i,$$

thus

$$\sum_{R \in \mathbf{R}^*} |I_R| = \sum_{i=1}^n \sum_{R \in \mathbf{R}^i} |I_R|$$

Moreover, $|I_R| \leq |I_{R^i}|$ for any $R \in \mathbf{R}^i$. Otherwise, if $|I_R| > |I_{R^i}|$, by the maximality condition of length and the fact that $R_M \cap R_M^k = \emptyset$ for all $k < i$, R should have been

¹³When no confusion can arise, we will suppress the dependence on $\mathbf{p}^*(R)$ of $T_R^j(f)$ and $S_R^j(f)$.

chosen instead R^i . This together with the observation that $MI_R \cap MI_{R^i} \neq \emptyset$ for each $R \in \mathbf{R}^i$ implies that $I_R \subset 3MI_{R^i}$. Thus,

$$(6.5) \quad \bigcup_{R \in \mathbf{R}^i} I_R \subset 3MI_{R^i}.$$

On the other hand for each $R, R' \in \mathbf{R}^i$ we know that $\omega_{R^i} \subset \omega_R \cap \omega_{R'} \neq \emptyset$, which together with $R \cap R' = \emptyset$ implies that $I_R \cap I_{R'} = \emptyset$. This together with (6.5) implies that

$$\sum_{R \in \mathbf{R}^*} |I_R| \leq 3M \sum_{i=1}^n |I_{R^i}| = 3M \sum_{R \in \tilde{\mathbf{R}}} |I_R|.$$

□

Definition 6.9. Let $j \in \{1, 2, 3\}$.

- (1) We say that two trees $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ and $(\mathbf{T}', \mathbf{p}_{\mathbf{T}'})$ are disjoint if $\mathbf{T} \cap \mathbf{T}' = \emptyset$.
- (2) We say that two trees $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ and $(\mathbf{T}', \mathbf{p}_{\mathbf{T}'})$ with tops $(I_{\mathbf{T}}, \xi_{\mathbf{T}})$ and $(I_{\mathbf{T}'}, \xi_{\mathbf{T}'})$ are j -strongly disjoint if they are disjoint and satisfy the following:
if $p \in \mathbf{p}(R, \mathbf{T})$, $p' \in \mathbf{p}(R', \mathbf{T}')$, $R \in \mathbf{T}$, $R' \in \mathbf{T}'$, $\omega_{p_j} \subsetneq \omega_{p'_j}$, then $I_{R'} \cap I_{\mathbf{T}} = \emptyset$

A family of trees is said to consist of j -strongly disjoint trees if any two trees in the family are j -strongly disjoint.

The following lemma will be the main tool in dealing with the tile sizes.

Lemma 6.10. Let $j \in \{1, 2, 3\}$, $f \in L^2$ and $\lambda > 0$. Let $\mathbf{R}^* \subset \mathbf{R}$ be a family of multi-rectangles, each of which is associated with a collection of multi-tiles $\mathbf{p}^*(R) \subseteq \mathbf{p}(R)$. Assume that the rectangles $(R_j)_{R \in \mathbf{R}^*}$ are pairwise disjoint.

Assume also that for each $R \in \mathbf{R}^*$ we have

$$(6.6) \quad S_{R, \mathbf{p}^*(R)}^j(f) \geq \lambda |I_R|^{1/2}.$$

Then

$$\sum_{R \in \mathbf{R}^*} |I_R| \lesssim A^{\frac{2}{N-2}} \lambda^{-2} \|f\|_2^2.$$

Proof. To simplify notation we will drop the j dependence of the various operators and will index them only by R . Since the rectangles R_j are pairwise disjoint, by Lemma 6.8 it suffices to assume that they are A^ϵ -separated with $\epsilon = \frac{2}{N-2}$, and to prove that

$$\sum_{R \in \mathbf{R}^*} |I_R| \lesssim \lambda^{-2} \|f\|_2^2.$$

We assume that $\|f\|_2 = 1$. We may also assume that for each $R \in \mathbf{R}^*$

$$(6.7) \quad \lambda |I_R|^{1/2} \leq S_R(f) \leq 2\lambda |I_R|^{1/2}.$$

To see this latter assumption, one can split \mathbf{R}^* into subcollections $\mathbf{R}^* = \bigcup_{k \geq 0} \mathbf{R}_k^*$ such that for each $R \in \mathbf{R}_k^*$ we have $2^k \lambda |I_R|^{1/2} \leq S_R(f) \leq 2^{k+1} \lambda |I_R|^{1/2}$. In other words, each subcollection satisfies (6.7) with λ replaced by $2^k \lambda$, and applying the estimate to each

subcollection and summing a geometric series will prove the general form of the lemma. The proof that follows is a classical instance of the TT^* argument.

We have

$$\begin{aligned} \sum_{R \in \mathbf{R}^*} \|T_R(f)\|_2^2 &= \sum_{R \in \mathbf{R}^*} \langle T_R^*(f), T_R^*(f) \rangle \\ &= \sum_{R \in \mathbf{R}^*} \langle T_R T_R^*(f), f \rangle \\ &\leq \left\| \sum_{R \in \mathbf{R}^*} T_R T_R^*(f) \right\|_2 \end{aligned}$$

which due to (6.3) implies

$$\begin{aligned} \left(\sum_{R \in \mathbf{R}^*} S_R(f)^2 \right)^2 &\lesssim \sum_{R, R' \in \mathbf{R}^*} \langle T_{R'} T_{R'}^*(f), T_R T_R^*(f) \rangle \\ &= \sum_{R, R' \in \mathbf{R}^*} \langle T_{R'}^*(f), T_{R'}^* T_R T_R^*(f) \rangle \\ &\leq \sum_{R, R' \in \mathbf{R}^*} \|T_{R'}(f)\|_2 \|T_{R'}^* T_R\|_{2 \rightarrow 2} \|T_R(f)\|_2. \end{aligned}$$

Using this, hypothesis (6.7) and again (6.3) we get

$$\left(\sum_{R \in \mathbf{R}^*} \lambda^2 |I_R| \right)^2 \lesssim \lambda^2 \sum_{R, R' \in \mathbf{R}^*} |I_R|^{1/2} |I_{R'}|^{1/2} \|T_{R'}^* T_R\|_{2 \rightarrow 2}.$$

By symmetry and the fact that $T_{R'}^* T_R \equiv 0$ if $\omega_{R_j} \cap \omega_{R'_j} = \emptyset$ we have

$$(6.8) \quad \left(\sum_{R \in \mathbf{R}^*} |I_R| \right)^2 \lesssim \lambda^{-2} \left(\sum_{R \in \mathbf{R}^*} |I_R| \|T_R^* T_R\|_{2 \rightarrow 2} + \sum_{R \in \mathbf{R}^*} \sum_{R' \in \mathcal{F}_{\text{freq}}(R)} |I_R|^{1/2} |I_{R'}|^{1/2} \|T_{R'}^* T_R\|_{2 \rightarrow 2} \right)$$

where $\mathcal{F}_{\text{freq}}(R) = \{R' \in \mathbf{R}^* : R' \neq R, |I_{R'}| \leq |I_R|, \omega_{R_j} \cap \omega_{R'_j} \neq \emptyset\}$. It suffices to prove now that the term in (6.8) is $O(\lambda^{-2} \sum_{R \in \mathbf{R}^*} |I_R|)$. To achieve this, we will first estimate the operator norms $\|T_{R'}^* T_R\|_{2 \rightarrow 2}$.

The diagonal term is immediately seen to be $O(\lambda^{-2} \sum_{R \in \mathbf{R}^*} |I_R|)$, due to (6.3), since $\|T_R^* T_R\|_{2 \rightarrow 2} \leq \|T_R\|_{2 \rightarrow 2}^2 \lesssim 1$. To estimate the off diagonal, we first note that

$$(6.9) \quad \begin{aligned} |\langle T_{R'}^* T_R(f), g \rangle| &= |\langle T_R(f), T_{R'}(g) \rangle| \\ &\leq \sum_{p_j \in \mathbf{p}_j^*(R)} \sum_{p'_j \in \mathbf{p}_j^*(R')} |\langle f, \phi_{p_j} \rangle| |\langle g, \phi_{p'_j} \rangle| |\langle \phi_{p_j}, \phi_{p'_j} \rangle| \\ &\leq A^2 \max_{\substack{p_j \in \mathbf{p}_j^*(R) \\ p'_j \in \mathbf{p}_j^*(R')}} |\langle \phi_{p_j}, \phi_{p'_j} \rangle| \|f\|_2 \|g\|_2. \end{aligned}$$

From Lemma 4.1 we know the bound

$$(6.10) \quad |\langle \phi_{p_j}, \phi_{p'_j} \rangle| \lesssim \left(\frac{|I_{p'_j}|}{|I_{p_j}|} \right)^{1/2} (1 + |I_{p_j}|^{-1} |c(I_{p_j}) - c(I_{p'_j})|)^{-N}.$$

If $R' \in \mathcal{F}_{\text{freq}}(R)$, it follows that $A^\epsilon I_R \cap A^\epsilon I_{R'} = \emptyset$ since R, R' are A^ϵ separated. This implies that

$$(6.11) \quad 1 + |I_{p_j}|^{-1} |c(I_{p_j}) - c(I_{p'_j})| \geq \max\{1 + |I_R|^{-1} |c(I_R) - c(I_{R'})|, A^\epsilon/2\}.$$

We use this and (6.10) to argue that

$$|\langle \phi_{p_j}, \phi_{p'_j} \rangle| \lesssim \left(\frac{|I_{R'}|}{|I_R|} \right)^{1/2} (1 + |I_R|^{-1} |c(I_R) - c(I_{R'})|)^{-2} A^{\epsilon(2-N)}$$

Thus

$$(6.12) \quad \|T_{R'}^* T_R\|_{2 \rightarrow 2} \lesssim A^{2-\epsilon(N-2)} \left(\frac{|I_{R'}|}{|I_R|} \right)^{1/2} (1 + |I_R|^{-1} |c(I_R) - c(I_{R'})|)^{-2}$$

We use this inequality to bound the sum corresponding to the off diagonal term in (6.8) by

$$(6.13) \quad C A^{2-\epsilon(N-2)} \sum_{R \in \mathbf{R}^*} \sum_{R' \in \mathcal{F}_{\text{freq}}(R)} |I_{R'}| (1 + |I_R|^{-1} |c(I_R) - c(I_{R'})|)^{-2}.$$

Now we fix $R \in \mathbf{R}^*$. We note that if $R' \neq R''$ and $R', R'' \in \mathcal{F}_{\text{freq}}(R)$ then $I_{R'} \cap I_{R''} = \emptyset$. With these observations we may write

$$\begin{aligned} \sum_{R' \in \mathcal{F}_{\text{freq}}(R)} |I_{R'}| (1 + |I_R|^{-1} |c(I_R) - c(I_{R'})|)^{-2} &\lesssim \sum_{R' \in \mathcal{F}_{\text{freq}}(R)} \int_{I_{R'}} \chi_{I_R}(x)^2 dx \\ &\lesssim \int_{I_R^c} \chi_{I_R}(x)^2 dx, \\ &\lesssim |I_R|. \end{aligned}$$

Finally, we get

$$\left(\sum_{R \in \mathbf{R}^*} |I_R| \right)^2 \lesssim \lambda^{-2} \left(\sum_{R \in \mathbf{R}^*} |I_R| + A^{2+\epsilon(2-N)} \sum_{R \in \mathbf{R}^*} |I_R| \right) \lesssim \lambda^{-2} \sum_{R \in \mathbf{R}^*} |I_R|.$$

□

Definition 6.11. (*M-separated tiles in a tree*) We say that a tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ with top $(I_{\mathbf{T}}, \xi_{\mathbf{T}})$ is *M-separated* if $M I_R \subseteq I_{\mathbf{T}}$ for each $R \in \mathbf{T}$.

Lemma 6.12. Let $i \in \{0, 1, 2, 3\} \setminus \{j\}$, $M \geq 1$, $f \in L^2$ and $\lambda > 0$. Let \mathcal{F} be a collection of *j-strongly disjoint*¹⁴ *i-trees* $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ satisfying for each $\mathbf{T} \in \mathcal{F}$ and each

¹⁴The lemma can be formulated without involving strongly disjointness in either the hypothesis or the conclusion; we choose this formulation since this is how the lemma will be applied.

$R \in \mathbf{T}$

$$(6.14) \quad S_{R,\mathbf{T}}^j(f) \leq 10^{-2} M^{-1/2} \lambda |I_R|^{1/2}$$

$$(6.15) \quad \lambda^2 |I_{\mathbf{T}}| / 4 \leq \sum_{R \in \mathbf{T}} S_{R,\mathbf{T}}^j(f)^2 \leq \lambda^2 |I_{\mathbf{T}}|.$$

Assume also that for each subtree $\mathbf{T}' \subseteq \mathbf{T} \in \mathcal{F}$ with top $(I_{\mathbf{T}'}, \xi_{\mathbf{T}'})$ we have

$$(6.16) \quad \sum_{R \in \mathbf{T}'} S_{R,\mathbf{T}'}^j(f)^2 \leq \lambda^2 |I_{\mathbf{T}'}|.$$

Then for each $\mathbf{T} \in \mathcal{F}$ we can find a collection $\tilde{\mathbf{T}} \subseteq \mathbf{T}$ such that the trees $\{(\tilde{\mathbf{T}}, \mathbf{p}_{\tilde{\mathbf{T}}}) := \bigcup_{R \in \tilde{\mathbf{T}}} \mathbf{p}(R, \tilde{\mathbf{T}}) : \mathbf{T} \in \mathcal{F}\}$ (understood as having the same tops as the original trees) with $\mathbf{p}(R, \tilde{\mathbf{T}}) = \mathbf{p}(R, \mathbf{T})$ for each $R \in \tilde{\mathbf{T}}$, are M -separated, j -strongly disjoint and they satisfy

$$\frac{1}{20} \lambda^2 |I_{\tilde{\mathbf{T}}}| \leq \sum_{R \in \tilde{\mathbf{T}}} S_{R,\mathbf{T}}^j(f)^2 \leq \lambda^2 |I_{\tilde{\mathbf{T}}}|.$$

Proof. To get the new trees we proceed by removing those tiles in a tree that are either too close to the edges of the tree top-tile or too close in scale to it. More precisely, for any i -tree $\mathbf{T} \in \mathcal{F}$ we let $I(\mathbf{T}) = \frac{9}{10} I_{\mathbf{T}}$ and we define the subcollections

$$\begin{aligned} \mathbf{T}_1 &= \{R \in \mathbf{T} : I_R < I(\mathbf{T})\} \\ \mathbf{T}_2 &= \{R \in \mathbf{T} : I_R > I(\mathbf{T})\} \\ \mathbf{T}_3 &= \{R \in \mathbf{T} : |I_R| > (100M)^{-1} |I_{\mathbf{T}}|\} \end{aligned}$$

where $I_R < I(\mathbf{T})$ means $\sup\{x : x \in I_R\} \leq \inf\{x : x \in I(\mathbf{T})\}$. Then, we define

$$\tilde{\mathbf{T}} = \mathbf{T} \setminus (\mathbf{T}_1 \cup \mathbf{T}_2 \cup \mathbf{T}_3).$$

With these definitions we have by (6.16)

$$\sum_{R \in \mathbf{T}_1} S_R^j(f)^2 \leq \lambda^2 |I_{\mathbf{T}_1}| \leq \frac{1}{20} \lambda^2 |I_{\mathbf{T}}|$$

and the same for \mathbf{T}_2 , while by (6.14)

$$\sum_{R \in \mathbf{T}_3} S_R^j(f)^2 \leq 10^{-4} M^{-1} \lambda^2 \sum_{R \in \mathbf{T}_3} |I_R| \leq \frac{1}{10} \lambda^2 |I_{\mathbf{T}}|.$$

It easily follows that each tree $\tilde{\mathbf{T}}$ is M -separated. The fact that the new collection of trees is j -strongly disjoint is inherited from the initial collection. Finally,

$$\begin{aligned} \sum_{R \in \tilde{\mathbf{T}}} S_R^j(f)^2 &\geq \sum_{R \in \mathbf{T}} S_R^j(f)^2 - \sum_{i=1,2,3} \sum_{R \in \mathbf{T}_i} S_R^j(f)^2 \\ &\geq \frac{1}{4} \lambda^2 |I_{\mathbf{T}}| - \frac{2}{10} \lambda^2 |I_{\mathbf{T}}| \geq \frac{1}{20} \lambda^2 |I_{\mathbf{T}}|. \end{aligned}$$

□

Definition 6.13. (*Rectangles M -separated in scales*) We say that a collection \mathbf{R}^* of multi-rectangles is M -separated in scales if $R \neq R' \in \mathbf{R}^*$ and $|I_R| = |I_{R'}|$ imply that $\text{dist}(c(I_R), c(I_{R'})) \geq M|I_R|$.

We are now ready to prove the analog of Lemma 6.10 for the case when the trees may consist of more than just one multi-rectangle. This lemma will be the main tool in dealing with the tree sizes.

Lemma 6.14. Let $i \in \{0, 1, 2, 3\} \setminus \{j\}$, $M \geq 1$, $f \in L^2$ and $\lambda > 0$. Let \mathbf{R}^* be a collection of multi-rectangles which is M -separated in scales. Assume we also have a collection \mathcal{F} of j -strongly disjoint i -trees $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ with $\bigcup_{\mathbf{T} \in \mathcal{F}} \mathbf{T} = \mathbf{R}^*$ satisfying for each $\mathbf{T} \in \mathcal{F}$ and each $R \in \mathbf{T}$

$$(6.17) \quad S_{R, \mathbf{T}}^j(f) \leq 10^{-2} M^{-1/2} \lambda |I_R|^{1/2}$$

$$(6.18) \quad \lambda^2 |I_{\mathbf{T}}| / 4 \leq \sum_{R \in \mathbf{T}} S_{R, \mathbf{T}}^j(f)^2 \leq \lambda^2 |I_{\mathbf{T}}|.$$

Assume also that for each subtree $\mathbf{T}' \subseteq \mathbf{T} \in \mathcal{F}$ with top $(I_{\mathbf{T}'}, \xi_{\mathbf{T}'})$ we have

$$(6.19) \quad \sum_{R \in \mathbf{T}'} S_{R, \mathbf{T}'}^j(f)^2 \leq \lambda^2 |I_{\mathbf{T}'}|.$$

Then we have

$$\sum_{\mathbf{T} \in \mathcal{F}} |I_{\mathbf{T}}| \lesssim (1 + A^2 M^{3-N}) \lambda^{-2} \|f\|_2^2.$$

Proof. We will drop the j and \mathbf{T} dependence of various operators. By normalizing we can assume that $\|f\|_2 = 1$.

Moreover, by Lemma 6.12 we can assume the trees in \mathcal{F} are M -separated, with some loss in the constants from (6.18) and (6.19). Indeed, the new trees fabricated by the procedure in Lemma 6.12 have the same tops as the old ones so that the quantity $\sum_{\mathbf{T} \in \mathcal{F}} |I_{\mathbf{T}}|$ does not change.

The proof is another TT^* argument, that follows along the lines of the one in Lemma 6.10. Due to (6.18) we get as before

$$(6.20) \quad \left(\lambda^2 \sum_{\mathbf{T} \in \mathcal{F}} |I_{\mathbf{T}}| \right)^2 \lesssim \sum_{\substack{R, R' \in \mathbf{R}^* \\ |I_{R'}| = |I_R|}} \|T_{R'}(f)\|_2 \|T_{R'}^* T_R\|_{2 \rightarrow 2} \|T_R(f)\|_2$$

$$(6.21) \quad + \sum_{\substack{R, R' \in \mathbf{R}^* \\ |I_{R'}| < |I_R|}} \|T_{R'}(f)\|_2 \|T_{R'}^* T_R\|_{2 \rightarrow 2} \|T_R(f)\|_2.$$

We estimate each term separately. By Cauchy-Schwartz, the first sum can be bounded by

$$(6.22) \quad \frac{1}{2} \sum_{\substack{R, R' \in \mathbf{R}^* \\ |I_{R'}| = |I_R| \\ \omega_{R_j} = \omega_{R'_j}}} (\|T_R(f)\|_2^2 + \|T_{R'}(f)\|_2^2) \|T_R^* T_{R'}\|_{2 \rightarrow 2}.$$

By using (6.9) and the fact that whenever $p \in \mathbf{p}(R)$, $p' \in \mathbf{p}(R')$ we have

$$|I_{p_j}|^{-1}|c(I_{p_j}) - c(I_{p'_j})| \geq |I_R|^{-1}|c(I_R) - c(I_{R'})|.$$

we can derive similar to (6.12)

$$\|T_{R'}^* T_R\|_{2 \rightarrow 2} \lesssim A^2(1 + |I_R|^{-1}|c(I_R) - c(I_{R'})|)^{-N},$$

whenever $|I_{R'}| = |I_R|$. By using this inequality in the case $R' \neq R$ and the fact that $\|T_{R'}^* T_R\|_{2 \rightarrow 2} \lesssim 1$, the term in (6.22) can further be bounded by

$$(6.23) \quad \sum_{R \in \mathbf{R}^*} \|T_R(f)\|_2^2 (1 + \sum_{\substack{R' \in \mathbf{R}^* \setminus R \\ |I_{R'}| = |I_R| \\ \omega_R = \omega_{R'}}} A^2(1 + |I_R|^{-1}|c(I_R) - c(I_{R'})|)^{-N}).$$

Finally, using the M -separatedness in scales, the term in (6.23) (and thus the term in (6.20)) is bounded by

$$\sum_{R \in \mathbf{R}^*} \|T_R(f)\|_2^2 (1 + A^2 M^{-N}) \lesssim \lambda^2 (1 + A^2 M^{-N}) \sum_{\mathbf{T} \in \mathcal{F}} |\mathbf{T}|.$$

We will next concentrate on proving similar bounds for the term in (6.21). We start with a few observations. Fix R and \mathbf{T} such that $R \in \mathbf{T}$ and denote

$$\mathbf{R}^*(R) = \{R' \in \mathbf{R}^* : |I_{R'}| < |I_R|, T_{R'}^* T_R \neq 0\}.$$

The first point we make is that if $R' \in \mathbf{R}^*(R)$ then $R' \notin \mathbf{T}$. This is an immediate consequence of Remark 6.1. Using this and the j -strongly disjointness we see that $R' \in \mathbf{R}^*(R)$ implies $I_{R'} \cap I_{\mathbf{T}} = \emptyset$.

Secondly, we observe that $R' \neq R'' \in \mathbf{R}^*(R)$ implies that $I_{R'} \cap I_{R''} = \emptyset$. To prove this, we first note that the definition of $\mathbf{R}^*(R)$ guarantees the existence of $\mathbf{T}', \mathbf{T}'' \in \mathcal{F}$, $p^{(1)}, p^{(2)} \in \mathbf{p}(R, \mathbf{T})$ and $p^{(3)} \in \mathbf{p}(R', \mathbf{T}')$, $p^{(4)} \in \mathbf{p}(R'', \mathbf{T}'')$ such that $\omega_{p_j^{(1)}} \subsetneq \omega_{p_j^{(3)}}$ and $\omega_{p_j^{(2)}} \subsetneq \omega_{p_j^{(4)}}$. Due to (5.16) and due to the grid structure it follows that $\omega_{R_j} \subseteq \omega_{p_j^{(3)}} \cap \omega_{p_j^{(4)}}$. In particular, $\omega_{p_j^{(3)}} \cap \omega_{p_j^{(4)}} \neq \emptyset$. We distinguish two cases. If $|\omega_{p_j^{(3)}}| = |\omega_{p_j^{(4)}}|$ then clearly $I_{R'} \cap I_{R''} = \emptyset$, since otherwise we would get $R' = R''$. If $|\omega_{p_j^{(3)}}| < |\omega_{p_j^{(4)}}|$ then we first argue as above using Remark 6.1 that $\mathbf{T}' \neq \mathbf{T}''$, and then using the j -strongly disjointness that $I_{R'} \cap I_{\mathbf{T}''} = \emptyset$. We conclude again that $I_{R'} \cap I_{R''} = \emptyset$.

We next estimate $\|T_{R'}^* T_R\|_{2 \rightarrow 2}$ for $R' \in \mathbf{R}^*(R)$. Note that due to the first observation above and the M -separatedness of the trees we have $M I_R \cap I_{R'} = \emptyset$. By estimating like in (6.9) and (6.11) we then get

$$\begin{aligned} \|T_{R'}^* T_R\|_{2 \rightarrow 2} &\lesssim A^2 \left(\frac{|I_{R'}|}{|I_R|} \right)^{1/2} (1 + |I_R|^{-1}|c(I_R) - c(I_{R'})|)^{-N} \\ &\lesssim A^2 M^{4-N} \left(\frac{|I_{R'}|}{|I_R|} \right)^{1/2} (1 + |I_R|^{-1}|c(I_R) - c(I_{R'})|)^{-4}. \end{aligned}$$

We use (6.17) to estimate

$$\|T_{R'}(f)\|_2 \lesssim \|S_{R'}(f)\|_2 \lesssim M^{-1/2} \lambda |I_{R'}|^{1/2}$$

and similarly for R . If we take into account all these observations, we can bound the term in (6.21) by

$$\begin{aligned}
 & A^2 M^{3-N} \lambda^2 \sum_{\mathbf{T} \in \mathcal{F}} \sum_{R \in \mathbf{T}} \sum_{R' \in \mathbf{R}^*(R)} |I_{R'}| (1 + |I_R|^{-1} |c(I_R) - c(I_{R'})|)^{-4} \\
 & \lesssim A^2 M^{3-N} \lambda^2 \sum_{\mathbf{T} \in \mathcal{F}} \sum_{R \in \mathbf{T}} \sum_{R' \in \mathbf{R}^*(R)} \int_{I_{R'}} (1 + |I_R|^{-1} |c(I_R) - x|)^{-4} dx \\
 & \lesssim A^2 M^{3-N} \lambda^2 \sum_{\mathbf{T} \in \mathcal{F}} \sum_{R \in \mathbf{T}} \int_{I_{\mathbf{T}}^c} (1 + |I_R|^{-1} |c(I_R) - x|)^{-4} dx \\
 & \lesssim A^2 M^{3-N} \lambda^2 \sum_{\mathbf{T} \in \mathcal{F}} \sum_{R \in \mathbf{T}} |I_R| (1 + |I_R|^{-1} \text{dist}(c(I_R), I_{\mathbf{T}}^c))^{-2} \\
 & \lesssim A^2 M^{3-N} \lambda^2 \sum_{\mathbf{T} \in \mathcal{F}} |I_{\mathbf{T}}|.
 \end{aligned}$$

□

6.3. The Peeling Lemma. The following lemma will provide a decomposition of the multi-tiles in collections with good control over various sizes.

Lemma 6.15. *Let $i \in \{0, 1, 2, 3\}$, $j \in \{1, 2, 3\}$ and $f \in L^2$. Let $\mathbf{p}^* \subset \mathbf{p}$ be a finite collection of multi-tiles and let $\mathbf{R}^* \subset \mathbf{R}$ be a finite collection of multi-rectangles such that each $p \in \mathbf{p}^*$ belongs to some $R \in \mathbf{R}^*$. We assume that the collection \mathbf{R}^* of multi-rectangles is M -separated into scales with $M = A^{\frac{2}{N-2}}$. We also assume that $\text{size}_{j,i}(\mathbf{p}^*) \leq \lambda$. Then there is a collection \mathcal{F} of trees $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ with $\mathbf{p}_{\mathbf{T}} \subset \mathbf{p}^*$ such that*

$$\begin{aligned}
 \sum_{\mathbf{T} \in \mathcal{F}} |I_{\mathbf{T}}| & \lesssim A^{\frac{4}{N-2}} \lambda^{-2} \|f\|_2^2 \\
 \text{size}_{j,i} \left(\mathbf{p}^* - \bigcup_{\mathbf{T} \in \mathcal{F}} \mathbf{p}_{\mathbf{T}} \right) & \leq \lambda/2.
 \end{aligned}$$

Proof. We first describe the proof in the case we deal with tree sizes ($i \neq j$), which practically also contains the proof for the much simpler case of tile sizes. This will be briefly mentioned in the end of the proof.

First we eliminate all the multi-rectangles which have big $\text{size}_{j,i}$. We do that in order to set the stage for an application of Lemma 6.14. Consider the collection \mathcal{F}_0 of all singleton i -trees $(R, \mathbf{p}^*(R, \xi))$ with top (I_R, ξ) , for some $R \in \mathbf{R}^*$, $\xi \in \mathbb{R}$ and some $\mathbf{p}^*(R, \xi) \subseteq \mathbf{p}^*(R)$, such that

$$S_{R, \mathbf{p}^*(R, \xi)}^j(f) > 10^{-2} M^{-1/2} \lambda |I_R|^{1/2}.$$

Note that a given R may appear in more than just one pair $(R, \mathbf{p}^*(R, \xi))$. Define \mathcal{F}_{00} to be the collection of all R that contribute to \mathcal{F}_0 , that is $(R, \mathbf{p}^*(R, \xi_R^i)) \in \mathcal{F}_0$ for some ξ_R^i .

Start with $\mathcal{F}_1 := \emptyset$ and perform the following algorithm. Select some $R \in \mathcal{F}_{00}$, with the additional property that I_R is maximal with respect to inclusion, among all such R . It does not matter which one is selected, if there is more than one R that qualifies to be selected. Set $\mathcal{F}_1 := \mathcal{F}_1 \cup \{R\}$.

Define the vector $\vec{\xi}_R \in \langle \gamma \rangle$ as the one uniquely determined by the coordinate ξ_R^i : if $i \neq 0$, then ξ_R^i is the i^{th} coordinate of this vector, while if $i = 0$, it is either the first or the second coordinate, depending on whether $(R, \mathbf{p}^*(R, \xi))$ is a 0^1 -tree or a 0^2 -tree.

Define $\mathcal{F}_R := \{R' \in \mathcal{F}_{00} : R' \cap R_j \neq \emptyset\}$. Set $\mathcal{F}_{00} := \mathcal{F}_{00} \setminus \mathcal{F}_R$ and restart the algorithm.

Due to the maximality of I_R it follows that $I_{R'} \subseteq I_R$ for each $R' \in \mathcal{F}_R$. Let us observe next that

$$\bigcup_{R' \in \mathcal{F}_R} \mathbf{p}^*(R') \subseteq \mathcal{S}(I_R, \vec{\xi}_R).$$

This follows from Lemma 6.2 if $R' = R$, and from Lemma 6.3 if $R' \neq R$. From (6.1) we deduce that $\bigcup_{R' \in \mathcal{F}_R} \mathbf{p}^*(R')$ can be split into the union of five trees, each of which with top interval I_R .

It suffices to prove that

$$\sum_{R \in \mathcal{F}_{00}} |I_R| \lesssim A^{\frac{2}{N-2}} M \lambda^{-2} \|f\|_2^2.$$

But this follows immediately from Lemma 6.10, since the rectangles $(R_j)_{R \in \mathcal{F}_{00}}$ are pairwise disjoint. This ends the first stage of the construction.

In the second stage of the construction we perform the following algorithm

Step 0: Initialize $\mathbf{p}_0 := \mathbf{p}^* \setminus \bigcup_{R \in \mathcal{F}_1} \mathcal{S}(I_R, \vec{\xi}_R)$, $\mathcal{F}_i^{(1)} = \emptyset$, $\mathcal{S}_{\text{aux}}^{(1)} = \emptyset$, $\mathcal{F}_i^{(2)} = \emptyset$, $\mathcal{S}_{\text{aux}}^{(2)} = \emptyset$.

Step 1: Select an i -tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ with top $(I_{\mathbf{T}}, \xi_{\mathbf{T}}^i)$, $\mathbf{T} \subseteq \mathbf{R}^*$ and $\mathbf{p}_{\mathbf{T}} \subseteq \mathbf{p}_0$ such that the following requirements are satisfied

(i) $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ is the maximal tree with the given top $(I_{\mathbf{T}}, \xi_{\mathbf{T}}^i)$ that can be constructed out of the multi-tiles that are available.

(ii) $\sum_{R \in \mathbf{T}} S_{R, \mathbf{T}}^j(f)^2 \geq \frac{1}{8} \lambda^2 |I_{\mathbf{T}}|$

(iii) $\xi_{\mathbf{T}}^j < \omega_{p_j}$ for each¹⁵ $p \in \mathbf{p}_{\mathbf{T}}$

(iv) $\xi_{\mathbf{T}}^j$ is maximal over all the trees that satisfy (i), (ii) and (iii) above.

If no such tree can be found then go to Step 5.

Step 2: Put the tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ in the collection $\mathcal{F}_i^{(1)}$ and the multi-tiles $\mathcal{S}(I_{\mathbf{T}}, \vec{\xi}_{\mathbf{T}})$ in $\mathcal{S}_{\text{aux}}^{(1)}$

Step 3: Upgrade $\mathbf{p}_0 := \mathbf{p}_0 \setminus \mathcal{S}(I_{\mathbf{T}}, \vec{\xi}_{\mathbf{T}})$

Step 4: Go to Step 1

Step 5: Select an i -tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ with top $(I_{\mathbf{T}}, \xi_{\mathbf{T}}^i)$, $\mathbf{T} \subseteq \mathbf{R}^*$ and $\mathbf{p}_{\mathbf{T}} \subseteq \mathbf{p}_0$ such that the following requirements are satisfied

(i) $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ is the maximal tree with the given top $(I_{\mathbf{T}}, \xi_{\mathbf{T}}^i)$ that can be constructed out of the multi-tiles that are available.

(ii) $\sum_{R \in \mathbf{T}} S_{R, \mathbf{T}}^j(f)^2 \geq \frac{1}{8} \lambda^2 |I_{\mathbf{T}}|$

¹⁵Recall that $\vec{\xi}_{\mathbf{T}} \in \langle \gamma \rangle$ is the vector uniquely determined by the coordinate $\xi_{\mathbf{T}}^i$, as in Stage 1.

(iii) $\xi_{\mathbf{T}}^j > \omega_{p_j}$ for each $p \in \mathbf{p}_{\mathbf{T}}$

(iv) $\xi_{\mathbf{T}}^j$ is minimal over all the trees that satisfy (i), (ii) and (iii) above.

If no such tree can be found then go to Step 9.

Step 6: Put the tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ in the collection $\mathcal{F}_i^{(2)}$ and the multi-tiles $\mathcal{S}(I_{\mathbf{T}}, \vec{\xi}_{\mathbf{T}})$ in $\mathcal{S}_{\text{aux}}^{(2)}$

Step 7: Upgrade $\mathbf{p}_0 := \mathbf{p}_0 \setminus \mathcal{S}_{\text{aux}}^{(2)}$

Step 8: Go to Step 5

Step 9: Stop. The algorithm is over.

The first part of Lemma 6.4 easily implies that if \mathbf{p}_0 denotes the value after the algorithm above ends, then $\text{size}_{j,i}(\mathbf{p}_0) \leq \lambda/2$. It suffices now to prove that

$$\sum_{\mathbf{T} \in \mathcal{F}_i^{(1)} \cup \mathcal{F}_i^{(2)}} |I_{\mathbf{T}}| \lesssim A^2 M^{3-N} \lambda^{-2} \|f\|_2^2.$$

This will follow from Lemma 6.14 once we prove that both $\mathcal{F}_i^{(1)}$ and $\mathcal{F}_i^{(2)}$ consist of j -strongly disjoint trees. It suffices to prove this for $\mathcal{F}_i^{(1)}$.

We verify the second requirement of j -strongly disjointness. Assume for contradiction that there are two distinct trees $(\mathbf{T}, \mathbf{p}_{\mathbf{T}}), (\mathbf{T}', \mathbf{p}_{\mathbf{T}'}) \in \mathcal{F}_i^{(1)}$ and $R \in \mathbf{T}, R' \in \mathbf{T}', p \in \mathbf{p}(R, \mathbf{T}), p' \in \mathbf{p}(R', \mathbf{T}')$ with $\omega_{p_j} \subsetneq \omega_{p'_j}$ and $I_{R'} \subseteq I_{\mathbf{T}}$. By using Lemma 6.4, (5.16) and (iii) in Step 1 of the construction of both $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ and $(\mathbf{T}', \mathbf{p}_{\mathbf{T}'})$, we get that $\xi_{\mathbf{T}}^j > \xi_{\mathbf{T}'}^j$. Thus, by (iv) in Step 1 we know $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ was selected before $(\mathbf{T}', \mathbf{p}_{\mathbf{T}'})$.

On the other hand, by the grid properties we know that $\omega_{R_j} \subsetneq \omega_{R'_j}$. We can then invoke Lemma 6.3 with $I := I_{\mathbf{T}}$ to conclude that $p' \in \mathcal{S}(I_{\mathbf{T}}, \vec{\xi}_{\mathbf{T}})$. But then it is clear that p' was eliminated before the selection of the tree \mathbf{T}' , giving rise to a contradiction.

We now verify the first requirement in the definition of j -strongly disjointness. Assume by contradiction that $R \in \mathbf{T} \cap \mathbf{T}'$ for some $\mathbf{T}, \mathbf{T}' \in \mathcal{F}_i^{(1)}$, and assume without loss of generality that \mathbf{T} was selected before \mathbf{T}' . But then, by Lemma 6.2 with $I = I_{\mathbf{T}}$ it follows that $\mathbf{p}(R) \subseteq \mathcal{S}(I_{\mathbf{T}}, \vec{\xi}_{\mathbf{T}})$. This means the whole $\mathbf{p}(R)$ was eliminated before the selection of the tree \mathbf{T}' , giving rise to a contradiction.

Note that the first stage of this proof is essentially what needs to be done when dealing with tile sizes ($i = j$). Precisely, at each step of the selection algorithm we search for singleton j -trees $(R, \mathbf{p}^*(R, \xi_R^i))$ with top (I_R, ξ_R^i) such that

$$S_{R, \mathbf{p}^*(R, \xi_R^i)}^j \geq \lambda |I_R|^{1/2},$$

and such that I_R is maximal with respect to inclusion. We eliminate the multi-tiles $\mathcal{S}(I_R, \vec{\xi}_R)$ from \mathbf{p}^* . Let \mathcal{F}_{00} be the collection of the selected multi-rectangles R . The fact that

$$\sum_{R \in \mathcal{F}_{00}} |I_R| \lesssim \lambda^{-2} \|f\|_2^2$$

is an immediate consequence of Lemma 6.10 and of the fact that the rectangles R_i with $R \in \mathcal{F}_{00}$ are pairwise disjoint.

As a final observation, we note that -due to (6.1)- at each stage in the Peeling Lemma we eliminate with each multi-tile $p \in \mathbf{p}(R)$ all the multi-tiles in $\mathbf{p}(R)$. \square

6.4. Size estimates. In this section we will see how to estimate various sizes. Before we do so, we recall two lemmata that will be used in the sequel with the words ‘quartiles’ or ‘tri-tiles’ replaced by ‘multi-tiles’.

Lemma A (Lemma 4.2 in [26] pg. 410)

Let \mathbf{P} be a finite collection of quartiles, $j = 1, 2, 3$ and let $\{a_{P_j}\}_{P \in \mathbf{P}}$ be a sequence of complex numbers. Then

$$\sup_{T \in \mathbf{P}} \left(\frac{1}{|I_T|} \sum_{P \in T} |a_{P_j}|^2 \right)^{1/2} \sim \sup_{T \in \mathbf{P}} \frac{1}{|I_T|} \left\| \left(\sum_{P \in T} |a_{P_j}|^2 \frac{1_{I_P}}{|I_P|} \right)^{1/2} \right\|_{L^{1,\infty}(I_T)}$$

where T ranges over all trees in \mathbf{P} which are i -trees for some $i \neq j$.

Lemma B (Lemma 6.8 in [27] pg. 443)

Let $j = 1, 2, 3$, E_j be a set of finite measure, f_j be a function in $X(E_j)$, and let \mathbf{P} be a finite collection of tri-tiles. Then we have

$$\sup_{T \in \mathbf{P}} \left(\frac{1}{|I_T|} \sum_{P \in T} |\langle f_j, \phi_{P_j} \rangle|^2 \right)^{1/2} \lesssim \sup_{P \in \mathbf{P}} \frac{\int_{E_j} \chi_{I_P}^M}{|I_P|}$$

for all M with implicit constant depending on M .

We can now state our lemmas.

Lemma 6.16. Let $f \in X(E)$ and $1 < p < \infty$. For each $R \in \mathbf{R}$, $\xi \in \mathbb{R}$ and l we have

$$\left(|I_R|^{-1} \sum_{\substack{p_l \in \mathbf{p}_l(R) \\ \xi \in \omega_{p_l}}} |\langle f, \phi_{p_l} \rangle|^2 \right)^{1/2} \lesssim \frac{1}{|I_R|^{1/p}} \|1_{E} \chi_{I_R}^{N-1}\|_p.$$

For each $i \in \{0, 1, 2, 3\} \setminus \{j\}$ and each i -tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ with top $(I_{\mathbf{T}}, \xi_{\mathbf{T}}^i)$ we have

$$(6.24) \quad \left(\frac{\sum_{R \in \mathbf{T}} \sum_{p_j \in \mathbf{p}_j(R, \mathbf{T})} |\langle f, \phi_{p_j} \rangle|^2}{|I_{\mathbf{T}}|} \right)^{1/2} \leq C_A \sup_{I \in \mathcal{I}_{\mathbf{T}}} \frac{1}{|I|^{1/p}} \|1_{E} \chi_I^{N-1}\|_p,$$

where

$$\mathcal{I}_{\mathbf{T}} = \{I \text{ dyadic: } I_R \subseteq I \subseteq I_{\mathbf{T}} \text{ for some } R \in \mathbf{T}\},$$

$C_A = O(A^{1/2})$ if $i \in \{0, 3\}$ and $j \in \{1, 2\}$, and $C_A = O(1)$ if $i \in \{1, 2\}$.

Proof. This is a version of Lemma B above. Here we prove only the cases that are a bit different from the case in Lemma B. Namely we will only prove the second part of our lemma, and only in the case when $i = 3$ and ($i = 0, j \in \{1, 2\}$). These are the “worst case scenarios” because of the presence of A in the corresponding type of lacunarity.

Define $a_{R_j} = (\sum_{p_j \in \mathbf{p}_j(R, \mathbf{T})} |\langle f, \phi_{p_j} \rangle|^2)^{1/2}$. We first focus on the case $i = 3$. We note that

$$\begin{aligned} a_{R_j}^2 &\leq A \sup_{p \in \mathbf{p}(R, \mathbf{T})} |\langle f, \phi_{p_j} \rangle|^2 \\ &= A \sup_{p \in \mathbf{p}(R, \mathbf{T})} |\langle f * \check{1}_{\omega_{R_j}}, \phi_{p_j} \rangle|^2 \\ &\lesssim A |I_R| \inf_{x \in I_R} M_1^2(f * \check{1}_{\omega_{R_j}})(x). \end{aligned}$$

By Lemma A above, it suffices¹⁶ to show that for each subtree \mathbf{T}' of \mathbf{T}

$$(6.25) \quad \left\| \left(\sum_{R \in \mathbf{T}'} a_{R_j}^2 \frac{\chi_{I_R}}{|I_R|} \right)^{1/2} \right\|_p \lesssim A^{1/2} \|1_E \chi_{I_{\mathbf{T}'}}^{N-1}\|_p.$$

To simplify notation, we will continue to write \mathbf{T} rather than \mathbf{T}' . and by writing $f = f_1 + f_2$ with $f_1 = f 1_{2I_{\mathbf{T}}}$, it further suffices to prove (6.25) for both f_1 and f_2 .

In the case of f_2 we use the decay of ϕ_{p_j} to write

$$a_{R_j} \lesssim A^{1/2} \left(\frac{|I_R|}{|I_{\mathbf{T}}|} \right)^{N-\frac{1}{2}} |I_{\mathbf{T}}|^{-1/2} \int_E \chi_{I_{\mathbf{T}}}^N,$$

which by summation and Hölder's inequality proves (6.25).

To deal with f_1 we apply the Fefferman-Stein inequality first and then invoke the Littlewood-Paley theory and the rank property (4) to get

$$\begin{aligned} \left\| \left(\sum_{R \in \mathbf{T}} a_{R_j}^2 \frac{\chi_{I_R}}{|I_R|} \right)^{1/2} \right\|_p &\lesssim A^{1/2} \left\| \left(\sum_{R \in \mathbf{T}} M_1^2(f_1 * \check{1}_{\omega_{R_j}})(x) \right)^{1/2} \right\|_p \\ &\lesssim A^{1/2} \left\| \left(\sum_{R \in \mathbf{T}} (f_1 * \check{1}_{\omega_{R_j}})^2(x) \right)^{1/2} \right\|_p \\ &\lesssim A^{1/2} \|1_E\|_p, \end{aligned}$$

where $M_1(f)$ denotes the Hardy-Littlewood maximal function of f .

Let us now briefly see the case $i = 0$. The argument is very similar to above. Denote by $\xi_{\mathbf{T}}^j$ the j^{th} component of the vector $\vec{\xi}_{\mathbf{T}}$ associated with $\xi_{\mathbf{T}}^i$ as before. By modulation symmetry it suffices to assume that $\xi_{\mathbf{T}}^j = 0$. For each $R \in \mathbf{T}$ and each $p \in \mathbf{p}(R, \mathbf{T})$ let $\omega(p)$ be an interval of the form $[\epsilon 2^k, \epsilon 2^{k+3}]$ ($\epsilon \in \{-1, 1\}$, $k \in \mathbb{Z}$) such that $\omega_{p_j} \subset \omega(p)$. This is possible due to Lemma 6.4. We will estimate as before the term corresponding to f_2 , and then write for f_1

$$a_{R_j}^2 \lesssim A \sup_{p \in \mathbf{p}(R)} |I_R| \inf_{x \in I_R} M_1^2(f_1 * \check{1}_{\omega(p)})(x).$$

¹⁶This reduction is made possible by and explains the presence of the collection $\mathcal{I}_{\mathbf{T}}$ in (6.24).

By Lemma 6.4 and (5.16) we know that for each interval $\omega := [\epsilon 2^k, \epsilon 2^{k+3}]$ there is at most one scale $|I_R|$ such that $\omega(p) = \omega$. The proof follows as in the previous case, by applying the Fefferman-Stein inequality and the Littlewood-Paley theory. \square

Lemma 6.17. *For each $R \in \mathbf{R}$, $\xi \in \mathbb{R}$ and l we have*

$$\left(|I_R|^{-1} \sum_{\substack{p_l \in \mathbf{p}_l(R) \\ \xi \in \omega_{p_l}}} |\langle f, \phi_{p_l} \rangle|^2 \right)^{1/2} \lesssim \frac{1}{|I_R|^{1/2}} \|f \chi_{I_R}^{N-2}\|_2.$$

For each i -tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ with $i \in \{0, 1, 2, 3\} \setminus \{j\}$ we have

$$\left(\frac{\sum_{R \in \mathbf{T}} \sum_{p_j \in \mathbf{p}_j(R, \mathbf{T})} |\langle f, \phi_{p_j} \rangle|^2}{|I_{\mathbf{T}}|} \right)^{1/2} \lesssim \frac{1}{|I_{\mathbf{T}}|^{1/2}} \|f \chi_{I_{\mathbf{T}}}^{N-2}\|_2.$$

Proof. Use (6.3) and (6.4) with $f := f \chi_{I_{\mathbf{T}}}^{N-2}$ and $\phi_{p_j} := \phi_{p_j} \chi_{I_{\mathbf{T}}}^{-N+2}$, and note that $(M_{-c(\omega_{p_j})} \phi_{p_j}) \chi_{I_{\mathbf{T}}}^{-N+2}$ is L^2 adapted of order 2 to I_{p_j} and has the same frequency support as $M_{-c(\omega_{p_j})} \phi_{p_j}$. \square

By interpolating between the previous two lemmas we get

Corollary 6.18. *Let $f \in X(E)$ and $1 < p \leq 2$ and $\epsilon > 0$. For each $R \in \mathbf{R}$, $\xi \in \mathbb{R}$ we have*

$$\begin{aligned} \left(|I_R|^{-1} \sum_{\substack{p_l \in \mathbf{p}_l(R) \\ \xi \in \omega_{p_l}}} |\langle f, \phi_{p_l} \rangle|^2 \right)^{1/2} &\lesssim \frac{1}{|I_R|^{1/p}} \|1_E \chi_{I_R}^{N-2}\|_p \\ &\lesssim \left(\sup_{x \in E} \chi_{I_R}(x) \right)^{\frac{N-4}{p}} \left(\inf_{x \in I_R} M_1(1_E)(x) \right)^{1/p}. \end{aligned}$$

For each i -tree $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ with $i \in \{0, 1, 2, 3\} \setminus \{j\}$ we have

$$\begin{aligned} \left(\frac{\sum_{R \in \mathbf{T}} \sum_{p_j \in \mathbf{p}_j(R, \mathbf{T})} |\langle f, \phi_{p_j} \rangle|^2}{|I_{\mathbf{T}}|} \right)^{1/2} &\lesssim C \sup_{I \in \mathcal{I}_{\mathbf{T}}} \frac{1}{|I|^{1/p}} \|1_E \chi_I^{N-2}\|_p \\ &\lesssim C \left(\sup_{\substack{I \in \mathcal{I}_{\mathbf{T}} \\ x \in E}} \chi_I(x) \right)^{\frac{N-4}{p}} \left(\sup_{I \in \mathcal{I}_{\mathbf{T}}} \inf_{x \in I} M_1(1_E)(x) \right)^{1/p}, \end{aligned}$$

where $C = A^{\epsilon + \frac{1}{p} - \frac{1}{2}}$ if $i \in \{0, 3\}$ and $j \in \{1, 2\}$, and $C = 1$ if $i \in \{1, 2\}$.

6.5. Proof of Theorem 5.5. We may assume \mathbf{R} is finite, and get bounds independent of \mathbf{R} . At the expense of losing a factor of $A^{O(\frac{1}{N})}$ in the bounds, it suffices to assume that the collection \mathbf{R} of multi-rectangles is M -separated into scales with $M = A^{\frac{2}{N-2}}$. Since N can be taken arbitrarily large, all the factors of the form $A^{O(\frac{1}{N})}$ contributing to various bounds may and will be tolerated.

By scaling invariance we may assume that $|E_{j_0}| = 1$. Define

$$\Omega = \bigcup_{j=1}^3 \{x : M_1(1_{E_j})(x) > 100|E_j|\}$$

and $\tilde{E}_{j_0} := E_{j_0} \setminus \Omega$, and note that $|\tilde{E}_{j_0}| > \frac{1}{2}|E_{j_0}|$.

Let $f_j \in X_2(E_j)$, $j \neq j_0$ and $f_{j_0} \in X_2(\tilde{E}_{j_0})$. All sizes $\text{size}_{j,i}$ are understood with respect to f_j . We need to show that for some $\delta'' < \delta$

$$(6.26) \quad |\Lambda(f_1, f_2, f_3)| \lesssim A^{\delta''} |E_1|^{\gamma_1} |E_2|^{\gamma_2} |E_3|^{\gamma_3},$$

where $\gamma_i := \alpha_i - \frac{1}{2}$. We note that due to our restrictions, we have that $0 < \gamma_{j_1}, \gamma_{j_2} < \frac{1}{2}$ and $\gamma_{j_1} + \gamma_{j_2} = -\alpha_{j_0} < \frac{1}{2}$. Thus we can find $0 < \beta_1, \beta_2 < \frac{1}{2}$ sufficiently close to $\frac{1}{2}$ such that $a_{j_1} := 1 - \frac{\gamma_{j_1}}{\beta_1} > 0$, $a_{j_2} := 1 - \frac{\gamma_{j_2}}{\beta_2} > 0$ and $a_{j_0} := 2 - a_{j_1} - a_{j_2} \in (0, 1)$.

We shall make the assumption that either

- (1) $I_R \cap (\mathbb{R} \setminus \Omega) \neq \emptyset$ for all¹⁷ $R \in \mathbf{R}$, or
- (2) $I_R = I$ for all $R \in \mathbf{R}$, for some (fixed) dyadic $I \subset \Omega$ with

$$(6.27) \quad 2^l < 1 + \frac{\text{dist}(I, \mathbb{R} \setminus \Omega)}{|I|} \leq 2^{l+1}, \text{ for some (fixed) } l \geq 0,$$

and prove (6.26) for both case (1) and (2), with an additional multiplicative factor of $2^{-l}|I|$ in the bound, in case (2). If we can prove these special cases with the indicated gain, the general case follows by summation in l and I , since $|\Omega| \lesssim 1$. We present the argument for case (1), and then will indicate how to modify it for case (2).

Define $p_{j_1}, p_{j_2} \in (1, 2)$ such that $\beta_1 = \frac{1}{p_{j_1}} - \frac{1}{2}$, $\beta_2 = \frac{1}{p_{j_2}} - \frac{1}{2}$ and define $p_{j_0} = 2$. Note that by Corollary 6.18 it easily follows that for each $\epsilon > 0$

$$(6.28) \quad \max_i \text{size}_{j_1,i}(\mathbf{p}) \lesssim |E_{j_1}|^{\beta_1} A^{\beta_1 + \epsilon}$$

$$(6.29) \quad \max_i \text{size}_{j_2,i}(\mathbf{p}) \lesssim |E_{j_2}|^{\beta_2} A^{\beta_2 + \epsilon}$$

$$(6.30) \quad \max_i \text{size}_{j_0,i}(\mathbf{p}) \lesssim 1.$$

Fix $j \in \{1, 2, 3\}$. We successively use the Peeling Lemma 6.15, simultaneously for each $i \in \{0, 1, 2, 3\}$, to decompose $\mathbf{p} = \bigcup_{k=-\infty}^{\max_i \text{size}_{j,i}(\mathbf{p})} \mathbf{p}_k^{(j)}$ such that $\mathbf{p}_k^{(j)}$ consists of the union of a family $\mathcal{F}_k^{(j)}$ of trees $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$, $\mathbf{p}_k^{(j)} = \bigcup_{\mathbf{T} \in \mathcal{F}_k^{(j)}} \mathbf{p}_{\mathbf{T}}$, satisfying

$$(6.31) \quad \max_i \text{size}_{j,i}(\mathbf{p}_k^{(j)}) \lesssim 2^k$$

$$(6.32) \quad \sum_{\mathbf{T} \in \mathcal{F}_k^{(j)}} |I_{\mathbf{T}}| \lesssim A^{O(\frac{1}{N})} 2^{-2k}.$$

¹⁷The collection of multi-tiles is also appropriately restricted.

We get

$$|\Lambda(f_1, f_2, f_3)| \leq \sum_{k_1, k_2, k_3} \sum_{p \in \mathbf{p}_{k_1}^{(1)} \cap \mathbf{p}_{k_2}^{(2)} \cap \mathbf{p}_{k_3}^{(3)}} |I_R|^{-1} |I_{p_3}|^{1/2} \prod_{i=1}^3 |\langle f_j, \phi_{p_j} \rangle|,$$

where we implicitly assume that

$$2^{k_j} \leq \max_i \text{size}_{j,i}(\mathbf{p}).$$

By symmetry we may restrict ourselves to the case $k_{j_*} = \max_j k_j$, for some $j_* \in \{1, 2, 3\}$. We can further estimate the sum above by

$$(6.33) \quad \sum_{k_1, k_2, k_3} \sum_{(\mathbf{T}, \mathbf{p}_{\mathbf{T}}) \in \mathcal{F}_{k_{j_*}}^{(j_*)}} \sum_{p \in \tilde{\mathbf{p}}_{\mathbf{T}}} |I_R|^{-1} |I_{p_3}|^{1/2} \prod_{i=1}^3 |\langle f_j, \phi_{p_j} \rangle|,$$

where $\tilde{\mathbf{p}}_{\mathbf{T}} := \mathbf{p}_{\mathbf{T}} \cap \mathbf{p}_{k_j}^{(j)} \cap \mathbf{p}_{k_{j'}}^{(j')}$, $j, j' \in \{1, 2, 3\} \setminus j_*$. Note that \mathbf{T} gets partitioned by the intersection with various trees from $\mathcal{F}_{k_{j_*}^{(1)}}$ and $\mathcal{F}_{k_{j_*}^{(2)}}$, where $\{j_*^1, j_*^2\} = \{1, 2, 3\} \setminus j_*$. By the final observation in the proof of the Peeling Lemma, two different such trees in some $\mathcal{F}_{k_{j_*}^{(l)}}$, $l \in \{1, 2\}$, will not share any multi-rectangle. It follows that we have the following natural partition

$$\begin{aligned} \mathbf{T} &= \bigcup_{r \in R(\mathbf{T})} \mathbf{T}_r \\ \tilde{\mathbf{p}}_{\mathbf{T}} &= \bigcup_{r \in R(\mathbf{T})} \mathbf{p}_{\mathbf{T}_r} \end{aligned}$$

where $(\mathbf{T}_r, \mathbf{p}_{\mathbf{T}_r})$ is a subtree of $(\mathbf{T}, \mathbf{p}_{\mathbf{T}})$ which arises by an intersection, as described above. Due to the elimination of the saturations $\mathcal{S}(I_{\mathbf{T}'}, \vec{\xi}_{\mathbf{T}'})$ in Step 2 and Step 6 of the algorithm in the Peeling Lemma (here \mathbf{T}' is a generic tree in $\mathcal{F}_{k_{j_*}^{(l)}}$, $l \in \{1, 2\}$), it easily follows that the trees $(\mathbf{T}_r, \mathbf{p}_{\mathbf{T}_r})$ can be assigned tops $I_{\mathbf{T}_r} \subseteq I_{\mathbf{T}}$ which are pairwise disjoint for $r \in R(\mathbf{T})$. In particular,

$$\sum_{r \in R(\mathbf{T})} |I_{\mathbf{T}_r}| \leq |I_{\mathbf{T}}|.$$

We also note that each subtree $(\mathbf{T}_r, \mathbf{p}_{\mathbf{T}_r})$ satisfies $\max_i \text{size}_{j,i}(\mathbf{p}_{\mathbf{T}_r}) \lesssim 2^{k_j}$ for each $j \in \{1, 2, 3\}$. Using these observations and then invoking (6.2) and (6.32) with $j = j_*$, we may estimate (6.33) by

$$\sum_{k_1, k_2, k_3} \sum_{(\mathbf{T}, \mathbf{p}_{\mathbf{T}}) \in \mathcal{F}_{k_{j_*}}^{(j_*)}} \sum_{r \in R(\mathbf{T})} \sum_{p \in \mathbf{p}_{\mathbf{T}_r}} |I_R|^{-1} |I_{p_3}|^{1/2} \prod_{i=1}^3 |\langle f_j, \phi_{p_j} \rangle| \leq \sum_{k_1, k_2, k_3} \sum_{(\mathbf{T}, \mathbf{p}_{\mathbf{T}}) \in \mathcal{F}_{k_{j_*}}^{(j_*)}} 2^{k_1 + k_2 + k_3} |I_{\mathbf{T}}|$$

$$\leq \sum_{k_1, k_2, k_3} \sum_{(\mathbf{T}, \mathbf{p}_{\mathbf{T}}) \in \mathcal{F}_{k_{j_*}}^{(j_*)}} 2^{k_1+k_2+k_3} 2^{-2k_{j_*}} \leq \sum_{k_1, k_2, k_3} 2^{k_1(1-a_1)} 2^{k_2(1-a_2)} 2^{k_3(1-a_3)},$$

where a_i have been defined in the beginning of the argument. Finally, by invoking (6.28) - (6.30) we can further estimate the above by

$$\begin{aligned} & \sum_{k_1, k_2, k_3 \leq 0} 2^{k_1(1-a_1)} 2^{k_2(1-a_2)} 2^{k_3(1-a_3)} (|E_{j_1}|^{\beta_1} A^{\beta_1+\epsilon})^{1-a_1} (|E_{j_2}|^{\beta_2} A^{\beta_2+\epsilon})^{1-a_2} \\ & \lesssim |E_{j_1}|^{\gamma_1} |E_{j_2}|^{\gamma_2} A^{\gamma_1+\gamma_2+\epsilon a_{j_0}} \lesssim |E_{j_1}|^{\gamma_1} |E_{j_2}|^{\gamma_2} A^{\epsilon a_{j_0} - \alpha_{j_0}}. \end{aligned}$$

This ends the proof in case (1), since $\alpha_{j_0} > -\delta$. To deal with case (2) we make the following modifications. Redefine $f_j := f_j \chi_I^2$ and $\phi_{p_j} := \phi_{p_j} \chi_I^{-2}$, and note that the new functions f_j have the same properties as the old ones. Moreover $(M_{-c(\omega_{p_j})} \phi_{p_j}) \chi_{I_{\mathbf{T}}}^{-2}$ is L^2 adapted of order $N-2$ to I_{p_j} and has the same frequency support as $M_{-c(\omega_{p_j})} \phi_{p_j}$. Then run the same argument as in case (1). As we said earlier, we expect the presence of $|I|$ and 2^{-l} in the bound for (6.26). The presence of $|I|$ is explained by the localized estimate

$$\|f_j\|_2^2 \lesssim |I| \inf_{x \in I} |E_j|^{-1} M_1(1_{E_j})(x)$$

which becomes effective in the application of the Peeling Lemma in (6.32). The decay in l is due to the classical estimates

$$\begin{aligned} \inf_{x \in I} M_1(1_{E_j})(x) & \lesssim 2^l \inf_{x \in 2^{l+1}I} M_1(1_{E_j})(x) \lesssim 2^l, \\ \sup_{x \in \tilde{E}_{j_0}} \chi_I(x) & \lesssim 2^{-l}, \end{aligned}$$

which become effective in the application of Corollary 6.18 in estimating sizes.

7. THE GENERAL CASE: MODULATION INVARIANT PARAPRODUCTS

Given any function f in BMO, we shall construct a trilinear form Λ satisfying the bounds in the conclusion of Theorem 2.7 (and thus also its assumptions) and also

$$\begin{aligned} \Lambda(1, 1, \cdot) &= f \\ \Lambda(1, \cdot, 1) &= 0 \\ \Lambda(\cdot, 1, 1) &= 0 \end{aligned}$$

Such form and its symmetric counterparts under permutation of the three arguments will be called modulation invariant paraproducts. By subtracting three paraproducts we can reduce every trilinear Calderón-Zygmund form as in Theorem 2.7 to another one satisfying the special cancellation conditions $\Lambda(1, 1, \cdot) = \Lambda(1, \cdot, 1) = \Lambda(\cdot, 1, 1) = 0$. Thus the construction of the paraproduct will finish the proof of Theorem 2.7.

Define ϕ_1, ϕ_2, ϕ_3 such that $\widehat{\phi}_1 = \widehat{\phi}_2 = \widehat{\Phi}$ and $\widehat{\phi}_3 = \tau_{10}\widehat{\Phi} + \tau_{-10}\widehat{\Phi}$, where $\widehat{\Phi}$ was introduced in (3.1). Consider

$$\psi(x) = \int \phi_1(x + (\beta_1 - \beta_3)t) \phi_2(x + (\beta_2 - \beta_3)t) \phi_3(x) dt.$$

By using Fourier transforms it follows immediately that ψ is a non zero Schwartz function. The function

$$(7.1) \quad \phi_1(x + (\beta_1 - \beta_3)t)\phi_2(x + (\beta_2 - \beta_3)t)\phi_3(x)$$

is easily seen to have zero integral in x for each t . Hence ψ itself has mean zero.

By Calderón's reproducing formula, we have (with some constant c)

$$f = c \int_0^{+\infty} f * \psi_t * \psi_t \frac{dt}{t}$$

This well-know formula in L^2 also extends to distributions modulo polynomials provided $\widehat{\psi}$ vanishes in a neighborhood of the origin. In particular, for f in BMO the formula holds in the sense

$$f = \lim_{\epsilon \rightarrow 0} c \int_{\epsilon}^{1/\epsilon} f * \psi_t * \psi_t \frac{dt}{t}$$

at least in the distributional sense when tested against bump functions with mean zero.

Defining

$$\psi_{k,n}(x) := 2^{-k/2}\psi(2^{-k}x - n),$$

a simple change of coordinates gives (with a new constant c)

$$(7.2) \quad f = \lim_{\kappa \rightarrow +\infty} c \int_{|k| \leq \kappa} \int_{\mathbb{R}} \langle f, \psi_{k,n} \rangle \psi_{k,n} dk dn$$

with the equality holding in the sense of distributions when tested against functions with mean zero.

If we define $\phi_{i,k,n}$ by translation and dilation in the analogous manner, then we have

$$\psi_{k,n}(x) = \int \phi_{1,k,n}(x + (\beta_1 - \beta_3)t)\phi_{2,k,n}(x + (\beta_2 - \beta_3)t)\phi_{3,k,n}(x) dt$$

Set

$$c_{k,n} := c \langle f, \psi_{k,n} \rangle$$

Then for each $\kappa \in \mathbb{R}$ and each $f_i \in \mathcal{S}(\mathbb{R})$ we define

$$(7.3) \quad \begin{aligned} \Lambda_{\kappa}(f_1, f_2, f_3) &= \int_{|k| \leq \kappa} \int_{\mathbb{R}} \int_{\mathbb{R}} \int_{\mathbb{R}} c_{k,n} \left[\prod_{i=1}^3 f_i(x + \beta_i t) \phi_{i,k,n}(x + \beta_i t) \right] dx dt dn dk \\ &= \int_{\mathbb{R}} \int_{\mathbb{R}} \prod_{i=1}^3 f_i(x + \beta_i t) K_{\kappa}(x, t) dx dt, \end{aligned}$$

where

$$K_{\kappa}(x, t) = \int_{|k| \leq \kappa} \int_{\mathbb{R}} c_{k,n} \prod_{i=1}^3 \phi_{i,k,n}(x + \beta_i t) dn dk.$$

Since f is in BMO, we have that $|c_{k,n}| \lesssim 2^{k/2}$ (this is a particular instance of (7.5)). By discretizing the integral representing \tilde{K}_κ , we can write it as an average over $[0, 1]^2$ of sums of the form

$$\tilde{K}_\kappa(x, t) = \sum_{\substack{2^{-\kappa} \leq |I| \leq 2^\kappa \\ I \text{ dyadic}}} c_I \prod_{i=1}^3 \phi_{i,I}(x + \beta_i t),$$

with $\phi_{i,I}$ being L^2 -adapted to I and $|c_I| \lesssim |I|^{1/2}$. It is now an easy exercise to conclude that each \tilde{K}_κ satisfies (2.1) and (2.2) with $\delta = 1$ and with uniform constants $C_{\tilde{K}_\kappa} = O(1)$. Moreover, \tilde{K}_κ is locally integrable since in particular $|\tilde{K}_\kappa(x, t)| \lesssim \min\{2^\kappa, |t|^{-1}\}$. These facts will easily prove that the integral in (7.3) is indeed convergent for arbitrary Schwartz functions.

Let now f_1, f_2, f_3 be three bump functions L^2 - adapted of order 2 to some interval J . We next prove an inequality that will justify some of our claims. Note first that for each x , $f_2(x + (\beta_2 - \beta_1)t)f_3(x + (\beta_3 - \beta_1)t)$ is L^2 - adapted of order 2 (as a function of t) to some interval of size similar to $|J|$ with implicit constant $O(|J|^{-1/2})$. Similarly, $\phi_{2,I}(x + (\beta_2 - \beta_1)t)\phi_{3,I}(x + (\beta_3 - \beta_1)t)$ is L^2 - adapted of order 2 to some interval of size similar to $|I|$ with implicit constant $O(|I|^{-1/2})$. Moreover, this latter function also has mean zero with respect to t . By applying (4.2) to these functions and (4.1) to f_1 and $\phi_{1,I}$ we conclude that

$$\begin{aligned} & \sum_{I \text{ dyadic}} |c_I| \left| \int_{\mathbb{R}} \int_{\mathbb{R}} \left[\prod_{i=1}^3 f_i(x + \beta_i t) \phi_{i,I}(x + \beta_i t) \right] dx dt \right| \\ &= \sum_{I \text{ dyadic}} |c_I| \left| \int_{\mathbb{R}} f_1(x) \phi_{I,1}(x) \int_{\mathbb{R}} \left[\prod_{i=2}^3 f_i(x + (\beta_i - \beta_1)t) \phi_{i,I}(x + (\beta_i - \beta_1)t) \right] dt dx \right| \lesssim \\ &\lesssim \sum_{I \text{ dyadic}} |c_I| |I|^{-1/2} |J|^{-1/2} (1 + (\max(|I|, |J|))^{-1} \text{dist}(I, J))^{-4} \min\left(\left(\frac{|I|}{|J|}\right)^2, \left(\frac{|J|}{|I|}\right)^2\right) \lesssim |J|^{-1/2}. \end{aligned}$$

Define now for each $f_i \in \mathcal{S}(\mathbb{R})$

$$\Lambda(f_1, f_2, f_3) = \lim_{\kappa \rightarrow +\infty} \Lambda_\kappa(f_1, f_2, f_3).$$

Since each Schwartz function is adapted to the unit interval centered at the origin, the above computations show that the above limit exists. Moreover, due to the earlier estimates for \tilde{K}_κ , the form Λ is associated with a kernel K satisfying (2.1) and (2.2) with $\delta = 1$.

Since the function

$$\phi_1(x) \phi_2(x + (\beta_2 - \beta_1)t) \phi_3(x + (\beta_3 - \beta_1)t)$$

has mean zero in t for every fixed x , it is easy to verify using the kernel representation and the definition of $\Lambda_\kappa(\cdot, 1, 1)$ that $\Lambda_\kappa(\cdot, 1, 1) = 0$. Then, by invoking (3.4) and (3.5) we conclude that $\Lambda(\cdot, 1, 1) = 0$. Likewise we see $\Lambda(1, \cdot, 1) = 0$.

To see that $\Lambda(1, 1, \cdot) = f$, we replace the integration variable x by $y = x + \beta_3 t$, then execute the integration in t to obtain for each compactly supported $f_3 \in \mathcal{S}(\mathbb{R})$ with mean zero

$$\Lambda_\kappa(1, 1, f_3) = \int_{\mathbb{R}} \left[\int_{|k| \leq \kappa} \int_{\mathbb{R}} c_{k,n} \psi_{k,n}(y) dn dk \right] f_3(y) dy.$$

By (7.2), the limit on the right hand side is $\int_{\mathbb{R}} f(y) f_3(y) dy$, and so we conclude that $\Lambda(1, 1, \cdot)$ is f as tempered distributions modulo constants.

It remains to prove that Λ is bounded as in the conclusion of Theorem 2.7. Using that

$$\int f|_{\gamma^\perp} d\gamma^\perp = \int \widehat{f}|_{\langle \gamma \rangle} d\langle \gamma \rangle,$$

where $d\gamma^\perp$ and $d\langle \gamma \rangle$ are, respectively, the normalized Lebesgue measures on γ^\perp and $\langle \gamma \rangle$, we note that for each $f_i \in \mathcal{S}(\mathbb{R})$, $\Lambda(f_1, f_2, f_3)$ coincides up to some universal constant with

$$\lim_{\kappa \rightarrow +\infty} \int_{|k| \leq \kappa} \int_{\mathbb{R}^2} c_{k,n} 2^{-k} \left[\prod_{i=1}^3 \int f_i(x) \phi_{i,k,n}(x) e^{2\pi i \gamma_i 2^{-k} l x} dx \right] dn dl dk.$$

Hence Λ is up to a universal constant an average of forms of the type

$$(7.4) \quad \sum_{k,n,l \in \mathbb{Z}} c_{k,n} 2^{-k} \prod_{i=1}^3 \langle f_i, \phi_{i,k,n,l} \rangle,$$

where for some $k_0, n_0, l_0 \in [0, 1]$

$$\phi_{i,k,n,l}(x) = \overline{\phi_{i,k+k_0,n+n_0}(x)} e^{-2\pi i \gamma_i 2^{-(k+k_0)}(l+l_0)x}$$

The form (7.4) is our basic model form that we wish to estimate. The function $\phi_{i,k,n,l}$ is an L^2 -normalized bump function adapted to the interval

$$[2^{k+k_0}(n+n_0), 2^{k+k_0}(n+n_0+1))$$

By changing the bump function constants mildly, we can assume that the function is adapted to the dyadic interval $I_{k,n} = [2^k n, 2^k(n+1))$.

The function $\widehat{\phi}_{i,k,n,l}$ is supported in an interval $\omega_{i,k,l}$ of length 2^{-k+2} and we may assume the following properties (in case $i = 3$ we split the generating function ϕ_3 into a sum of two generating functions, one with Fourier support contained in $[-12, -8]$ and the other with Fourier support contained in $[8, 12]$). Without loss of generality we may replace ϕ_3 by one of the two):

$$\omega_{1,k,l} = \omega_{2,k,l}$$

for all k, l , and if

$$\omega_{i,k,l} \cap \omega_{i,k',l'} \neq \emptyset$$

for some k, k', l, l' , then for some universal constants $1 \ll c_2 \ll c_1$

$$c_2 \omega_{j,k,l} \cap c_2 \omega_{j,k',l'} = \emptyset$$

and

$$c_1\omega_{j,k,l} \cap c_1\omega_{j,k',l'} \neq \emptyset$$

whenever $i \neq j$ and at least one of i and j is equal to 3. By pigeonholing into finitely many summands if necessary, we also may assume that

$$\omega_{i,k,l} \cap \omega_{i,k,l'} = \emptyset$$

if $n \neq n'$. We adopt the usual geometric picture that the parameter tuple (k, n, l) is identified with a triple $p = (p_1, p_2, p_3)$ of tiles

$$p_i = I_p \times \omega_{p,i} = I_{k,n} \times \omega_{i,k,l}$$

Compared to the theory of the bilinear Hilbert transform, the new element here is that two tiles in this triple are equal. This lack of separation is offset by better estimates for the coefficients $c_{k,n}$ than in the model forms for the bilinear Hilbert transform. Since f is in BMO, the coefficients $c_{k,n}$ satisfy a Carleson sequence condition

$$(7.5) \quad \sum_{I_{k,n} \subset J} |c_{k,n}|^2 \leq C_f |J|.$$

This is what we need to know about the basic model operator (7.4) we have to estimate. The proof runs parallel to the proof of boundedness of the bilinear Hilbert transform, e.g. in [29]. The only difference concerns the estimate on an individual tree for which both p_1 and p_2 are overlapping and only p_3 are disjoint. These trees are estimated by using (7.5) as follows:

$$\begin{aligned} & \sum_{p \in \mathbf{T}} |I_p|^{-1} c_{I_p} \prod_{j=1}^3 |\langle f_j, \phi_{p_j} \rangle| \\ & \leq \left(\sum_{p \in \mathbf{T}} |c_{I_p}|^2 \right)^{1/2} \left(\sum_{p \in \mathbf{T}} |\langle f_3, \phi_{p_3} \rangle|^2 \right)^{1/2} \prod_{j=1}^2 \left(\sup_{p \in \mathbf{T}} \frac{|\langle f_j, \phi_{p_j} \rangle|}{|I_p|^{1/2}} \right) \\ & \lesssim |I_{\mathbf{T}}| \left(\frac{1}{|I_{\mathbf{T}}|} \sum_{p \in \mathbf{T}} |\langle f_3, \phi_{p_3} \rangle|^2 \right)^{1/2} \prod_{j=1}^2 \left(\sup_{p \in \mathbf{T}} \frac{|\langle f_j, \phi_{p_j} \rangle|}{|I_p|^{1/2}} \right). \end{aligned}$$

The factors in the last expression are as in [29] estimated by the tree sizes defined there. The rest of the proof is identical to the one in [29] and one obtains the same bounds as for the bilinear Hilbert transform.

We close this section by mentioning an interesting application of the constructions we have performed above. For each dyadic interval I with length at least 1, let c_I be a coefficient selected in such a way that $|c_I| \leq |I|^{1/2}$ and such that

$$(7.6) \quad \sup_J \frac{1}{|J|} \sum_{\substack{I \subset J \\ J \text{ dyadic}}} |c_I|^2 = \infty.$$

It can be easily seen by using (4.2) that

$$(7.7) \quad \lim_{\kappa \rightarrow \infty} \int \sum_{|I| \leq \kappa} c_I \psi_I(y) f_3(y) dy$$

exists for each Schwartz function f_3 with mean 0. Define

$$\Lambda(f_1, f_2, f_3) = \sum_{I \text{ dyadic}} c_I \int_{\mathbb{R}} \int_{\mathbb{R}} \left[\prod_{i=1}^3 f_i(x + \beta_i t) \phi_{i,I}(x + \beta_i t) \right] dx dt.$$

By reasoning as before, it is easy to check that the bilinear form $\Lambda(., ., 1)$ satisfies the weak boundedness condition, and moreover that $\Lambda(., 1, 1) = \Lambda(1, ., 1) = 0$. Remark 2.1 shows that these imply that $\Lambda(., ., 1)$ is a bilinear form bounded on $L^2 \times L^2$. Also, by (7.7) it easily follows that the action on $H^1(R)$ atoms of $\Lambda(1, 1, .)$ coincides with that of $\sum_I c_I \psi_I$. Due to (7.6), $\Lambda(1, 1, .)$ can not be identified with a BMO function. By invoking Remark 2.1 again, it follows that the bilinear form $\Lambda(1, ., .)$ is not bounded, in spite of being completely represented by the same kernel as $\Lambda(., ., 1)$. Moreover, the trilinear form is itself unbounded, since otherwise $\Lambda(1, 1, .)$ would necessarily have to be a BMO function. Hence $\Lambda(., ., 1)$ is a bounded bilinear Calderón-Zygmund form associated with a Calderón-Zygmund kernel that is not the restriction of a bounded trilinear form with the given parameter β and associated with the same K .
