FOREWORD

Many types of planning efforts depend on information about the future size and composition of the population. The projections in this report are intended for use in planning. Even under the best of circumstances, however, making projections that accurately indicate future prospects is difficult. Therefore, caution should be exercised when using these or any population projections.

The population projections in this report are the direct product of specific assumptions about future trends in fertility, mortality, and migration. These assumptions, in turn, are based on information about past trends in factors which are considered to be the principal determinants of population change. It is the responsibility of the users of this report to evaluate the reasonableness of the assumptions underlying the projections and choose projections appropriate to their needs or employ additional information that may be available to them to arrive at different assumptions.

In no sense should the projections herein be interpreted as statements of what should, or what necessarily must, happen to population; they simply show what will happen if the assumptions set forth prove correct. If planners, policy makers, and other interested groups are sufficiently disturbed by the projected course of events, it is entirely appropriate that they design programs and policies which ultimately will render the projections wrong.

INTRODUCTION

This report presents population projections for Nebraska and its planning regions, counties, and towns at five-year intervals to the year 2000 and for the year 2020. The state projections were made using a cohort-survival method, and the state totals were allocated to counties and communities using ratio methods. Three projection series -- low, medium, and high -- are included.

The three projection series are based on alternative sets of assumptions concerning future birth and migration rates for Nebraska. The choice of migration and birth-rate assumptions in turn is based on analysis of past population growth trends in Nebraska and on a subjective assessment of the likelihood of future changes in these trends. As background for interpreting the population projections, the following three sections assess the historical pattern of population growth in Nebraska, describe the methodology and assumptions used to make the projections, and discuss some of the important features of the projections which appear in the tables in sections IV through VI.

I. POPULATION TRENDS IN NEBRASKA

State Trends

Figure 1(a) shows population growth trends for Nebraska and the nation from 1900 to 1970 with projections to 2000. The Nebraska share of the United States population peaked in 1890 and has declined in every decade since then. Between 1890 and 1970 national population more than tripled (increasing 223 percent) compared with only a 40 percent increase in Nebraska. The trend of relative population decline in Nebraska has been long and persistent, but there are some indications that this trend is weakening and may be coming to an end.

During the 1930s the population of Nebraska actually fell. During the 1940s the population increased, but by less than one percent. During the 1950s the Nebraska population increased at its fastest rate (6.5 percent) since the decade of 1910 to 1920. In the 1960s the population growth rate fell slightly (to 5.2 percent) from the rate of the 1950s, but the fall in the growth rate was less than the drop in the national growth rate.

Thus, although the Nebraska growth rate was still less than 40 percent of the national growth rate in the 1960s, the state growth rate has risen relative to the national rate in every decade since the 1930s. In fact, if migration rather than population change is examined, the slowing of the trend of relative decline can be seen more clearly.

In the 1950s Nebraska population grew at 35 percent of the national rate. In the 1960s Nebraska population growth was 39 percent of the national rate. Accompanying this modest change in relative population

growth, however, was a 42 percent drop in the rate of net out-migration from the 1950s to the 1960s. While net out-migration from Nebraska exceeded five percent of the population in the 1960s, the significance of the decline of the rate from the 1950s can be appreciated if it is noted that the decline occurred in spite of two sets of adverse circumstances. First, the statewide decline in out-migration occurred in spite of temporary economic reversals which resulted in a slowdown of the rate of net in-migration into the Omaha metropolitan area and in a reversal of the migration pattern for the Lincoln metropolitan area from net in-migration to net out-migration. Second, the rate of net out-migration declined in spite of a sharp increase in the number of people entering their twenties, the age group that normally leaves the state in the greatest numbers.

Because of declining birth rates in the 1960s, the population of nonmetropolitan Nebraska continued to decline at a somewhat reduced rate even though the rate of net out-migration dropped off significantly. Thus an examination of population-change trends alone obscures a strong trend toward stabilization of the economic base of much of rural Nebraska.

In the early 1970s the prospects for continuation of the trend toward stabilization in rural Nebraska and for continued or increasing growth in the urban parts of the state appear to be good. Currently agricultural prices and incomes are relatively high in Nebraska, and 1971 and 1972 were the first years with increases in agricultural employment in more than a decade. Since the agricultural sector is volatile and since the long-term trend of agricultural decline has been so persistent, it would be premature to suggest that the farm population will cease to decline in the near future. The indications are, however, that the rate of

rural decline is slowing; and a slowdown in the rate of rural decline accompanied by the shrinking size of the rural population relative to the urban population in the state increases the likelihood that most of the future net out-migration from rural areas will be absorbed within the state.

Perhaps the strongest evidence that the relative decline of Nebraska may be ending lies in the United States Bureau of the Census estimates of the Nebraska population for 1971 and 1972. Provisional estimates for the 1970-1972 period place the rate of increase of the Nebraska population at 2.7 percent compared with a national growth rate of 2.5 percent. These estimates imply a small net in-migration into the state since 1970, and while the potential error in estimated migration is high, the estimates do provide further evidence that chronic net out-migration may be ending.

Even if net in-migration into Nebraska actually did take place from 1970 to 1972, it should not necessarily be taken as evidence that the future will bring a trend of continuing net in-migration, since much of the in-migration could be accounted for by returning veterans accompanying the national reduction of military forces since 1970. Moreover, net in-migration might have resulted partly from reduced out-migration accompanying high unemployment rates in some traditional destinations (such as California) for Nebraska out-migrants. As economic conditions in the rest of the country improve it is entirely possible that Nebraska will resume its "normal" pattern of out-migration. The next few years will be very important in determining the extent to which the historical trend of net out-migration from Nebraska has diminished.

Although there is a good chance that net out-migration from Nebraska will not be a significant force affecting future population growth, it is

unlikely that there will be a sharp rise in the rate of population growth in the state in the near future. The major reason for expecting a continuation of relatively slow growth rates is that decreased out-migration is being offset to a large extent by declining birth rates. In 1972 the crude birth rate for Nebraska was the lowest ever recorded, and the absolute number of births was the smallest since the early 1940s. Birth rates have fluctuated considerably in the past and are likely to move both up and down in the future, but it currently appears that attitudes concerning desirable family size have changed sufficiently in recent years to make a return to the high birth rates of the 1950s and early 1960s very unlikely in the near future.

In summary, recent trends show declining net out-migration and declining birth rates in Nebraska with relatively small changes in the rate of population growth. These trends provide the basis for the assumptions underlying the population projections presented in this report.

County and Town Trends

Most of the counties in Nebraska have been losing population for some time. In 1970 over two-thirds (63) of the counties of the state had populations less than 75 percent of their highest previously-attained level; and 59 counties lost population in each of the three decades since 1940, whereas only 11 counties increased in population in each of those decades. In general it is the largest counties which have increased in population, while the smaller counties have declined. Population change by county for the 1950-1970 period is displayed in Figure 2(a).

In quantitative terms most of the growth of Nebraska population since 1950 has occurred in the Lincoln and Omaha metropolitan areas. The

remainder of the state lost population during both the 1950s and the 1960s. The nonmetropolitan counties, however, can be further divided into two sets on the basis of size and growth characteristics -- "middle-sized" counties (from 25,000 to 50,000) which have generally increased in population, and "small" counties (under 25,000) which, with relatively few exceptions, have consistently decreased in population.

As noted above, there is evidence that the rate of net out-migration from small rural counties in Nebraska has been falling. There are two important reasons why some further population decline in these counties may be expected in the near future. First, the "baby boom" of the 1950s and early 1960s has resulted in a relatively large number of teenagers living in the smaller counties. Hence, there will be many more potential labor-force entrants in the near future than will be needed to replace expected deaths and retirements, and unless past patterns are sharply changed this "excess labor supply" will migrate from the small counties. The second factor which points to probable future population declines is the small number of young adults and the relatively advanced age structure of the population in most small counties. In the last five years more than half the Nebraska counties have experienced at least one year in which deaths have exceeded births, and many counties are rapidly becoming areas of chronic "natural population decrease." Therefore, even if the absolute number of economic opportunities in rural areas ceases to decline, the combination of generally declining birth rates with the high death rates associated with an elderly population implies continuing population decline for many Nebraska counties.

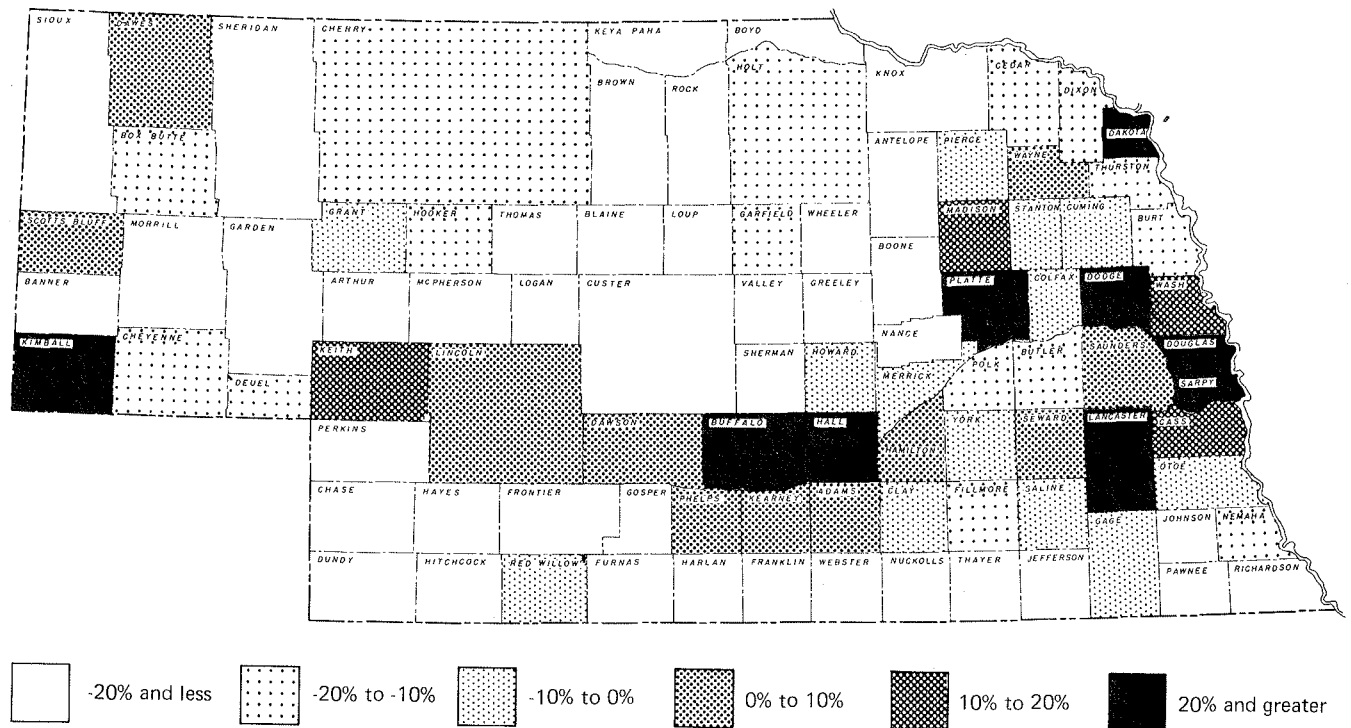

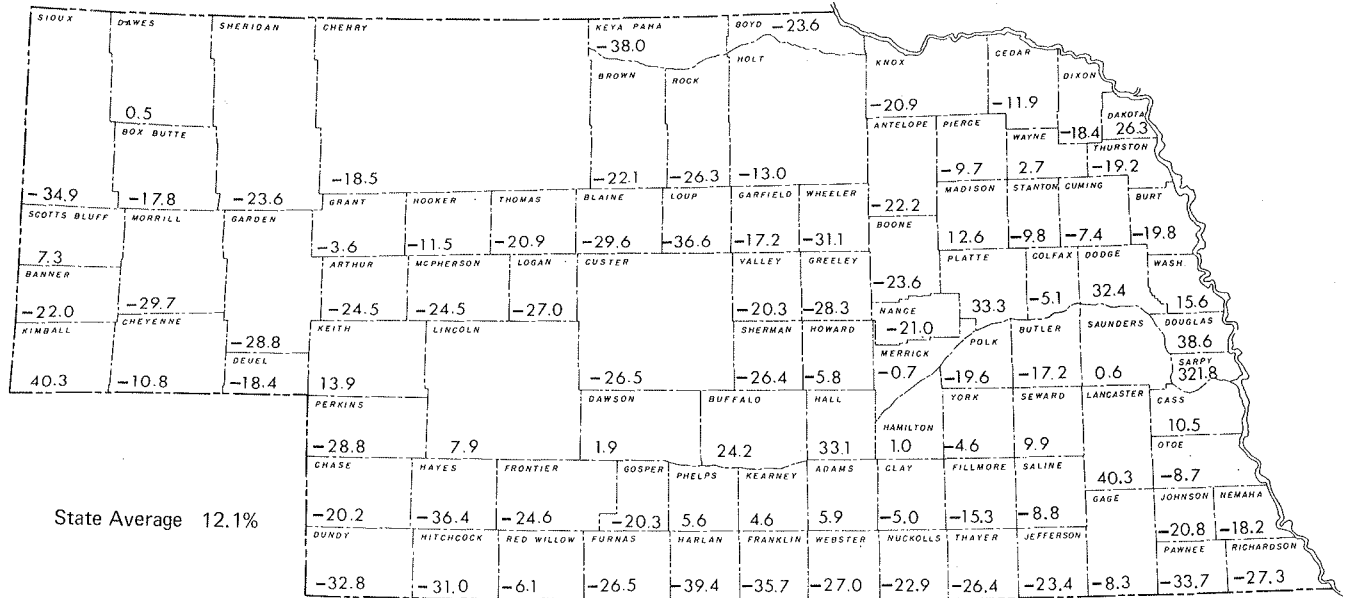

Figure 2(a) Population Change by County, 1950-1970

The greatest decline in Nebraska population has occurred in the rural farm population. Very small towns (those having fewer than 500 residents) also generally have been losing population although at slower rates than the decline of the rural farm population. Towns large enough to be classified as urban (over 2500 residents) generally have been increasing in population, while other towns (500 to 2500 residents) as a group have been relatively stable. In a number of cases small towns which have lost population have, nevertheless, increased their share of county population, since the rate of population loss in many agricultural counties has been much more rapid than the decline in the small towns serving the agricultural population.

The future trend of population change in small towns is currently somewhat uncertain. Prior to the 1970 census, each successive census since 1930 had revealed a trend toward decline for larger and larger towns. The 1960s, however, witnessed an apparent reversal of this trend. In the 1950s more than half of the towns ranging between 1,000 and 2,000 in population experienced population loss, whereas during the 1960s not only did most of the towns over 1,000 grow, but more than half of the towns in the 500-to-1,000 size class also increased in population. Although many of the small towns which experienced population growth in the 1960s were within commuting distance of larger cities and towns, there were also population increases in some relatively isolated small towns. Thus there is some evidence that a revitalization process may be occurring, at least in a portion of small-town Nebraska. On the other hand, there are no strong indications of potential for rapid population growth in most small towns.

Metropolitan Trends

Four counties in Nebraska are included in officially-designated Standard Metropolitan Statistical Areas. Lancaster County constitutes the Lincoln SMSA; Douglas and Sarpy counties together with Pottawatomie County, Iowa, constitute the Omaha SMSA; and Dakota County and Woodbury County, Iowa, comprise the Sioux City SMSA. The four Nebraska metropolitan counties grew from a combined population of 426,856 in 1950 to 636,764 in 1970; consequently the percentage of the state's population residing in metropolitan areas rose from 32.2 in 1950 to 42.9 in 1970. The increase in the metropolitan share of total state population has been closely associated with the increasing concentration of service activities in metropolitan areas and the decline of agricultural opportunities in non-metropolitan areas.

While Nebraska metropolitan areas are growing rapidly relative to Nebraska nonmetropolitan areas, it should be noted that the total Nebraska metropolitan growth rate is not much higher than the average growth rate for all United States metropolitan areas and that, except for Sarpy County, net in-migration of population is not the principal factor in Nebraska metropolitan growth. The Nebraska metropolitan growth rate of 49.2 percent from 1950 to 1970 compares with a national metropolitan growth rate of 47.4 percent over the same period and over 80 percent of the Nebraska metropolitan growth from 1950 to 1970 resulted from an excess of births over deaths. Because of the importance of natural increase in the past growth of the metropolitan areas in Nebraska, current trends toward low birth rates are likely to be an important factor in the future population growth of the metropolitan areas.

II. METHODOLOGY AND ASSUMPTIONS

A general discussion of methods and assumptions is given in this section. The specific equations and a detailed listing of the parameter values used in making the projections are presented in the Appendix.

State Projections

Projections of the state population by sex and five-year age groups were made using a cohort-survival method. For each five-year projection period each living five-year age cohort was "survived" into the next higher age group by deducting estimated deaths and adjusting for estimated migration. The number of persons aged four or less at the end of each projection period was estimated by applying age-specific birth rates to those female cohorts which would be in the childbearing age group (15 through 44) during the projection period and adjusting the resulting estimate of births for estimated migration and deaths of young children.

A single set of age- and sex-specific death rates, three alternative birth-rate assumptions, and three alternative assumptions about net migration were used in the projections. The age-specific birth rates were derived from the Bureau of the Census series D, E, and F. The D birth series assumes an average completed fertility rate of 2.5 children per woman reaching childbearing age. The corresponding rates for the E and F series are 2.1 and 1.8 children respectively. The three net-migration assumptions involve basic migration rates of (i) net in-migration of one percent per five-year period; (ii) no net migration; and (iii) net out-migration beginning

at one percent per period in the 1975-to-1980 period and declining linearly by .1 percentage point per period to the end of the projection period. The high-projection series combines net in-migration with the series D birth rate; the medium-projection series combines zero net migration with the series E birth rate; and the low-projection series combines net out-migration with the series F birth rate.

Projections to 1975 were made using special assumptions which incorporate data available for 1971 and 1972. The high, medium, and low basic net-migration rates for 1970 to 1975 were each moved up by one percentage point (to two, one, and zero percent respectively) to adjust for an estimated in-migration of about one percent from 1970 to 1972. There was also an adjustment in male population in the ages 20 to 30 (in 1975) to allow for the increase in the number of returning veterans in the early 1970s. Birth-rate assumptions were also modified for the 1970-1975 period to take into account the data available for the period from 1970 through 1972. The projected number of births for the 1970-1975 period was 135,000 for the high series, 125,000 for the medium series, and 115,000 for the low series. The average number of births per year for the 1970-1972 period was 25,000 which, if continued, would produce the medium assumption of 125,000 births in the 1970-1975 period. This medium number of births corresponds to a rate slightly above the series E rate; but, since birth rates have been dropping, the series E rate is maintained as the medium assumption from 1975 onward.

The choice of medium birth-rate and migration assumptions and the choice of the range of assumptions are necessarily somewhat subjective, but the evidence is strong that Nebraska has been approaching a position char-

acterized by little or no net migration together with birth rates close to the long-term replacement level (i.e., the series E birth rates). There is, of course, no guarantee that these levels will be maintained for any extended period of time into the future; but there is little evidence to indicate large-scale net in-migration or out-migration from Nebraska in the near future, and there is some evidence that the two-child family is becoming more firmly entrenched as the norm.

As in the past, the future will almost certainly bring significant year-to-year fluctuations in birth and migration rates, but such fluctuations are essentially unpredictable except possibly for very short periods. Therefore, long-term projections should be focused on assumptions which appear most likely to represent average future behavior. At the moment the most probable migration and fertility patterns appear to be little or no net migration and a dominance of the two-child family. The high and the low assumptions provide a reasonable range around these medium assumptions, but the range of assumptions does not allow for major unforeseen technical, economic, or social developments which would significantly alter migration patterns or birth or death rates.

County and Town Projections

County projections by sex and-age and projections of the total population of towns were made using a ratio method to allocate the state projections to counties and, in turn, to allocate the county projections to towns and other parts of the county. The major reason for using an allocation method is the belief that a better state projection can be made if the state is treated as a unit rather than being treated as the sum of in-

dependent county constituents. The basis for this belief is evidence that there has been a close association between the growth patterns of urban and rural Nebraska. In particular, the past net in-migration into the metropolitan areas of Nebraska has been largely the result of in-migration of young people from rural Nebraska and other similar agricultural areas. Evidence suggests that the Omaha and Lincoln areas have become large enough and dynamic enough to absorb a net in-migration equal to the net out-migration which could be generated from rural Nebraska;¹ there is, however, little evidence to suggest that Lincoln or Omaha will experience significant net in-migration from sources outside the state. Therefore, much more confidence may be placed in the assumption of little or no net migration for the state as a whole than may be placed in any particular set of assumptions about individual-county migration rates.

Although it may be easier to project the state as a unit than to project the parts separately, projections for the parts necessarily involve assumptions about any redistribution of population within the state. In making the county projections for Nebraska, two sets of assumptions were made concerning the redistribution of population among counties. One assumption involves differences in overall growth forces among counties;

¹Omaha receives a relatively large number of in-migrants from rural areas in western Iowa. On the other hand, many of the rural residents of western Nebraska have closer links to Denver than to Omaha. Since there are more potential rural-urban migrants in western Iowa than in western Nebraska, it is possible that this situation could lead to some net in-migration into Nebraska; but since the number of competing metropolitan destinations close to the residents of western Iowa (e.g., Minneapolis, Des Moines, or Kansas City) also exceeds the number of nearby metropolitan destinations for the residents of western Nebraska, there is no strong evidence that Nebraska is likely to experience a significant net in-migration of rural-urban migrants.

the other involves differences in the age pattern of change by county.

In general there has been a close association between population change and the age structure of that change. Declining counties almost always suffer disproportionately large net out-migration in the young adult age groups and experience much smaller net out-migration -- or in some cases net in-migration -- in older age groups. The loss of young-adults in turn contributes to reduced birth rates and natural decrease or low rates of natural increase of the population. On the other hand, rapidly growing counties and counties with large college populations usually experience disproportionate net in-migration of young adults and much slower net in-migration or even net out-migration of older age groups.

More than half of the Nebraska counties are small, rural, and declining, and have experienced very similar age patterns of migration. For these counties a common assumption about the age pattern of future population change was made. It was assumed that in passing through the age groups 15 through 19 and 20 through 24 a five-year population cohort would decline by approximately one-third more than the county's share of total state population. The cohort will gradually recoup the relative loss thereafter.² This factor of one-third relative loss is somewhat less than the average recent experience of most counties in Nebraska; but if a trend toward stabilization of the rural economic base continues, the relative decline in the young-adult population may be expected to slacken some-

²The relative change was estimated from past change in the fraction a county constitutes of the state's population in each cohort divided by the county's average change in the fraction of total state population. Thus the relative measure adjusts partly for differences among counties in average overall growth.

what. Nevertheless, a significant proportion of the high-school graduates of most small counties will probably continue to leave, at least temporarily, to attend college.

The decline as groups pass through the ages 15 through 24 in rural counties was offset by assumed increases in these ages in the larger metropolitan counties and in counties with significant college populations. Finally, there is a group of counties (most of them having populations from 25,000 to 50,000) which seem to have no pronounced differences in net migration among age groups. These counties were assigned a uniform age distribution of population change.

The age distribution of population change was assumed to remain constant for all the projection periods for each county. The overall average level of change, however, was allowed to vary from period to period. It was assumed that the metropolitan counties, along with a few other counties with significant growth potential (especially those near metropolitan areas), will experience overall growth rates in excess of the state average up to 1985, while most of the smaller counties will experience overall relative decline, and most of the middle-sized counties will grow at rates near the state average. After 1985 a sharp drop in the number of potential young out-migrants from rural counties may lead to a significant decline in the net movement of population from rural to urban Nebraska, so the overall growth factors were allowed to converge to the state average after 1985 for all counties.

Since the overall growth factors were designed principally to reflect average net migration trends for all ages, equal growth factors for all counties do not imply that projected population growth will be equal for

all counties. The beginning age structure of an area's population and the age distribution of migration for the area will also affect population change. Most rural counties in Nebraska have such a large deficit of population in the younger age brackets compared with older age brackets that they can be expected to continue to decline relative to the state as a whole, even if net out-migration ceases, simply because the number of births will be low and the number of deaths high.

For nonmetropolitan counties, projected town populations were derived from the county projections by using two factors to project the ratio of town population to county population. The first factor is specific to the county and represents an estimate of the rate of change in the ratio of total population living in all towns in the county to total county population. The second factor is specific to the town and represents an estimate of the ratio of that town's growth rate to the average growth rate of all towns in the county combined. The first factor was derived from an analysis of the 1950 to 1970 trends in the change in the proportion of county population living in town and from an estimate of likely future declines in rural farm population by county. The second factor was determined on the basis of past differences among towns in growth relative to the county over the period 1950 to 1970. Growth differentials were assumed to be maintained into the future much as they had occurred from 1950 to 1970 except that upper and lower limits were placed on deviations from average town growth within a county, and some allowance was made for convergence of growth rates toward the county average over time. The growth trends of towns from 1960 to 1970 were given greater weight in projecting future changes than were the trends from 1950 to 1960.

Metropolitan Projections

The spatial dynamics of urban growth often create particularly difficult problems for projecting the population of individual towns and other parts of metropolitan areas. Among the factors which should be considered in projecting metropolitan town populations are intraurban migration, residential saturation, and the highly irregular patterns of urban sprawl and annexation. Projections of future growth for the small towns in Lancaster and Dakota counties are based principally on past growth trends since most of these towns do not lie in the immediate path of urban expansion. In Douglas and Sarpy counties, however, past trends could not be used as a guide to probable future growth for many of the towns.

The initial step in projecting town populations for Douglas and Sarpy counties was to project the proportion of county population living in towns. The medium-projection series assumes a continuation of the present patterns of annexation and conversion of land into urban uses within the Omaha metropolitan area. The high-projection series requires a greater rate of land conversion than the medium series, and it was assumed that the higher rate of land conversion will not be matched by corresponding increase in annexation rates. Consequently, the proportion of the population residing outside existing towns will increase. Conversely, for the low series it was assumed that lower rates of land conversion will allow annexation to keep up with urban expansion, resulting in a gradual increase in the proportion of the metropolitan population living in towns (as town populations increase while the rural farm population remains stable or declines).

Individual towns were projected on the basis of their capacity for residential expansion and their location relative to existing and probable future paths of expansion. Planned future expansions of transportation facilities and public utilities were used extensively in projecting the timing of future growth in different towns. Boys Town in Douglas County and Offutt East and Offutt West in Sarpy County were projected independently because of the special residential functions these places serve. After the individual town projections were made the projections for Omaha were adjusted as required so that the projected division between town and non-town population was maintained.

III. FEATURES OF THE PROJECTIONS

State Projections

Figure 1 shows the high, medium, and low state projections to the year 2000. The characteristics of the projections are a direct product of the birth, death, and net-migration-rate assumptions which underlie the projections. In the case of the medium assumptions, the projected population growth rate exceeds the rates of the 1950s and 1960s until 1990 and then falls below these past rates and gradually approaches zero population growth (although ZPG would not be reached until well after the year 2000).

Two factors should play an important role in maintaining the rate of population growth near or even above recent rates for the next few decades. The most important force is the assumed disappearance of the net out-migration which characterized the 1950s and 1960s. The second factor is the increase in the number of young adults expected over the next few years resulting from the large number of births occurring in the 1950s and early 1960s. This increase in the young-adult population will tend to offset the effects of low age-specific birth rates which are assumed to be significantly below those of the 1950s and 1960s. By 1990, however, the decline in births which began in Nebraska in the latter part of the 1960s will begin to reduce the number of women in the childbearing ages and should result in a steady drop in the rate of population growth unless birth rates return to high levels.

Although the growth rate of Nebraska population in the near future is projected to be relatively close to the growth rates of the recent past,

the composition of change should be quite different. The rate of natural increase of the population will drop substantially because of the lower birth rates, but the declining rate of natural increase will be compensated for by the elimination of net out-migration. This difference in the components of population change, in turn, will have important implications for the age composition of the population. In 1970, for example, 28.4 percent of the population was under 15 years of age. By 1980 that proportion is projected to be 24 percent and by 2000 to be 22.5 percent. In contrast, the 25-through-44 age group was 22 percent of the population in 1970, while the projected figures for 1980 and 2000 are 27 and 29.5 percent respectively. Reduced birth rates and reduced out-migration, therefore, imply a smaller proportion of children and a larger proportion of the population in the working ages over the next several decades. The changing age structure implied by the medium projection series is illustrated in the population pyramids in Figure 3(a).

The medium-projection series shows a growth rate during the 1970s and 1980s somewhat more than twice the growth rate of the low series and somewhat over half of the growth rate of the high series. From 1990 to 2000 the growth rate of the low series drops almost to zero (with actual declines projected after 2000), while the growth of the medium series drops to less than half of the growth rate of the high series. In 1980 the high-level projection is 8.7 percent above the low-level projection and by 2000 the difference widens to 32.5 percent.

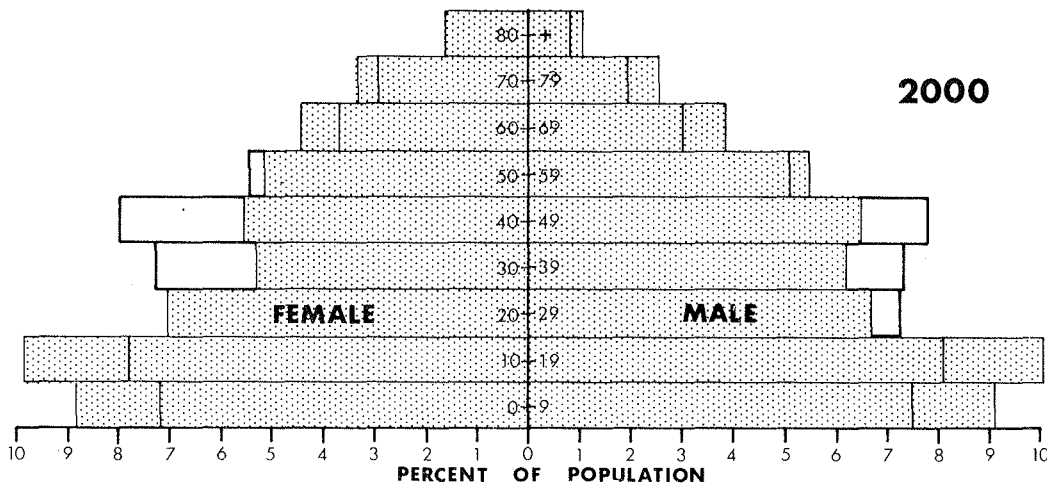

Aside from differences among the projection series in total population estimates, there are differences in the age composition of the population from series to series. Generally the lower the assumed birth rate

the lower is the projected proportion of children and the higher is the projected proportion of working age and older groups in the population for each of the projection periods. In 1980, for example, the low series indicates that children under age 15 will account for 22.4 percent of the population; while the comparable figure for the high series is 25.8 percent (which is still below the actual 1970 level of 28.4 percent). The differences in age structure between the high- and the low-projection series are illustrated in Figure 3(b).

County Projections

Figure 2(b) is a map showing the projected percentage change in population by county from 1970 to 1990 for the medium series. If this map is compared with the map showing population changes from 1950 to 1970 (Figure 2(a)), it is seen that, with only a few exceptions, counties which were declining from 1950 to 1970 are projected to continue declining, while counties which were growing are projected to continue growing. The rates of change, however, are projected to slow down in most cases. All but one of the counties which experienced population losses from 1950 to 1970 are projected to have smaller rates of loss (or even small increases) from 1970 to 1990, while most of the counties which grew from 1950 to 1970 are projected to grow at slower rates from 1970 to 1990.

There are 41 counties which declined in population by more than 20 percent from 1950 to 1970, while only one county is projected to decline by as much as 20 percent from 1970 to 1990. At the opposite extreme nine counties increased in population by more than 20 percent from 1950 to 1970, but only four are projected to increase by more than 20 percent from 1970

to 1990. Falling between these extremes are 24 counties which had population changes of less than ten percent (up or down) between 1950 and 1970, while there are 41 counties projected to have population changes of less than ten percent between 1970 and 1990. On balance, reduced population losses in declining counties are projected to more than offset reduced population increases in the growing counties, so that the state as a whole is expected to grow somewhat more rapidly from 1970 to 1990 (14.8 percent) than from 1950 to 1970 (12.1 percent).

Although most counties are expected to have smaller rates of population change in the future than they have experienced in the past, there are a few counties which increased in population from 1950 to 1970 and are projected to increase at a somewhat greater rate in the near future. The most apparent case of faster population growth is Washington County, which is projected to increase by 29.5 percent from 1970 to 1990 as compared with a growth of 15.6 percent from 1950 to 1970. This increased growth rate is projected primarily on the basis of current estimates of increasing local industrial growth and makes little or no provision for the accelerating growth that could arise if extensive suburban development extends north from Omaha into Washington County. Neither is there any provision in the projections for extensive spillover of urban growth into other counties surrounding Omaha, Lincoln, and the smaller urban centers of the state. The absence of such provisions in the projections should not be interpreted as a prediction that dispersion of growth will not occur in the future, but rather as an indication that the timing and magnitude of possible spillover growth is so uncertain at present that reliable projections of such growth are virtually impossible.

In addition to making no allowance for potential urbanization in counties adjacent to the state's principal towns where such urbanization was not already under way in the 1950 to 1970 period, the projections similarly include no provision for the significant changes in rates of population growth which intensive future industrial development may produce in particular parts of the state. Small upward adjustments were made in the projections for Dakota, Lincoln, Madison, Saline, and Washington counties. In the case of Saline and Madison counties, the adjustments were based partly on current plans for major new plant locations. In neither case, however, do the adjustments represent an attempt to predict increases in growth arising directly from the new plants, since even with the adjustments both Saline and Madison counties are projected to grow at about the same rate from 1970 to 1980 as from 1960 to 1970. Dakota and Lincoln counties are projected to experience increased growth rates over the next ten to fifteen years, but current population estimates for 1972 indicate that much of the increased growth projected after 1970 has already occurred. Therefore, the county projections should be considered as conservative estimates which make no allowance for rapid growth in any areas that have not experienced rapid growth in the past.

Of four counties projected to increase by more than 20 percent by 1990, three (Dakota, Lancaster, and Sarpy) are already classified as metropolitan and the fourth (Washington) is contiguous to the Omaha area. Although these counties are expected to have some net in-migration for at least the next 10 to 15 years, the principal factor which should keep the rate of population growth in these counties above the rate for the remainder of the state is the younger average age of their citizens. The age

structure of the population in the urbanized counties is inherently conducive to a significant excess of births over deaths. Because assumed birth rates are relatively low and because there is projected to be decreasing net migration from rural Nebraska to metropolitan Nebraska, however, the projected growth rates for the Lincoln and Omaha metropolitan areas for the 1970 to 1990 period are significantly below the actual growth rates from 1950 to 1970 (29.9 vs. 40.3 percent for Lincoln and 33.3 vs. 53.6 percent for Omaha).

In addition to the metropolitan counties and Washington County, there are seven other counties projected to grow faster than the state average from 1970 to 1990. Each of these counties is projected to grow between 15 and 20 percent during the 1970 to 1990 period. Four of the counties (Buffalo, Dodge, Hall, and Platte) had growth rates from 1950 to 1970 that were substantially above the state average and each of these counties is projected to have a reduced growth rate from 1970 to 1990. The other three counties (Lincoln, Madison, and Scotts Bluff) grew more slowly than the state from 1950 to 1970 and are projected to have somewhat higher growth rates in the 1970 to 1990 period. As noted above, the Lincoln County projection was adjusted upward because current estimates show substantial growth in population has already occurred since 1970. The Madison County projection was also adjusted upward, but even with the adjustment the projection shows only a small change in growth rate from a position slightly below the state average for 1950 to 1970 (12.6 vs. 12.9 percent) to a position slightly above the state average between 1970 and 1990 (16.1 vs. 14.8 percent). Since Madison County had already moved from a growth rate below the 1950 to 1960 state average to a rate above the 1960 to 1970 state average, the 1970 to 1990 projection is consistent with past trends.

Scotts Bluff County also grew faster than the state from 1960 to 1970 (although it lost population in the 1950s) so its projection to 1990 is not markedly divergent from recent trends. Since the Scotts Bluff projection was not adjusted upward for presumed in-migration, the major factor contributing to the above-average projected growth for the county is the population age structure, which is conducive to a relatively rapid natural increase.

In addition to the 12 counties projected to grow faster than the state from 1970 to 1990 there are 15 other counties projected to increase in population over the 1970 to 1990 period. In most instances the projected rates of population growth for these counties are fairly close to the actual rates of change from 1950 to 1970. In five cases a reversal from population loss to population gain is projected; in six cases an increase in the population growth rate is projected; and in four cases a decrease in the population growth rate is projected.

Of the 66 counties projected to lose population between 1970 and 1990, only Kimball County experienced population growth from 1950 to 1970; and in this case the growth occurred entirely in the 1950s and was followed by a substantial loss in the 1960s. Of the remaining 65 counties expected to lose population from 1970 to 1990, all but one had larger rates of loss from 1950 to 1970 than are projected to 1990. The extent to which the rate of decline is projected to fall varies from county to county, but in nearly all cases the projected reduction in the rate of loss to 1990 is greater than 25 percent of the 1950 to 1970 rate of loss, and in many instances the reduction exceeds 50 percent.

Since most declining counties were assumed to have similar migration patterns, the major factor determining the differences in projected rates of population change for declining counties is differences in the age structure of the population in those counties. Generally, those counties with the largest proportions of older people are projected to lose population at the fastest rates because these counties can be expected to have low crude birth rates and high crude death rates.

With the exception of some counties in the Sandhills and Panhandle areas of Nebraska, heavy population losses in the past generally have been associated with increasing relative concentrations of persons in the older brackets of the age distribution. Therefore, in many instances it is the same counties that have declined at the fastest rates in the past which are projected to decline fastest in the future. Many of the counties bordering Kansas, for example, have among the oldest population age structures in the state, and this area includes five of the ten counties which declined by more than 30 percent from 1950 to 1970 as well as eight of the ten counties which are projected to decline by more than 15 percent from 1970 to 1990.

In a few small counties in western Nebraska where there is relatively little nonfarm population, large population losses in the past have not resulted in concentrations of elderly people because of a tendency for farmers to move into towns in other counties when they retire. Some allowance was made for a continuation of the migration of older people out of these counties, but the allowance was small and most of the affected counties are projected to have substantially lower rates of population decline in the future than they have experienced in the past.

The high and low series of county projections show essentially the same relative pattern of population change among counties as does the medium series, although there is a slight tendency for the percentage difference between the high and the low projections to be greater for faster-growing counties than for declining counties. In the high-series projections, nearly all counties are projected to increase in population after 1980 or 1985; and in the low series, where the birth rate is below the long-term replacement level, nearly all counties are projected to begin to decrease by 2020.

Town Projections

The dearth of good data for most small towns in Nebraska precludes the use of sophisticated methods for making town projections. The town projections are keyed to the county projections because the more detailed data on population characteristics and migration trends at the county level permit more reliable projections at that level. In distinguishing between towns within a county and between town and nontown population within a county, heavy reliance was placed on past trends in relative population change in the different areas, since aggregate population data are about the only data that exist on a uniform basis for all towns.

In general, those towns which have been declining in the past are projected to continue declining, and those towns which have grown are projected to continue growing. In most parts of the state the proportion of the population living in towns is projected to continue to increase but at a decreasing rate.

For many individual towns the past trend of population change will not be a good indicator of future changes. Therefore, when the projections for an individual area are used they should be considered in light of any supplementary information available which might indicate sharp departures from previously established growth patterns. It would be helpful if detailed information relating to growth prospects could be collected and incorporated into the projections for each town in Nebraska, but with over 500 incorporated towns a detailed study of each town is far beyond the scope of this projections project.

IV. STATE AND PLANNING REGION PROJECTIONS

This section presents high, medium, and low projections of the state population by sex and five-year age groups followed by projections for the state and planning regions for broader age groupings. The projections by broad age group include a sex breakdown only for the medium series. The county constituents of each of the 26 planning regions are identified in the map in Figure 4, which also shows the percentage population change by region from 1950 to 1970 and the projected percentage change from 1970 to 1990 for the medium series.

VI. TOWN PROJECTIONS

The 539 towns for which population was projected are arranged in alphabetical order within counties. County projections and the sum of the town projections for each county are listed in addition to the projections for each individual town.

Since the 1970 Census, Parkview (in Hall County) has been annexed by Grand Island and Millard (in Douglas County) has been annexed by Omaha. Therefore, Parkview and Millard have been omitted from the projections and the population totals for Grand Island and Omaha have been adjusted to reflect the annexations. Otherwise the projections include each of the towns listed in the 1970 Census of Population for Nebraska. These towns include all incorporated places and unincorporated places with populations of 1,000 or more. Unincorporated places are identified by the symbol, (U).

There are seven towns which are located in more than one county. Each town was listed only in the county which contained the greatest share of its population in 1970 and is marked with an "*" for identification. The town total for the county in which one or more such towns is listed is also marked with an "*" to indicate that the total includes some town population which is not located within the county. The town total for counties in which such a town is partly located but not listed is marked with a "+" to indicate that the total excludes some town population located within the county. The seven towns and their 1970 percentage distribution of population by county are listed at the end of this section.

Notes:

- Towns which cross county borders are listed below together with each constituent county's share of the town's population in 1970.
 Emerson..... Dakota (20.7%), Dixon* (65.6%), Thurston (13.7%)
 Halsey..... Blaine (2.3%), Thomas* (97.7%)
 Newman Grove... Madison* (99%), Platte (1%)
 Oxford..... Furnas* (78.7%), Harlan (21.3%)
 Tilden..... Antelope (27.7%), Madison* (72.3%)
 Trumbull..... Adams (1.8%), Clay* (98.2%)
 Wakefield..... Dixon* (91.7%), Wayne (8.3%)
- The symbols "+", "*", and "(U)" used in the table are explained in the introductory page for this section.

APPENDIX

State Projection Equations

Except for the youngest and oldest age groups for each sex, the following basic equation is used to project the population in a given five-year age-sex group:

$$(1) \quad P_t^{i,j} = S^{i,j-1} \times MR_{t-1}^{i,j-1} \times P_{t-1}^{i,j-1}$$

where $P_t^{i,j}$ is the population as of year t in the i th sex group and the j th age group, $S^{i,j-1}$ is the fraction of the population in sex group i and age group $j-1$ which is expected to survive into the next higher age group over the given (five-year) time interval, and $MR_{t-1}^{i,j-1}$ is defined by the equation

$$(2) \quad MR_{t-1}^{i,j-1} = BMR_{t-1} \times PP^{i,j-1} + 1.$$

BMR_{t-1} is the basic migration rate indicating the expected net migration for all persons during the period from time $t-1$ to time t as a fraction of the total population at time $t-1$, and $PP^{i,j-1}$ is the age-phasing pattern indicating the expected net migration rate of the i th sex and $j-1$ st age group as a fraction of BMR_{t-1} .

The number of persons in the oldest or residual age group, group n , in a given period is estimated by combining the oldest two age cohorts from the preceding period by means of the following relationship:

$$(3) \quad P_t^{i,n} = S^{i,n-1} \times MR_{t-1}^{i,n-1} \times P_{t-1}^{i,n-1} + S^{i,n} \times MR_{t-1}^{i,n} \times P_{t-1}^{i,n}$$

For the youngest age group (group 1: birth through age four) the population is derived from estimated births as follows:

$$(4) \quad P_t^{i,1} = S^{i,0} \times MR_{t-1}^{i,0} \times a^i \times BH_{t-1}$$

where BH_{t-1} is the estimate of births during the period from $t-1$ to t , and a^i is the expected ratio of births of the i th sex to total births. Births, in turn, are estimated from the number of females in the child-bearing cohorts

$$(5) \quad BH_{t-1} = \sum_{i,j} \left[\frac{1 + S^{i,j} \times MR_{t-1}^{i,j}}{2} \right] \times BR^{i,j} \times P_{t-1}^{i,j}$$

where $BR^{i,j}$ is the five-year birth rate for the i th sex and j th age group. ($BR^{i,j}$ is zero except for females in the childbearing ages from 15 through 44.)

County Projection Equations

Except for the youngest and oldest age-sex groups, the basic equation for estimating the ratio of county to state population is

$$(6) \quad R_t^{k,i,j} = GF_{t-1}^k \times CPP^{k,i,j-1} \times R_{t-1}^{k,i,j-1}$$

where $R_t^{k,i,j}$ is the ratio of population in the i th sex and j th age group in county k at time t to state population in the same group at time t , GF_{t-1}^k is a growth factor indicating the expected average growth of all cohorts in county k relative to the state average from period $t-1$ to t , and $CPP^{k,i,j-1}$ is an age-phasing pattern indicating the expected relative change in the ratio of the population of county k in the i th sex and $j-1$ st age group to state population in the same group as a cohort moves from the $j-1$ st to the j th age group. ("Relative" means relative to GF_{t-1}^k .)

The equation for the oldest age group, group n , is

$$(7) \quad R_t^{k,i,n} = GF_{t-1}^k \times CPP^{k,i,n-1} \times R_{t-1}^{k,i,n*}$$

where $R_{t-1}^{k,i,n*}$ is the ratio of county to state population for age groups $n-1$ and n at time $t-1$.

The ratio of county to state population for the youngest age cohorts is derived as a weighted average of the county-state ratios of the female cohorts in the childbearing ages. (The weights, $W^{i,j}$, depend on $BR^{i,j}$.)

$$(8) \quad R_t^{k,i,1} = GF_{t-1}^k \times CPP^{k,i,0} \times F_{t-1}^k$$

where F_{t-1}^k is defined as follows:

$$(9) \quad F_{t-1}^k = \sum_{i,j} W^{i,j} \times \left[\frac{R_{t-1}^{k,i,j} + R_t^{k,i,j}}{2} \right]$$

Town Projection Equations

The ratio of total town population to total county population was estimated for nonmetropolitan towns by the following equation:

$$(10) \quad RT_t^{m,k} = CC_{t-1}^k \times TC_{t-1}^{m,k} \times RT_{t-1}^{m,k}$$

where $RT_t^{m,k}$ is the ratio of population of town m in county k to the total population of county k in period t, CC_{t-1}^k is an estimate of the expected average change in the ratio of total town population to total county population in county k from period t-1 to period t, and $TC_{t-1}^{m,k}$ is an estimate of expected change in the ratio of town m population to county k population relative to the average change for all towns in county k (CC_{t-1}^k) during the period t-1 to t. For most towns $TC_{t-1}^{m,k}$ was estimated as a weighted average of $TC_{t-2}^{m,k}$ and $TC_{t-3}^{m,k}$

$$(11) \quad TC_{t-1}^{m,k} = 3/4 \times TC_{t-2}^{m,k} + 1/4 \times TC_{t-3}^{m,k}.$$

Where $TC_{t-2}^{m,k}$ or $TC_{t-3}^{m,k}$ exceeded preassigned maximum values (TC_{t-2}^{\max} and TC_{t-3}^{\max}) they were replaced by a maximum to compute $TC_{t-1}^{m,k}$. Similarly where $TC_{t-2}^{m,k}$ or $TC_{t-3}^{m,k}$ were less than preassigned minimum values (TC_{t-2}^{\min} and TC_{t-3}^{\min}) they were replaced by the minimum.

Assumed Parameter Values for the County Projections

1. Age-Phasing Patterns of Population Change

Counties can be divided into three broad groups depending on whether the county has (I) a deficit, (II) parity, or (III) a surplus relative to the national proportion of persons age 15 through 24.

Most counties in Nebraska fall into group I. Among this large group of counties, four subgroups were identified.

- a. Counties with histories of chronic and substantial population loss and a relative surplus of population in older age brackets: Antelope, Boone, Box Butte, Boyd, Brown, Burt, Butler, Cedar, Chase, Cherry, Cheyenne, Clay, Cuming, Custer, Deuel, Dixon, Dundy, Fillmore, Franklin, Frontier, Furnas, Garden, Garfield, Gosper, Grant, Greeley, Harlan, Hitchcock, Holt, Hooker, Howard, Johnson, Kimball, Knox, Morrill, Nance, Nuckolls, Pawnee, Perkins, Pierce, Polk, Richardson, Rock, Sheridan, Sherman, Thayer, Thurston, Valley, Webster.
- b. Counties with histories of chronic and substantial population loss with an additional tendency for net out-migration of people reaching retirement age: Arthur, Banner, Blaine, Hayes, Keya Paha, Logan, Loup, McPherson, Sioux, Thomas, Wheeler.
- c. Counties with relatively stable or growing populations which exhibit a significant tendency toward out-migration in the 15-24 age group (but a lesser tendency toward out-migration in that age group than is found in the more rapidly declining counties): Colfax, Dawson, Hamilton, Kearney, Keith, Merrick, Otoe, Phelps, Stanton.

d. Counties which experienced little net out-migration in the 15-19 age group (e.g., because of a junior college) but did have a substantial loss in the 20-24 age group: Jefferson, Red Willow, York.

The counties in group II generally were growing at rates near the state average and contained a town with more than 10,000 population, or were situated adjacent to a metropolitan area. Included in group II are:

Adams, Cass, Dakota, Dodge, Gage, Hall, Lincoln, Madison, Platte, Saline, Saunders, Scotts Bluff, Washington.

The counties in group III are relatively few in number and were treated individually in Table 5. Most of these counties contained a significant college population.

The phasing patterns were derived by examination of similar age-phasing patterns computed for the periods 1950 to 1960 and 1960 to 1970 for individual counties. Data on migration from 1955 to 1960 and 1965 to 1970 for the state economic areas were used to help convert the ten-year change patterns to five-year patterns. Counties were divided into a relatively small number of groups because it was felt that data quality does not justify fine distinctions among counties that have had quite similar past histories of growth and decline. The phasing patterns by group appear in Table 5.

TABLE 5

Phasing Patterns*

65-69	70-74	1.01	0.98	1.00	1.01	1.00	1.00	1.00	0.99	0.98	1.00	1.00
70-74) 75+)	75+	1.01	0.98	1.00	1.01	1.00	1.00	1.00	0.99	0.98	1.00	1.00

*Sex differences in age patterns were considered small enough to ignore.

**Douglas and Sarpy counties were first projected as a single unit and then separated using different techniques.

2. Growth Factors

Growth factors were varied from county to county only up to 1985. After that, differences in the rate of population change among counties are due only to differences in age structure (a younger age structure generally means greater growth) and differences in the age-phasing pattern (age-phasing pattern Ia, for example, is less conducive to growth than phasing pattern II or III).

Counties are divided into three classes depending on whether their proportion of the state's population has been (I) declining significantly, (II) roughly stable, or (III) increasing significantly.

- I. Antelope, Arthur, Banner, Blaine, Boone, Box Butte, Boyd, Brown, Burt, Butler, Cedar, Chase, Cherry, Cheyenne, Custer, Deuel, Dixon, Dundy, Fillmore, Franklin, Frontier, Furnas, Gage, Garden, Garfield, Gosper, Grant, Greeley, Harlan, Hayes, Hitchcock, Holt, Hooker, Jefferson, Johnson, Keya Paha, Kimball, Knox, Logan, Loup, McPherson, Morrill, Nance, Nemaha, Nuckolls, Pawnee, Perkins, Polk, Richardson, Rock, Sheridan, Sherman, Sioux, Thayer, Thomas, Thurston, Valley, Webster, Wheeler.
- II. Adams, Cass, Clay, Colfax, Cuming, Dawes, Dawson, Hamilton, Howard, Kearney, Keith, Merrick, Otoe, Phelps, Pierce, Platte, Red Willow, Saunders, Scotts Bluff, Seward, Stanton, Wayne, York.
- III. Buffalo, Dakota, Douglas-Sarpy, Dodge, Hall, Lancaster, Lincoln, Madison, Saline, Washington.

Counties in Class I were assigned growth factors less than one up to 1985, while those in Class II were assigned a factor of one, and those in Class III were assigned factors greater than one. The growth factors are listed in Table 6.

TABLE 6

Growth Factors
 (GF Values in Equation (6))

<u>Counties</u>	<u>1970-1975</u>	<u>1975-1980</u>	<u>1980-1985</u>
Group I			
Dominant Pattern	0.960	0.980	0.990
Cedar, Cherry	0.940	0.970	0.990
Kimball	0.900	0.960	0.990
Group II			
All Counties	1.000	1.000	1.000
Group III			
Buffalo, Hall, Lancaster, Lincoln, Saline	1.020	1.010	1.000
Douglas-Sarpy*	1.025	1.015	1.005
Dodge, Madison	1.030	1.020	1.010
Dakota	1.050	1.030	1.010
Washington	1.050	1.050	1.050

*Douglas and Sarpy counties were first projected as a single unit and then separated using different techniques.

Nearly all the counties in Class I were assigned the same growth factors: 1970-75, .96; 1975-80, .98; and 1980-85, .99. Many of the counties in Class I also had common age-phasing patterns. Growth rates, however, will still vary among these counties because of differences in the initial-period age structure of the population. Generally the counties which have declined most rapidly in the past have the oldest age structure and are projected to decline fastest in the future. The growth factors for three counties in Class I were adjusted downward somewhat. The adjustment was made because relatively young age structures of the population in these counties would otherwise lead to substantially less projected population loss for these counties than for other counties in the class. Since the young age structures were due to special circumstances (e.g., high birth rates or past in-migration that is not likely to be repeated), it was not felt that the age structures in these counties were an accurate indication of likely future growth.

The counties in Group III have either grown significantly faster than the state since 1950 or are currently experiencing growth forces which should tend to make them grow relatively faster in the near future than they have in the past. The metropolitan counties of Douglas, Sarpy, and Lancaster and the counties of Buffalo, Dodge, and Hall have each grown significantly more than the state since 1950. The counties of Dakota and Washington have grown somewhat faster than the state average since 1950, and might be expected to increase their relative growth rates in the near future because of their proximity to metropolitan centers and a growing industrial base. The counties of Lincoln, Madison, and Saline have not grown significantly faster than the state in the past, but may be expected

to grow faster in the near future than would be indicated by past trends because of recent industrial expansion.

Assumed Parameter Values for the Town Projections

The change in the ratio of total town population to county population (CC in Equation (10)) is assumed to be positive for nearly all counties up to 1985 and then to level off to no change (CC = 1). Of 89 nonmetropolitan counties, 66 were fitted into two large groups and the remainder divided into smaller groups on the basis of assumed values of CC up to 1985.

The counties in the first large group (I) include:

Antelope, Boone, Boyd, Burt, Cedar, Cuming, Custer, Dixon, Dundy, Fillmore, Franklin, Frontier, Garden, Hamilton, Holt, Howard, Johnson, Knox, Loup, Nance, Nemaha, Otoe, Pawnee, Perkins, Pierce, Rock, Saline, Seward, Sheridan, Sherman, Sioux, Thomas, Thurston, Valley, Washington, Webster, Wheeler, York.

The counties in the second large group (II) include:

Brown, Butler, Cass, Chase, Cherry, Cheyenne, Clay, Colfax, Dawson, Deuel, Furnas, Greeley, Harlan, Jefferson, Kearney, Keith, Kimball, Logan, Madison, Merrick, Morrill, Nuckolls, Phelps, Platte, Polk, Richardson, Saunders, Thayer.

The values of CC for these two groups and the remainder of the nonmetropolitan counties appear in Table 7.

Even though the value of CC is set equal to one for all counties after 1985, the projected ratio of town population to county population continues to rise slowly for most counties because of the composition of growth among towns within the county and because of the provision for

TABLE 7

CC Values
(for Equation (10))

<u>Counties</u>	<u>1970-1975</u>	<u>1975-1980</u>	<u>1980-1985</u>
Group I	1.050	1.040	1.030
Group II	1.040	1.030	1.020
Other Counties			
Arthur	1.080	1.060	1.040
Gosper, Keya Paha, Wayne	1.060	1.050	1.040
Buffalo, Dawes, Garfield	1.035	1.025	1.015
Blaine, Dodge, Hitchcock, Lincoln, Stanton	1.030	1.020	1.010
Adams, Box Butte, Gage, Hall, Red Willow, Scotts Bluff	1.025	1.015	1.005
Hooker	1.020	1.010	1.000
Grant, Hayes	1.000	1.000	1.000

maximum and minimum values for change relative to the county change (TC^{\max} and TC^{\min}). If the largest town in the county makes up a sizable fraction of the total town population, the average change in the ratio of town to county population will be dominated by that town. Consequently, as is frequently true, if the largest town has grown much faster than the other towns, the past relative change of the smaller towns may be well below the minimum allowed (TC^{\min}); hence the provision for setting a minimum may impart an upward bias to the projection of total town population. The maximum and minimum values for TC appear in Table 8.

TABLE 8

Maximum and Minimum Values for TC by Period
(for Equation (11))

	1950- 1960 ¹	1960- 1970 ¹	1970- 1975 ²	1975- 1980 ²	1980- 1985 ²	1985- 1990 ²	1990- 1995 ²	1995- 2000 ²	2000- 2005 ²	2005- 2010 ²	2010- 2015 ²
TC^{\max}	1.10	1.10	1.09	1.08	1.07	1.06	1.05	1.04	1.03	1.02	1.01
TC^{\min}	0.90	0.90	0.91	0.92	0.93	0.94	0.95	0.96	0.97	0.98	0.99

¹Calculation of TC is based on one-half of the actual rate of change for the ten-year census periods.

²Calculation of TC is based on the total projected rate of change for the five-year projection periods.

The values of TC are the same for the high and low series as for the medium series. However, the values of CC for all periods after 1970 were increased by one-half percentage point for the high series and decreased by one-half percentage point for the low series for all counties

except those for which the procedure resulted in a lower nontown population projection for the high series than for the low series. In the latter case (12 counties) the medium series values for CC were carried over to the high and low series. The adjustments in the CC values for the high and low series generally resulted in a wider range between the high and low projections for towns than for the high and low nontown projections.

In some counties the estimating procedures described above resulted in very low projections of nontown population for some years. Minimum acceptable levels of nontown population for each county were set at 70 percent of the 1970 level for the high series, 60 percent of 1970 for the medium series, and 50 percent of 1970 for the low series. In counties where the standard projection methods led to nontown projections below the minimum values, the town population projections were adjusted downward to raise the nontown projection to the minimum values.
