20 **Abstract**

21

22 Understanding factors associated with varying efficacy of Bacillus Calmette-Guérin (BCG)
23 would aid the development of improved vaccines against tuberculosis (TB). In addition,
24 investigation of individual-level factors affecting mycobacterial-specific immune responses
25 could provide insight into confounders of vaccine efficacy in clinical trials. Mycobacterial
26 growth inhibition assays (MGIA) have been developed to assess vaccine immunogenicity *ex*
27 *vivo* and provide a measure of immune function against live mycobacteria. In this study, we
28 assessed the impact of immune cell phenotype, cytomegalovirus (CMV)-specific response
29 and sex on *ex vivo* growth inhibition following historical BCG vaccination in a cohort of
30 healthy individuals (n=100). A higher frequency of cytokine-producing NK cells in
31 peripheral blood was associated with enhanced *ex vivo* mycobacterial growth inhibition
32 following historical BCG vaccination. A CMV-specific response was associated with T-cell
33 activation, a risk factor for TB disease and we also observed an association between T-cell
34 activation and *ex vivo* mycobacterial growth. Interestingly, BCG-vaccinated females in our
35 cohort controlled mycobacterial growth better than males. In summary, our present study has
36 shown that individual-level factors influence capacity to control mycobacterial growth
37 following BCG vaccination and the MGIA could be used as a tool to assess how vaccine
38 candidates may perform in different populations.

43 Introduction

44 Tuberculosis (TB) is the number one cause of death from an infectious disease worldwide
45 and it is currently estimated that a quarter of the world population is infected with
46 *Mycobacterium tuberculosis* (*Mtb*) [1, 2]. The introduction of Bacillus Calmette-Guérin
47 (BCG) vaccination and chemotherapy in the past century provided optimism to fight the
48 disease. Despite this, drug-resistant TB is now a major risk to global health security, and
49 BCG as the only licensed vaccine for TB is known to have a variable efficacy against
50 contagious adult pulmonary TB [3, 4]. BCG remains as the most widely used vaccine
51 worldwide, primarily because it provides good protection against TB in children [3].
52 Understanding factors associated with varying BCG protection could aid the development of
53 improved vaccination practice as well as novel vaccines against TB.

54 It has been proposed that the observed variation in BCG efficacy is attributed to individual-
55 level factors which influence host mycobacteria-specific immune responses [5-7]. In a recent
56 systematic review, protection following BCG vaccination was shown to vary according to the
57 geographical latitudes in which the vaccine was given. In the UK, a country where exposure
58 to environmental mycobacteria and/or *Mtb* is regarded to be lower (latitude $> 40^{\circ}$), BCG is
59 known to provide efficacy of up to 80% against pulmonary TB [8] and vaccination of school-
60 aged children could provide protection for more than 20 years [9]. Another factor that may
61 influence the mycobacteria-specific immune response is sex. Globally, TB case rates are
62 much higher in men than in women, as reflected by a global male to female ratio (M:F) of 1.7
63 for case notifications in 2016 [10]. Males contribute to 65% of TB cases worldwide and
64 although it is thought that socioeconomic and cultural factors are contributing to the observed
65 sex bias, differences in the immune responses between the sexes also play a role [11, 12]. It is
66 generally acknowledged that females exhibit more robust immune responses towards
67 infection and vaccination compared to males [13]. In the context of susceptibility to TB,
68 differences in immune cells frequencies and functions have been thought to contribute to
69 higher TB rates in males [14]. With regard to BCG vaccination, there is currently limited
70 evidence concerning the impact of sex on its protective effect against pulmonary TB in
71 adults. Interestingly, BCG is thought to provide a non-specific protective effect against
72 unrelated pathogens, thus contributing in reduction of overall cause of mortality, and this
73 effect is more pronounced in females rather than males [15-17].

74 Recently, Fletcher *et al.* found that T-cell activation is an immune correlate of risk of TB
75 disease in BCG-vaccinated infants in a study enrolling a large cohort of infants [18]. Chronic
76 exposure to antigen from persistent viral or bacterial infection is known to drive continuous
77 T-cell activation which could lead to dysfunction of antigen specific T-cells [19]. Further to
78 the findings of the infant study, it was identified that cytomegalovirus (CMV)-specific IFN- γ
79 responses were associated with T-cell activation and could have contributed to increased risk
80 of developing TB disease [20].

81 The mycobacterial growth inhibition assay (MGIA) has been developed as a measure of
82 vaccine immunogenicity *ex vivo*. Following optimisation works in the past few years [21-23],
83 the assay has gained attention for its potential ability to detect vaccine-mediated inhibition of
84 growth following BCG vaccination in adults and infants [24-26]. The assay described in the
85 present study involves direct co-culture of peripheral blood mononuclear cells (PBMCs) with
86 mycobacteria, and subsequent measurement of mycobacterial growth inhibition as a
87 functional assessment of vaccine response. Several studies have demonstrated the ability of
88 the MGIA to detect changes in the innate and adaptive compartment following vaccination
89 [25, 27-30]. Recently, Joosten and colleagues (2018) found that the capacity to control
90 mycobacterial growth following recent *Mtb* exposure or BCG vaccination is associated with
91 nonclassical monocytes, and this observation is reflective of the trained innate immune
92 mechanism [26]. In a study by Jensen *et al.*, IFN- γ was associated with reduction of
93 mycobacterial growth *ex vivo* following immunisation with a TB vaccine candidate in mice
94 [31]. However, in that study the source IFN- γ was not found among the investigated vaccine-
95 specific T-cells, suggesting potential contribution from other cell types, such as NK cells.

96 In this study, we demonstrated the impact of immune cell phenotype, CMV-specific response
97 and sex on vaccine-specific mycobacterial growth inhibition following historical BCG
98 vaccination in adult healthy volunteers.

99

100

101 **Materials and Methods**

102 **Study participants and ethics statement**

103 We recruited 100 healthy adult participants with (i) no history of BCG vaccination or (ii) a
104 history of BCG vaccination more than 6 months before study enrolment. Verbal interviews

105 were conducted to determine eligibility based on the absence of any major chronic illness,
106 current medication administration or symptoms of infection. Participants were aged 18 to 80
107 years with no evidence of exposure or infection with TB. Participants were excluded if they
108 were suffering from any persistent medical condition or infection. Sample size was calculated
109 based on the assumption of effect size 0.70, with power 0.8 and significance level 0.05.
110 Written informed consent was obtained from all participants prior to enrolment in the study.
111 Individuals were recruited under protocols approved by the LSHTM Observational Research
112 Ethics Committee (ref 8762 and 10485). All procedures were conducted in accordance with
113 the Declaration of Helsinki, as agreed by the World Medical Association General Assembly
114 (Washington, 2002) and ICH Good Clinical Practice (GCP).

115

116 **PBMCs isolation and IFN- γ Enzyme-linked immunospot (ELISpot) assay**

117 Peripheral blood (50ml) was collected and processed within 6 hours. PBMCs isolation and
118 IFN- γ ELISpot assay were performed as previously described [32]. PBMCs were
119 cryopreserved in FBS (Labtech International Ltd, Uckfield, UK) containing 10% DMSO
120 (Sigma-Aldrich) and stored in -80 °C freezer using CoolCell containers (VWR International,
121 Lutterworth, UK). PBMCs were thawed and an *ex vivo* IFN- γ ELISpot assay was performed
122 to assess antigen-specific response. PBMCs were incubated overnight for 18 hours with 20
123 μ g/ml purified protein derivative (PPD) (Oxford Biosystem, Oxfordshire, UK). Positive
124 control Phytohemagglutinin (PHA) (10 μ g/ml, Sigma-Aldrich) and negative control
125 (medium-only) wells were included for each participant samples. Results are reported as spot
126 forming cells (SFC) per million PBMCs, calculated by subtracting the mean of the
127 unstimulated wells from the mean of antigen wells and correcting for the numbers of PBMC
128 in the wells. Spots were quantified using an automated plate reader with ELISpot 5.0
129 software as well as checked visually.

130

131 ***Ex vivo* Mycobacterial Growth Inhibition Assay**

132 The growth inhibition assay was performed using cryopreserved PBMCs of the study
133 participants, as previously described [32]. In brief, a 2-ml screw-cap tubes containing 3×10^6
134 PBMCs in 600 ml of medium were rotated at 37°C with ~100 Colony Forming Units (CFU)
135 of BCG Pasteur Aeras strain (Rockville, MD, USA) for 4 days. The PBMCs were then lysed
136 with sterile water, and the lysate transferred to a Bactec MGIT supplemented with PANTA
137 antibiotics and OADC enrichment broth (all from Becton Dickinson, Oxford, UK). The tube

138 was placed in a Bactec MGIT 960 and incubated until growth was detected (measured as time
139 to positivity [TTP]). Use of a standard curve enables conversion of the TTP of a sample tube
140 into bacterial numbers (log CFU) (Supplementary Fig. S1). All work with cells pre-BCG
141 infection and involving BCG infected samples was done in Biosafety Level (BSL) 2
142 laboratory.

143

144 **Enzyme-linked immunosorbent assay (ELISA)**

145 MGIA supernatants were analysed to assess cytokine concentrations by ELISA. The levels of
146 following cytokines were measured: IFN- γ , interleukin (IL)-12p40, IL-6 [BD OptiEIA kits,
147 Becton Dickinson, UK], tumor necrosis factor alpha (TNF- α), granulocyte-macrophage
148 colony-stimulating factor (GM-CSF), interferon-gamma-induced protein 10 (IP-10),
149 granzyme B, IL-32, IL-22 [R&D Systems, Abingdon, UK], IL-10, IL-17 [BioLegend,
150 London, UK] and perforin [Abcam, Cambridge, UK]. Assays were performed according to
151 the manufacturers' instruction.

152

153 **Flow cytometric immune phenotyping**

154 PBMC were washed and stained with 1 μ l/ml Live Dead Blue Stain (Invitrogen), followed by
155 staining with the following titrated antibody for the Lymphocyte panel: 2.5 μ l CD3-AF700
156 (clone UCHT1, Ebioscience, Loughborough, UK), 1.25 μ l CD4-APC/Cy7 (clone RPA-T4,
157 BioLegend), 1.25 μ l CD8-Superbright645 (clone RPA-T8, Ebioscience), 2.5 μ l CD19-FITC
158 (clone HIB19, BioLegend), 2.5 μ l CD56-APC (clone HCD56, BioLegend), 2.5 μ l CD16-
159 BV510 (clone 3G8, BioLegend), 5 μ l HLA-DR-PE (clone L243, BioLegend), 5 μ l LAG3-
160 PE/Cy7 (clone 11C3C65, BioLegend) and 1.25 μ l PD1-BV421 (clone EH12.2H7,
161 BioLegend). For the Monocyte panel, the cells were stained with the following titrated
162 antibodies: 2.5 μ l CD3-AF700 (clone UCHT1, Ebioscience), 2.5 μ l CD19-FITC (clone
163 HIB19, BioLegend), 2.5 μ l CD14-BV421 (clone HCD14, BioLegend), 2.5 μ l CD16-BV510
164 (clone 3G8, BioLegend), 1.25 μ l CD86-APC/Cy7 (clone IT2.2, BioLegend), 5 μ l HLA-DR-
165 PE (clone L243, BioLegend), 5 μ l CD206-APC (clone 15-2, BioLegend), 5 μ l CD163-
166 BV605 (clone GHI/61, BioLegend), 2.5 μ l CD64-APC/Cy7 (clone 10.1, BioLegend) and 5 μ l
167 CD123-BV650 (clone 6H6, BioLegend). Fluorescence minus one (FMO) controls were set
168 using cells for each antibody and used to guide gating. Cells were acquired on a BD LSR II
169 flow cytometer. Data was analysed with FlowJo software version 10.4 (Treestar Inc., USA).

170 Results are presented as percentages of cells after gating out of dead cells and doublets.
171 Gating strategies for the lymphocyte and monocyte panels are described in Supplementary
172 Fig. S2A and S2B.

173

174 **Intracellular cytokine staining (ICS) flow cytometry**

175 The ICS flow cytometry was performed as previously described [32]. In brief, PBMCs were
176 then incubated alone (medium only) as a negative control, with 5 µg/ml *Staphylococcus*
177 enterotoxin B (SEB; Sigma, UK) as a positive control, with ~100 CFU BCG (as per the
178 MGIA protocol) and with 10 µg/ml CMV peptide pool (5 peptides, 2 µg/ml/peptides,
179 ANASPEC, Fremont, CA, USA). The CMV peptide pool used is the same as the Fletcher *et*
180 *al.* study [20]. The incubation with BCG was performed for 4 days and the addition of SEB
181 and CMV was performed on Day 3. Two hours after the addition of SEB and CMV to the
182 respective tubes, brefeldin A (Sigma, UK) was added to all tubes which were then incubated
183 for 18 hours at 37°C until Day 4. Data was acquired using an LSRII flow cytometer (BD
184 Biosciences) and FACSDiva acquisition software (BD Biosciences). ICS flow cytometry data
185 was analysed using FlowJo software version 10.4 (TreeStar Inc., Ashland, OR, USA).
186 Samples were gated sequentially on singlet, live, CD14⁻CD19⁻, CD3⁺ (lymphoid), CD4⁺,
187 CD8⁺ cells and negative control stimulation tubes were used to set cytokine gates (see
188 Supplementary Fig. S3, ICS gating).

189

190 **Statistical analysis**

191 To identify statistical significance of *ex vivo* growth inhibition (log CFU values) and ELISA
192 responses, students *t*-test were used. Mann-Whitney *U* Test was performed to identify
193 significant differences of the ELISpot, cell surface flow cytometry and ICS responses
194 between groups. Spearman's correlation coefficient was used to test for correlations between
195 growth inhibition and immune responses. A multiple comparison correction was included
196 (Bonferroni), as indicated in each figure legend. Statistical analyses were performed in
197 Graphad Prism 7 (GraphPad, La Jolla, CA, USA).

198

199

200 **Results**

201 **Demographics of enrolled participants**

202 One hundred participants were enrolled in the study; 37 vaccine-naïve volunteers with no
203 history of BCG vaccination and 63 volunteers previously-vaccinated with BCG (average time
204 since vaccination 29.4 years prior to enrolment). Table 1 summarises the characteristics of
205 the study participants. Almost 70% of the BCG-vaccinated participants were from the UK.

206

207 **Assessment of *ex vivo* growth inhibition and mycobacterial antigen-specific cytokine** 208 **responses**

209 The growth inhibition assay was performed to assess impact of historical BCG vaccination on
210 *ex vivo* mycobacterial growth control. Using cryopreserved PBMCs, enhanced growth
211 inhibition in PBMCs from BCG-vaccinated individuals was observed compared to vaccine-
212 naïve individuals (median log CFU 1.680 and 2.027, $p < 0.0001$, Figure 1A). The IFN- γ
213 ELISpot assay was performed to measure the magnitude of the mycobacteria-specific
214 response. The secretion of IFN- γ in response to PPD was elevated in samples from vaccinated
215 individuals in comparison to unvaccinated individuals (median SFC 109.5 and 48, $p < 0.0001$,
216 Figure 1B). There was a significant inverse correlation between higher IFN- γ ELISpot
217 response and lower mycobacterial growth ($p = 0.022$, Spearman $r = -0.23$, Figure 1C).

218 Trends for higher production of Th1-type cytokines (IFN- γ , IP-10, TNF- α , IL-12) as well as
219 GM-CSF were observed in the BCG-vaccinated group compared to the vaccine-naïve group
220 (Table 2). There was a statistically significant correlation between higher IL-10 production
221 and higher mycobacterial growth (Spearman $r = 0.37$, $p = 0.0003$, Table 2). Meanwhile,
222 historical BCG-vaccination was associated with significantly increased frequency of
223 mycobacterial antigen specific IL-2⁺ CD4 T-cells in the BCG-vaccinated group upon 4 days
224 of stimulation with BCG ($p = 0.008$, Supplementary Figure S4). Similar trends were observed
225 with the frequencies of IFN- γ ⁺ as well as TNF- α ⁺ CD4 T-cells (Supplementary Figure S4).
226 There were no significant correlations between the frequencies of BCG-specific CD4 and
227 CD8 T-cells and mycobacterial growth, although the observed trends suggest that these cells
228 may contribute to control of growth (Supplementary Table S1).

229

230 **Associations between historical BCG vaccination and the frequency of circulating** 231 **leukocyte subsets**

232 Historical BCG vaccination was not associated with frequencies of circulating leukocytes in
233 T-cell, NK cell and monocyte compartments (Supplementary Table S2). However, significant
234 correlations were observed between the frequencies of NK cells and enhanced control of
235 mycobacterial growth *ex vivo* in the naïve and BCG-vaccinated groups ($p < 0.05$, Spearman's
236 correlations, Table 3). In the BCG-vaccinated group, higher frequency of cytokine-producing
237 NK cells was associated with reduced mycobacterial growth (Spearman $r = -0.41$, $p = 0.015$,
238 Figure 2A). A higher production of perforin was observed from the cells of BCG-vaccinated
239 participants compared to naïve ($p = 0.018$, Figure 2B). The production of perforin significantly
240 correlated with enhanced growth inhibition (Spearman $r = -0.44$, $p = 0.013$, Figure 2C and
241 Supplementary Table S3), and the association was still significant when the correlation was
242 performed in the BCG-vaccinated group only (Spearman $r = -0.36$, $p = 0.037$, data not shown).
243 Correlations with other measured NK cell associated markers (granzyme, IL-32, IL-22) did
244 not reach significance (Supplementary Table S3).

245

246 **Impacts of CMV-specific T-cell response and T-cell activation on *ex vivo* mycobacterial** 247 **growth inhibition**

248 CMV-specific T-cells producing $\text{IFN-}\gamma^+$ and $\text{TNF-}\alpha^+$, notably in the CD8 compartment, were
249 significantly associated with the frequency of T-cells expressing LAG3 and PD1 markers
250 ($p < 0.05$, Spearman's correlations, Table 4 and Figure 3 A-D). Historical BCG-vaccination
251 was not associated with differences in CMV-specific response nor T-cell activation
252 (Supplementary Table S2 and S4). However, T-cell activation was shown to correlate with
253 higher growth of mycobacteria *ex vivo*, particularly in the naïve group (Figure 3 and
254 Supplementary Table S5). LAG3^+ CD4 T-cells were significantly associated with growth of
255 mycobacteria ($p = 0.047$), with a similar trend for LAG3^+ CD8 T-cells ($p = 0.072$) (Figure 3 F
256 and I).

257

258 **Impact of sex on *ex vivo* mycobacterial growth inhibition and cytokine responses, and its** 259 **association with immune cell phenotype**

260 In this study, we demonstrated that sex was associated with differences in immune response
261 following historical BCG vaccination. First, BCG-vaccinated females exhibited a superior
262 capacity to control mycobacterial growth when compared to males ($p = 0.029$, Figure 4B). In
263 contrast, males showed a trend towards higher $\text{IFN-}\gamma$ response from PPD-stimulated PBMCs

264 as well as higher IP-10 production in the MGIA supernatant, both in naïve and BCG-
265 vaccinated groups (Figure 4 C-F). Supplementary Table S6 summarises the sex comparisons
266 of all measured cytokines from the MGIA supernatants.

267 In the BCG-vaccinated group, females had a higher frequency of cytokine-producing NK
268 cells ($p=0.018$, Figure 5A). There was also a higher CD4/CD8 ratio in females compared to
269 males in the naïve group ($p=0.028$, Figure 5B). Interestingly, there was a higher frequency of
270 monocytes in males in the BCG-vaccinated group ($p=0.049$, Figure 5C), with a trend of
271 higher monocyte-to-lymphocyte (ML) ratio in BCG-vaccinated males compared to females
272 ($p=0.08$, Supplementary Table S7). In terms of T-cell activation, BCG-vaccinated females
273 exhibited a lower frequency of LAG3⁺ CD8 T-cells ($p=0.0297$, Figure 5D). While in the
274 naïve group, females also had lower frequencies of activated CD8 T-cells expressing HLA-
275 DR, LAG3 and PD1 ($p<0.05$, Supplementary Table S7). The lower frequencies of activated
276 T-cells in females may be a consequence of lower CMV-specific CD8 T-cells response
277 (Figure 5E and Supplementary Table S7).

278

279

280 Discussion

281 The present study reports that mycobacterial growth inhibition *ex vivo* is enhanced following
282 historical BCG vaccination in adult healthy volunteers. In this study, the average time since
283 BCG vaccination was 29.4 years prior to enrolment. Our results are in line with previous
284 studies such as Fletcher *et al.* [24] and Prabowo *et al.* [32] which detected the impact of
285 historical BCG vaccination after more than 20 years using the same PBMC-based MGIA.
286 Most vaccinated individuals enrolled in our study are UK participants in which BCG
287 vaccination is known to be effective [9]. A higher IFN- γ response was also observed in the
288 BCG-vaccinated group compared to the naïve group using the ELISpot assay, reflecting the
289 presence of mycobacterial-specific memory cells. Moreover, there was a significant
290 correlation between IFN- γ response and lower mycobacterial growth. Several published
291 MGIA studies reported increased IFN- γ production following BCG vaccination [24, 33, 34],
292 and BCG-specific IFN- γ response measured by ELISpot assay is known to be associated with
293 reduced TB disease risk following BCG vaccination in infants [18]. The ELISpot assay
294 measures all cells that secrete IFN- γ in response to antigen stimulation, including NK cells
295 and $\gamma\delta$ T-cells in addition to conventional T-cells. Focusing on the conventional T-cells
296 response, in our study, we did not observe a significant association between Th1-type

297 cytokine-expressing T-cells and *ex vivo* mycobacterial growth inhibition. This finding was in
298 contrast with the study of Smith *et al.* [25] which showed an association between MGIA
299 control capacity and the frequency of polyfunctional CD4 T-cells using studying a small
300 cohort of BCG-vaccinated infants. However, our results were consistent with the finding of
301 Joosten *et al.* [26] using the same PBMC-based MGIA, as well as with a study by Kagina *et*
302 *al.* [35] which showed no association between polyfunctional T-cells and the risk to develop
303 TB disease following BCG vaccination.

304 We also observed trends of higher Th1-type cytokines in the MGIA supernatants from BCG-
305 vaccinated participants compared to the naïve. Interestingly, there was a strong significant
306 correlation between IL-10 production and reduced control of mycobacterial growth. This
307 observation replicates earlier findings, in which IL-10 was associated with reduced *ex vivo*
308 growth inhibition, and was significantly predictive of mycobacterial growth through
309 inhibition of other pro-inflammatory cytokines [36, 37]. IL-10 is known to have
310 immunosuppressive activity by inhibiting T-cell proliferation and IFN- γ production, leading
311 to reduced macrophage activation [38]. The capacity of individuals to produce IL-10 may
312 need to be considered when assessing TB vaccine effects in clinical trials.

313 In this study, the frequency of NK cells – in particular cytokine-producing NK cells – is
314 associated with enhanced *ex vivo* mycobacterial growth inhibition following historical BCG
315 vaccination. This may account for our correlation between IFN- γ ELISpot response and
316 control of mycobacterial growth as IFN- γ secreting NK cells will be measured in addition to
317 CD4 and CD8 positive T-cells. Our results again support a recent finding, in which a greater
318 frequency of putative cytokine-producing CD16⁻ NK cells was associated with reduced
319 mycobacterial growth in the multiple regression analysis of MVA85A correlate of risk study
320 [36, 39]. Cytokine-producing NK cells are the main source of NK-cell derived cytokines such
321 as IFN- γ , TNF- α and GM-CSF [40], which were modestly increased in the MGIA
322 supernatants of the BCG-vaccinated group in our study. Initially, cytotoxicity and cytokine-
323 producing functions of NK cells were regarded as two distinct functions with little synergy
324 between them [40, 41]. However, it was recently shown that IFN- γ and TNF- α could
325 synergistically enhance NK cell cytotoxicity [42]. In our study, cells obtained from BCG-
326 vaccinated participants produced a higher level of perforin and the secretion of this lytic
327 granules was associated with enhanced growth inhibition.

328 Although considered a component of innate immune system, an emerging body of evidence
329 has revealed that NK cells can also behave in a memory-like manner following infection or
330 vaccination [reviewed in [43, 44]]. NK cells isolated from pleural fluid express the memory
331 marker CD45RO and produce higher amounts of IFN- γ and IL-22 in response to stimulation
332 with IL-12, IL-15 and BCG when compared with CD45RO⁻ cells [45, 46]. Even though NK
333 cells do not have antigen receptors generated by genetic rearrangement, they possess
334 receptors which allow direct antigenic contact, resulting in subsequent cellular activation
335 [44]. This process will generate antigen-specific NK cells, which lead to enhanced response
336 following re-exposure with the same stimulus [47, 48]. In addition, work by Kleinnijenhuis *et*
337 *al.* reveals that BCG vaccination promotes augmented secondary responses towards the same
338 and unrelated stimulus through trained innate immunity mechanism [49]. The growth
339 inhibition assay has recently been shown to be able to detect contribution from the trained
340 innate immune compartment, following *Mtb* exposure or BCG vaccination, by the role of
341 nonclassical monocytes [26]. Our present study has shown the additional contribution of NK
342 cells to *ex vivo* mycobacterial growth control, and in line with this, recent clinical trials also
343 reported that immune cells associated with protection from TB disease and after BCG
344 vaccination were not T-cells, but IFN- γ -producing NK cells [50, 51].

345 Furthermore, we have demonstrated that a CMV-specific response may be associated with T-
346 cell activation, in particular in the CD8 compartment, and this activation is correlated with
347 mycobacterial growth *ex vivo*. In HIV, T-cell activation has been established as a risk factor
348 for acquisition of infection as well as progression from infection to disease [52-54]. In TB,
349 evidence has emerged denoting the role of CMV and T-cell activation on TB disease risk [18,
350 20], and our study is the first to show such association with *ex vivo* mycobacterial growth. In
351 this study, we chose to measure CMV-specific T-cell cytokine response with ICS flow
352 cytometry rather than with serology, as evidence in the literature showed that CMV-antibody
353 levels do not correlate with the size of the T-cell response against CMV and the ICS method
354 is more sensitive for detection of CMV-specific cytokine-producing T-cells [55, 56].
355 Unfortunately in this study due to a technical limitation, we were unable to perform CMV
356 serology in our cohort samples. CMV infection is recognised to drive the expansion of
357 NKG2C⁺ NK cells [57], which do not respond well to cytokine stimulation discussed above
358 [58, 59]. Further studies are required to better understand the interplay between CMV-
359 specific response, T-cell activation and NK cells in the context of BCG vaccination.

360 Differences in TB disease notification rates between the sexes are well documented and
361 thought to be a result of biological factors, in addition to social factors [11, 14, 60].
362 Therefore, it is of interest that our study demonstrated a higher capacity of BCG-vaccinated
363 females to control mycobacterial growth *ex vivo* compared to males. In conjunction to this
364 data, we found that females had a higher frequency of cytokine-producing NK cells, and
365 lower frequency of activated T-cells as well CMV-specific response. In addition, females also
366 had a lower monocyte frequency, with a trend of a lower ML ratio compared to males.
367 Altogether, these individual-level factors appear to contribute to the enhanced growth
368 inhibition in females following BCG vaccination. Such sex specific effect has also been
369 observed with measles and smallpox vaccines, where females are more protected than males
370 following vaccination [61, 62]. The epidemiological observation that the sex bias in TB does
371 not arise until puberty has suggested the important role of sex hormones [11]. In general,
372 testosterone is considered to downregulate the Th1 response, whereas estrogen is believed to
373 enhance it [14]. Moreover, genetic or epigenetic differences between sex may also play a role
374 as well in the observed sex-differential protective effect [13].

375 In summary, we have demonstrated the impact of individual-level factors on *ex vivo*
376 mycobacterial growth inhibition in a cohort of healthy, adult volunteers. Our results indicate
377 that immune cell phenotype, cytomegalovirus-specific response and sex have impacts on
378 immunity following BCG vaccination. These *ex vivo* observations are reflective of
379 epidemiological data and published human studies, and such impacts may need to be
380 considered when testing TB vaccine candidates in trial populations. Importantly, researchers
381 should consider the impact of sex in clinical vaccine studies, as the impact of sex in
382 infectious diseases is common but often neglected [63]. The MGIA assay offers an *ex vivo*
383 testing platform for assessment of a wide range of candidate TB vaccines, either using BCG
384 or virulent *Mtb* as the immune target, with the ability to reflect inter-individual variation
385 which may be important for vaccine effectiveness. The *ex vivo* MGIA is therefore an
386 important additional tool for the TB vaccine community and should continue to be assessed
387 for its ability to act as a correlate of vaccine-induced protection.

584

585

586 **Table 1.** Characteristics of study participants.

587

Characteristic	Total Participants : 100	
	Naïve (n = 37)	BCG Vaccinated (n = 63)
Female [no. (%)]	28 (75.7 %)	42 (66.7 %)
Median age [yr (range)]	31 (23 – 70)	39 (24 – 80)
Average time since BCG vaccination [yr (range)]	-	29.4 (10 – 58)
Country of Origin UK [no. (%)]	8 (21.6 %)	44 (69.8 %)

588

589 **Table 2. Summary of mean cytokine responses measured with ELISA assays**, assessed
 590 from MGIA supernatant samples after 4 days of co-culture. Comparisons were made between
 591 naïve and BCG-vaccinated groups (unpaired t-test), the values indicate mean of concentration
 592 in pg/ml [95% CI]. Correlations were assessed with *ex vivo* mycobacterial growth among
 593 responders (Spearman's correlation). A p value <0.05 was considered statistically significant
 594 (in bold), and after a multiple testing correction only values with p <0.0063 were considered
 595 significant (underlined). n= 37 BCG-naïve and n=63 BCG-vaccinated participants.
 596 ***p<0.001.

Cytokine (pg/ml)	Comparison			Correlation with <i>ex vivo</i> mycobacterial growth	
	Naïve	BCG-vaccinated	p-value	r	p-value
IFN- γ	12.47 [8.245-16.69]	23.37 [10.8-35.94]	0.1962	-0.027	0.8432
IP-10	111.7 [55.42-168]	204.5 [112.1-297]	0.1505	0.19	0.1158
TNF- α	37.97 [2.547-73.4]	97.98 [38.61-157.4]	0.1471	-0.35	0.0558
IL-12	27.6 [3.033-52.17]	63.61 [20.83-106.4]	0.2299	-0.23	0.3158
IL-10	52.55 [31.07-74.03]	59.99 [36.56-83.41]	0.6688	<u>0.37***</u>	0.0003
GM-CSF	7.729 [-1.688-17.15]	88.54 [26.19-150.9]	0.0512	-0.37	0.1552
IL-6	356.7 [246.1-467.3]	315 [236.5-393.4]	0.5293	0.071	0.5449
IL-17	0.00 [0.00-0.00]	0.1596 [0.00-0.4083]	0.3291	-0.13	0.2141

597

598 **Table 3.** Correlation of immune cell frequencies in peripheral blood and *ex vivo*
 599 mycobacterial growth inhibition. Assessment was performed from 16 BCG-naïve and 34
 600 BCG-vaccinated participants. Correlations were performed from a total of 50 participants, as
 601 well as from each naïve and BCG-vaccinated groups respectively (Spearman's correlation). A
 602 p value <0.05 was considered statistically significant (in bold), and after a multiple testing
 603 correction only values with p <0.0031 were considered significant (underlined). Note: The
 604 ML ratio was obtained by dividing the percentage of monocytes by the sum of the
 605 percentages of T- and B-cells. The NK cell ratio was obtained by dividing the percentage of
 606 cytokine-producing by cytotoxic NK cells. *p<0.05, **p<0.01.

Leukocyte subsets	Correlation with <i>ex vivo</i> mycobacterial growth					
	All participants		Naïve		BCG-vaccinated

607

608 **Table 4.** Correlation of CMV-specific T-cell responses and T-cell activation. Associations
609 were investigated from 3 different subsets of CMV-specific cytokine⁺ T-cells producing IFN-
610 γ^+ , IL-2⁺ or TNF- α^+ , respectively. Three markers were used for T-cell activation: HLA-DR,
611 LAG3 and PD1. A p value <0.05 was considered statistically significant (in bold), and after a
612 multiple testing correction only values with p <0.0083 were considered significant
613 (underlined) (Spearman's correlation). n=50 participants, consisted of 16 BCG-naïve and
614 n=34 BCG-vaccinated participants. *p<0.05, **p<0.01.

CMV-specific cytokine ⁺ T-cells	Correlation with activated T-cells					
	HLA-DR ⁺ CD4 T-cells		LAG3 ⁺ CD4 T-cells		PD1 ⁺ CD4 T-cells	
	r	p-value	r	p-value	r	p-value
IFN- γ^+ CD4 T-cells	0.026	0.8748	-0.004	0.9805	0.20	0.2112
IL-2 ⁺ CD4 T-cells	-0.045	0.7823	-0.056	0.7310	-0.0082	0.9601
TNF- α^+ CD4 T-cells	0.054	0.7401	0.058	0.7239	0.091	0.5757
	HLA-DR ⁺ CD8 T-cells		LAG3 ⁺ CD8 T-cells		PD1 ⁺ CD8 T-cells	
IFN- γ^+ CD8 T-cells	0.31	0.0552	0.39*	0.0140	<u>0.44**</u>	0.0049
IL-2 ⁺ CD8 T-cells	-0.087	0.5917	0.0024	0.9885	-0.15	0.3609

617 **Figure Legends**

618

619

620 **Figure 1. Growth inhibition and immune responses following historical BCG**
 621 **vaccination.** Assessment was performed from 37 BCG-naïve and 63 BCG-vaccinated
 622 participants. (A) Growth inhibition was compared using BCG input ~ 100 Colony Forming
 623 Unit (CFU) as immune target (unpaired t-test). Data is presented as total number of log CFUs
 624 per sample, which was determined by use of a standard curve. (B) IFN- γ production from
 625 PBMC following stimulation with PPD was compared (Mann-Whitney test). Numbers above
 626 each group represent median (range). SFC, spot forming cells. (C) The correlation between
 627 *ex vivo* growth inhibition and PPD-specific IFN- γ response was assessed (Spearman's
 628 correlation). A p value <0.05 was considered statistically significant. Dots and squares
 629 represent individual data points, and the central lines indicate the median response with inter-
 630 quartile range (IQR). ****p<0.0001.

631

632 **Figure 2. NK cells correlations.** A higher frequency of cytokine-producing NK cells
 633 (CD56^{bright} CD16⁺) correlated with enhanced *ex vivo* mycobacterial growth inhibition
 634 (Spearman's correlation) (A). A perforin ELISA was performed from MGIA supernatants
 635 and the response was compared between vaccination groups (unpaired t-test) (B). The
 636 production of perforin was associated with enhanced *ex vivo* growth inhibition (Spearman's)
 637 (C). A p value <0.05 was considered statistically significant. *p<0.05, **p<0.01.

638

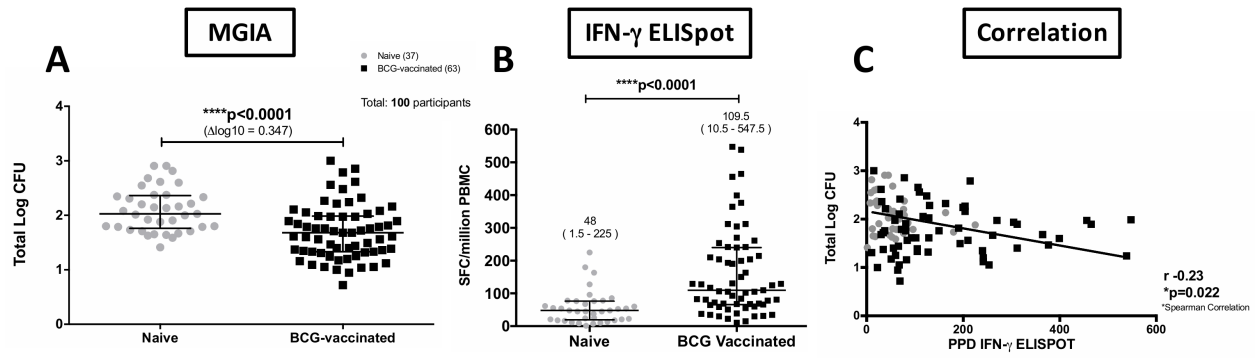

639 **Figure 3. CMV-specific responses** were associated with higher CD8 T-cell activation,
 640 expressing markers LAG3 (A-B) and PD1 (C-D) respectively. Activated CD4 and CD8 T-
 641 cells (E-J) were correlated with higher growth of mycobacteria, notably in the naïve groups
 642 (F, I). A p value <0.05 was considered statistically significant (Spearman's correlation). n=50
 643 participants, consisted of 16 BCG-naïve and 34 BCG-vaccinated participants. *p<0.05,
 644 **p<0.01.

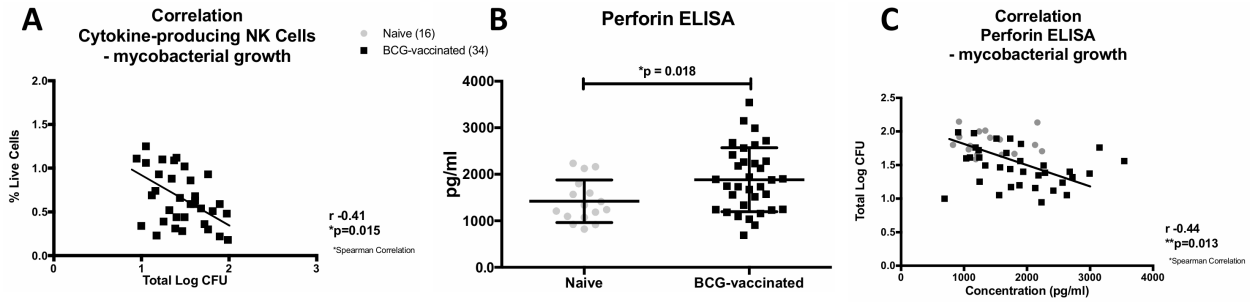

645

646 **Figure 4. Sex impact on growth inhibition and immune responses following historical**
 647 **BCG vaccination.** Assessment was performed from 37 BCG-naïve (A,C,E) and 63 BCG-
 648 vaccinated participants (B,D,F). (A-B) Growth inhibition was compared between sex and
 649 data was presented as total number of log CFUs per sample (unpaired t-test). (C-D) IFN- γ
 650 production from PBMC following stimulation with PPD was compared (Mann-Whitney test).
 651 Numbers above each group represent median (range). SFC, spot forming cells. (E-F) IP-10
 652 was measured from MGIA supernatants using ELISA assay (mean, unpaired t-test). Dots and
 653 squares represent individual data points, and the central lines indicate the median response
 654 with IQR. *p<0.05.

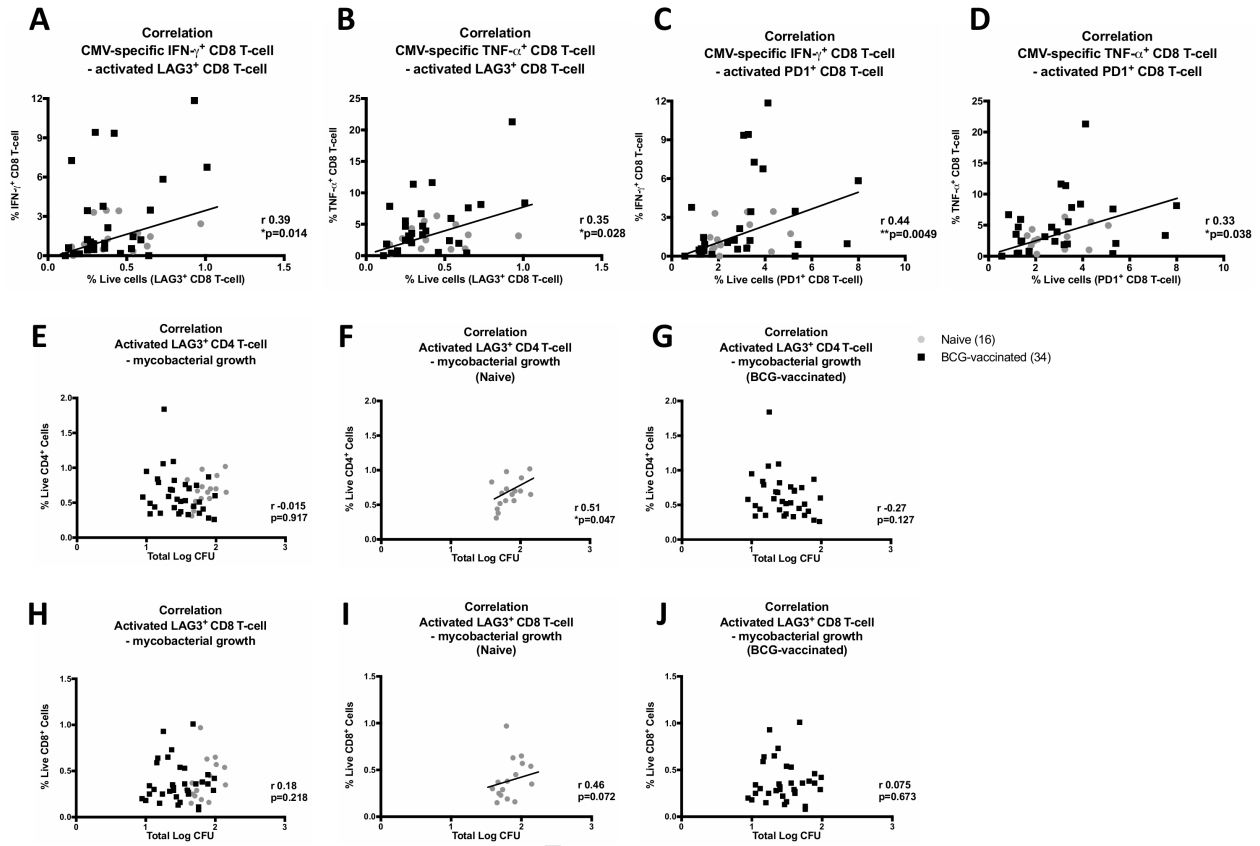

655

656 **Figure 5. Comparison by sex of immune cells phenotype (A-C), T-cell activation (D) and**
 657 **CMV-specific T-cell response (E).** Assessment was performed from 16 BCG-naïve and 34
 658 BCG-vaccinated participants. The box plots show the minimum and maximum values (ends
 659 of the whiskers), the median (band near the middle of the box) and interquartile ranges. Blue
 660 and red colour represent males and females, respectively. A p value <0.05 was considered
 661 statistically significant (Mann-Whitney). *p<0.05, **p<0.01, ****p<0.0001.
