## ACKNOWLEDGEMENTS

First of all, I would like to thank my advisor, Prof. Birman, for his immense patience and understanding while working with difficult and stubborn me, for his geniusness in what he does, for his guidance and support through my struggles as a graduate student, for all the knowledge passed to me and my fellow labmates in his classes and our group meetings, for his crazy mad scientist hair (had to add that in there), for his humbleness, curiosity in all things, his interesting and unique perspective on things, for being one step closer to home, since we share similar cultural background; I wouldn't have wanted another PI.

I would like also to extend my gratitude to my annual committee members, Prof. Moeller and Prof. Taylor, for helpful suggestions, critique, questions, answers, knowledge given in our meetings and their classes that to this day serve as invaluable resources and will continue to do so till I am old and senile. Prof. Taylor, my Italian is ugly, but I hope you understand this from Spanish: "Fue un placer aprender NMR y quimica en su franqueza". Prof. Moeller, you have a gift in teaching that I hope I will acquire with time. A special thank you to my first advisor, Prof. Gaspar, who welcomed me warmly to the PhD program here at WashU and, more importantly, gave me that initial boost of confidence and a direction to learning that I needed so much. I appreciate the kindness that Prof. Marshall and Prof. Lapi showed by accepting to serve on my committee, despite their crazy schedule, and all the arrangements they (and others too) had to do to attend my thesis defense. I will be forever thankful to all of you.

I send a big thank you (and a hug) to my fellow labmates and dear friends, Xing and Srinivas, for being just darn awesomely smart and inspiring mentors, friends, and people, for all the little conversations about Chemistry and anything under the blue moon. I didn't realized how much I
would miss them until they graduated. My gratitude also goes to Prasad, Krishna, Nick, Curtius, Guojian, Prashanth, and previous group members, who have made the lab environment so much more enjoyable. Manmilan, Sophia, and Sakshi, school was more fun because of you, so "gracias, amigos".

My acknowledgements go to the staff that have just been wonderfully supportive and helpful and that make this program spin on wheels: Dr. Rachel, Miss Jessica, Dr. Ed Hiss, Angie Stevens, the NMR experts Andre and Jeff. I also would like to extend my appreciation to Dr. Kinsley and Dr. Fields for letting me have the most amazing teaching experiences here, for their mentoring and interesting perspectives on everything.

Last but not least, thank you, thank you, thank you to my adorable son, Leon, for being the air beneath my wings, to my wonderful and the coolest on earth parents, brother, and grandparents for being my roots, to my husband, Octavian, for his belief in me, patience, and immense support, to my best friends, Dana, Liuda, Emily, and Olga for flowering my life, and to a few other special people for just existing and dancing under same sky as me.

PhD has been a journey I will never forget because of all of you, so "Multzumesc" from the bottom of my heart.

PS: Additional thanks go to the funding parties for my work: NIGMS (2005-2009), NSF (20102013), and Washington University in St. Louis. Without it, this research would not have been possible.

To my parents, my son, and my husband

## ABSTRACT OF THE DISSERTATION

# Kinetic Resolution of $\mathbf{N}$-Acyl- $\boldsymbol{\beta}$-Lactams, $\boldsymbol{\beta}$-Lactams, and $\mathbf{N}$-Acyl-Thiolactams Using Amidine-Based Catalysts 

by<br>Valentina Bumbu<br>Doctor of Philosophy in Chemistry<br>Washington University in St. Louis 2013<br>Professor Vladimir Birman, Chair

In the context of enantioselective nucleophilic acyl substitution, there are 3 types of processes depending where chirality is present: Type I, where the nucleophile (alcohol or amine) gets resolved, Type II, where chirality resides in the leaving group, and Type III, where a chiral acyl donor is attained in enantioenriched form. All these transformations can be used to physically separate enantiomers from a racemate in the presence of an asymmetric acylation catalyst and thus can be termed as "kinetic resolutions" or KR. Considerable progress has been done in the Type I transformation, where chiral alcohols, thiols, and amines are achieved with great selectivities via asymmetric enzymatic and non-enzymatic acylation. KR of chiral acyl donors (Type III) has also been accomplished using both enzymatic and non-enzymatic modes of catalysis. However, Type II process has only been reported enzymatically.

Since 2003 our group has developed 4 consecutive generations of amidine-based catalysts (ABCs) that have engaged in a variety of enantioselective acylation transformations, mostly

Type I (KR of various alcohols and lactams (and thiolactams) via asymmetric acylation) and Type III (enantioselective alcoholysis of $\alpha$-substituted acids and azlactones) processes.

As a contribution and an extension to enantioselective, catalytic, nucleophilic acyl substitution study with ABCs, my work has left a mark in all three types of processes discussed above. An unprecedented KR of N -acyl- $\beta$-lactams via enantioselective alcoholysis (Type III) has been achieved with great results. The established protocol leads to preparation of $\beta$-amino acids derivatives in enantioenriched form. Equally unique in this transformation is the mode of action of ABCs, where for the first time the nucleophilic attack of our catalysts on chiral acyl donors was in itself highly enantioselective - a phenomenon in contrast to usual behavior of ABCs in previously studied processes in our lab. Similarly novel, or at least conceptually, was the accomplishment of the first asymmetric de-acylation (Type II) process reported to date using non-enzymatic acyl transfer catalyst in the form of asymmetric alcoholysis of N -acylthiolactams. The KR poses an alternate route to obtaining enantioenriched thiazolidin-2-thiones and oxazolidine-2-thiones. And last but not least, the first enantioselective N -acylation of $\beta$ lactams (a Type I process) has been obtained with acceptable to good selectivities. This method complements the enantioselective alcoholysis of N -acyl- $\beta$-lactams, since it achieves unscathed enantioenriched $\beta$-lactams.

## Chapter I

## Introduction to Nucleophilic Acyl Substitution. Fundamentals and Terminology.

#### Abstract

1.1 Types of enantioselective nucleophilic acyl substitution in kinetic resolution

Enantioselective acyl substitution reactions may be classified according to the location of the stereogenic centers: 1) in the nucleophile Y (Type I); 2) in the leaving group X (Type II); or 3) in the acyl group (Type III) (Figure 1.1-1).

Figure 1.1-1: Three ways to induce chirality in asymmetric nucleophilic acyl substitution

These three types of processes can be exemplified by using formation and hydrolysis of esters as shown in Figures 1.1-2 and 1.1-3. In Type I process (Figures 1.1-2, left) an achiral acyl donor acylates one of the enantiomers of a racemic alcohol forming an ester, while the other enantiomer remains mostly unreacted. In Type II transformation, the reverse happens (Figures 1.1-2, right): one of the enantiomers of a racemic ester is hydrolyzed selectively. Type I and II processes will produce the same mixture of the enantioenriched alcohol and ester, if their enantioselectivities are opposite. Both enantioselective esterification of a chiral acid and the complementary hydrolysis of the corresponding ester belong to Type III process.

[^0]Figure 1.1-2: Examples of Type I and II processes

Figure 1.1-3: Examples of Type III process

All of the aforementioned transformations can be used to achieve physical separation of a racemic mixture into individual enantiomers and, thus, can be termed "kinetic resolutions" or
$K R^{1}$. By IUPAC definition, "KR is the achievement of partial or complete resolution by virtue of unequal rates of a reaction of the enantiomers in a racemate with a chiral agent (reagent, catalyst, solvent, etc.)". All three types of enantioselective nucleophilic acyl substitutions discussed above have been successfully carried out using enzymes ${ }^{2}$. Considerable progress has also been made in the development of non-enzymatic asymmetric acylation catalysts. They have accomplished considerable success especially in the KR of alcohols and, to a lesser extent, amines and thiols (Type I). ${ }^{3}$ However, until recently, there have been no reports of these catalysts working in the "reverse" to achieve enantioselective deacylation (Type II). The first non-enzymatic example of such a transformation can be found in Chapter IV of this thesis. Several examples of Type III process (enantioselective alcoholysis of activated chiral acyl donors) have also been achieved using non-enzymatic catalysts. ${ }^{4}$

The efficiency of KR is often described by selectivity factor (s), which is the ratio of relative rate constants of the two enantiomers $\left(\mathrm{s}=\mathrm{k}_{\text {fast }} / \mathrm{k}_{\text {slow }}\right)$ (Scheme 1.1-1). ${ }^{5}$ S-value remains unchanged throughout the progress of a reaction unlike enantiomeric excess (ee), which changes in the course of $K R$.

Many common asymmetric catalysts that have been effective in catalyzing acylation reactions are just chiral versions of simpler achiral catalysts, such as 4-dialkylaminopyridines (i.e. DMAP) ${ }^{6}$, N -alkylimidazoles (i.e NMI) ${ }^{7}$, phosphines (i.e. tributylphosphine) ${ }^{8}$, N heterocyclic carbenes (NHC) ${ }^{9}$ (Figure 1.1-4). They are believed to operate through a similar catalytic cycle via an acyl transfer mechanism. In the step I, the nucleophilic catalyst :Nu in the presence of an acyl donor RCOX would form a reactive intermediate (usually a zwitterionic
salt), which gets attacked by a sufficiently nucleophilic substrate Y-H in step II, forming product RCOY and releasing the catalyst :Nu for subsequent reuse.

Scheme 1.1-1: Determination of selectivity factor (s) in KR

$( \pm)$-Starting Material (SM) $\underset{\mathrm{k}_{\mathrm{R}}>\mathrm{k}_{\mathrm{S}}}{\longrightarrow}(R)$-Product $+(S)-e_{\mathrm{P}} \quad e e_{\mathrm{SM}}$
Enatiomeric Excess: $\frac{[\text { Major }]-[\text { Minor }]}{[\text { Major }]+[\text { Minor }]}$

Conversion: $\quad \mathrm{C}=\frac{e e_{\mathrm{SM}}}{e e_{\mathrm{SM}}+e e_{\mathrm{P}}}$

Selectivity factor: $\quad \mathbf{s}=\frac{\mathrm{k}_{\text {fast }}}{\mathrm{k}_{\text {slow }}}=\frac{\ln \left[(1-\mathrm{C})\left(1-e e_{\mathrm{SM}}\right)\right]}{\ln \left[(1-\mathrm{C})\left(1+e e_{\mathrm{SM}}\right)\right]}$

Calculated for $s=7$

Figure 1.1-4: Common achiral acylation catalysts and catalytic cycle

### 1.2 Acyl trasfer catalysts designed in our group and their application in Types I-III processes

From 2003 till 2009, our group designed and synthesized four consecutive generations of amidine-based catalysts (ABCs) I-1 through I-4 that operate via an enantioselective acyl transfer mechanism ${ }^{10}$ (Figure 1.2-1). Their advantages are simple design, ease of preparation, versatility, and high enantioselectivity.

Figure 1.2-1: Amidine-Based Catalysts developed in our group

Prior to the studies described in this thesis, ABCs demonstrated their efficacy in Type I KR of various secondary alcohols (benzylic, allylic, propargylic, cyclic) ${ }^{11}$, displaying good to excellent selectivity factors (Scheme 1.2-1, s-value in bold color corresponding to the catalyst used in the study, \% conversion in [brackets]). Based on experimental results later confirmed by computational studies of transition state (TS) models in KR of benzylic alcohols, the catalysts' mode of action has been described by $\pi$-cation interactions between the nucleophilic substrate and the N -acylated catalyst ${ }^{12}$. Later, ABCs were used to resolve oxazolidinones, with a similar mechanism to the one of alcohols (Scheme 1.2-2). ${ }^{13}$

Scheme 1.2-1: KR of $2^{\circ}$ alcohols using ABCs and TS model with CF $_{3}$-PIP

Scheme 1.2-2: KR of oxazolidiones using ABCs

ABCs have also proved to be successful in less explored Type III transformation with KR of acyl donors - a study pioneered by Xing Yang in our group. One could envision mechanistic similarities between the KR of alcohols and acyl donors, yet in the latter both acyl
activation and alcoholysis steps in the catalytic cycle could result in enantiodiscrimination (Scheme 1.2-3).

Scheme 1.2-3: KR of alcohols (Type I process) vs KR of acyl donors (Type III process)

Xing demonstrated that HBTM can resolve various $\alpha$-substituted carboxylic acids with good enantioselectivities ${ }^{14}$ (Scheme 1.2-4, A). Furthermore, Xing was able to accomplish the dynamic kinetic resolution (DKR) of $\alpha$-arylthio- and $\alpha$-alkylthio-alkanoic acids with great ees and yields ${ }^{15}$ (Scheme 1.2-4, B). Unlike conventional KR, DKR is based on a rapid in situ equilibration between fast- and slow-reacting enantiomers. Hence, it is a more efficient process since it can generate up $100 \%$ yield of only one enantioenriched product. In both cases (KR and DKR), Xing noticed that enantioselectivity was strongly dependent on the nature of alcohol used. The need to use the bulky di(1-naphthyl)methanol indicated that the second step in the catalytic cycle determined enantiodifferentiation, analogously to previously studied acylation of alcohols and oxazolidinones (Figure 1.2-2). Experimental results, later confirmed by computational studies ${ }^{16}$, suggested the origin of enantioselectivity stemmed from cation $-\pi$ interaction between the bulky alcohol and acylated HBTM and that the alcohol attack was according to the polar Felkin-Ahn model ${ }^{17}$. Another example of Type III process accomplished by Xing in
collaboration with Guojian Lu was the DKR of azlactones. ${ }^{18}$ This work served as a point of reference for the subsequent studies discussed in Chapter II and, hence, will be described in more detail later.

Scheme 1.2-4: KR (and DKR) of $\alpha$-substituted carboxylic acids using HBTM

Figure 1.2-2: Proposed catalytic cycle and TS model in the KR (or DKR) of $\alpha$-substituted acids

In the following chapters of this thesis, I will be describing my contribution in the enantioselective nucleophilic acyl substitution field, apart from what has been discussed above. I was fortunate to have had my work leave a mark in all Types I-III processes using ABCs developed in our group.

## Chapter II

## Kinetic Resolution of N-Acyl- $\beta$-Lactams via Enantioselective Alcoholysis using Amidine-based Catalysts

### 2.1 Introduction

Due to their specific biological properties, $\beta$-amino acids and their derivatives have been known and used in various applications ${ }^{1}$. There are many approaches to their preparation in enantiopure form, one of which is through ring opening of enantioenriched $\beta$-lactams or $\beta$-lactam derivatives ${ }^{2}$. Despite the breakthroughs in the asymmetric synthesis of the latter, the $\beta$-lactam substrate scope often remained limited ${ }^{3}$. Hence, the enzymatic hydrolysis of their racemates ${ }^{4}$ still remains a viable method for preparing enantiopure $\beta$-amino acids ${ }^{5}$ (Scheme 2.1-1). Despite their high efficacy, enzymes have serious shortcomings, such as availability only in one enantiomeric form, narrow substrate or reaction scope, and/or, at times, high cost.

Scheme 2.1-1: Enzymatic approaches to KR of $\beta$-lactams

Although non-enzymatic kinetic resolution (KR) of $\beta$-lactam racemates would be an attractive method to obtain enantioenriched $\beta$-amino acids, to the best of our knowledge, it has
not been reported until our work in this area ${ }^{6,7}$. Hence, in this chapter, I will be describing the first enantioselective alcoholysis of $\beta$-lactam derivatives and my efforts to elucidate the mechanism of this process using ABCs I-2 through I-4.

In the investigation of KR of various chiral acyl donors $^{8}$, Xing Yang in collaboration with Guojian Lu has developed a protocol for DKR of azlactones ${ }^{9}$ (Scheme 2.1-2) to obtain enantioenriched $\alpha$-amino acids. They have noticed that changing the amount of benzoic acid relative to the catalyst did not have a significant effect on the reaction rate or enantioselectivity, although in its absence the reaction did not seem to proceed at all. Such activation with Brønsted acid in combination with an enantioselective acyl transfer catalyst has been previously reported by others. ${ }^{10}$ Apart from that, the catalytic cycle and catalyst's mode of action in this process seemed to be consistent with ABCs previous behavior (Figure 2.1-1), ${ }^{8,11,12}$. The success of the DKR of azlactones with BTM led me to investigate other classes of chiral acyl donors that could use a combination of ABC with a Brønsted acid and that would generate enantioenriched products of practical use.

Scheme 2.1-2: DKR of azlactones

Figure 2.1-2: Proposed catalytic cycle and origin of enantioselectivity in DKR of azlactones

### 2.2 Experimental design and findings

Initially we turned our attention to oxazinones, the ring-expanded homologues of azlactones, which would lead to enantioenriched $\beta$-amino acid derivatives. The KR of oxazinones has been previously achieved by Berkessel et al using a bifunctional thiourea catalyst with impressive selectivities ${ }^{13}$. When 4-phenyl oxazinone II-1 was subjected to KR with di(1-naphthyl)methanol in the presence of our catalytic system it did react, however, the selectivity was disappointingly low (Table 2.2-1, entry 1). Interestingly, when less hindered alcohols were used, the results were approximately the same (entries 2,3).

Table 2.2-1: KR of oxazinone ( $\pm$ )-II-1: Alcohol screening ${ }^{\text {a }}$

| Entry | R | Conversion (\%) | s |
| :---: | :---: | :---: | :---: |
| 1 | $(1-\mathrm{Np})_{2} \mathrm{CH}(\mathbf{I I}-2 a)$ | 56 | 3.9 |
| 2 | $\mathrm{PhCH}_{2}(\mathbf{I I}-2 b)$ | 51 | 2.9 |
| 3 | $\mathrm{Me}(\mathbf{I I}-2 \mathbf{c})$ | 48 | 3.3 |

Reaction conditions: $0.1 \mathrm{mmol}( \pm)-\mathrm{II}-1,0.05 \mathrm{mmol} \mathrm{ROH},(\mathrm{S})-\mathrm{BTM}(10 \mathrm{mmol} \%), \mathrm{PhCO}_{2} \mathrm{H}(10 \mathrm{mmol} \%)$, in $\mathrm{CDCl}_{3}$, rt. [a] Results averaged from duplicate runs

This suggested that the mechanism of this transformation might be entirely different from what was observed in the DKR of azlactones, where enantioselectivity depended critically on the alcohol used. The absence of such dependence in the case of oxazinones indicated to us that enantioselectivity might arise in the first step in the catalytic cycle. Witnessing a new phenomenon, we were excited about its prospects despite initial disappointing results. Therefore, we decided to try the KR of N -acyl- $\beta$-lactam II-3a, the constitutional isomer of II-1 (Figure 2.2-1). Since II-3a would produce the same reactive intermediate II-4 upon ring-opening as II-1, we reasoned that the N -acyl- $\beta$-lactam could potentially undergo KR in similar fashion to $\mathbf{I I}-\mathbf{1}$ in the presence of BTM, but hopefully with better enantioselectivity.

Figure 2.2-1: Proposed catalytic cycle for oxazinone II-1 and N-acyl- $\beta$-lactam II-3a

Gratifyingly, when I tried the KR conditions with di(1-naphthyl)methanol on N-bezoyl-4-phenyl- $\beta$-lactam II-3a, the selectivity significantly improved (Table 2.2-2, entry 1 ). Furthermore, again, switching to less hindered alcohols gave essentially the same results with this substrate (entries 2,3), suggesting a similar mechanism as in the case of oxazinone II-1 (Figure 2.2-1). This observation seemed to indicate that the enantioselectivity-determining step is irreversible and that N -acyl- $\beta$-lactams are more suitable substrates for appreciable induction of asymmetry during the nucleophilic attack of our catalyst than oxazinones.

Table 2.2-2: KR of N-acyl- $\beta$-lactam ( $\pm$ )-II-3a: Alcohol screening ${ }^{\text {a }}$

| Entry $^{\mathrm{a}}$ | R | Time (hrs) | Conversion (\%) | s |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $(1-\mathrm{Np})_{2} \mathrm{CH}$ (II-2a’’’) | 68 | 51 | 21 |
| 2 | PhCH $_{2}$ (II-2a’’) | 68 | 52 | 19 |
| 3 | Me (II-2a') | 24 | 52 | 21 |

General conditions: $0.1 \mathrm{mmol}( \pm)-\mathrm{II}-3 \mathrm{a}, 0.5 \mathrm{mmol} \mathrm{ROH}, 10 \mathrm{~mol} \%(S)-\mathrm{BTM}, 10 \mathrm{~mol} \% \mathrm{PhCO}_{2} \mathrm{H}, \mathrm{in} \mathrm{CDCl}_{3}$, rt. [a] Results averaged from duplicate runs

As part of the optimization study, I briefly investigated whether a Lewis acid (LA) could also be applied to the catalytic alcoholysis of N -acyl- $\beta$-lactam II-3a with comparable mode of action to benzoic acid. It was a challenge, however, to find common Lewis acids that would dissolve in chloroform and, hence, to run accurate and reproducible experiments (I could not
make stock solutions and working with very small amounts of Lewis acids could have led to experimental errors). When $\mathrm{LiBF}_{4}$ was tried in the KR of II-3a with benzyl alcohol, despite its poor solubility, it did give similar selectivity and reaction times to the case of benzoic acid (Scheme 2.2-1).

Scheme 2.2-1: KR of N-acyl- $\beta$-lactam ( $\pm$ )-II-3a in presence of a Lewis Acid

Mindful of the fact that LAs could potentially catalyze alcoholysis of the substrates by themselves, a qualitative background test with several Lewis acids varying in potency was performed (Table 2.2-3). These results indicate that some $\mathrm{LAs}, \mathrm{Sc}(\mathrm{OTf})_{3}$ and $\mathrm{Cu}(\mathrm{OTf})_{2}$, do indeed catalyze the alcoholysis of N -acyl- $\beta$-lactams. This observation could provide some ideas for future new designs of asymmetric catalysts including the corresponding metals. Since LAs did not offer any apparent advantages compared to benzoic acid, we continued to use the latter in our optimization study.

Table 2.2-3: Lewis acid background reaction check for $N$-acyl- $\beta$-lactam ( $\pm$ )-II-3a

| Entry | Lewis Acid (10 mol\%) | Solubility of LA <br> in $\mathrm{CDCl}_{3}$ | Time | Background reaction |
| :---: | :---: | :---: | :---: | :---: |
| 1 | LiCl | Not soluble | 40 hrs | no |
| 2 | $\mathrm{Mg}\left(\mathrm{ClO}_{4}\right)_{2}$ | Not soluble | 40 hrs | no |
| 4 | $\mathrm{Sc}(\mathrm{OTf})_{3}$ | Not soluble | 17 hrs | Only ester product observed |
| 6 | $\mathrm{Cu}(\mathrm{OTf})_{2}$ | Not soluble | 17 hrs | Only ester product observed |
| 7 | $\mathrm{Zn}(\mathrm{OTf})_{2}$ | Not soluble | 40 hrs | no |
| 8 | $\mathrm{ZnBr}_{2}$ | Not soluble | 40 hrs | no |

Reaction conditions: $0.1 \mathrm{mmol}( \pm)-\mathrm{II}-3 \mathrm{a}$ and 0.1 mmol BnOH in $\mathrm{CDCl}_{3}, 0.01 \mathrm{mmol}$ Lewis Acid, rt.

We then proceeded to test our other most potent ABCs, HBTM I-4a and Cl-PIQ I-2
(Table 2.2-4). Although the alcoholysis occurred in both cases, the KR proved to be less enantioselective than in the one of BTM ent-I-3 (Entries 3,4 vs 2). As expected, no reaction happened in the absence of catalyst (entry 1).

Table 2.2-4: KR of N-acyl- $\beta$-lactam ( $\pm$ )-II-3a: Catalyst screening ${ }^{a}$

| Entry $^{\mathrm{a}}$ | Catalyst | Time (days) | Conversion (\%) | s |
| :---: | :---: | :---: | :---: | :---: |
| 1 | none | 1 | $\mathrm{NR}^{\mathrm{b}}$ | $\mathrm{ND}^{\mathrm{C}}$ |
| 2 | $(S)-$ BTM ent-I-3 | 1 | 60 | 18 |
| 3 | $(S)-H B T M ~ I-4 a$ | 3 | 62 | $12^{-1}$ |

| 4 | $(R)-C l-P I Q ~ I-2 ~$ | 7 | 42 | $2.5^{-1}$ |
| :---: | :---: | :---: | :---: | :---: |

General conditions: $0.1 \mathrm{mmol}( \pm)$-II-3a, 0.075 mmol ROH , catalyst ( $10 \mathrm{~mol} \%$ ), $\mathrm{PhCO}_{2} \mathrm{H}(10 \mathrm{~mol} \%)$, in $\mathrm{CDCl}_{3}$, rt. [a] Results averaged from duplicate runs. [b] Determined by H ${ }^{1}$ NMR. [c] No reaction. [d] Not determined

The variation of acyl group on the $\beta$-lactam nitrogen was explored next (Table 2.2-5). Both $N$-Boc II-3b and $N$-isobutyryl II-3c derivatives were unreactive (entries 2,3). Introducing an electron-withdrawing group to the benzoyl substituent proved to affect both the rate and the enantioselectivity in this process. 4-Chlorobenzoyl derivative underwent KR with an appreciable enhancement of selectivity factor with similar rate compared to the benzoyl compound (entry 4). When reaction was run at $0^{\circ} \mathrm{C}$, the enantioselectivity did improve notably, but the rate was much too slow to be considered practical (entry 5). However, 4-Nitrobenzoyl group demonstrated, as expected, the acceleration in methanolysis rate led to a diminished enantioselectivity (entry 6). The selectivity factor did not improve when the temperature of the reaction was lowered to $0^{\circ} \mathrm{C}$ (entry 7). 3,5-Dinotrobenzoyl substrate II-3f underwent ring-opening even faster, but with considerably lower selectivity factor (entry 8).

Table 2.2-5: KR of N -acyl- $\beta$-lactam ( $\pm$ )-II-3a: N -acyl group screening ${ }^{\text {a }}$

| Entry $^{\mathrm{a}}$ | R | Time | Conversion (\%) | s |
| :---: | :---: | :---: | :---: | :---: |
| 1 | Ph | 24 hrs | 60 | 18 |
| 2 | OBu-t (II-3b) | 7 days | NR | ND |
| 3 | $\mathrm{Me}_{2} \mathrm{CH}(\mathbf{I I}-3 \mathbf{c})$ | 7 days | NR | ND |

| 4 | $p-\mathrm{ClC}_{6} \mathrm{H}_{4}(\mathbf{I I}-\mathbf{3 d})$ | 20 hrs | 53 | 26 |
| :---: | :---: | :---: | :---: | :---: |
| $5^{\text {b }}$ | $p-\mathrm{ClC}_{6} \mathrm{H}_{4}(\mathbf{I I}-\mathbf{3 d})$ | 7 days | 51 | 37 |

| 8 | $3,5-\left(\mathrm{NO}_{2}\right)_{2} \mathrm{C}_{6} \mathrm{H}_{4}(\mathbf{I I}-\mathbf{3 f})$ | 1 hrs | 72 | 2.6 |

General conditions: $0.1 \mathrm{mmol}( \pm)-\mathbf{I I}-3,0.05 \mathrm{mmol} \mathrm{MeOH}, 10 \mathrm{~mol} \%(S)-\mathrm{BTM}, 10 \mathrm{~mol} \% \mathrm{PhCO}_{2} \mathrm{H}$, in $\mathrm{CDCl}_{3}$, rt. [a] Results based on duplicate runs [b] Reaction conducted at $0^{\circ} \mathrm{C}$.

Due to the limited solubility of N -benzoyl- $\beta$-lactams, the solvent screening was a relatively short process (Table 2.2-6). The substrate II-3d dissolved best in chloroform and methylene chloride, the latter leading to a lower selectivity factor (entry 2 vs 1). Toluene gave comparable enantioselectivity to chloroform, albeit at a more sluggish rate (entry 3). Additionally, it was a poor medium for a smooth KR as the starting material precipitated out within minutes from the beginning of reaction despite a decrease in concentration, affecting the accuracy of results. Although the substrate displayed better solubility in acetonitrile than toluene, the selectivity suffered significantly (entry 4). Tetrahydrofuran seemed to be an unsuitable solvent for this system altogether, as the reaction was very slow and led to undesired side products that complicated the purification and analysis process (entry 5).

Table 2.2-6: KR of N-acyl- $\beta$-lactam ( $\pm$ )-II-3d: Solvent screening ${ }^{\text {a }}$

| Entry $^{\mathrm{a}}$ | Solvent | Time (days) | Conversion (\%) | s |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathrm{CDCl}_{3}$ | 1.5 | 47 | 28 |
| 2 | $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ | 3.5 | 55 | 20.5 |
| 3 | $\mathrm{~d}^{8}$-toluene | 7 | 38 | 29 |
| 4 | $\mathrm{CD}_{3} \mathrm{CN}$ | 3.5 | 54 | 12 |
| 5 | $\mathrm{~d}^{8}-\mathrm{THF}$ | 7 | $20^{b}$ | ND |

General conditions: $0.1 \mathrm{mmol}( \pm)-\mathbf{I I}-\mathbf{3 d}, 0.075 \mathrm{mmol} \mathrm{MeOH}, 10 \mathrm{~mol} \%(R)-\mathrm{BTM}, 10 \mathrm{~mol} \% \mathrm{PhCO}_{2} \mathrm{H}$, in solvent, rt. [a] Results based on duplicate runs [b] Determined by $\mathrm{H}^{1}$ NMR

Once the optimization process was completed, we began to investigate the substrate scope (Table 2.2-7). Surprisingly, having $\mathrm{R}^{3}$ changed from phenyl to 1-napthyl improved enantioselectivity only slightly (entry 2 vs 1 ), while isopropyl substituent gave an unexpectedly impressive selectivity factor of 78 (entry 3 ). To our delight, once cis-ring-fused N -acyl- $\beta$-lactams from II-7 to II-12 were subjected to the same KR conditions, the results were even more exciting, enantioselectivities ranging from 111 to 211 (entries 4-9). Unfortunately, when we switched to trans-disubstituted monocyclic substrate II-13, it failed to react completely over the course of one week (entry 10).

Table 2.2-7: KR of N -acyl- $\beta$-lactams: Substrate scope ${ }^{\text {a }}$

| 9 |  | 32 h | 96 | 82 | 46 | 124 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  | $\mathbf{I I - 1 2}$ |  | 7 d | ND | ND | NR |

General conditions: $0.1 \mathrm{mmol}( \pm)$-substrate, $0.075 \mathrm{mmol} \mathrm{MeOH}, 10 \mathrm{~mol} \%(S)-\mathrm{BTM}, 10 \mathrm{~mol} \% \mathrm{PhCO}_{2} \mathrm{H}$, in $\mathrm{CDCl}_{3}$, rt. [a] Results based on duplicate runs. [b]The absolute configuration of the fast reacting enantiomer shown.

To demonstrate the practical utility of this process, the KR of substrate II-11 on a 1-gram scale was performed, giving similar results to the small scale KR of the same substrate, with excellent yields of enantioenriched species and a 76\% catalyst recovery (Scheme 2.2-2).

Scheme 2.2-2: Preparative-scale KR of N-acyl- $\beta$-lactam ( $\pm$ )-II-11

To explain the origin of enantioselectivity, we initially envisioned that the catalyst would prefer a facial attack on $\beta$-lactam carbonyl with the N -benzoyl group away from the catalyst’s phenyl substituent at C-2 to avoid steric interactions with the ring hydrogens (Figure 2.2-2).

Figure 2.2-2: Initial proposed model for enantiodiscrimination in KR of N -acyl- $\beta$-lactams

The proposed model also explained the increase in enantioselectivity with cis-ring-fused substrates and lack of reaction with trans-substituted N -acyl- $\beta$-lactams. Having $\mathrm{R}^{2}$ and $\mathrm{R}^{3}$ groups cis to each other would only enhance the blockage on the face they are pointing towards, while trans substitution would hinder the catalyst attack from either face. The model excluded the acid, since it was unclear to us at that time what role it played.

Subsequent preliminary computational studies on II-3a, however, demonstrated that our initially proposed model was too simplistic, even if it accounted for the available experimental results (Figure 2.2-3). The transition states were built with Xing Yang's help introducing two important interactions, not taken in consideration in our initial proposed model for enantiodifferentiation: 1) the $\pi$-cation interaction between the benzothiazolium moiety and phenyl in the aroyl group of N -acyl- $\beta$-lactam and 2 ) the $\mathrm{S}-\mathrm{O}$ interaction, where the amide
carbonyl from the $\beta$-lactam core lies in the same plane as the catalyst and is directed toward its benzothiazolium part (Figure 2.2-3). Throughout this study, the method used was Gaussian, DFT B3LYP/3-21G(d). According to these preliminary calculations, the fast-reacting enantiomer (in TS-(S)-BTM-(R)-II-3a) was favored energetically by $4.5 \mathrm{kcal} / \mathrm{mol}$ over the slow-reacting enantiomer (TS-(S)-BTM-(S)-II-3a), presumably due to taking advantage of the $\pi$-cation stacking. The S-O interaction stays prevalent in both TSs ( $\sim 2.5 \AA$ ). That said, please note that these studies are crude and might provide only qualitative clues to the substrate chiral recognition in this KR. Additional research needs to be performed to explore all possible TSs before we can confirm that the proposed draft models do indeed represent the global minima. Those have not yet been carried out due to limited time and demand of expertise in computational chemistry and software.

Figure 2.2-3: Preliminary computational studies of TSs of fast- and slow-reacting enantiomers of II-3a

TS-(S)-BTM-(R)-II-3a
$\Delta \Delta \mathrm{G}^{\ddagger}=0.0 \mathrm{kcal} / \mathrm{mol}$

TS-(S)-BTM-(S)-II-3a
$\Delta \Delta \mathrm{G}^{\ddagger}=4.5 \mathrm{kcal} / \mathrm{mol}$

### 2.3 An extension to the study on other modes of catalysis and the role of the Brønsted acid in the KR of $\mathbf{N}$-acyl- $\boldsymbol{\beta}$-lactams

After examining enantioselective alcoholysis of N -acyl- $\beta$-lactams promoted by $\mathrm{ABCs}^{14}$, we were curious whether other known types of asymmetric catalysts might also be effective in this process. Keeping in mind that chiral thioureas were highly successful in the alcoholysis of azlactones ${ }^{15}$ and oxazinones ${ }^{13 a}$, we tested the catalysts II-14 through II-16 available in our lab. Among these only II-15 proved to be catalytically active in the KR of II-11. However, the enantioselectivity was low (Table 3.2-1, entry 2). Switching the solvent to toluene or acetonitrile did not change the outcome (entries 3, 4). Chiral phosphoric acid-based catalyst II-17 previously identified in our lab by Guojian Lu as an efficient catalyst in the DKR of azlactones ${ }^{16}$, also turned out to be completely ineffective (entry 5).

Table 2.3-1: KR of N-acyl- $\beta$-lactam ( $\pm$ )-II-11: Screening of other catalysts ${ }^{\text {a }}$

| Entry $^{\mathrm{a}}$ | Catalyst | Time <br> (days) | ee $\mathrm{ex}_{\mathrm{PR}}$ (\%) | ee $\mathrm{e}_{\mathrm{SM}}$ (\%) | Conv (\%) | s |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 6 | $\mathbf{I I - 1 7}$ | 7 | ND | ND | NR | ND |

General conditions: $0.05 \mathrm{mmol}( \pm)$-II-11, $0.025 \mathrm{mmol} \mathrm{MeOH}, 10 \mathrm{~mol} \%$ catalyst, in $\mathrm{CDCl}_{3}$, rt, unless otherwise specified. [a] Results averaged from duplicate runs. [b] Reaction conducted in toluene. [c] Reaction conducted in acetonitrile

We soon shifted our attention to the investigation of the role of acid (benzoic acid in this case) in the KR of N -acyl- $\beta$-lactam. Initially we thought that Brønsted acid (or Lewis acid) was paramount to the KR of N-acyl- $\beta$-lactams, as in the case of the DKR of azlactones, where the reaction would not proceed at all in its absence. However, when benzoic acid was omitted from our standard alcoholysis protocol, the ring-opening did occur, albeit with a reduced selectivity (Scheme 2.3-1). We also noticed the formation of a side product by $\mathrm{H}^{1}$ NMR that was not observed previously in the presence of $\mathrm{PhCO}_{2} \mathrm{H}$. The initial attempt to collect it and analyze it after purification failed, as it would decompose on silica gel. We came to suspect, however, that the mysterious side product might be the isomeric oxazinone II-1a. That indeed was the case when compound II-1a was synthesized according to a modified procedure established by Berkessel et al ${ }^{13}$. The unique sets of doublet of doublets at $5.04,3.04$, and 2.64 ppm of $\mathbf{I I}-\mathbf{1 a}$ matched very closely the ones of previously reported II-1 (5.07, 3.06, and 2.68 ppm ).

Scheme 2.3-1: KR of N -acyl- $\beta$-lactam ( $\pm$ )-II-3d in the absence of benzoic acid

We initially reasoned that the formation of an oxazinone, which KR was not as effective as in the case of N -acyl- $\beta$-lactams under our protocol, might be the culprit of lower ester enantioselectivity when acid was not added. For that to be true we needed to demonstrate that the oxazinone II-1a formed was not enantioenriched. To measure the $e e$ and monitor the formation of oxazinone over time, KR of N -acyl- $\beta$-lactam II-3d was run in the presence and absence of benzoic acid and analyzed by $\mathrm{H}^{1}$ NMR using 2,6-methoxytoluene as an internal standard (Scheme 2.3-2). In the absence of acid, we noticed that initially ester and oxazinone were forming at approximately the same rate, but at around the $4^{\text {th }}$ hour the ester stopped forming while the N -acyl- $\beta$-lactam continued to get consumed, leading to more oxazinone in solution. Furthermore, after careful purification and analysis, the oxazinone II-1a's ee was comparable to that of unreacted starting material and ester. This process was a case where we formed 3 enantioenriched species and we no longer could discuss enantioselectivity in terms of conversion and selectivity factor as we did in Chapter I, 1.1. We used an alternative equation, also devised by Kagan ${ }^{16}$, to calculate the selectivity factor to account only for the product formed: $s=\ln [1-$ $\left.\mathrm{C}\left(1+\mathrm{ee}_{\mathrm{PR}}\right)\right] / \ln \left[1-\mathrm{C}\left(1-\mathrm{ee}_{\mathrm{PR}}\right)\right]$, where C (\% conv) was determined by ${ }^{1} \mathrm{H}$ NMR. On the other hand,
in the presence of acid, oxazinone II-1a was barely detectable by $\mathrm{H}^{1} \mathrm{NMR}$, which explained why it has not been noticed before.

Scheme 2.3-2: KR of N-acyl- $\beta$-lactam ( $\pm$ )-II-3d in the presence and absence of acid

All these findings were puzzling to us, because although we had more details on the acid's mechanistic role, we could not explain why the ees were lower in the absence of acid. The opening of the oxazinone under this catalytic system would produce product ester equally or very similarly enantioenriched as the one produced by opening the fast-reacting N -acyl- $\beta$-lactam enantiomer. That said, it is noteworthy to mention a $10 \%$ discrepancy between the percentage of N -acyl- $\beta$-lactam used and the percentage sum of products formed, which may be due to inaccuracy in weighing of reagents and/or analyzing ${ }^{1} \mathrm{H}$ NMR spectra.

To get more insights on the mechanism of this transformation, a series of reactions were performed by tweaking the catalytic system (Table 2.3-2). As expected, no reaction happened in the absence of catalyst within 24 hours, with or without benzoic acid (entries 5,4 ). We were wondering if increasing the amount of acid in the presence of our catalyst would further improve the selectivity factor, and that did not seem to be the case when amount of benzoic acid was changed to $20 \mathrm{~mol} \%$ or $50 \mathrm{~mol} \%$ (entries 2, 3). Eliminating the possibility that this process might
be base catalyzed, BTM I-3 was substituted with 1 equivalent of 2,6-collidine and only $15 \%$ conversion after 48 hours was observed (however, no ester peaks were visible after 24 hours).

Table 2.3-2: KR of N -acyl- $\beta$-lactam ( $\pm$ )-II-3d: Testing the catalytic system

With no methanol in the reaction medium, we could technically achieve the KR of N -acyl- $\beta$-lactams to obtain enantioenriched oxazinones (Scheme 2.3-3). This in itself could be an interesting study to be investigated alone. Again the presence of Brønsted acid made a difference in the selectivity factor and reaction times. Albeit the reaction occurred at a slower rate, the acid seemed to contribute somehow towards higher enantioselectivity ( $\mathrm{s}=45$ vs 35 ).

Scheme 2.3-3: KR of N-acyl- $\beta$-lactam ( $\pm$ )-II-3d in the absence of methanol

Interestingly, when the KR of oxazinone II-1a was investigated in the presence and absence of acid, it was not a discrepancy in selectivities that became visible, but in rates (Scheme 2.3-4). Using benzoic acid, the KR happened three times faster compared to KR in the absence of acid. This could suggest that the acid not only hindered the formation of oxazinone but also sped up its alcoholysis (in case any oxazinone did form) so it would not linger in the reaction mixture as much as it did when no acid was there.

Scheme 2.3-4: KR of oxazinone ( $\pm$ )-II-1a in absence and presence of acid

Based on all these findings we proposed the mechanism of acid's role in the process of asymmetric alcoholysis of N -acyl- $\beta$-lactams described in Figure 2.3-1.

Figure 2.3-1: Proposed mechanism of acid's role in alcoholysis of N -acyl- $\beta$-lactam II-3d

In the set of conditions $\boldsymbol{a}$ (BTM I-3, $\mathrm{PhCO}_{2} \mathrm{H}, \mathrm{MeOH}$ ), the nucleophilic attack of BTM I3 would generate reactive intermediate II-18a (benzoate counterion omitted for clarity). Experimental results did suggest oxazinone II-1a formation, but we have reason to believe that the direction of equilibrium would be more towards the intermediate II-18a, since the amide moiety is not as nucleophilic in protonated form for subsequent cycloaddition. Even when oxazinone II-1a forms, it would be in activated form, which would become more susceptible to ring opening back to intermediate $\mathbf{I I}-\mathbf{1 8 a}$. It could also be that the rate of methanolysis was faster than that of forming the oxazinone II-1a. In the set of conditions $\boldsymbol{b}$ (BTM I-3, MeOH), the attack
of the catalyst would form the zwitterion II-18b, which possesses a nucleophilic amide moiety that could lead to the cyclized I-1a more readily than in the case of protonated intermediate II18a. Having witnessed experimentally a build-up of oxazinone I-1a in this case and a reduction in ester product II-2d' formation might suggest a difference in rates of methanolysis and oxazinone II-1a formation. This scheme might hypothesize more on the mechanism of acid's mode of action, but it does not explain how its addition helps/leads to a more enantioselective process. Showing an equilibrium between zwitterionic intermediate II-18b and oxazinone I-1a contradicts our initial statement that in the case of KR of oxazinone the first step in the catalytic cycle would be irreversible. At this point, it would be more cautious to say that the first step is just the enantioselectivity determining step in the case of KR of oxazinones, since no apparent improvement in selectivity was observed when bulkier alcohols were added instead of methanol. However, in the case of alcoholysis of N -acyl- $\beta$-lactams, the likelihood of reversibility in the first step in the catalytic cycle (attack of catalyst on the chiral acyl donor) is minimal, due to energetically disfavored formation of a strained 4-membered lactam ring under those set of mild conditions.

As a result, this project was more complex and time-consuming than envisioned and additional tools, such as computational and more careful kinetic studies, are needed to untangle it - an investigation that prevails in the group's future plans.

### 2.4 Substrate synthesis

Despite that racemic $\beta$-lactams have been mentioned in numerous studies, their synthesis to achieve a wide scope of substrates with decent yields was not a trivial matter. Hence, it is
noteworthy to discuss the methods that were used in making them and some of the challenges we have encountered while doing so.

Racemic $\beta$-lactams can be obtained via three main approaches (Figure 2.4-1): 1) [2+2] reaction of olefins with clorosulfonyl isocyanate (CSI) ${ }^{4 a, b, e}$ (Eq. 1); 2) Enolate-imine cyclocondensation ${ }^{18}$ (Eq. 2); 3) Staudinger reaction ([2+2] reaction of ketenes generated in situ and imines) followed by CAN deprotection (Eq. 3).

From all these methods, the one depicted in Eq. 1 was the most efficient, when conditions were previously reported for particular cases or established by trial and error in our lab. Substrates II-19, III-4 (see Chapter III), and all the cis-ring-fused $\beta$-lactams were generated by this method. However, the [2+2] cycloaddition of each substrate depended on different and special conditions: temperature (from $0^{\circ} \mathrm{C}$ to reflux at $80^{\circ} \mathrm{C}$ ), reaction time (from 2 hours to 3 days), solvent (neat, diethyl ether, methylene chloride, toluene). If one parameter was changed for optimization purposes, it raised the risk of obtaining little to no product at all. Hence, it was impossible to operate under one general procedure. Due to their similarity in structures, it was puzzling to us why their synthesis was so particular to each case. The enolate-imine cyclocondesation (Eq. 2) was an equally important route to obtaining the substrates (especially the ones used in Chapter III) we could not otherwise make using the one discussed in Eq. 1. The method, however, was not efficient and produced low yields of desired product with numerable undesired ones, making the purification process painful. Even though, at times, I had to repeat the procedure more than once just to obtain enough material for further processing, it was gratifying to have generated products not previously achieved under any other method. I did, however, fail to make the methyl- and o-methylphenyl-substituted $\beta$-lactams using this route.

Figure 2.4-1: Methods for $\beta$-lactam synthesis

To extend the study on other substrates with practical utility, I intended to synthesize II20, II-21, and II-22 under method described in Eq. 3, having the starting materials readily available in our lab. In the case of II-20, the Staudinger reaction failed, despite trying two different protocols using the same starting materials ${ }^{19}$. In the cases of substrates $\mathbf{I I}-\mathbf{2 1}^{6 \mathrm{c}, \mathrm{d}, 20}$ and $\mathbf{I I}-\mathbf{2 2}^{21}$, the Staudinger reaction itself occurred as previously described in the literature (with up
to $40 \%$ yield). The unreported deprotection with CAN of II-22 PMP-protected derivative was troublesome and, despite all efforts taken, I was not successful at obtaining the desired product II-22. The substrate II-21 was relevant to taxol synthesis ${ }^{6}$ and the reported CAN oxidation of its PMP-protected derivative did lead to II-21, although in disappointing yield overall. However, benzoylation of II-21 generated two compounds in 1:3 ratio. The one in least amount seemed to be the desired product. Unfortunately, I did not have enough material to be tested in the subsequent KR and had to repeat the whole synthesis again to obtain more substrate II-21. Due to unexpected difficulties encountered in the preparation of other substrates, this study of substrate scope was postponed, and we moved on to other pending projects that were seeking immediate attention.

### 2.5 Conclusion

The asymmetric alcoholysis of N -acyl- $\beta$-lactams with BTM has proven to be an effective method of obtaining enantioenriched $\beta$-amino acids. This transformation demonstrates for the first time that the nucleophilic attack of ABC on chiral acyl donors can in itself be highly enantioselective - a phenomenon in high contrast to the usual behavior of these catalysts. Cis ring-fused substrates display higher enantioselectivity. The plausible origin of enantioselectivity has been discussed/debated. Brønsted acid was necessary for higher enantioselectivity, but was not paramount to the occurrence of the KR. The mechanistic role of the acid in this transformation remains yet unclear and will be subject to further investigation in our group, along with extension of this mechanism to other classes of substrates.

## Chapter III

# Kinetic Resolution of $\boldsymbol{\beta}$-Lactams via Enantioselective $\mathbf{N}$-Acylation using Amidine-based Catalysts 

### 3.1 Introduction

$\beta$-Lactams have had a well-known application in pharmaceuticals (e.g. antibiotics ${ }^{1}$ and cholesterol lowering drugs ${ }^{2}$ ) and have been serving as versatile intermediates in the preparation of other classes of organic compounds (e.g. amino acids derivatives, nylon-3 polymers, etc.) ${ }^{3}$. Despite successfully accomplishing the asymmetric alcoholysis of $N$-acyl- $\beta$-lactams ${ }^{4}$ in our lab, the method does not generate enantioenriched $\beta$-lactams, since deprotection of the N -acyl- $\beta$ lactam would cause ring opening. Asymmetric synthesis of $\beta$-lactams ${ }^{5}$ has been achieved by a number of groups, from which most promising results were attained by Fu et al using chiral DMAP-based catalyst ${ }^{6}$, Bode et al using NHC-based catalyst ${ }^{7}$, and Lectka et al using cinchona alkaloid derivative benzoylquinine ${ }^{8}$. However, in all those cases the substrate scope remained limited. Therefore, enzymatic kinetic resolution $(\mathrm{KR})^{9}$ of their racemates, achieved via $\beta$-lactam ring opening ${ }^{10}$ or O -acylation of N -hydroxymethyl derivatives ${ }^{11}$, continues to be a viable approach to enantioenriched $\beta$-lactams (Scheme 2.1-1, Chapter II 2.1). When $\beta$-lactams are available in racemic form, their nonenzymatic, catalytic KR can be accomplished directly via enantioselective N -acylation - a protocol that had not been established before.

In 2006, our group became successful at resolving chiral oxazolidinones via asymmetric N acylation using ABCs. ${ }^{12}$ Before our work in this area, there were no reports of KR of any lactams via enantioselective N -acylation. Having racemic $\beta$-lactams available from KR of N -acyl- $\beta$ -
lactams, we wondered whether they were suitable substrates for asymmetric N -acylation and, hence, suitable nucleophiles for Type I process using our most efficient ABCs I-2 through I-4.

### 3.2 Experimental design and findings

While working on the KR of N-acyl- $\beta$-lactams, I also tried the enantioselective acylation of $( \pm)$-4-phenyl- $\beta$-lactam III- $\mathbf{1}$ under the set of conditions established in our group in the successful catalytic, asymmetric N -acylation of oxazolidinones ${ }^{12}$ (Table 3.2-1). Disappointingly, BTM ent-$\mathbf{I}-\mathbf{3}$ proved to be inept in this process as no reaction happened after 24 hours (entry 1). HBTM I4a did not show much superiority to ent-I-3 with only $10 \%$ conversion after 48 hours, despite its higher catalytic activity to previously developed catalysts in our lab (entry 2). Those results did not come as too surprising, since we thought that the $\mathrm{pK}_{\mathrm{a}}$ of the amide moiety would be too high to allow acylation. Just when we were about to give up on the project, my labmate, Xing Yang, tried the acylation with Cl-PIQ I-2 and, to our delight, it gave promising results ( entry 3).

Table 3.2-1: KR of $\beta$-lactam ( $\pm$ )-III-1: Catalyst screening

| Entry | Catalyst | Time (hrs) | Conv (\%) | s |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $(S)-$ BTM ent-I-3 | 24 | NR | ND |
| 2 | $(S)-H B T M ~ I-4 a ~$ | 48 | $\sim 10$ | ND |
| 3 | (S)-Cl-PIQ ent-I-2 | 24 | 33 | 10 |

General conditions: $0.1 \mathrm{M}( \pm)$-III-1, $0.1 \mathrm{M}(\mathrm{i}-\mathrm{PrCO})_{2} \mathrm{O}, 0.1 \mathrm{M} \mathrm{i}-\mathrm{Pr}_{2} \mathrm{NEt}, 0.01 \mathrm{M}$ catalyst in $\mathrm{CDCl}_{3}$.

Encouraged by this finding and acquired experience in synthesizing many of the requisite substrates in the course of my earlier study (Chapter II), Xing and I started a collaboration. Xing continued with the optimization studies by varying the anhydride and the solvent (Table 3.2-2) and I began synthesizing additional substrates according to established procedures (see Figure 2.4-1, Chapter II, 2.4) to be investigated after optimization was complete. The bulk of isobutyric anhydride proved to be crucial for notable selectivity (entry 1), since acetic and propionic anhydrides generated little to no enantioselectivity (entry 2 and 3). Methylene chloride and tetrahydrofuran produced lower selectivities compared to chloroform (entries 4,5 vs. 1). Switching to tert-amyl alcohol led to improved results both enantioselectivity and rate wise, despite a reduction in substrate concentration due to limited solubility (entry 6). Lowering the temperature to $0^{\circ} \mathrm{C}$ enhanced the selectivity factor appreciably and the rate was still acceptable (entry 7). Lowering the catalyst or acylating agent/base loading only prolonged the rate of reaction and was considered impractical (entries 8, 9). Using 2-methyl-3-butyn-2-ol at room temperature led to similar results to tert-amyl alcohol (entry 10); however, due to its higher freezing point ( $+3 \mathrm{vs}-12{ }^{\circ} \mathrm{C}$ ) lowering the temperature to $0{ }^{\circ}$ would not be a viable route to increase enantioselectivity in this case. Therefore, tert-amyl alcohol became the solvent of choice.

Table 3.2-2: KR of $\beta$-lactam ( $\pm$ )-III-1: Acyl donor and solvent screening

| Entry | R | Solvent | Temp ( ${ }^{\circ} \mathrm{C}$ ) | Time (hrs) | Conv (\%) | S |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $i-\operatorname{Pr}($ III-2a) | $\mathrm{CDCl}_{3}$ | 23 | 24 | 33 | 10 |
| 2 | Me (III-2b) | $\mathrm{CDCl}_{3}$ | 23 | 4 | 35 | 1.0 |
| 3 | Et (III-2c) | $\mathrm{CDCl}_{3}$ | 23 | 10 | 35 | 1.8 |
| 4 | $i-\operatorname{Pr}$ (III-2a) | $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ | 23 | 24 | 21 | 5.5 |
| 5 | i-Pr (III-2a ) | THF | 23 | 24 | 22 | 6.6 |
| $6^{\text {a }}$ | $i-\operatorname{Pr}(\mathbf{I I I}-2 \mathrm{a})$ | EtMe 2 COH | 23 | 10 | 45 | 16 |
| $7^{\text {a }}$ | i-Pr (III-2a ) | EtMe 2 COH | 0 | 24 | 47 | 20 |
| $8^{\text {b }}$ | $i-\operatorname{Pr}($ III-2a $)$ | EtMe 2 COH | 0 | 48 | 33 | 19 |
| $9^{\text {c }}$ | i-Pr (III-2a ) | EtMe 2 COH | 0 | 24 | 35 | 21 |
| $10^{\text {a }}$ | $i-\operatorname{Pr}$ (III-2a ) | $\mathrm{HC} \equiv \mathrm{CMe}_{2} \mathrm{COH}$ | 23 | 10 | 41 | 16 |

General conditions: $0.1 \mathrm{M}( \pm)$-III-1, $0.2 \mathrm{M}(i-\mathrm{PrCO})_{2} \mathrm{O}, 0.2 \mathrm{M}$ i- $\mathrm{Pr}_{2} \mathrm{NEt}, 0.01 \mathrm{M}(S)$-Cl-PIQ, unless otherwise specified. [a] $0.05 \mathrm{M}( \pm)-\mathrm{III}-1,0.1 \mathrm{M}(i-\mathrm{PrCO})_{2} \mathrm{O}, 0.1 \mathrm{M}$ i-Pr ${ }_{2} \mathrm{NEt}, 0.005 \mathrm{M}(\mathrm{S})$-Cl-PIQ ( $10 \mathrm{~mol} \%$ ). [b] $0.05 \mathrm{M}( \pm)-$ III-1, $0.1 \mathrm{M}(i-\mathrm{PrCO})_{2} \mathrm{O}, 0.1 \mathrm{M} \mathrm{i}-\mathrm{Pr}_{2} \mathrm{NEt}, 0.0025 \mathrm{M}(\mathrm{S})-\mathrm{Cl}-\mathrm{PIQ}(5 \mathrm{~mol} \%)$. [c] $0.05 \mathrm{M}( \pm)$-III-1, $0.05 \mathrm{M}(i-\mathrm{PrCO})_{2} \mathrm{O}$, 0.05 M i-Pr ${ }_{2} \mathrm{NEt}, 0.005 \mathrm{M}(\mathrm{S})-\mathrm{Cl}-\mathrm{PIQ}(10 \mathrm{~mol} \%)$.

With optimization conditions and most starting materials in place, Xing and I worked on the substrate scope together (Table 3.2-3). We explored a range of substrates bearing aryl, heteroaryl, and alkyl groups at C-4. Counterintuitively, both p-chloro- and p-methoxy-phenyl substituted substrates III-3 and III-4 gave higher selectivity compared to their phenyl-substituted analogue III-1 (entries 2,3 vs 1). The 2-naphthyl group led to the best results in this study (entry 6). Having chlorine in the ortho position on the ring hindered the KR, as both rate and s-value diminished considerably (entry 4). The heteroaryl-substituted substrate III-8 underwent N acylation, albeit with lower enantioselectivity (entry 7). Additional alkyl groups at C-3 were tolerated, although both reaction times and selectivity factors were negatively affected (entries 8 ,
9). All of the substrates discussed above were limited to bearing aryl (or heteroaryl) groups, as we expected that cation- $\pi$ interactions with the catalyst would be crucial for the reaction to occur. In accord with this prediction, when the non-aryl substrate III-12 was subjected to the same conditions, it failed to react altogether (entry 11).

Table 3.2-3: KR of $\beta$-lactams: Substrate scope

General conditions: $0.05 \mathrm{M}( \pm)$-substrate, $0.1 \mathrm{M}(i-\mathrm{PrCO})_{2} \mathrm{O}, 0.1 \mathrm{M} \mathrm{i}-\mathrm{Pr}_{2} \mathrm{NEt}, 0.01 \mathrm{M}(\mathrm{S})-\mathrm{Cl}-\mathrm{PIQ}$, tert-amyl alcohol, $0{ }^{\circ} \mathrm{C}$, unless otherwise specified. [a] Absolute configuration of the fast reacting enantiomer is shown [b] Results based on duplicate runs. [c] $0.05 \mathrm{M}( \pm)$-substrate, $0.2 \mathrm{M}(i-\mathrm{PrCO})_{2} \mathrm{O}, 0.2 \mathrm{Mi}$ - $\mathrm{Pr}_{2} \mathrm{NEt}, 0.01 \mathrm{M}(\mathrm{S})$-Cl-PIQ (10 mol\%). [d] Reaction performed in $\mathrm{CDCl}_{3}$ at rt $0.05 \mathrm{M}( \pm)$-substrate, $0.1 \mathrm{M}(i-\mathrm{PrCO})_{2} \mathrm{O}, 0.1 \mathrm{M} \mathrm{i}-\mathrm{Pr} 2 \mathrm{NEt}, 0.0025 \mathrm{M}(\mathrm{S})-\mathrm{Cl}-$ PIQ (5 mol\%).

The absolute configuration of III-1 and of the indene-derived substrate III-11 was consistent with the results previously obtained with oxazolidinones and alcohols. Thus, we hypothesized that the TS for the catalytic N -acylation of $\beta$-lactams should be qualitatively similar to our previously proposed model for alcohols ${ }^{13}$ (Figure 1.1-1, Chapter I, 1.1). Indeed, a computational study later carried out by Xing ${ }^{14,15}$ produced TS structures TS-(R)-Cl-PIQ-(R)-III-1 and TS-(R)-Cl-PIQ-(S)-III-1, which were in accordance with our predictions (Figure 3.21).

Figure 3.2-1: Transition states for fast- and slow-reacting enantiomers of $\beta$-lactam III-1

TS-(R)-Cl-PIQ-(R)-III-1

TS-(R)-Cl-PIQ-(S)-III-1
$\Delta \Delta \mathrm{G}^{\ddagger}=3.4 \mathrm{kcal} / \mathrm{mol}$

### 3.3 Conclusions

We have achieved the first non-enzymatic asymmetric KR of $\beta$-lactams via N -acylation using Cl-PIQ ent-I-2. The method requires the presence of aryl and heteroaryl substituted $\beta$ lactams - a trend of ABCs consistent with other studied classes of compounds in our group (i.e. alcohols, oxazolidinones) ${ }^{16}$. Our experimental observations and computational studies point to the involvement of cation- $\pi$ interactions between the fast-reacting enantiomer and catalyst, in analogy with alcohols and oxazolidinones.

## Chapter IV

## Kinetic Resolution of N-Acyl-Thiolactams via Catalytic Enantioselective Deacylation

### 4.1 Introduction

Oxazoldine-2-thiones and thiazolidine-2-thiones thiolactams have had a wide application in organic synthesis as chiral auxiliaries, ${ }^{1}$ intermediates, ${ }^{2}$ and chiral reagents in resolution of other compounds. ${ }^{3}$ Some oxazoldine-2-thiones can be actually found in the structure of natural products that display biological activity. ${ }^{4}$ Asymmetric synthesis of above mentioned thiolactams is usually achieved from the reaction of their corresponding chiral $\beta$-amino alcohols with carbon disulfide, ${ }^{5}$ although $\beta$-amino thiols have also been used in synthesis of thiazolidine-2-thiones. ${ }^{6}$ However, when the corresponding $\beta$-amino alcohols are not available in enantiopure form, the kinetic resolution ${ }^{7}(\mathrm{KR})$ of racemic thiolactams via asymmetric acyl transfer catalysis can serve as a practical protocol for obtaining them in enantioenriched form.

In Chapter I, 1.1, we mentioned that that Type I and II processes are often complimentary and can be catalyzed by a single enzyme (Figure 1.1-2). So far, we have only witnessed considerable progress in Type I transformation using various acyl transfer asymmetric catalysts. ${ }^{8}$ However, to the best of our knowledge, the asymmetric deacylation (Type II process) of any classes of compounds using acylation catalysts has not been reported yet. ${ }^{9}$ In 1999, Yan et al reported a reverse action of achiral acyl-transfer catalyst DMAP in deacylation of N -acyl-oxazolidine-2-thione via alcoholysis, ${ }^{10}$ followed by Wu et al with the same transformation of N -acyl-thiazolidine-2-thione. ${ }^{11}$ Of course, both these processes were not enantioselective. Thus, this chapter describes the first instances of asymmetric deacylation using ABCs, providing also an
alternative method to obtaining enantioenriched oxazolidine-2-thiones and thiazolidione-2thiones via alcoholysis of their corresponding racemic N -acyl-derivatives.

While working on the asymmetric acylation of lactams and thiolactams, ${ }^{12}$ Xing Yang subjected ( $\pm$ )-4-phenylthiozoline-2-thione IV-1 to standard acylating KR conditions ${ }^{13}$ with BTM I-3, which also included the quenching of excess anhydride with methanol when reaction reached $50 \%$ conversion by $\mathrm{H}^{1}$ NMR. His initial results are shown in Scheme 4.1-1. However, if the quenched mixture stayed too long in the presence of methanol, then the conversion (and selectivity) dropped significantly, which was not in agreement with the one observed by $\mathrm{H}^{1}$ NMR. We hypothesized that this could be a case where BTM I-3 participated also in the asymmetric deacylation (reverse reaction) of the enantioenriched N -acyl-thiozolidine-2-thione IV-2a, especially since we were aware that such a transformation has been previously reported with DMAP. These observations gave me the opportunity to step into this project and investigate the reverse process in more detail.

Scheme 4.1-1: KR of thiazolodin-2-thione ( $\pm$ )-IV-1 via enantioselective N -acylation

### 4.2 Experimental design and findings

To test this presupposition, I preliminarily subjected crude racemic N-acyl-thiazolidine-2-thione IV-2a, which was contaminated with traces of isobutyric acid, to methanolysis in the presence of

BTM I-3. And to our surprise, the selectivity factor improved significantly ( $\mathrm{s}=88$ vs 30 ), albeit at a slower rate (Scheme 4.2-1).

Scheme 4.2-1: Preliminary enantioselective deacylation of ( $\pm$ )-IV-2a

Encouraged by these data, IV-2a was purified and the optimization process was initiated (Table 4.2-1). Interestingly, once the pure IV-2a was subjected to the KR conditions with MeOH and (R)-BTM I-3 the reaction was sluggish and led to diminished enantioselectivity (entry 2). We quickly realized that the traces of isobutyric acid were adventitious in the initial trial, and that the acid served as a co-catalyst. Introducing benzoic acid made the protocol more reproducible (entry 3). As expected, in the absence of a catalytic system, the background reaction was insignificant (entry 1). Testing other most effective catalysts from our group, Cl-PIQ I-2 and HBTM I-4a, led to disappointing results (entries 4, 5). Making sure that the nature of the alcohol in the deacylation did not play a role in the chiral recognition of IV-2a, methanol was exchanged for its more sterically hindered analogues, benzyl alcohol and di(1-naphthyl)methanol (entries 6, 7). They delivered comparable results to methanol and, therefore, we continued with the optimization using the latter.

Table 4.2-1: KR of N-acyl-thiazolidine-2-thione ( $\pm$ )-4-5a: Catalyst and Alcohol screening ${ }^{\text {a }}$

| Entry | Catalyst | ROH | Time | Conv (\%) | s |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | none | MeOH | 7 days | $<10^{\mathrm{a}}$ | $\mathrm{ND}^{\mathrm{c}}$ |
| 2 | $(R)-\mathrm{BTM}$ | MeOH | 4 days | 55 | 26 |
| 3 | $(R)-\mathrm{BTM}+10 \mathrm{~mol} \% \mathrm{PhCO}_{2} \mathrm{H}$ | MeOH | 24 hrs | 48 | 78 |
| 4 | $(S)-\mathrm{HBTM}+10 \mathrm{~mol} \% \mathrm{PhCO}_{2} \mathrm{H}$ | MeOH | 7 days | $<10^{\mathrm{b}}$ | $\mathrm{ND}^{\mathrm{c}}$ |
| 5 | $(R)-\mathrm{Cl}-\mathrm{PIQ}+10 \mathrm{~mol} \% \mathrm{PhCO}_{2} \mathrm{H}$ | MeOH | 7 days | 37 | 6.7 |

| 7 | $(R)-\mathrm{BTM}+10 \mathrm{~mol} \% \mathrm{PhCO}_{2} \mathrm{H}$ | $(1-\mathrm{Np})_{2} \mathrm{CHOH}$ | 24 hrs | 50 | 84 |

General conditions: $0.05 \mathrm{mmol}( \pm)-\mathbf{I V}-2 \mathrm{a}, 0.075 \mathrm{mmol} \mathrm{ROH}, 0.01 \mathrm{mmol}$ catalyst, 0.75 mL CDCl 3 , rt, unless otherwise specified. [a] Results averaged from duplicate runs. [b]Determined by $\mathrm{H}^{1} \mathrm{NMR}$. [c] not determined

Using I-3 as the catalyst of choice, we continued the optimization by varying the N -acyl group, then the solvent (Table 4.2-2). The bulkiness of the isopropyl group was crucial for increased enantioselectivity (entry 1), since N -propionyl-derivative delivered only a selectivity factor of 15 , although at a much faster rate (entry 2). Switching the N -acyl group to benzoyl stalled the reaction considerably (entry 3). Among solvents examined, methylene chloride and tetrahydrofuran were inferior to chloroform, as they gave diminished results (entries 4, 6), while
toluene was a bit superior to chloroform (entry 5). For convenience while monitoring the reaction by NMR we used the latter for the rest of this study.

Table 4.2-2: KR of N-acyl-thiazolidine-2-thione ( $\pm$ )-IV-2: Solvent Screening ${ }^{\text {a }}$

| Entry $^{\mathrm{a}}$ | R | Solvent | Time | Conv (\%) | s |
| :---: | :---: | :---: | :---: | :---: | :---: |

| 6 | $i-\operatorname{Pr}(\mathbf{I V - 2 a )}$ | diethyl ether | 7 days | 42 | 3.9 |

General conditions: $0.05 \mathrm{mmol}( \pm)-\mathbf{I V}-2,0.075 \mathrm{mmol} \mathrm{MeOH}, 0.01 \mathrm{mmol}(R)-B T M, 0.75 \mathrm{~mL}$ solvent, rt. [a] Results based on duplicate runs. [b] Determined by $\mathrm{H}^{1}$ NMR.

With the optimization process complete, we continued with investigation of substrate scope in the case of N -isobutyryl-thiazolidine-2-thiones (Table 4.2-3). The phenyl-substituted derivatives with electron-donating group (EDG) on the phenyl ring gave the best selectivities in this study, 90 with p-methoxy- and 108 with o-methoxy (entries 2, 3). Having an electron-withdrawing group (EWG) on the phenyl ring led to significantly diminished enantioselectivities (entries 4, 5). An interesting observation was that in both those cases, with EDG and EWG, ortho substituents gave notably higher results compared to the para ones. Switching $\mathbf{R}$ to 1- and 2-
naphthyl, as well as with thienyl group, was no match in efficiency to the phenyl one in IV-2a, which was surprising considering that same groups displayed higher selectivities in the N acylation KR of analogous classes of compounds. Both substrates IV-10 and IV-11 underwent the KR, albeit with diminished results. However, they do play a more symbolic role since they are not aryl-substituted, but still contain extended $\pi$-systems. Any other attempt to expand the applicability of this method to other non-aryl substrates or other extended $\pi$-systems failed, as IV-12 did not react at all in the course of one week, and IV-13 gave insignificant selectivity. We had higher expectations for the indane-fused substrate $\mathbf{I V}-\mathbf{1 4}$, but its $K R$ produced a disappointing s-value of 2.3. This was in contrast to the results in the N -acylation with Cl-PIQ I2 of indane-fused oxazolidin-2-one and $\beta$-lactam, which gave selectivities 36 and 14 , respectively. To confirm that these results were not related to the nature of the deacylation process itself, the forward reaction of 4-18 (Scheme 4.2-2) was set up using previously set conditions for N -acylation of analogous compounds using Cl-PIQ 4-1 and BTM 4-2 ${ }^{12}$. Unfortunately, the results did not improve in either case.

Table 4.2-3: KR of N-isobutyryl-thiazolidine-2-thiones: Substrate scope ${ }^{\text {a }}$

| 9 | IV-10 | 1 | 88 | 77 | 47 | 37 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 10 | IV-11 | 0.6 | 75 | 73 | 49 | 15 |
| 12 | IV-12 | 7 | ND | ND | NR ${ }^{\text {b }}$ | ND |
| 12 | IV-13 | 7 | 15.5 | 6 | 27 | 1.4 |
| 13 | IV-14 | 7 | 32 | 16 | 33 | 2.3 |

General conditions: $0.05 \mathrm{mmol}( \pm)$-substrate, $0.075 \mathrm{mmol} \mathrm{MeOH}, 10 \mathrm{~mol} \% \mathrm{PhCO}_{2} \mathrm{H}, 10 \mathrm{~mol} \%(R)$-BTM, in $\mathrm{CDCl}_{3}$, rt. [a] Results averaged from at least duplicate runs [a] Results averaged from duplicate runs [b] NR = no reaction

Scheme 4.2-1: Enantioselective N -acylation of thiolactam ( $\pm$ )-IV-15

With study on N-isobutyryl-thiazolidine-2-thiones coming to an end, the investigation of KR of analogous N -isobutyryl-oxazolidin-2-thiones was only to begin (Table 4.2-4). Using the same study of optimized conditions established with N -isobutyryl-thiazolidine-2-thiones, a substrate scope started with KR of the N-isobutyryl-4-phenyl-oxazolidine-2-thione IV-16 (entry 1). The de-acylation of IV-16 gave what would be generally considered good selectivity factor of 57, although lower than in the case of the analogous thiazolidine-2-thione derivative IV-2a ( $\mathrm{s}=78$ ) and than in the KR via N -acylation of corresponding oxazolidine-2-thione ( $s=82$ ). Additionally, the reaction time was longer than in the case of IV-2a. Despite the fact that the rest of the substrates gave increasingly sluggish rates and diminished enantioselectivities compared to the phenyl-substituted one, they had not been resolved before in our study of asymmetric N acylation and, hence, their KR represented practical merit based on their overall good selectivities in the range of 13 to 59, with the exception of IV-21. By analogy, we thought that an EDG on the phenyl substituent would positively affect the results and an EWG would impede them. However, the data were random and did not follow any particular trend (entries 2-5). The ester-derivative IV-21 underwent methanolysis slowly and with only a 2.6 s-value (entry 6). Surprisingly at first, in the case of IV-21 we observed that the apparent enantioselectivity plummeted with time (entry 6 vs. 7).

Table 4.2-4: Asymmetric deacylation of N-isobutyryl-oxazolidin-2-thiones

General conditions: $0.05 \mathrm{mmol}( \pm)$-substrate, $0.075 \mathrm{mmol} \mathrm{MeOH}, 0.01 \mathrm{mmol}(R)-\mathrm{BTM}, 10 \mathrm{~mol} \% \mathrm{PhCO}_{2} \mathrm{H}, 0.75 \mathrm{~mL}$ $\mathrm{CDCl}_{3}$, rt. [a] Results averaged from at least duplicate runs

Hypothesizing that there might be a slow N -acyl exchange between deacylated product ( $R$ )-IV22 and (S)-IV-21 under the reaction conditions and, since the forward KR was accomplished faster, the N -acylation of 4-25 was performed and monitored over time by taking and analyzing aliquots by HPLC (Table 4.2-5). Our premises have been confirmed by experimental evidence, as indeed just 1.5 hours after which reaction reached $52 \%$ conversion and $\mathbf{s}$ of 17 , the ees of both (R)-IV-21 and (S)-IV-22 deteriorated significantly to give a 7.5 selectivity factor. The process reached almost complete racemization after 48 hours.

Table 4.2-5: Enantioselective acylation of thiolactam ( $\pm$ )-IV-22

| Entry $^{\mathrm{a}}$ | Time (hrs) | $e e \%$ of (R)-IV-21 | $e e \%$ of (S)-IV-22 | Conv (\%) | s |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 0.5 | 75 | 82 | 52 | 17 |
| 2 | 1 | 57 | 62 | 48 | 7.5 |
| 3 | 3 | 39 | 47 | 54 | 3.5 |
| 4 | 8 | 33 | 36 | 52 | 2.8 |
| 5 | 48 | 3.0 | 3.8 | 56 | 1.1 |

General conditions: $0.05 \mathrm{mmol}( \pm)$-IV-22, $0.05 \mathrm{mmol} i-\mathrm{Pr}_{2} \mathrm{NEt}, 0.05 \mathrm{mmol}\left(i-\mathrm{Pr}_{2} \mathrm{CO}\right)_{2} \mathrm{O}, 0.0025 \mathrm{mmol}(R)-\mathrm{BTM}$, $0.5 \mathrm{~mL} \mathrm{CDCl}_{3}$, rt. [a] Results averaged from duplicate runs

To find the culprit in this N -acyl exchange, a control experiment was set up in which roughly equimolar amounts of enantioenriched ( $R$ )-IV-21 and (S)-IV-22 were mixed with $10 \mathrm{~mol} \%$ of (R)-BTM I-3 in one vial and in separate vials with alternating additives that could be present
under the regular reaction condition (Hunig's base, isobutyric acid) (Table 4.2-6). Unexpectedly, the results indicated that BTM I-3 was responsible for the N -acyl exchange, in the presence (entry 3) or absence (entry 2) of benzoic acid, as the ees deteriorated significantly after 24 hours. Other additives did not seem to have contributed to the racemization process (entries 4, 5).

Table 4.2-6: Racemization of IV-21 and IV-22

| Entry | $\%$ ee after 24 hrs |  |  |
| :---: | :---: | :---: | :---: |
|  |  | $(R)-\mathbf{I V}-21$ | (S)-IV-22 |
| 1 | none | 81 | 77 |
| 2 | $10 \mathrm{~mol} \%(R)-\mathrm{BTM} \mathrm{I}-3$ | 18 | 14 |
| 3 | $10 \mathrm{~mol} \%(R)-\mathrm{BTM} \mathrm{I}-3+10 \mathrm{~mol} \% \mathrm{PhCO}_{2} \mathrm{H}$ | 20 | 11 |
| 4 | $50 \mathrm{~mol} \% \mathrm{i}-\mathrm{Pr}_{2} \mathrm{NEt}$ | 81 | 74 |
| 5 | $10 \mathrm{~mol} \% \mathrm{i}-\mathrm{PrCO}_{2} \mathrm{H}$ | 82 | 75 |

General conditions: $0.1 \mathrm{M}(R)-I V-21,0.1 \mathrm{M}(S)-I V-22$, additive(s), in $\mathrm{CDCl}_{3}$, rt.
There is a chance that this exchange might have happened to some extent in the case of other substrates in this study, especially when the reaction times were long. Therefore, the experimentally shown selectivity factors could be lower than their "actual" ones.

In proposing the origin of enantioselectivity, experimental data suggest that de-acylation of N -acyl-thiolactams most probably goes through the same TSs as the "forward" ( N -acylation) reaction of the corresponding thiolactams. Thus, the chiral recognition of the former can be described by analogy by TSs obtained in computational studies of N -acylation of 4phenyloxazolidinone IV-26, performed by Xing Yang (Figure 4.2-1). ${ }^{12}$ The fast-reacting diastereomer TS-(R)-BTM-(S)-IV-26 is favored by $3.1 \mathrm{kal} / \mathrm{mol}$ due to $\pi$-cation interaction
between tziazolium moiety of the catalyst and the phenyl ring of the substrate, analogous to enantioselective acylation of alcohols.

Figure 4.2-1: TSs of BTM-catalyzed N -acylation of oxazolidinone IV-26

TS-(R)-BTM-(S)-IV-26
$\Delta \Delta \mathrm{G}^{\ddagger}=0.0 \mathrm{kcal} / \mathrm{mol}$

TS-(R)-BTM-(R)-IV-26
$\Delta \Delta \mathrm{G}^{\ddagger}=3.1 \mathrm{kcal} / \mathrm{mol}$

### 4.3 Conclusion

We have demonstrated for the first time a catalytic asymmetric deacylation promoted by an acyl transfer catalyst. The asymmetric methanolysis of N -acyl-thiazolidine- and oxazolidine-2-thiones has been successfully accomplished with better enantioselectivities in the former case than the latter. The KR of N -acyl-thiazolidine-2-thiones produced better selectivity factors than in the forward N -acylation reaction of their deacylated derivatives and, hence, can be viewed as an alternative method for their enantioselective synthesis. There has been some evidence in one
investigated substrate case (although it could also be applicable to other substrates) of N -acyl exchange between enantioenriched products over prolonged time, promoted by the catalyst from the reaction mixture.

## Chapter V <br> Experimental Part

### 5.1 General

All reagents and solvents were obtained commercially and used as received. Solvents used for HPLC were HPLC grade and for other purposes ACS grade. HPLC Analyses were performed on a Shimadzu LC system using Chiracel OD-H, Chiralpak AD and AD-H analytical chiral stationary phase columns (4.6x250 mm, Chiral Technologies, Inc.). Flash column chromatography was performed over ICN Echochrom silica gel $(32-63 \mu \mathrm{~m}) .{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Unity 300 MHz Varian spectrometer. High-resolution mass spectral analyses were performed at Washington Univerity MS Center on a Kratos MS-40TA spectrometer using Electro Spray Ionization (ESI) method. Infrared spectra were obtained from a Perkin-Elmer Spectrum Bx FTIR spectrophotometer using potassium bromide plates. Melting points were measured on a Mel-Temp II capillary melting point aparatus. The signs of optical rotation were determined in $\mathrm{CHCl}_{3}$ on a Rudolph Autopol III polarimeter.

Catalysts BTM, Cl-PIQ, and HBTM were prepared as previously described. ${ }^{1}$

Selectivity factors and \% conversions were calculated using Kagan's equations ${ }^{2}$ : conversion $\mathbf{C}=$ $\mathrm{ee}_{S M} /\left(\mathrm{ee}_{S M}+\mathrm{ee}_{\mathrm{PR}}\right) 100 \%$ and selectivity factor $\left.\mathbf{s}=\ln \left[(1-\mathrm{C})\left(1-\mathrm{ee}_{\mathrm{Sm}}\right)\right] / \ln \left[(1-\mathrm{C})\left(1+\mathrm{ee}_{\mathrm{SM}}\right)\right]\right)$, unless otherwise specified.

### 5.2 KR of N-Acyl-b-Lactams via Enantioselective Alcoholysis using Amidine-based

## Catalysts

### 5.2.1 General

Refer to Chapter II for notation of compounds. Note: Recrystallization of BTM from $\mathrm{Et}_{2} \mathrm{O} /$ hexanes ${ }^{1}$ is recommended to ensure reproducible performance. Oxazinones II-1 and II-1a were prepared via a modification of a published procedure ${ }^{2}$ using DCC to effect the cyclization step. Racemic $N$-(p-nitrobenzoyl)- and $N$-(3,5-dinitrobenzoyl)-4-phenyl-azetidin-2-ones (see Table 5.2.2-3) were prepared via deprotonation of ( $\pm$ )-4-phenyl-azetidin-2-one with $n$ butyllithium and acylation with the corresponding acyl chloride. ${ }^{3}$ All substrates II-3 through II13 were prepared via DMAP-catalyzed acylation of the corresponding racemic $\beta$-lactams. ${ }^{4}$ The precursors to substrates II-3 and II-7 through II-12 were obtained via cycloaddition of the corresponding alkenes with chlorosulfonyl isocyanate. ${ }^{5}$ The precursors to substrates II-5 and 2-II-6 were synthesized from the corresponding aldehydes via condensation of their N (trimethylsilyl)imines with tert-butyl acetate Li enolate, according to a general procedure. ${ }^{6}$ The precursor to substrate II-13 was synthesized via dilithiation and alkylation of ( $\pm$ )-4-phenyl-azetidin-2-one, as previously described. ${ }^{7}$ The substrates II-20, II-21, II-22 were attempted to be synthesized by Staudinger reaction, followed by deprotection with CAN, using previously reported procedures ${ }^{8,9,10}$.

### 5.2.2 Kinetic Resolution experiments

### 5.2.2.1 Optimization studies

General procedure. To a solution of a racemic substrate ( 0.10 mmol ) in 0.25 mL of $\mathrm{CDCl}_{3}$ was added 0.25 mL of a stock solution of $0.040 \mathrm{M}(\mathrm{S})$-BTM ( 0.010 mmol ) and 0.040 M benzoic acid
( 0.010 mmol ) in $\mathrm{CDCl}_{3}$ followed by 0.25 mL of a 0.30 M solution of methanol in $\mathrm{CDCl}_{3}$ ( 0.075 mmol ). The reaction mixture was stirred magnetically at rt. Its progress was checked periodically by withdrawing aliquots, diluting them with $\mathrm{CDCl}_{3}$ and analyzing by ${ }^{1} \mathrm{H}$ NMR. Upon reaching approximately $50 \%$ conversion, the reaction mixture was diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, washed with water, dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, concentrated, and separated by flash chromatography (silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, then $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{EtOAc}$ ). Enantiomeric enrichment of the ester product and the unreacted starting material was determined by chiral stationary phase HPLC (for HPLC conditions, see individual compounds in Characterization Data and HPLC Propersties section 5.2.7). Each experiment was performed at least in duplicate, unless otherwise specified. The results compiled in following Tables in 5.2 section were obtained using variations of this basic protocol, as indicated.

### 5.2.2.2 Assignment of the absolute configuration

(a) The absolute configuration of the ester derived from substrate II-3a in the presence of (S)BTM was determined to be $(R)$ on the basis of HPLC comparison with an enantioenriched sample of the same compound synthesized by acylation of authentic (+)-(R)-ester A. ${ }^{11}$
(b) The unreacted substrate II-8 was determined to have the (1S, 2S) absolute configuration on the basis of HPLC comparison with an enantioenriched sample of the same compound synthesized by acylation of authentic $(-)-(1 R, 2 R)-\beta$-lactam $\mathbf{B} .{ }^{12}$

The absolute configurations of all other enantioenriched products were assigned by analogy with these two cases.

### 5.2.2.3 Preparative-scale KR of $\mathbf{N}$-acyl- $\beta$-lactam ( $\pm$ )-II-11

A 50 mL round-bottom flask was charged with the racemic substrate $\mathbf{I I}-\mathbf{1 1}(1.00 \mathrm{~g}, 3.62 \mathrm{mmol})$, $\mathrm{Na}_{2} \mathrm{SO}_{4}(\sim 0.4 \mathrm{~g}),(R)$-BTM ( $90.6 \mathrm{mg}, 0.362 \mathrm{mmol}$ ), benzoic acid ( $45.2 \mathrm{mg}, 0.362 \mathrm{mmol}$ ) and 27 ml of dry $\mathrm{CHCl}_{3}$. Once the reactants dissolved, methanol ( $108 \mu \mathrm{~L}, 2.71 \mathrm{mmol}$ ) was added at once. The reaction progress was monitored by ${ }^{1} \mathrm{H}$ NMR analysis of small aliquots of the reaction mixture. After 72 h , upon reaching $\sim 50 \%$ conversion by ${ }^{1} \mathrm{H}$ NMR, the reaction mixture was worked up with water. The organic phase was rotary evaporated and the crude residue was purified by flash chromatography on silica gel. The unreacted $N$-acyl- $\beta$-lactam (92.96\% ee, 0.473 $\mathrm{g}, 47 \%$ yield) and then the ester ( $95.23 \% \mathrm{ee}, 0.491 \mathrm{~g}, 45 \%$ yield) were eluted with pure $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. Further elution with $5 \%$ isopropanol and $1 \%$ triethylamine in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was used to recover the
catalyst ( $0.083 \mathrm{~g}, 76 \%$ recovery). Conversion and s were calculated using Kagan's equation to be $49 \%$ and 140 , respectively.

### 5.2.2.4 Other modes of catalysis in KR of $\mathbf{N}$-acyl- $\boldsymbol{\beta}$-lactam ( $\pm$ )-II-11

General Procedure: To a solution of a racemic substrate II-11 ( 0.05 mmol ) in 0.25 mL of $\mathrm{CDCl}_{3}$ was added 0.25 mL of a stock solution of 0.040 M catalyst ( 0.010 mmol ) and 0.15 M $\mathrm{MeOH}(0.0375 \mathrm{mmol})$ in $\mathrm{CDCl}_{3}$. See catalyst structures and notations in Chapter II, 2.3. The reaction mixture was stirred magnetically at rt. Its progress was checked periodically by withdrawing aliquots, diluting with $\mathrm{CDCl}_{3}$, and analyzing by ${ }^{1} \mathrm{H}$ NMR. Upon reaching approximately $50 \%$ conversion, the reaction mixture was diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and separated by flash chromatography (silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, then $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{EtOAc}$ ). Enantiomeric enrichment of the ester product and the unreacted starting material was determined by chiral stationary phase HPLC. Each experiment was performed at least in duplicate.

### 5.2.2.5 Study of acid role in KR of $\mathbf{N}$-acyl- $\boldsymbol{\beta}$-lactams

Entries from Table 5.2.2.5-1, 5.2.2.5-2, 5.2.2.5-3, 5.2.2.5-4 will generally follow one of these 4 procedures, unless otherwise specified.

Procedure A: To 0.05 mmol of substrate and $\mathrm{Na}_{2} \mathrm{SO}_{4}$ was added 0.2 mL of 0.025 M stock solution of $(R)$-BTM (10 mol\%) in $\mathrm{CDCl}_{3}$, followed by 0.175 mL of stock solution of 0.21 M of methanol ( 0.0375 mmol ) in $\mathrm{CDCl}_{3}$. Sample runs were analyzed and processed as described in any other procedure from above.

Procedure B: To 0.05 mmol of substrate was added 0.1 mL of 0.05 M stock solution of ( $R$ )BTM (10 mol\%) in $\mathrm{CDCl}_{3}$ and 0.1 mL of 0.05 M benzoic acid ( $10 \mathrm{~mol} \%$ ) in $\mathrm{CDCl}_{3}$, followed by 0.175 mL of stock solution of 0.21 M of $\mathrm{MeOH}(0.0375 \mathrm{mmol})$ in $\mathrm{CDCl}_{3}$. Sample runs were analyzed and processed as described in any other procedure from above.

The following stock solutions have been made for Procedures C and D: 1) Stock Solution A: $114.24 \mathrm{~g}, 8 \mathrm{mmol}$ of $\mathbf{2 - 7 d}$ and $60.8 \mathrm{mg}, 8 \mathrm{mmol}$ of 2,6-methoxy-toluene ( 8 mmol ) were dissolved in 1.6 mL CDCl 3.2 ) Stock Solution B: $10 \mathrm{mg}, 0.8 \mathrm{mmol}$ of ( $R$ )-BTM and 12 mL of methanol were dissolved in 0.8 mL of $\mathrm{CDCl}_{3}$. 2) Stock Solution C: $2.5 \mathrm{mg}, 0.4 \mathrm{mmol}$ of benzoic acid was dissolved in 0.3 mL of $\mathrm{CDCl}_{3}$.

Procedure C: To Vials \#1 and \#2 0.2 mL of Stock Solution A, 0.2 mL of Stock Solution B, 75 $\mu \mathrm{L} \mathrm{CDCl}_{3}$, and $\mathrm{Na}_{2} \mathrm{SO}_{4}$ were added. To Vial \#3 was added double the amounts of solutions added in Vial \#1, 2. Aliquots were removed exclusively from Vial \#3 for ${ }^{1} \mathrm{H}$ NMR analysis. After 14 hours, the reaction mixture from vial \#1, 2 were diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and separated by flash chromatography (silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, then $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{EtOAc}$ ). Enantiomeric enrichment of the products and the unreacted starting material was determined by chiral stationary phase HPLC.

Procedure D: To Vials \#1 and \#2 0.2 mL of Stock Solution A, 0.2 mL of Stock Solution B, 75 $\mu \mathrm{L}$ Stock Solution C, and $\mathrm{Na}_{2} \mathrm{SO}_{4}$ were added. To Vial \#3 was added double the amounts of solutions added in Vial \#1, 2. Aliquots were removed exclusively from Vial \#3 for ${ }^{1} \mathrm{H}$ NMR analysis. After 22 hours, the reaction mixtures from vial \#1, 2 were diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and separated by flash chromatography (silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, then $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{EtOAc}$ ). Enantiomeric enrichment of the products and the unreacted starting material was determined by chiral stationary phase HPLC.

### 5.2.3 Preliminary Computational Studies on KR of $\mathbf{N}$-acyl- $\boldsymbol{\beta}$-lactams

The proposed transition states for fast and slow reacting enantiomers were located under DFT B3LYP/3-21G(d) level calculations. The TSs were constructed under the following assumptions:
A. BTM attacks the acyl carbonyl from the less hindered face of the substrate.
B. The acyl carbonyl is nearly coplanar with the benzothiazolium moiety and points towards the sulfur atom (S-O interaction).

### 5.3 KR of b-Lactams via Enantioselective N-acylation using Amidine-based Catalysts

### 5.3.1 General

See Chapter III for substrate notation/numbering. Racemic $\beta$-lactams III-1, III-3, III-10, and III-12 were obtained via cycloaddition of chlorosulfonyl isocyanate with the corresponding olefins. ${ }^{1}$ Substrate III-9 was prepared via alkylation of ( $\pm$ )-III-1 as previously described. ${ }^{2}$ All other substrates were synthesized from the corresponding aldehydes via condensation of their N (trimethylsilyl)imines with tert-butyl acetate Li enolate, according to a general procedure. ${ }^{3}$

### 5.3.2 Kinetic resolution experiments

General Procedure: A racemic $\beta$-lactam ( 0.10 mmol ) and (S)-Cl-PIQ ( $2.8 \mathrm{mg}, 0.010 \mathrm{mmol}$ ) were stirred in 2 mL of tert-amyl alcohol at rt for ca . 10 min until most of the solids dissolved. Then, $i$ - $\operatorname{Pr}_{2} \mathrm{NEt}(34 \mu \mathrm{~L}, 0.20 \mathrm{mmol})$ was added, the solution was cooled to $0{ }^{\circ} \mathrm{C}$ and stirred for 5 min , and treated with isobutyric anhydride ( $34 \mu \mathrm{~L}, 0.20 \mathrm{mmol}$ ). After stirring at $0{ }^{\circ} \mathrm{C}$ for $24-72 \mathrm{~h}$, the reaction mixture was quenched by addition of methanol $(100 \mu \mathrm{~L})$ and the solvent removed under vacuum. After determining the $\%$ conversion in the crude residue by ${ }^{1} \mathrm{H}$ NMR, it was separated by flash chromatography (hexanes/EtOAc 1:1 in all cases, except substrates III-9 and III-10 requiring 2:1 ratio). The enantiomeric enrichment of the N -acylated product and the recoved $\beta$-lactam were analyzed by HPLC. The calculated value for conversion was in agreement with that estimated by ${ }^{1} \mathrm{H}$ NMR. The results are provided from duplicate runs, unless otherwise specified and are summarized in Table 5.3.2-2.

Optimization Study Procedure: Optimization studies were conducted in a similar fashion using General Procedure, except $0.025 \mathrm{mmol}(3.6 \mathrm{mg})$ of 4-phenyl-azetidin-2-one III-1. The conditions and results of these experiments are summarized in Table 5.3.2-1. Reaction mixtures were analyzed HPLC, by removing aliquots, diluting them with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and hexane, and injecting directly into the HPLC line.

Preparative Scale Resolution Procedure: Racemic 4-(p-chlorophenyl)-azetidin-2-one III-3 ( $545 \mathrm{mg}, 3.00 \mathrm{mmol}$ ), ( R )-Cl-PIQ ( $84 \mathrm{mg}, 0.30 \mathrm{mmol}$ ), and $\mathrm{N}, \mathrm{N}^{\prime}$-diisopropylethylamine ( 1.0 mL , 6.0 mmol ) were dissolved in 60 mL of tert-amyl alcohol. After cooling the reaction mixture to 0 ${ }^{\circ} \mathrm{C}$, isobutyric anhydride ( $1.0 \mathrm{~mL}, 6.0 \mathrm{mmol}$ ) was added and the stirring continued for 30 h at the same temperature, whereupon the reaction was quenched with 3 mL of methanol. After rotary evaporation of the solvent, the crude mixture was applied directly to a silica gel column and eluted first with dichloromethane, then 1:1 hexane/ethyl acetate mixture and finally isopropanol with $5 \%$ triethylamine until the bright-yellow catalyst was eluted ( $55 \mathrm{mg}, 65 \%$ recovery). The (R)-enantiomer of the N -acylated product was isolated with $74.4 \%$ ee ( 438 mg, ca. $98 \%$ pure, $57 \%$ yield); the (S)-enantiomer of the starting material was recovered with $97.9 \%$ ee ( 234 mg , ca. $98 \%$ pure, $42 \%$ yield). According to Kagan's equation, the reaction proceeded to $56.8 \%$ conversion with 29.8 selectivity factor (cf. Table 5.3.2-2, entry 2).

### 5.4 KR of N-Acyl-Thiolactams via Enantioselective De-Acylation using Amidine-based Catalysts

### 5.4.1 General

See Chapter IV for substrate notation/numbering. Racemic thazolidine-2-thiones and oxazolidine-2-thiones were prepared according to previously described procedures. ${ }^{1,2}$ Their N acylated derivatives were prepared via DMAP-catalyzed acylation with anhydrides as previously reported. ${ }^{3}$

### 5.4.2 Kinetic Resolution experiments

### 5.4.2.1 Optimization studies

General procedure. To a solution of a racemic substrate ( 0.05 mmol ) in 0.2 mL of $\mathrm{CDCl}_{3}$ was added 0.2 mL of a stock solution of $0.025 \mathrm{M}(R)-\mathrm{BTM}(0.005 \mathrm{mmol})$ and 0.025 M benzoic acid ( 0.005 mmol ) in $\mathrm{CDCl}_{3}$ followed by 0.1 mL of a stock solution of 0.375 M methanol ( 0.0375 mmol ) in $\mathrm{CDCl}_{3}$. The reaction mixture was stirred magnetically at rt. Its progress was checked periodically by withdrawing aliquots, diluting them with $\mathrm{CDCl}_{3}$ and analyzing by ${ }^{1} \mathrm{H}$ NMR. Upon reaching approximately $50 \%$ conversion, the reaction mixture was directly loaded on column and purified by flash chromatography $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$, then $\left.\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{EtOAc}\right)$. Enantiomeric enrichment of the deacylated product and the unreacted starting material was determined by chiral stationary phase HPLC (for HPLC conditions, see Characterization and HPLC Properties, 5.3.3). Each experiment in Section 5.4.2 was performed at least in duplicate.

### 5.4.2.2 Enantioselective $\mathbf{N}$-acylation of thiolactam ( $\pm$ )-IV-15

The previously published standard procedure was followed. ${ }^{4}$ Racemic thiazolidinethione IV-15 ( $10.4 \mathrm{mg}, 0.050 \mathrm{mmol}$ ) was dissolved almost completely in 0.4 mL of $\mathrm{CDCl}_{3}$ with gentle heating. The solution was allowed to cool to ambient temperature and stirred magnetically. A 0.1 mL stock solution of 0.375 M N , N -Diisopropylethylamine, 0.05 M ( $0.005 \mathrm{mmol}, 10 \mathrm{~mol} \%$ ) of the specified catalyst was added, followed by isobutyric anhydride ( $6 \mu \mathrm{~L}, 5.6 \mathrm{mg}, 0.0375 \mathrm{mmol}$ ). After stirring for several minutes, the solution became hazy. After the specified period of time, the reaction mixture was diluted with a small amount of methylene chloride, applied directly to a silica gel column, eluted, and analyzed as described above. The results are summarized in Table 4S below.

### 5.4.2.3 Enantioselective $\mathbf{N}$-acylation of thiolactam ( $\pm$ )-IV-22.

Racemic oxazolidinethione IV-22 ( $8.1 \mathrm{mg}, 0.050 \mathrm{mmol}$ ) was dissolved in 0.3 mL of $\mathrm{CDCl}_{3}$. The solution was stirred magnetically and treated sequentially with a 0.1 mL of stock solution of 0.25 M N,N-diisopropylethylamine ( 0.025 mmol ) and $0.02 \mathrm{M}(R)$-BTM ( $0.002 \mathrm{mmol}, 4 \mathrm{~mol} \%$ ), and 0.1 mL stock solution of 0.25 M isobutyric anhydride ( 0.025 mmol ). After the specified period of time, an aliquot of the reaction mixture was diluted with 1:1 hexane/methylene chloride and injected directly into HPLC (ODH, hexane/isopropanol 85:15, $1 \mathrm{~mL} / \mathrm{min}$ ). The results are summarized in Table 5S below.

### 5.4.2.4 N -Acyl exchange experiments

Five vials were each charged with partially enantioenriched samples of (R)-IV-21 ( 0.037 mmol , 82.06 \% ee), (S)-IV-22 ( $0.037 \mathrm{mmol}, 77.72 \% e e$ ) and 0.27 mL CDCl 3. Vial \# 1 was charged with an additional $0.1 \mathrm{~mL} \mathrm{CDCl}_{3}$ and left as a blank, Vial \#2 was treated with 0.1 mL 0.037 M solution of $(R)$-BTM ( $0.92 \mathrm{mg}, 0.0037 \mathrm{mmol}, 10 \mathrm{~mol} \%$ ) in $\mathrm{CDCl}_{3}$, Vial \#3 with 0.1 mL 0.037 M solution of (R)-BTM ( $0.92 \mathrm{mg}, 0.0037 \mathrm{mmol}, 10 \mathrm{~mol} \%$ ) and benzoic acid ( $0.46 \mathrm{mg}, 0.0037$ mmol, $10 \mathrm{~mol} \%$ ) in $\mathrm{CDCl}_{3}$,Vial \#4 with 0.1 mL 0.185 M solution of $\mathrm{N}, \mathrm{N}$-diisopropylethylamine (3.21 $\mu \mathrm{L}, 0.0185 \mathrm{mmol}, 0.5$ equiv) in $\mathrm{CDCl}_{3}$, and Vial $\# 5$ with 0.1 mL 0.037 M solution of isobutyric acid $(0.34 \mu \mathrm{~L}, 0.0037 \mathrm{mmol}, 10 \mathrm{~mol} \%)$ in $\mathrm{CDCl}_{3}$. All vials were left stirring at rt for 24 h and analyzed by injecting directly into HPLC (OD-H, 85:15 hexane/isopropanol). The results are listed in Table 6S below.
