## Abstract

This study examined the technical efficiency (TE) of fish farming in Edo State, Nigeria. A multistage sampling technique was used to select 180 respondents from whom data was collected using well-structured questionnaire and interview schedules. These were analyzed using both descriptive statistics and stochastic frontier production function. The result showed that the TE of the farmers ranged from 0.46 to 0.99, with a mean of 0.95 at which 77% of them were operating. The efficiency was significantly ( $p < 0.05$ ) influenced positively by stocking rate and negatively by the farmers' age, educational level as well as poor access to extension services. Serious constraints that affected optimum production include high cost of feed, limited capital, poor power supply, high cost of pond construction, disposal of effluents, increased fish price created by middlemen and inadequate water supply. Determination of efficiency of resource use revealed that pond size, fingerlings, feeds and fixed cost of items were underutilized while labour and operating cost were over utilized. Farmers' access to suitable extension services and the implementation of policies aimed at tackling the detected constraints would help to increase the efficiency of fish farming in the state.

**Keywords:** Technical efficiency, Fish farming, Pond, Resource use, Edo State

## INTRODUCTION

### Background to the Study

Rapid increase in population of Nigeria has led to a huge increase in the demand for animal protein which is essentially higher in quality than that of plant as it contains all essential amino acids for growth (Awoyemi and Ajiboye, 2011). Our country has insufficient access to the amount and variety of food for a healthy and productive life because she has not fully exploited her agricultural potentials. Thus, the average protein intake in Nigeria which is about 19.38g/caput/day is low and far below FAO requirement of 75g/caput/day (Oladimeji, 2014).

Fish production is economically viable and Nigeria has the resources to produce up to 5 million metric tonnes annually (Zayyard, 2008). For instance, Edo State is richly endowed with abundant inland water-bodies, flood plains-wetlands which are highly productive and ideal for artisan fisheries and aquaculture development (Edo State Economic Empowerment and Development Strategy (Edo SEEDS), 2005). While artisan fisheries (fish production from freshwater lakes, dams and reservoir) is largely underdeveloped, investments in fish farming have grown recently but production and employment has been modest. Edo SEEDS aim to bridge this gap, among other policies, with particular emphasis on both improved productivity and socio-economic well-being of the fish farmers. In order to achieve this, there need to be an understanding of the resource use efficiency and constraints militating against such venture in the state.

Therefore, this study was designed to examine the technical efficiency of fish production in Edo State. The objectives are to: (i) estimate technical efficiency of the fish farms, (ii) determine resources which affect efficiency of the business (iii) determine the constraints in fish production, and (iv) determine the resource use efficiency in fish production.

## MATERIALS AND METHODS

### Study Area

This study was carried out in Edo State, Nigeria. The state which has a population of 3,218,332 people (National Population Commission (NPC, 2006) occupies a land area of 19,281.93 km<sup>2</sup> and lies roughly between latitudes 05°44'N and 07°34'N and longitudes 05°4'E and 06°45'E. The tropical region which usually experience a mean temperature of 25°C is characterized by two distinct seasons: wet (April – October) and dry (November to April) with an average rainfall in the range of 1500 - 2500mm.

### Sampling Technique and data collection

A multi-stage sampling technique was used to select catfish farmers in the area. The first stage involved the selection of six (6) Local Government Areas (LGAs) namely Egor, Esan Central, Etsako East, Ikpoba-Okha, Oredo and Uhumwode from the three (3) Senatorial districts that make up the state based on their high involvement in fish farming. Data were obtained from the Federal Bureau of Statistics (FBS), Edo State Ministry

of Agriculture and Natural Resources (ESMANR), Agricultural Development Programme (ADP), and Federal Department of Fisheries (FDF). The second stage was the random selection of three communities from each of the 6 LGAs, namely: Aduwawa, Aduhanhan, Agenebode, Ekosodin, Eyean, Idogbo, Ikhimwinri, Igieduma, Irrua, Oguola, Okhoro, Oko, Ugbor, Ugbowo, Ugonoba, Urora, Uselu and Uteh; making total of 18 communities. The final stage involved the random selection of ten fish farmers from each of the communities, bringing the total number of respondents to 180.

Finally, primary data were collected using structured questionnaire aided with an interview schedule for those that could not read or write and these were analyzed using descriptive statistics (frequency count, percentages, means and standard deviation and inferential statistics) and inferential statistics which used the Maximum Likelihood Estimation (MLE) technique of the stochastic frontier production function.

**The general model:** The production activities of the fish farmers in the six selected LGAs were estimated using the Stochastic Frontier Production function defined by the functional form specified as:

$$\ln Y = B_0 + B_1 \ln X_1 + B_2 \ln X_2 + B_3 \ln X_3 + B_4 \ln X_4 + B_5 \ln X_5 + B_6 \ln X_6 + V_i - U_i$$

Where:  $Y_i$  = The fish output of the  $i$ th fish farmers (kg) per pond size.

- $X_1$  = Value of fingerlings (₦) per pond size.
- $X_2$  = Hired labour (mandays) per pond size
- $X_3$  = Family labour (mandays) per pond size
- $X_4$  = Quantity of feeds (kg) per pond size.
- $X_5$  = Annual cost of materials (₦) per pond size
- $X_6$  = Operating cost (₦) per pond size
- $\beta_1$  = unknown parameters to be estimated
- $V_i$  = Random component of error term
- $U_i$  = Technical inefficiency effect

**Inefficiency model:** This was used in determining the contribution of the socio-economic variables to the observed technical inefficiency (TI) of the fish farmers. The inefficiency model was estimated jointly with the general model, using the statistical software, FRONTIER version 4.1c. Usually, TI model is composed of vector variables ( $z$ ), which will be hypothesized to affect the TE of the fish farmers which was specified as:-

$$U_i = \delta_0 + \delta_1 Z_1 + \delta_2 Z_2 + \delta_3 Z_3 + \delta_4 Z_4$$

Where:

- $U_i$  = Technical inefficiency effect
- $\delta_0$  = constant term.
- $Z_1$  = Educational level of Respondents (years of schooling)
- $Z_2$  = Experience of the fish farmers (years in fish farming)
- $Z_3$  = Access to Extension Agents (dummy variable, with 1= Access, 0= no access)
- $Z_4$  = Access to credit facilities (dummy variable, with 1= Access, 0= No access)

### The Generalized Likelihood Ratio Test

$\chi^2$

This is defined by a test statistic given as:  $C = -2 \ln \{L(H_0) - L(H_a)\}$

Where:

- $L(H_0)$  = null hypothesis i.e. no TI effects in fish production.
- $L(H_a)$  = alternative hypothesis i.e. TI effects exist.

The generalized likelihood ratio tests for the presence of inefficiency effect in the frontier model.  $H_0$  is accepted when the computed is less than ( $<$ ) the tabulated chi-square at 5% level of probability or  $H_a$  is accepted otherwise.

The mean of 3-point Likert Scale (Osuala, 1993) was used to determine the seriousness of the constraints affecting the fish farmers. The constraints were scored as follows: Very serious = 3, Serious constraints = 2, Not serious = 1.

Mean score of  $\geq 2$  formed the bench mark for judgment  $d$ ; observed by the formula:

$$\bar{X} = \frac{\sum Xi}{N}$$

where:

$\bar{X}$  = mean

$i = 1, 2, 3 \dots 180$ .

$\Sigma$

= Summation notation.

X = the assigned value of constraint (i.e. very serious = 3, serious = 2, not serious = 1)

N = the number of occurrence (i.e. N=180)

### Resource use Efficiency

The marginal value productivity (MVP) analysis was used for determining resource use efficiency (r) using the equation:  $r = MVP/P_{xi}$ ; where  $x_i$  = mean value of inputs.

## RESULTS AND DISCUSSION

The distribution of respondents according to socio-economic characteristics (Table 1) showed that a large proportion (87.8%) of the fish farmers in the study area are 40 years old and above. This result conforms to those of Agbamu and Fubusoro (2001) as well as Ajayi and Allagenyi (2001), who stated that the ageing proportion of the population is more involved in farming. This study showed that majority (96%) of the respondents was married and the males were more (88.3%) than the females (11.7%). Data collected revealed that the literacy level of the respondents was high with all the fish farmers (100%) having attained a minimum of primary education. The relevance of education in agricultural production has been documented (Onuabugu and Nnadozie, 2005; Erie, 2008). The business is relatively new in the study area as majority (52%) of the respondents had an experience of 4 years and below. While a large proportion of them (88.9%) operate the business on full-time basis while the others were on part-time. Only few of the respondents (34%) operated a pond size of 401-500 m<sup>2</sup> (0.41- 0.5ha) while a majority of them (66%) operated a pond size even below 400 m<sup>2</sup> (0.4ha). The dominance of small size fish farms in the study area deprived the farmers from enjoying the benefits of economics of scale which is associated with large scale farming. It was also noticed that most of the respondents (81.7%) had no access to extension services in the study area.

The coefficients of the maximum likelihood estimates (MLE) of stochastic frontier production function (Table 2) showed that all the variables included in the model are significant and positively related to the output of fish farmers. This implies that fish production can be increased by increasing the variables under consideration. An increment of 100%, for example, would increase the total fish output of the pond size, feed, fingerlings, fixed cost items, operating expenses and labour by 52.2%, 30.5%, 6.5%, 6.1%, 2.4%, and 2.2%, respectively based on the order of importance. These entire variables indicate that collectively the fish farmers were operating at a rational stage (stage II) of production as indicated by the return to scale (RTS) score of 0.999. The figure, a summation of the coefficients of the estimated variables (elasticity), which serves as measure of total productivity indicate a positive decreasing returns to scale, hence, most of the fish farmers output was optimally produced at this stage.

The TE score was within the range of 0.459 and 0.991, with a mean value of 0.947 (Table 3). About 77% of the farmers were quite efficient beyond this mean value. This suggests that there is room for about 5.3% improvement. Over 97% and 71.11% of the fish farmers operated on a TE of 0.8 and above as well as 9.5 and above, respectively; an indication the most farmers are quite efficient in fish production. The maximum likelihood estimates are shown in Table 4. The positive signs of the parameter imply that the associated variables increase inefficiency while the reverse is true for the negative signs. The coefficients of age, education, and access to extension agents were positively and significantly related to technical inefficiency (TE gap) but contributed negatively to technical efficiency. Thus, as age increases, farmers tend to be less productive. The contribution of age variable to technical inefficiency conformed to a priori expectation that as the fish farmers grew older, their TE would drop. This finding however, negated the findings of Esobhawan (2007) that age was a positive contributor to technical efficiency. The contribution of education variable to technical inefficiency negated a priori expectation and the finding that all the fish farmers (100%) were literate, having obtained primary education and above. It could, however, be due to lack of technical education on aquaculture production. The positive contribution of access to extension agents to technical inefficiency was the result of the majority of them (87%) not having access to extension agents. Farming experience and stocking rate contributed positively to technical efficiency of the fish farmers. This was consistent with a priori expectation that business experience could be an indication of the practical knowledge acquired which enhance their business operations. Finally, the positive contribution of stocking rate to technical efficiency indicated the farmers' ability to maintain the required stocking rate which could enhance productivity and output growth.

The sigma squared ( $\sigma^2$ ) which is an indication of goodness of fit was statistically significant at 5% level (Table 4), showing the goodness of it of the survey data with the model used and the correctness of the specified

distributional assumption of the composite error term. The estimated value of gamma ( $\gamma$ ) (0.935) implies that 93.5% of the total variation in fish output is due to technical inefficiency or farmers' practices rather than random variability. Thus, the hypothesis that there is no significant relationship between fish output and the factors of production is rejected and that there are significantly inefficiency effects was confirmed by the Log Ratio Test (Table 5).

The serious constraints affecting of fish production were rated (Table 6) following the decreasing order: high cost of feed, limited of capital, electrical problems, high cost of pond construction, disposal of effluents, increased fish price by middlemen and inadequate water supply with means of 2.82, 2.60, 2.58, 2.46, 2.34, 2.28 and 2.18, respectively.

Economic efficiency of resource use which was computed using MVP (Table 7) showed that no optimization condition was obtained for fish production. The ratios obtained were either greater than unity (underutilization) or less than unity (overutilization). Pond size, fingerlings, fixed cost of items and feed were underutilized, while labour and operating cost were over utilized. Consequently, allocating more resources to the underutilized variables and reducing the employment of resources in the over utilized ones will increase efficiency.

## CONCLUSION AND RECOMMENDATIONS

The study revealed that most of the farmers in Edo State were technically efficient in the use of resources for fish production as over 97% of them operated efficiently at 80% and beyond. The average technical efficiency was 94.7%; leaving only about 5.3% room for improvement. Thus, constraints such as high cost of feed, limited of capital, poor power supply, high cost of pond construction, and disposal of effluents, increased fish price created by middlemen and inadequate water supply were discovered to have seriously affected optimum production. Stocking rate had a positive influence on technical efficiency while age and education of the farmers as well as poor access to extension workers had a negative influence. Government should formulate and implement proper policies that would eliminate these constraints and employ well trained extension agents to educate these farmers.
