A paper sent to the American Journal of Finance. Editor @ [jfinance.org](http://jfinance.org)

## Abstract

This paper attempts to investigate the impact of Government expenditure on infrastructure in Nigeria, using the cointegration and error correction Specifications.

The result of the error correction mechanism (ECM) indicates a feedback of about 99.38 percent of previous year's disequilibrium from long-run elasticity of rate of urbanization, openness, government revenue, external reserves, population density and type of government. The results of the Chow test revealed that public expenditure on infrastructure were stable and did not change over time as evidenced by F\* value of 1.8214 against F-critical value of 2.580 at the 5% level during the period.

**Keywords:** Government Expenditure, Economic Growth, External Reserve, Co-integration, Error Correction Mechanism, Infrastructure, Public Goods

## 1. INTRODUCTION

Development economists have long acknowledged the centrality of public expenditure, particularly on infrastructure as an important instrument in the development process. Public expenditure has remained a central issue in economic development, especially developing countries in Sub-Saharan Africa, whose economies are characterized by structural rigidities, weak support services and institutional framework, declining productivity, high level corruption cum policy instability. This gloomy picture has led to researches aimed at investigating whether public expenditure on infrastructure has yielded significant results over time. Several factors have influenced public expenditure on infrastructure, namely, rate of urbanization, openness, government revenue, external reserves, population density, type of government *ab initio*. Several studies have analyzed the impact of public spending on economic growth in the short and long-run in most developed and developing countries, using cross sectional data of many countries (Edame, 2008). Public expenditure, which refers to the expenses Government incurs for its own maintenance, society and the overall economy is found to be continuously increasing overtime. This is because these fiscal operations are recognized as major tools for the management of the economy and stimulation of economic growth and development (NISER, 2004; Agenor and Dodson, 2006).

Besides, government spending is varied ranging from education, defense, general administration, health, to water supply, electricity generation and supply, roads, telecommunications among others.

However, spending on infrastructure has been an issue for policy discourse among scholars the world over. Studies have shown that investment in infrastructure has tremendous positive impact on nation's economic growth and development. Such studies include that of Agenor and Dodson (2006), Adenikinju (2005), Sanchez – Robles (1998), Caning *et al.* (1994) and Aschauer (1989).

Therefore, a country with poorly developed infrastructure has a potential of increasing its gross output if it improves upon its infrastructural facilities. Investment in infrastructure according to Blejer and Khan (1984); Greene and Villarueva (1999) and Solano (1983) stimulates or crowds in private investment, reduces cost and opens new markets thereby engendering profits and employment. However, investment in infrastructure in developing countries has been reported to be suboptimal (Heller and Diamond, 1990; World Bank, 1994).

In Nigeria, several government policies have led to infrastructure decay, which has been characterized by erratic power supply, inefficient telecommunication, poor urban and rural road networks which have resulted in a near stagnant economic performance (BPE, 2003).

Deficiencies in infrastructure and inefficient delivery of social services such as roads, water, sanitation, shipping, transport, power, energy, information and telecommunications have led to crippling transaction costs that have affected trade thereby reducing the competitiveness of the countries products in the world market. However, the many areas of public expenditure call for the prioritizing of expenditure on growth enhancing sectors of the economy of which infrastructure are of utmost necessity.

The need for investment in infrastructure and other public goods as a strategy for increasing urban and rural productivity and national economic growth and development has remained a subject of renewed attention in most developing economies. Several studies have been carried out to ascertain the direction of association between expenditure on infrastructure and economic growth of several developed and developing countries. Among this early studies include Aschauer (1989a), Ghali (1997), Balducci *et al.* (2004), Caldevon and Servan (2004) and Agenor and Dodson (2006). In these studies, they established positive effect of expenditure on

infrastructure and economic growth. Most of these studies made use of the Ordinary Least Squares (OLS) technique of estimation, which may not be adequate where the data are non-stationary as it results in spurious regressions and long-run economic growth could not be established. Others who have used most recent econometric methods of analysis are Holten and Schwab (1991), Holtz-Eakin (1994), Garcia-Mila *et al.* (1996), Peirara (2000) and Fedderke *et al.* (2006) *inter alia*. Some of their results were contrary to those earlier obtained. In effect, there is no consensus on the direction of relationship between infrastructure and economic growth.

For Nigeria specifically, a number of studies that have been carried out on public expenditure in general had concentrated on the growth trend on public expenditure nationally and on State basis (Phillips, 1971; Olaloku, 1975; Lambo 1987; Olowoloni, 1981). Others considered the effect of public expenditure on infrastructure (specifically) on economic growth and obtained positive signs using the Ordinary Least Squares (OLS) analytical technique (Aigbokan, 1999; Odedokun 1997 and Odedokun, 2001). None of these studies in Nigeria has considered the determinants of expenditure on infrastructure. However, some authors in other countries have empirically verified the factors that influence public expenditure on some infrastructure (telecommunication and Transport). Included here are Randolph *et al.* (1996), James *et al.* (2007), and Chakraborty and Mazumdar (2006), Fedderke *et al.* (2006). There is a near absence of published empirical study on the determinants of public expenditure in Nigeria via cointegration and error correction approach. The importance of infrastructure in the economic growth process of any nation cannot be overemphasized. The use of cointegration and error correction modeling in this study will address the shortcomings of the Ordinary Least Squares and therefore provide reliable estimates of elasticity that will engender sound policy making.

The inadequacy of empirical information on the macroeconomic impact of expenditure on infrastructure in the study area makes it justifiable to carry out this study, given the importance of investment in infrastructure on the overall development of the economy. Essentially, the broad objective of the present study is to analyze the macro economic impact of public expenditure on infrastructure and economic growth using available time series data in the country from 1970 to 2006.

The remainder of this paper is organized as follows: section two provides a brief overview of infrastructure situation in Nigeria. The section that follows presents some theoretical issues on which the model is founded. The model and estimation procedures are presented in section three. Next is the empirical results and discussion, while the last section concludes and provides policy recommendations.

## 2. Some Theoretical Issues

The theoretical underpinning of this paper is anchored on four theories of public expenditure growth. These include:

- Samuelson's Pure Theory of Public Expenditure,
- Musgrave and Rostow Theory of Public Expenditure Growth,
- Wagner's Law of Increasing State Activity; and
- Peacock and Wiseman Theory of Public Expenditure.

Earlier researchers concentrated their findings on the effects of public expenditure growth on employment and prices (Asibola, 2005; Nyong, 2000 and 1998; Fan, Hazell, and Thorat, 2006). There are several of such theories, but a few of these would be examined in this paper.

Samuelson's pure theory of public expenditure is particularly concerned with the proper way of allocating resources between the public and private sectors. Samuelson assumed that there are two kinds of goods, namely, private good M and Public good Y and two individuals G and P. He upheld that the model of budget determination is based on individual preference function. Samuelson further maintains that whereas there is rivalry in the consumption of private goods, and non-rivalry in the consumption of public goods. This relationship could be presented in equation 2.1.

$$M = GM + PM \text{ -----(2.1)}$$

Where GM = consumption of private good M by G;

$$PM = \text{Consumption of private good M by P.}$$

It then follows that, an increase in the consumption of M by G leads to a corresponding decrease in the consumption of M of P and vice versa. This implies divisibility of supply and demand occasioned by rivalry in consumption of good M.

Conversely, in the case of public good whose consumption is non-rivalry, we have;

$$M = FM + EM \text{ ----- (2.2)}$$

From equation (2.2), consumption of M by E is not influenced by the consumption of F. The statement of the equation expresses non-rivalry and efficiency of distribution of good reached. Thus, it is not possible to attain redistribution from a given optimum solution without someone else worse off. This is the *Pareto Optimality* situation.

Musgrave and Rostow theory of public expenditure growth is based their explanations of increasing public expenditure on the need to provide social amenities for growth and development. They further averred that at the development stage of an economy, some capital projects are needed to accelerate the growth and development of the country such as establishment of hospital, good road network, schools *inter alia*. Thus, government expenditure is a function of the developmental stage of an economy (see equation 2.3).

$$GE = f(\text{Pop, Rev, Gov, GDP, Pp, BA} \dots\dots\dots X_n) \dots\dots\dots (2.3).$$

Where:

- GE = Government Expenditure;
- Pop = Population;
- Rev = Revenue;
- GDP = Gross Domestic product;
- Pp = Price of Crude Oil;
- BA = Budget Allocation;
- Xn = other indices such as health services delivery, transportation, road network, education, etc.

The central thesis of the prescribed theory is on the time pattern of government expenditure. According to Rostow (1961), in the early stages of economic growth and development, public sector investment as a proportion of total investment of the economy is found to be high. He affirmed that the public sector provides social overheads such as roads, transportation system, sanitation system, law and order. Others include; health, education and housing. This expenditure is essential to propel the economy into the take-off stage (see equation 2.4).

$$G \sum a \frac{1}{P_s} \dots\dots\dots (2.4)$$

- Where:  $G \sum$  = Government expenditure;  
 K = Constant maturity stage (in years);  
 Ps = Private Sector

Consequently, there is the tendency for government expenditure to increase in order to deal with the problem of market failure.

Musgrave's theory of public expenditure growth attempts to relate the demand for public services to the stage of economic development of a country.

At high level of per capita income which is a characteristic of advanced economies, the rate of public sector growth tends to fall as more basic needs are satisfied by the citizens. In sum, private sector expenditure rises while government expenditure falls at this stage (see equation 2.4).

Essentially, of Rostow's five stages of growth, the first three are relevant to developing countries with the take-off stage being central in Rostow's model. The plausible explanation for this is that as development expands, the rate of productive investment rises from 5% or less to over 10% of national income (Nyong, 2005; BECAO, 1992; Khan and Reinhart, 1990).

In a nutshell, Rostow's provocative application of a stage approach to development process provides broad-sweeping views of economic growth and development (Blejer and Khan, 1984, Brett, 1988; Landau, 1983).

Wagner's law of increasing state activity states that as per capita income in an economy grows; the relative size of the public sector will grow. He divides government expenditure into three categories, namely, administration and defense, cultural and welfare functions, and provision of direct services by government in cases of market failure.

Rather than allow for monopoly to emerge, government usually create statutory corporations such as NEPA (now Power Holding Company of Nigeria – PHCN), Water Boards, Nigeria Airways, NITEL, Post Office *inter alia* cushion harsh economic situation of her citizens (Taiwo, 1990; Landau, 1983; Lesser, 1991). He further posits that as the economy becomes industrialized, urbanization and high density living result. This invariably leads to externalities (market failure) and congestion which require government intervention and regulation (Nyong, 2005; Ayub, and Hegstad, 1986).

The growth in public expenditure on education, recreation, health, and welfare services is explained in terms of their income-elastic want (Meier, 1984; Swanson & Terferra, 1989; World Bank, 1981 Nyong, 2005). Wagner further submits that as real income increases public expenditure on education, health, transportation, road network etc would increase more than in proportion. This explains the rising ratio of government expenditure to gross national product (GNP) as reported by Nyong (2005) in his public policy assessment of Nigeria expenditure situation.

Peacock and Wiseman theory of public expenditure is based on the political theory of public expenditure determination which state that "government like to spend more money, that citizens do not like to

pay more taxes, and that government need to pay some attention to the aspiration and wishes of their people". Their contention was that government expenditure does not grow in a smooth and gradual manner, but in stepwise fashion (i.e. the displacement hypothesis).

The occurrence of unexpected social disturbance would necessitate an increase in government expenditure (Ajibola, 2005). For instance, the bomb blast in United States of America, London, Ikeja in Lagos – Nigeria in recent times, etc necessitated government spending money to repair the damage done to lives and property in the affected areas.

The arguments for public policy stance, in terms of expenditure as the key policy instrument, rest therefore on the fact that the functioning of the market cannot by itself, activate the signaling response and mobility of economic agents to achieve efficiency in both static (allocative efficiency) and dynamic (shift in the production frontier) terms (Arnat, 1998& Chakraborty, 2003)

The ideal of public expenditure proceeds from market failures of one kind or another. Markets fail to secure appropriate signals, responses and mobility due to:

- a) Not all goods and services are traded. Markets can not determine the prices of public goods
- b) State intervention is necessary also for securing income redistribution;
- c) Information asymmetry between the providers and consumers of services such as social insurance can give rise to the problems of moral hazard and adverse selection;
- d) Goods exhibiting externalities in consumption and production force a wedge between market prices and social valuation and the market will not ensure a socially desired supply; and
- e) Some goods are characterized by increasing returns to scale. In such situations as natural monopolies; society can gain from lower prices and higher output when public sector is the producer or a subsidy is paid to the private sector to cover the losses of producing optimal output (Reo, 1998, Chakraborty, 2003)

The theoretical and empirical advancement towards public policy and development intervention in providing infrastructural development reflect the community's growing concern with social aspects of development, roads, water supply, electricity, steel-mills, dams and machine building industries have now been displaced from the commanding heights of development strategy, on the other hand, the so-called soft sectors such as education, health, telecommunication and transportation have occupied the centre stage of development (Mundle, 1998 and Edame, 2008). However, certain public goods such as defense, administration, a clean environment, etc that cannot be provided by market, because no consumer can be excluded once these services are provided and hence consumers will not "buy" these services (Mundle, S. 1998)

### 3. METHODOLOGY

#### The Model

The hypothesized structural relationship between public expenditure growth and the factors that influence it will consist of a number of regression equations with expenditure on the specified infrastructure being the dependent variable. The model for the determinant of expenditure on infrastructure was a modified version of Chakraborty and Mazumdar (2003), Fedderke *et al.*( 2003 ) and Fan and Rao (2003).The structural form of the model is specified as follows:  $FY_{it} = \Phi Z_{it} + \beta X_{it} + U_{it}$  ----- (3.1)

#### Where

$FY_{it}$  = growth of expenditure on the specified infrastructure

$Z$  = Vector of conditioning variables;  $Z_{it}$  = Vector of fiscal variables on infrastructure in time  $t$ ;  $\Phi$  = Vector of parameters of conditioning variables;  $\beta$  = Vector of parameters of fiscal variables;  $U_{it}$  = error term  
Equation 2.1 would be specified as:

$$PE = \beta_0 + \beta_1 GREV + \beta_3 POPD + \beta_7 EXTRES + \beta_9 OPN + \beta_{10} URB + \beta_{12} PE_{t-1} + \beta_{13} DUM + U_t \dots \dots (3.2)$$

Where:

$PE$  = Public expenditure (N million)

$GREV$  = Government revenue (N million) ( $\beta_1 > 0$ )

$POPD$  = Population density ( $\beta_3 > 0$ )

$EXTRES$ =External reserves (N) ( $\beta_7 > 0$ )

$OPN$  = Openness. This is measured as fraction of imports and exports in  $GDP(X + M)/GDP$  ( $\beta_9 > 0$ )

$URB$  = Rate of urbanization. This is the annual percentage of total population living in urban areas ( $\beta_{10} > 0$ )

$PE_{t-1}$  = Lagged public expenditure ( $\beta_{12} < 0$ )

$DUM$ = Dummy, indicating transition from military to democratic rule between 1970-1983 and 1985-1999(military rule);=1 1979 -1983 and 1999 -2006 (Civilian rule)=2

$U_t$  = Error term, assumed to be distributed as *white noise*.

#### Model implementation procedures

The estimation of the model follows the Johnsen procedure in co-integration.

This approach is necessary because it has been found that a large number of time-series data used in econometric analysis are non-stationary which means they have tendency to increase or decrease over time. The

### Chow test

The test of stability (parameter constancy) of the public expenditure function was carried out using the Chow test (Chow, 1960). The test is to ascertain whether public expenditure function over the years has been stable. Specifically, it was used to determine whether the public expenditure function was same before the military and post-military era was introduced. The test sought to investigate whether public expenditure has a predictable impact on economic development and other variables over the years.

The Chow test formula is expressed thus:

$$F^* = \left[ \frac{(\sum e_p^2 - (\sum e_1^2 + \sum e_2^2)/k) \dots \dots \dots}{(\sum e_1^2 + \sum e_2^2)/(n_1 + n_2 - 2k)} \right] \dots \dots \dots (3.8)$$

Where:

$F^*$  = observed F ratio

$\sum e_p^2$  = Pooled unexplained variations of two periods: 1970 – 1983 and 1985 – 1999 and between 1979-1983 and 1999-2006 for the military and democratic government respectively;

$\sum e_1^2$  = unexplained variations of public expenditure growth rate during the military government 1970 – 1983 and between 1985-1999;

$\sum e_2^2$  = unexplained variations of public expenditure growth rate during the democratic government 1979 – 1983 and between 1999-2006;

$n_1$  = number of observations during the military period; (1970 – 1983 and 1985-1999);

$n_2$  = number of observations during the democratic period (1979 – 1983 and 1999-2006);

$k$  = total number of coefficients including the intercept.

$n_1 + n_2 - 2k$  = Degrees of freedom.

### Switching Regression test

We apply the switching regression model to test hypothesis two as adopted by Maddala (1983), Lokshin and Sajala (2000) given the latent structure (equations 3.9-3.10)

Thus, we specify using the observed separation indicator as follows:

$$PE_0 = G_0 + b_1 x_{ij} + b_2 SAP + b_3 RGDP_{t-1} + U_t \dots \dots \dots (3.9)$$

$$PE_0 = G_0 + b_0 x_{0j} + b_2 SAP + b_3 RGDP_{t-1} + U_t \dots \dots \dots (3.10)$$

Where:

PE = public expenditure (N million)

$X_{ij}$  = observed indicate for military value 1 ( $X_{ij} > 0$ )

$X_{0j}$  = observed indicate for democratic governance value 0 ( $X_{0j} > 0$ )

SAP = government policy shift (0 = pre-SAP, 1 = SAP and thereafter (SAP > 0))

$U_t$  = error term, assumed to be distributed as white noise  $b_1, b_2, b_3$  = regression coefficient.

$G_0$  = Regression constant

$b_1, b_2, b_3$  = regression coefficients

Although the use of switching regression in time series econometrics have not been popular, and it has been widely criticized on grounds of inefficiency, particularly in the estimation of binomial series in recent times. In spite of its inefficiency, a switching equation has been found to sort individuals over two different states (with one regime observed). The econometric problem of estimating a model with endogenous switching arises in a variety of settings, especially in labour economics (see for instance, Lee (1978), modeling of housing demand (Thorst, 1977) and the modeling of markets in disequilibrium (Adamchik and Bedi, 2000). In spite of its ill-characteristics, models with endogenous switching can be estimated one equation at a time either by two-stage Least Square (2SLS) or Maximum Likelihood Estimation Techniques (MLE). These approaches, however, require potentially cumbersome adjustments to derive consistent standard errors. Besides, the use of this model relies on joint normality continuous equations (Lokshin and Sajaia, 2004).

### The data

The study made use of secondary time series data. The data were sourced from various issues of the Central Bank of Nigeria (CBN) Statistical Bulletin, World Bank, the International Financial Statistics (IFS) of the International Monetary Fund (IMF) and the Federal Bureau of Statistics (FBS).

## 4. EMPIRICAL RESULTS

### Tests for Stationarity

The results of the unit root tests are presented in Table 4.1. The null hypothesis of the presence of a unit root (non-stationarity) was tested against the alternative hypothesis of the absence of a unit root (stationarity),

PE(public expenditure), GREV (Government Revenue), URB (rate of urbanization and DUM (Dummy – Administration) were not stationary at their levels as shown by the calculated ADF statistics which are lower in absolute terms than the standard critical values. Thus, they were differenced once each to make them stationary.

On application of the ADF test on their first differences, they all became stationary as indicated by the value of their respective ADF statistic which are both larger (in absolute terms) than the standard critical values, thus leading to the rejection of the null hypothesis. From the above results, it is evident that the variables are integrated of order 1, that is, are  $I(1)$ . Conversely, POPD (population density), OPN (openness) and EXTRESS (External reserves) were stationary at their levels as the null hypothesis of the presence of a unit root in the series was rejected as shown by the higher values (in absolute terms) of the calculated ADF statistics compared with their respective critical values. In this case, we say that these series are integrated of order zero that is  $I(0)$ . We then proceed to discuss the results of the multivariate cointegration analysis. Since the time series are non-stationary, it became necessary to test for cointegration. By using the log-level form of the series, we estimate a multivariate cointegration relationship to establish the existence of a long-man equilibrium relationship.

### Cointegration Tests

Table 4.2 shows the results of the multivariate cointegrating tests. The Johansen Maximum Likelihood method, which uses the trace test and maximal-eigen value test statistics to determine the rank  $r$ , of the long-man impact matrix of the error correction mechanism was employed. The test relations were estimated with intercept and linear deterministic trend in a vector Auto Regression (VAR) model of order  $I$  with a Lag Length of 1, which was found to be the most parsimonious for the data series. The Johansen cointegration tests are based on the Maximum Eigen value of the stochastic matrix as well as the Likelihood Ratio tests which is in turn based on the trace of the stochastic matrix.

From our results, it is evident that both the trace test and maximum eigen value test indicate one cointegrating equation as the null hypothesis of  $r=0$  is rejected. Thus, we conclude that there is a unique long-man equilibrium relationship between public expenditure on infrastructure, government revenue, population density, openness, external measures, rate of urbanization and administration.

However, the Johansen model is a form of VECM and where only one cointegrating vector exists, its parameters can be interpreted as estimates of the long-run cointegrating relationship between the variables concerned (Hallam and Zanoli, 1993). Our cointegration coefficients normalized on the determinants of public expenditure on infrastructure in Nigeria are presented as long-run estimates in Table 4.3.

### Vector Error Correction (VEC) Estimates

Table 4.3 shows the results of the VECM estimates for the determinants of public expenditure on infrastructure in Nigeria.

Both the long and short-run estimates, the parameter constancy (Chow test) cum diagnostics are presented (see Table 4.3). From the results, it can be observed that the model fits the observed data fairly well as indicated by the adjusted  $R^2$  (0.9763) and F-statistic (152.3468) of the relevant error correction equation (Table 4.3). Moreso, the signs of the coefficients meet *a priori* expectations. Thus, this implies that government revenue population density openness and external reserves jointly explain public expenditure growth on infrastructure during the periods under investigation.

These results are over bearing and carry with them some relevant policy implications. In the short-man government revenue is inelastic (0.1201) but with the sign conjectured, while in the long-run, government revenue is 0.0909 (inelastic). Clearly, both coefficients are inelastic and suggest that 10% increase in government revenue increases public expenditure by 1.201% in the short-run while less than unity (0.909%) in the long-run (Table 4.3). This is an indication that a policy geared towards increasing public expenditure by increasing government revenue may not achieve its purpose, at least in the short-run.

In the same vein, the elasticity of the population density is -0.884 in the long-run, while the short-run estimate is 0.0248 both of which are inelastic and not significant respectively. Albeit the short-run estimate is appropriately signed in contrast to the long-run. This implies that a 10% rise in population density would reduce public expenditure by 0.884% in the long-run, while the same amount of increase in population density would increase public expenditure by 0.248% in the short-run (Table 4.3). Thus, a rise in population density would evoke a proportionate increase in public expenditure growth in the long-run.

By the same token, openness is 0.1461 and 0.0953 and is inelastic respectively for long and short-run estimates though with the signs conjectured. Only the short-run estimates were significant at 10% level. These results indicate that a 10% increase in openness would have a corresponding increase of 1.461% and 0.953% in public expenditure growth for long and short-run respectively.

Thus, this means policy actions to significantly encourage openness in the economy would be meaningful in the long-run compared to the short-run estimates. Moreso, the long-run (0.1749) and short-run (0.0403) elasticities of the external reserves are inelastic though not appropriately signed at the long-run. Clearly, the external reserve is more desirable in the short-run than the long-run estimates. Thus, increasing external

reserves by 10%, for instance, would increase public expenditure growth by 0.403% in the short-run (Table 4.3).

The elasticity of rate of urbanization is  $-2.0409$  in the long-run, while the short-run estimates is  $-0.0772$  though with the expected signs, and not significant respectively.

This implies that, a 10% rise in rate of urbanization would reduce public expenditure growth by 20.409% in the long-run, while the short-run changes is 0.772% based on *a priori* consideration. In the theoretical sense, a 10% rise in the rate of urbanization, evokes a greater than proportionate (about 20%) increase in public expenditure growth, at least in the long-run while a 0.772% could be achieved in the short-run during the prescribed periods.

The dummy (Military – Civilian Administration) showed an inverse relationship, but significant at the 1% level and explain changes in public expenditure growth. This result indicates that the administration (Military/Civilian) impacted negatively though significantly on the growth in public expenditure during the periods under investigation.

The error correction coefficient ( $-0.9938$ ), which measures the speed of adjustment towards long-run equilibrium carries the expected negative sign and it is very significant at the 1% level. The coefficient indicates a feedback of about 99.38% of the previous year's disequilibrium from the long-run elasticity of government revenue, population density, openness, external reserves and rate of urbanization. This implies that the speed with which government revenue, population density, openness, external reserves and rate of urbanization adjust from short-run disequilibrium to changes in public expenditure growth in order to attain long-run equilibrium is 99.38% within one year.

The strong significance of the ECM support cointegrating and suggest the existence of a long-run equilibrium relationship between public expenditure growth on infrastructure and the aforementioned variables, which determines it.

These facts suggest that short-run changes in government revenue population density openness, external reserves and rate of urbanization remarkably shaped public expenditure growth in Nigeria from 1970 to 2006.

**Table 4.1: Results of Augmented Dickey-Fuller (ADF) Unit root tests**

Variable level	ADF Statistic	Critical level 1%	Variable First Difference	ADF Statistic	Critical level 1%	Order of integration
PE	3.5845	-3.6892	$\Delta$ PE	-4.6481	-3.6998	1

The strong significance of the ECM support cointegrating and suggest the existence of a long-run equilibrium relationship between public expenditure growth on infrastructure and the aforementioned variables, which determines it. These facts suggest that short-run changes in government revenue, population density, openness, external reserves and rate of urbanization remarkably shaped public expenditure on economic growth in Nigeria from 1970 to 2006.

In sum, based on the granger causality test results, there is a strong evidence that administration, external reserves, government revenue, population density and rate of urbanization could collectively or individually influence infrastructural growth vis-à-vis long-run economic growth.

### Conclusions and Policy Recommendations

One interesting thing about this study is that it attempt to compare methodological empirics of studies conducted by early researchers to the present one, which made use of he vector error correction approach. The study analyzed the macroeconomic impact of public expenditure on infrastructure and economic growth in Nigeria from 1970 to 2006 using cointegration and error correction mechanism approach. (ECM)

Results indicate that the response of rate of urbanization, openness, government revenue, external

reserves, population density and type of government to public expenditure is high, particularly in the short-run and with a higher adjustment toward long-run static equilibrium. Thus, short-run changes in rate of urbanization, openness, government revenue, external reserves, population density and type of government (administration), remarkably shaped growth on public expenditure in Nigeria. On the contrary, the Vector Error Correction (VEC) show that the level of public infrastructure (road construction, water supply, electricity supply, transport/telecommunication and housing/ environment is very low, particularly in the short-run and with a weak adjustment toward long-run static equilibrium. This result is very informative as it clearly shows the deterioration in our public utilities, which suggests that expenditure in the aforementioned infrastructure, has not yielded positive results over time.

The results of the error correction mechanism (ECM) indicates a feedback of about 99.38% of previous year's disequilibrium from long-run elasticity of rate of urbanization, openness, government revenue, external reserves, population density and type of government.

The analysis further revealed that public expenditure on infrastructure in Nigeria has been stable between 1970 and 2006 based on the Chow test results and the switching regression test. This indicates that public expenditure have been having predictable effect on the variables which influence it.

The study has shown that rate of urbanization, government revenue, population density, external reserves and type of government jointly or individually influence public expenditure on infrastructure in Nigeria, as indicated by their inclusion in the parsimonious model. Based on this analysis and the results earlier discussed, it is concluded that although expenditure on infrastructure has significantly influenced its growth. It is pertinent too, to investigate whether huge public expenditure truly influences development.

The study recommends the need for government and its agencies to monitor the expenditure on infrastructure, adhere strictly to *due process* in accordance with the enabling fiscal policy and the Millennium Development Goal (MDG) blue prints. Specifically, these can be achieved via the following media;

- a. Openness of the economy had a significant and positive effect on expenditure on infrastructure, therefore, policies that would engender the openness in the economy especially in the long-run is recommended.
- (b) There is also need for government to use the external reserves to finance infrastructural development, given the negative relationship between external reserve and expenditure growth on infrastructure
- (c) Government at all levels should hasten the rate of urbanization in the short-run, with a view to reducing the expenditure on infrastructure in the long-run.
- (d) Public expenditure growth on infrastructure was higher in the democratic regime than in the military, therefore to achieve more in infrastructural development, efforts should be made to sustain democratic rule in the country.
- (e) In spite of the increasing trend in public expenditure on the selected infrastructure, the reality on ground appears dismal, it is therefore imperative that agencies responsible for project monitoring to be up and doing to ensure that infrastructural project are actually implemented.
