Foreword

Urban public transport is an important part of the transport task and effective public transport systems provide benefits for both the community and the environment. Public transport in Australia's capital cities has been undergoing a resurgence in the last decade. The factors are many and varied, and include population growth, increasing densities and rising road congestion. However, consumer responses to increased interest rates, increased food prices and increased petrol prices are the main reasons for the recent rapid growth in public transport patronage.

This report presents modelling and forecasting of urban public transport use in Australia's capital cities. The work brings together data for all Australian capital cities and puts public transport into the context of total passenger travel within our cities. The modelling and forecasting help provide an understanding of the forces shaping the demand for public transport in our cities.

This project was undertaken by Dr Afzal Hossain and Dr David Gargett, assisted by Dr David Cosgrove.

Gary Dolman

At a glance

From the end of the Second World War in 1945 to the late 1970s, Australian urban public transport (UPT) suffered a large decline in absolute terms, and much more in mode share terms, as car ownership and suburban development boomed.

This report models UPT in the period from the late 1970s - when the decline in UPT mode share started to bottom out. The aim has been to be able to develop models of UPT that would allow long-term forecasting of UPT demand to be made. These would then be available to inform policy decisions regarding UPT infrastructure planning, urban transport reform, urban form, congestion and road safety.

The basic finding of the modelling was that UPT's share of total passenger travel has been basically flat at about 10 per cent from the late 1970s to 2004. But from 2005 to 2010 the UPT share rose, due to lower UPT fares and constraints on household disposable income.

Forecasting using the models reveals that the rapid growth in UPT in the late 2000s is likely to slow. Nevertheless, even with lower growth rates, UPT demand should increase by about one third between 2010 and 2030, with implications for infrastructure provision and other policy issues associated with public transport in our cities.

Contents

Executive Summary.....	1
Chapter 1 Introduction.....	9
1.1 Background to the study.....	9
1.2 Context of the study	10
1.3 Objectives of the study	11
1.4 Structure of the report	11
Chapter 2 Long-term passenger transport tasks in Australian capital cities.....	13
2.1 Long-term patterns in urban public transport passenger trips, 1900–2010	14
2.2 Public transport trips in metropolitan Australia, 1945–2010	14
2.3 Passenger transport task, personal vehicle travel and public transport travel, all capital cities, 1945–2010	25
2.4 Passenger transport task, 1977–2010	37
Chapter 3 Modelling urban public transport passenger task by capital cities, 1977–2010.....	49
3.1 Background	50
3.2 Methodology	50
3.3 Modelling results.....	54
3.4 Real fare and disposable income constraint elasticities	72
Chapter 4 Modelling and forecasting total passenger transport task by capital cities, 1965–2030	75
4.1 Background	76
4.2 Methodology for modelling (1965–2010) and forecasting (2011–2030) total passenger transport task.....	76
4.3 Results on total passenger transport task by capital cities: estimates (1977–2010) and forecasts (2011–2030)	104

Chapter 5	Forecasting the public transport passenger task, capital cities, 2011–2030.....	113
	5.1 Methodology for forecasting UPT tasks.....	114
	5.2 UPT passenger task, estimates (1977–2010) and forecasts (2011–2030).....	129
Chapter 6	Sensitivity Analysis.....	137
	6.1 Background	137
	6.2 Methodology	138
	6.3 Results	138
Chapter 7	Discussions and concluding remarks.....	147
	7.1 Background.....	147
	7.2 Methodology	147
	7.3 Results of the study	147

Glossary of terms

Base case	A medium scenario that reflects the economic conditions as at 2010.
Dead running	Journeys by a bus where no passengers are being transported over specified routes. An example of dead running is journeys between the depot and the bus station.
DIC	Disposable Income Constraint – the cost of petrol, food, rent/ mortgage, and savings.
Elasticity	The percentage change in the dependent variable resulting from a one per cent change in the independent variable, all else held constant (Litman 2004). For example, a real fare elasticity of -0.4 means that each 1.0 per cent increase in transit fares, causes a 0.4 per cent reduction in ridership. So, a 10 per cent fare increase will cause ridership to decline by about 4 per cent.
Estimate	Outcomes of modelling using data from 1977–2010.
Forecast	Outcomes of modelling using data from 2011 –2030.
GFC	Global Financial Crisis, starting in late 2008.
Household disposable income constraint	A derivative of several cost factors, such as mortgage, rent, food, petrol and household savings.
In-service kilometres	In-service kilometres are the kilometres travelled by buses operating over their scheduled routes over a year, excluding 'dead running' kilometres. Aggregate in-service kilometres are affected by a number of variables, including the number of buses, frequency of services and length of services (BITRE 2009).
'Larger capital cities'	Sydney, Melbourne, Brisbane, Perth and Adelaide
Predicted	Both estimates and forecasts
Saturating trend	A flattening upward trend
Significant effect	A statistical effect that reached the 5 per cent level of significance.
'Smaller capital cities'	Canberra, Darwin and Hobart
Time	A variable that increases by 1 for every year
Time squared	The square of 'Time'
Total metropolitan transport task	The sum of the passenger transport task across all eight Australian capital cities

Total transport task	Total passenger-kilometres by both private vehicles and public transport vehicles.
urban passenger task	See 'total passenger task'
Urban public transport	Transport of passengers by bus, rail, tram and ferry within cities
UPT	Urban public transport

Executive Summary

Background

Shortly after World War II, Australian cities were grouped tightly around a core central business district, with spokes radiating outward along railway lines. Urban public transport (UPT) accounted for about 70 per cent of passenger-kilometres (pkm).

Post-war expansion of the motor vehicle fleet both coincided with, and contributed to, the transformation of our cities from tightly knit cores to sprawling suburbs. For example, by 1970, urban extent of Sydney was triple its 1945 size, and by 2005 was five times the size of Sydney in 1945.

Most of these massive expansions to our cities were serviced by the growing motor vehicle fleet. From 1945 to 1980, the level of total pkm performed by UPT actually fell in most Australian cities (Gargett 1990). The share of total pkm performed by UPT declined from 70 per cent after WWII, to about 10 per cent of urban pkm in 1980, and remained at about that level for 25 years. In the last decade however, UPT has been undergoing a resurgence as a result of lower real UPT fares and disposable income constraints that have encouraged a switch from private motor vehicles.

The key features of urban passenger transport trends in Australian capital cities include:

- Between 1900 and 2010, UPT journeys in Sydney, Melbourne Brisbane peaked just after WWII, and then declined gradually until 1980. Since 1980, public transport passenger journeys have increased. A rapid increase in UPT share during the 2000's was due to pressures on household budgets from interest rates, food prices, petrol prices and a desire by households to increase savings.
- In 1945, total metropolitan public transport patronage, the sum of all UPT transport modes across Australia, was 1915.6 million passenger journeys. In 1979 this Figure decreased to its lowest point of 992.6 million passenger journeys, before rising again to 1513.4 million passenger journeys by 2010.
- Between 1977 and 2010, the total estimated metropolitan UPT task increased from 10.1 billion passenger-kilometres (PKM) to 19.1 billion pkm, an average annual growth of 1.96 per cent,
- Among the five major capital cities, the share of UPT in the total passenger task (UPT plus private road vehicles) grew in Brisbane and Perth, while the shares in Sydney, Melbourne and Adelaide decreased at first and then returned to their 1977 share by 2010. Among three minor capital cities, the shares of UPT passenger task increased in Darwin and Canberra, but decreased in Hobart.

Objectives of the study

The major objective of this study was to model the capital city UPT task in Australia between 1976–77 (hereafter referred to as 1977) and 2009–10 (hereafter referred to as 2010) and to provide long-term forecasts of these modelled estimates from 2010–11 (hereafter referred to as 2011) to 2029–30 (hereafter referred to as 2030). The aim was to provide information to assist policy-makers and planners in developing responses to projected future growth.

Methodology

UPT patronage was modelled using a two-step process:

1. Model total per-person travel in each capital city, and
2. Model UPT's share of that travel.

Total UPT patronage is then the product of modelled total passenger travel times UPT's mode share.

Several methods and procedures were used to estimate and forecast UPT tasks in capital cities.

Total travel per person in each capital city was modelled as a function of a saturating trend, petrol price, unemployment and the on-going effect of the global financial crisis (GFC).

UPT's mode share was modelled as a function of a "disposable income constraint" variable and real UPT fares. The disposable income constraint variable is a derivative of several socio-economic factors, such as mortgage, rent and food costs, petrol prices and household savings.

Sensitivity analysis was also carried out to assess the possible effect of petrol prices, UPT fares and the on-going impact of the GFC on the future UPT tasks in all capital cities.

Results

Modelling the urban public transport passenger task by capital city

For each capital city, a model of UPT mode share was constructed, of the form:

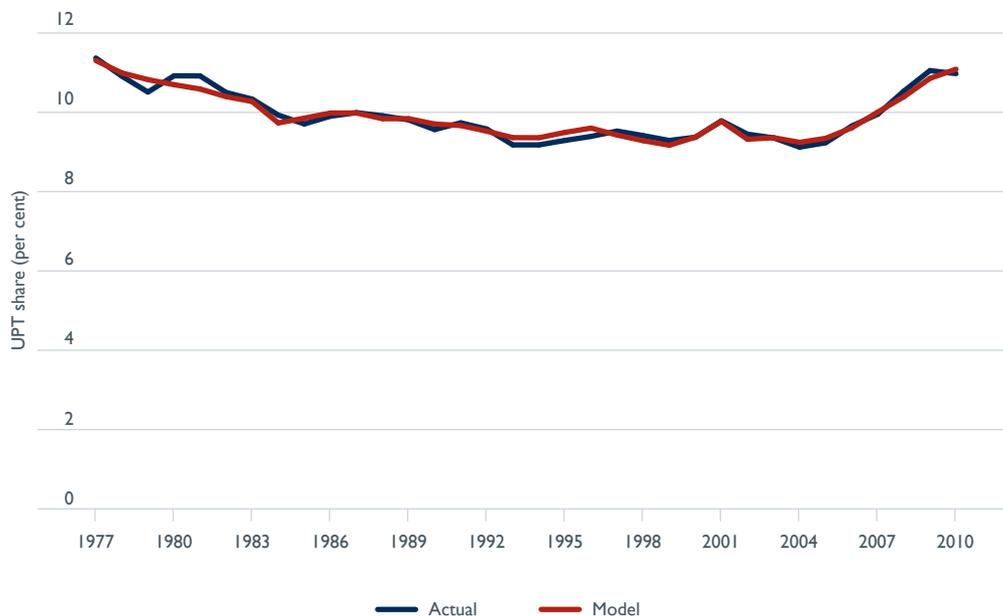

$$\text{UPT mode share} = f(\text{real UPT fares, household disposable income constraint, GFC effects, and event/supply/trend dummies})$$

The disposable income constraint (DIC) variable is a composite of several factors, such as mortgage, rent and food costs, petrol prices and the level of household savings.

The UPT fare and DIC variables were the most important of the explanatory variables.

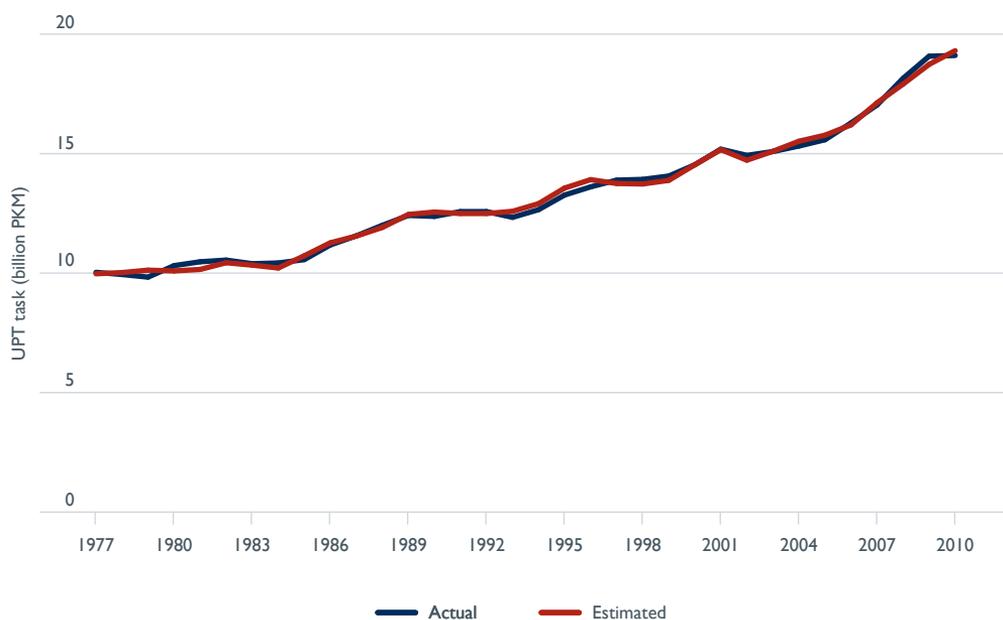

The models succeeded in explaining most of the variation in UPT mode share since 1977. Figure ES-1 shows the actual and modelled UPT mode share for metropolitan Australia.

Figure ES-1 Actual and modelled UPT mode share, metropolitan Australia

Multiplying the predicted UPT mode share by the estimated total urban pkm gives the modelled aggregate UPT task. This is shown in Figure ES-2 along with the actual UPT task since 1977. The fit is good.

Figure ES-2 Actual and modelled UPT task, metropolitan Australia

Modelling the total passenger transport task by capital city

For each capital city, a model of total passenger-kilometres per person (pkmpp) was constructed of the form:

$$pkmpp = f(\text{saturation trend, petrol prices, unemployment, GFC and dummies})$$

The saturating trend was approximated with a combination of a linear upward trend (time) and an exponentially increasing negative effect (time squared). Both variables were frozen once saturation was reached. The saturating trend was the most important of the variables considered. Petrol prices, unemployment, the GFC and dummies simply served to explain small and varying perturbations below the saturating trend. Figure ES-3 shows the various components of the predicted and actual passenger-kilometres per person for metropolitan Australia.

Figure ES-3 Actual and predicted components of passenger-kilometres per person, metropolitan Australia

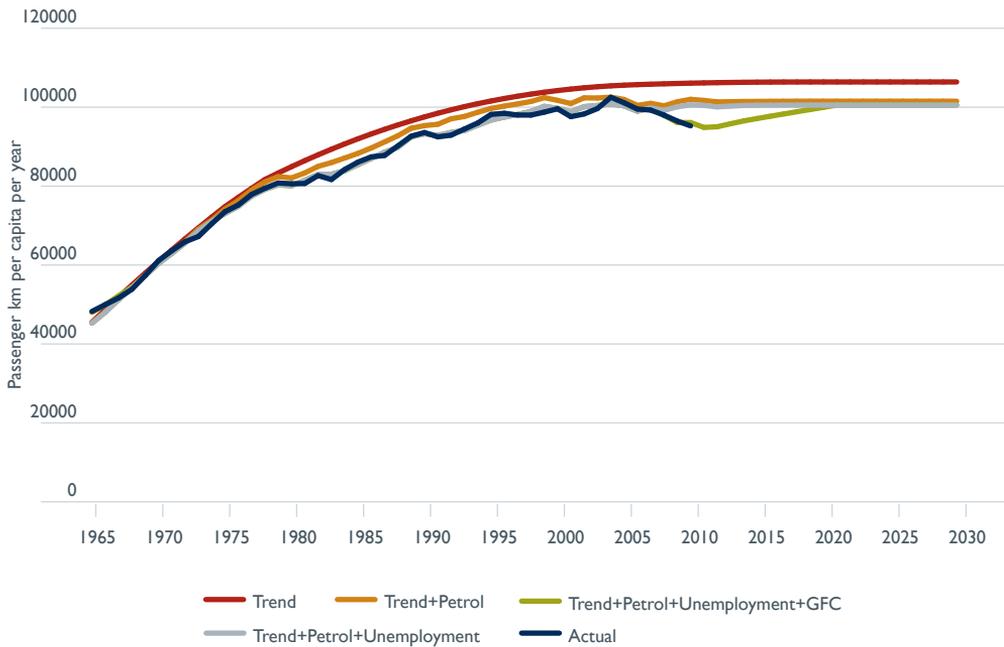

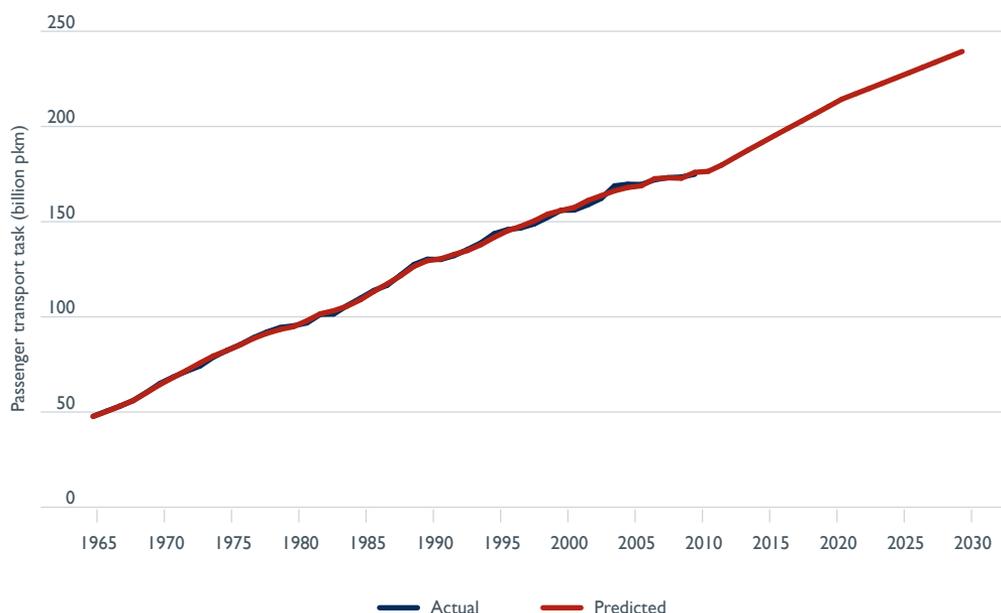

Figure ES-4 shows that the resulting prediction of the aggregate metropolitan Australia passenger-kilometre task lies very close to the actual series

Figure ES-4 Actual and predicted aggregate passenger-kilometre task, metropolitan Australia

Forecasts (2011–2030) of public transport passenger task by capital city

Forecasts of UPT mode share were made assuming constant real fares and a constant discretionary income constraint. (except for the GFC effect, which was assumed to wear off by 2020, with the result that the savings rate drops back to 3 per cent of GDP). The resulting forecast of UPT mode share is shown in Figure ES-5a for metropolitan Australia.

Forecasts of the total urban passenger task (UPT plus private vehicles) were made assuming petrol prices and unemployment would not change, while the GFC effect would wear off by 2020. Figure ES-5b shows the forecast for the aggregate passenger-kilometre task for metropolitan Australia. The recent (2005-2010) period of slow growth gives way to a period of rapid growth to 2020 as the GFC effect wears off. Thereafter growth returns to trend.

Multiplying the forecast aggregate task by the forecast UPT mode share gives the forecast for the UPT task to 2030. Under the basecase assumptions, the UPT task is forecast to grow by one third, from 19.1 billion pkm in 2010 to 25.3 billion pkm in 2030, as shown in Figure ES-5c. The average annual growth rate predicted for UPT over the next 20 years is thus 1.35 per cent per year.

Among five major capital cities, the share of the UPT passenger task is forecast to increase in Brisbane and Perth, while the shares are forecast to decrease in Sydney, Melbourne and Adelaide (see Table ES.1).

Irrespective of capital city, the UPT task is projected to grow at a slower pace than the historical growth rates.

Sensitivity analyses indicated that only increased UPT fares had much effect on these base-case forecasts.

Table ES.1 Forecasts of UPT passenger tasks (billion pkm) by capital city, 2011–2030

Capital city	UPT task (billion pkm)		Growth ^a (per cent)	UPT share (per cent)	
	2011	2030		2011	2030
Sydney	8.50	10.56	1.15	15.1	14.8
Melbourne	5.85	7.38	1.23	11.6	10.7
Brisbane	2.49	3.71	2.13	9.8	12.3
Adelaide	0.89	0.98	0.52	6.4	6.10
Perth	1.58	2.18	1.70	6.8	6.70
Hobart	0.09	0.1	0.86	3.5	3.50
Darwin	0.07	0.1	2.10	5.8	5.90
Canberra	0.26	0.33	1.31	5.3	5.30
All capitals	19.72	25.34	1.33	11.1	11.0

a Average annual growth rate of UPT task between 2011 and 2030.

Figure ES-5a Forecast UPT mode share, metropolitan Australia

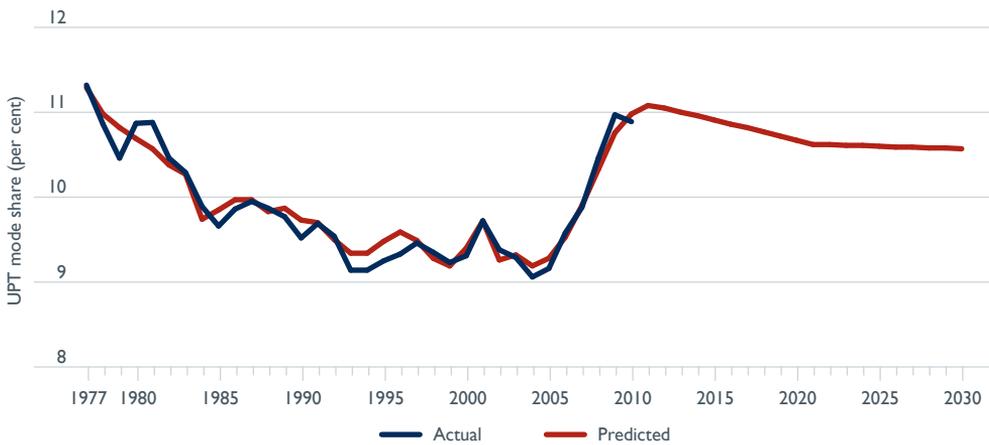

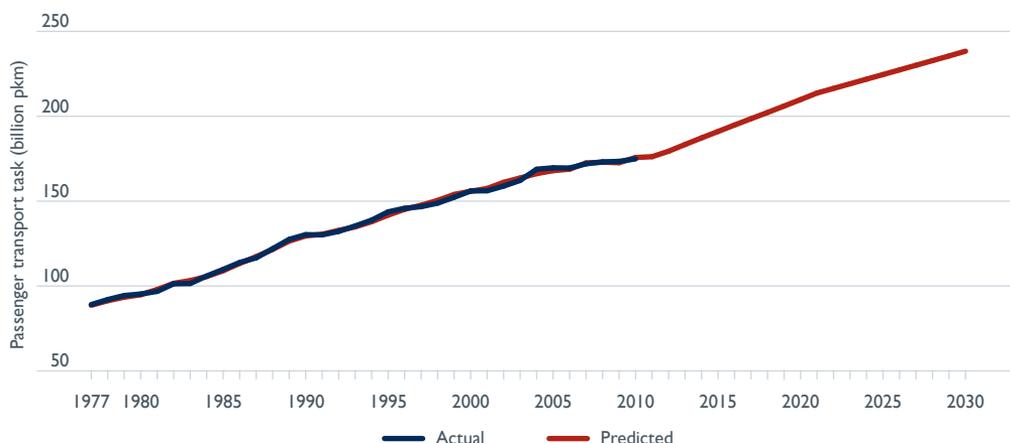

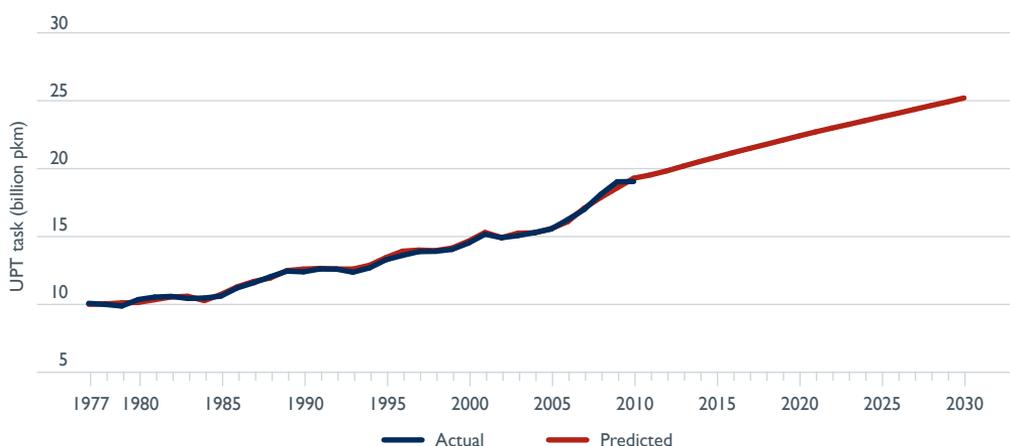

Figure ES-5b Forecast aggregate passenger-kilometres, metropolitan Australia**Figure ES-5c** Forecast UPT task, metropolitan Australia

Policy implications and conclusion

The forecasts suggest that demand for urban public transport in Australia should grow by about one-third over the 20 years from 2011 to 2030. This estimate of the future growth of the UPT task is useful for infrastructure planning, urban transport reform and energy-efficiency policy. The forecasts will assist local, state and federal government agencies, investors, transport regulators, public transport users and city planners to prepare for future transport growth in urban areas. The analyses will contribute to new and emerging policy issues in the areas of development of urban infrastructure, congestion amelioration and road safety.

CHAPTER I

Introduction

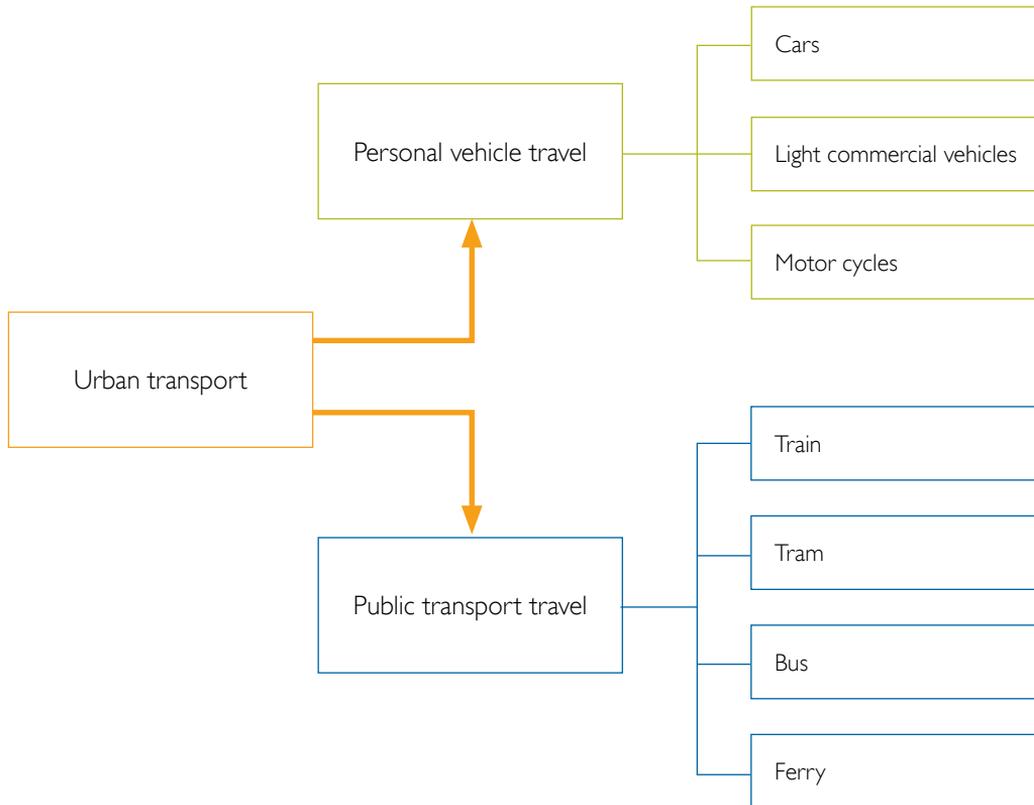

1.1 Background to the study

Australia is one of the most urbanised countries in the world. In 2011, around 65 per cent of the total estimated resident population (i.e. 14.5 million, out of 22.3 million) lived in capital cities (ABS 2012).

Private vehicle travel has been the growing mode of travel over the last 65 years. Urban public transport, once the dominant means of passenger transport around our capital cities (Gargett 1990, BTE 1999), now only accounts for approximately 10 per cent of total urban passenger travel. Yet despite its apparent low share of overall travel, UPT is still an essential component of urban transport systems, responsible for the majority of commuter trips to/from the CBDs of our major cities and providing specialist services for school children.

Urban public transport services in Australian cities are mostly by bus (bus and tram in Melbourne), with an important heavy rail share in Sydney and Melbourne, and a smaller rail share in Brisbane, Adelaide and Perth. Figure 1.1 shows the various components of road transport systems in Australia's capital cities.

Figure 1.1 Breakdown of urban transport modes in Australia’s capital cities

1.2 Context of the study

BTRE has previously produced estimates of all-modes capital city passenger tasks (in pkm) from 1977–2004 (BTRE 2007), subsequently updated to 2008 (BITRE 2009a). These two studies also produced capital city passenger task forecasts up to 2020.

Recently, Cosgrove (2011) presented long-term time-series for the usage patterns of UPT compiled for each Australian capital city, covering more than a century from 1900–2010. Long-term historical estimates are important because they demonstrate how the share of total urban travel done by UPT has changed over time. Public transit was dominant through the early part of last century, accounting for more than half of total urban pkm until around 1950, before gradually losing market share to the growing popularity of private car travel.

For this study, the capital city passenger task data was assessed and long-term forecasts between 2010 and 2030 were developed using econometric models.

1.3 Objectives of the study

The major objectives of this study were:

1. to model capital city public transport task in Australia between 1976–77 (hereafter referred to as 1977) and 2009–10 (hereafter referred to as 2010) and
2. to produce long-term forecasts of these modelled estimates from 2010–11 (hereafter referred to as 2011) to 2029–30 (hereafter referred to as 2030).

1.4 Structure of the report

The structure of this report is shown below.

- Chapter 2 Chapter 2 presents the historical trend (1900–2010) in urban public transport passenger journeys for Sydney, Melbourne and Brisbane, and the long-term trend (1945–2010) in urban passenger transport task by personal vehicle and public transport for all capital cities, including growth rates and share of total task.
- Chapter 3 Chapter 3 presents modelling of the urban public transport share of the total passenger task in each capital city for 1977–2010. The parameters used in modelling include household disposable income constraint, UPT fares, GFC effect and dummies. The disposable income constraint variable is a derivative of factors such as mortgage, rent and food costs, petrol prices, and desired levels of household savings.
- Chapter 4 Chapter 4 outlines the methodology for modelling and forecasting the total urban passenger task. The forecast results for the total passenger transport tasks from 2011 to 2030 for each capital city are also detailed.
- Chapter 5 Chapter 5 describes the methodology for forecasting the UPT passenger task in the eight Australian capital cities between 2011 and 2030. It also provides 'base-case' forecasts of future trends for the UPT tasks in each capital city, as well as the sum of all capital cities.
- Chapter 6 Chapter 6 gives the results of sensitivity analyses that assessed the possible impact of high and low petrol prices, high UPT fares and ongoing effects from the GFC on future UPT tasks in all capital cities.
- Chapter 7 Chapter 7 discusses the results and makes concluding remarks.

The appendices to this report provide more detail on various aspects of the report:

- Appendix A Metropolitan public transport trips by capital city by transport mode, 1945–2010
- Appendix B Annual public transport trips per person by capital cities, 1945–2010
- Appendix C Public and private passenger transport task and shares by capital cities, 1977–2010
- Appendix D Personal vehicle and public transport task by type of vehicle, all capital cities, 1977–2010

- Appendix E Estimates of real fares by capital cities, 1977–2010
- Appendix F Estimates of household disposable income constraint by capital cities, 1977–2010
- Appendix G Modelling data by capital cities, 1977–2010
- Appendix H Actual and estimated urban public transport share and passenger task by capital city, 1977–2010
- Appendix I Regression data for forecasting total passenger task, capital cities, 1965–2010
- Appendix J Actual and predicted metropolitan passenger-kilometres per person, individual capital city and total capital cities, 1965–2030
- Appendix K Actual and predicted total transport task, urban public transport share and urban public transport task, capital cities
- Appendix L Sensitivity analysis data and calculated urban public transport task by capital cities.

CHAPTER 2

Long-term passenger transport tasks in Australian capital cities

Summary

The key features of urban passenger transport trends in Australian capital cities are summarised below:

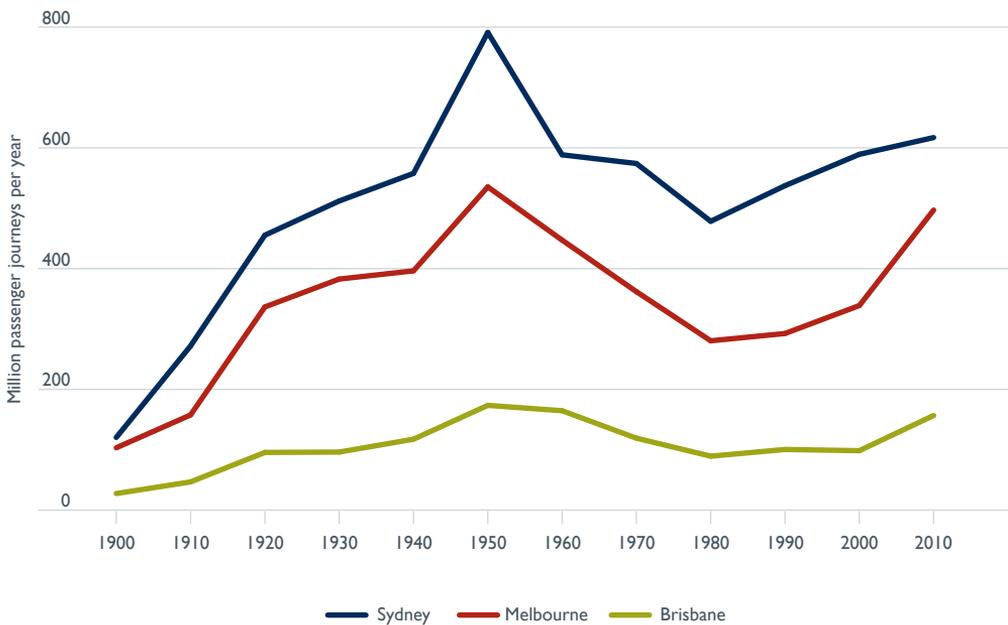

- Total passenger travel in capital cities, that is, travel by both private vehicle and public transport, has grown from 19.6 billion pkm in 1945 to 175 billion pkm in 2010, 9 times its former level.
- By contrast, the transport task by public transport vehicles increased from 13.6 billion pkm in 1945 to 19.1 billion pkm in 2010, only 1.4 times its former level.
- As a consequence, between 1945 and 2010, the personal vehicle share of the total passenger kilometres increased from 30.5 per cent to 89.1 per cent, while public transport's share decreased from 69.5 per cent to 10.9 per cent. By 2010, the passenger task by personal vehicles represented more than 90 per cent of the total passenger task in all capital cities except Sydney, where personal vehicles represented around 85 per cent.
- Most of the decline in UPT share happened between 1945 and the late 1970s. From then until 2004, UPT shares in most cities were unchanged, meaning that UPT was growing as fast as private vehicle travel.
- From 2005 to 2010, UPT has been undergoing a period of more rapid growth, leading to increased UPT shares in most cities.

2.1 Long-term patterns in urban public transport passenger trips, 1900–2010

Figure 2.1 shows the long-run pattern of urban public transport passenger trips in Sydney, Melbourne, and Brisbane since 1900. The number of passenger trips on public transport reached a peak in Sydney, Melbourne and Brisbane just after World War II. However, after the war, the growth shifted to private car ownership in the 1950s and continued to rise throughout the decades of the 1960s, 1970s and 1980s (Gargett 1990). This rise in private car ownership was accompanied by a corresponding shift away from the use of urban public transport in these three capital cities until the early 1980s.

This downward trend ended in the late 1970s and early 1980s and the use of urban public transport started to increase slowly. Rising petrol prices, increasing traffic congestion and parking problems, and (since 1985) increased prices of new automobiles contributed to a resumption of UPT growth.

Figure 2.1 Long-run pattern of urban public transport passenger trips: Sydney, Melbourne and Brisbane, 1900–2010

Source: Gargett (1990) and BITRE estimates

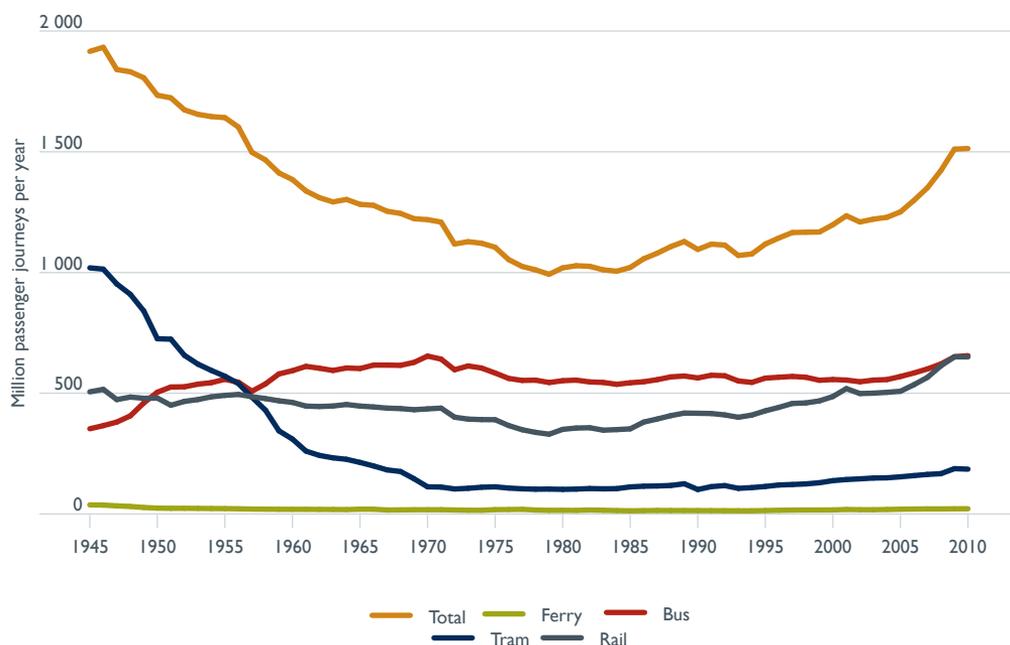

2.2 Public transport trips in metropolitan Australia, 1945–2010

This section presents data on metropolitan public transport trips in Australia between 1945 and 2010 by (a) transport modes and by (b) capital city. More detailed data on metropolitan public transport trips by capital city and transport modes and data on public transport trips per person by all capital cities during the same period is presented in Appendix A (see Table A.1).

2.2.1 By transport mode

Figure 2.2 shows metropolitan public transport patronage by millions of passenger trips by transport mode, as well as total metropolitan public transport patronage between 1945 and 2010. Figure 2.3 shows the average annual growth rates of total metropolitan public transport patronage and Figure 2.4 shows the share of metropolitan public transport trips by transport mode during the same period. The data underlying these three figures is in Table 2.1.

Figure 2.2 Metropolitan public transport trips (million passenger trips) by transport mode, 1945–2010

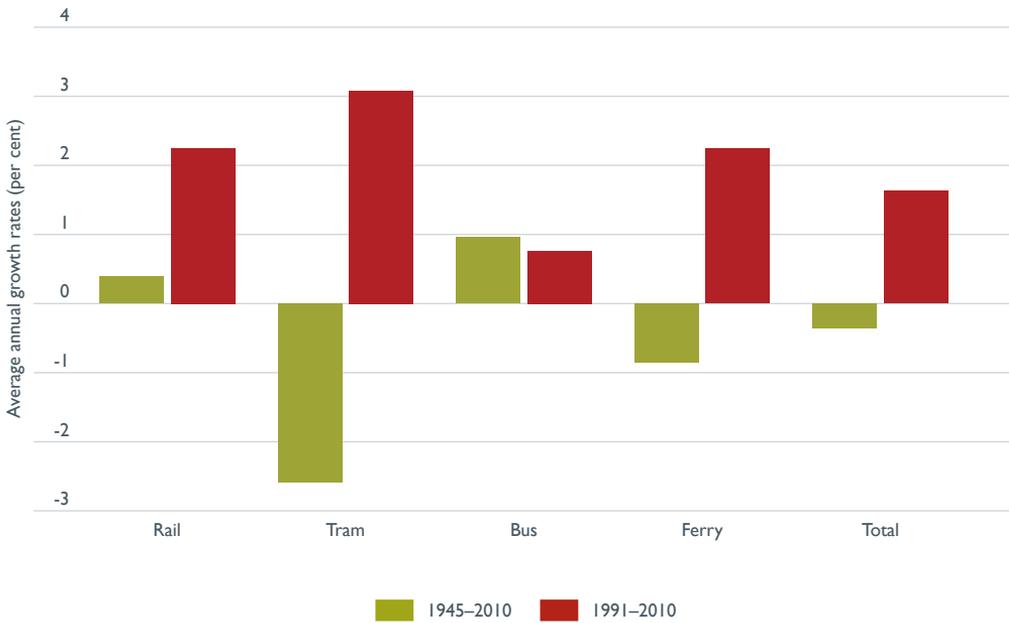

Source: BITRE estimates.

In 1945, total metropolitan public transport patronage for all transport modes was 1915.6 million passenger trips and it decreased to 1513.4 million passenger trips in 2010 (Figure 2.2 and Table 2.1). Among the various transport modes, bus transport patronage increased in the earlier years and then remained relatively unchanged until 2000, followed by an increase until 2010. On the other hand, rail transport patronage decreased in the earlier years and increased in recent years. There was a sharp fall in tram patronage until the early 1970s. However, tram patronage increased gradually from the late 1970s. Ferry patronage decreased slightly between 1945 and 2010.

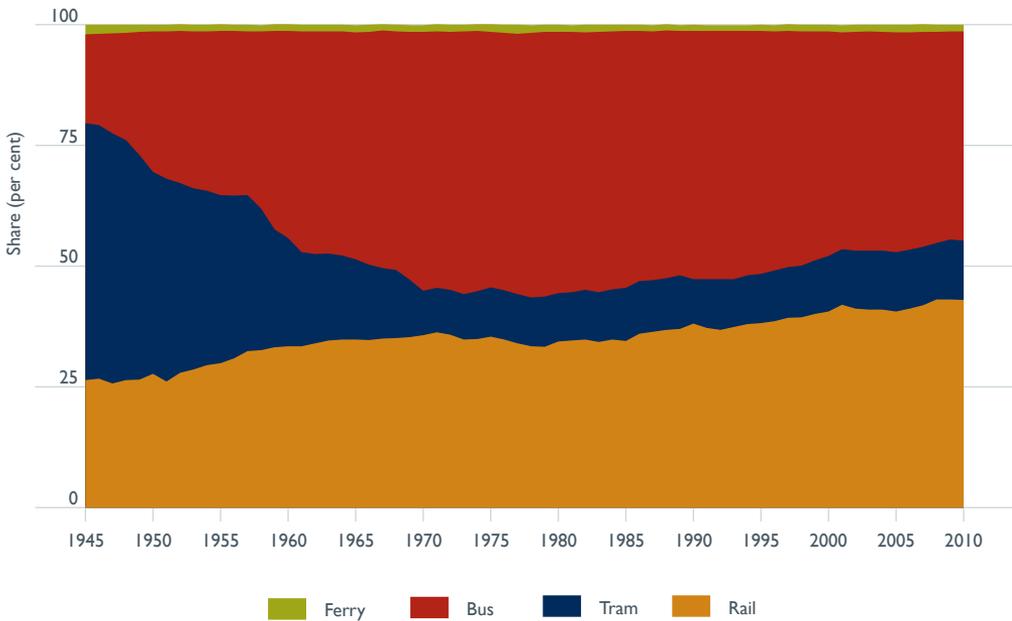

Rail and bus shares of total metropolitan public transport trips increased between 1945 and 2010 (Figure 2.4 and Table 2.1). In 1945, the rail journey share was 47.4 per cent and it increased to 61.7 per cent in 2010. Similarly, the bus journey share increased from 13.2 per cent in 1945 to 33.6 per cent in 2010. Between 1945 and 2010, the tram share decreased sharply until the early 1970s and then increased marginally, while the ferry journey share declined slowly during this period.

2.2.2 By capital cities

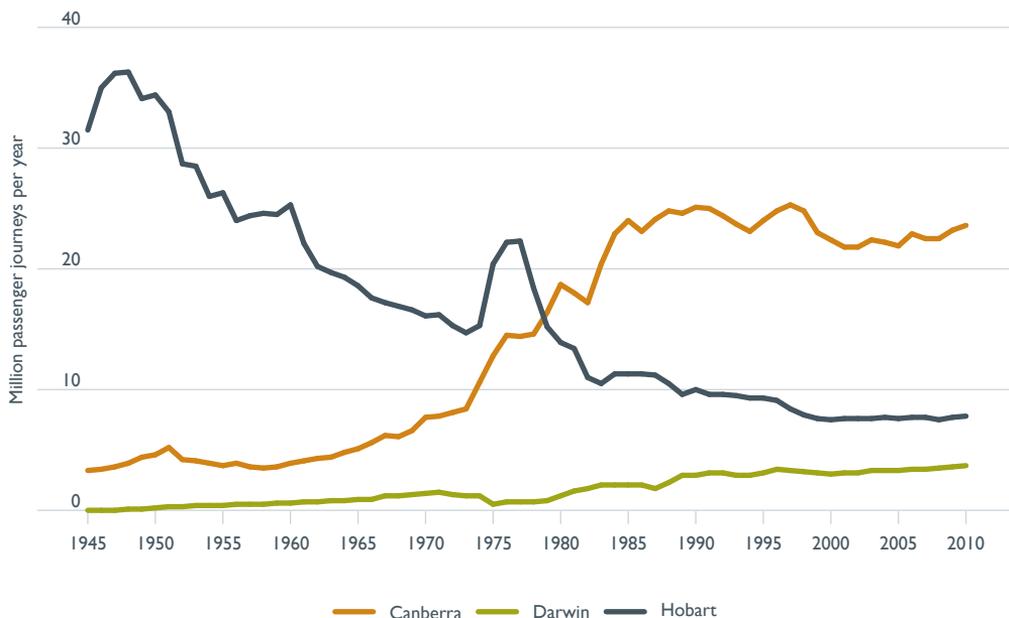

Figure 2.5 shows metropolitan public transport patronage by millions of passenger trips by capital city between 1945 and 2010. Figure 2.6 shows average annual growth rates and Figure 2.7 shows the city share of total metropolitan public transport trips during the same period. Data underlying these three figures is in Table 2.2 and Table 2.3.

Figure 2.5 Metropolitan public transport patronage (million passenger trips) by capital city, 1945–2010

(a) Larger capital cities

(b) Smaller capital cities

Source: BITRE estimates (see Table 2.2).

Most capital cities (Sydney, Melbourne, Brisbane, Adelaide and Hobart) showed a decline in public transport trips between 1945 and 2010. However, metropolitan public transport trips were much higher in Sydney and Melbourne. In 1945, metropolitan public transport patronage

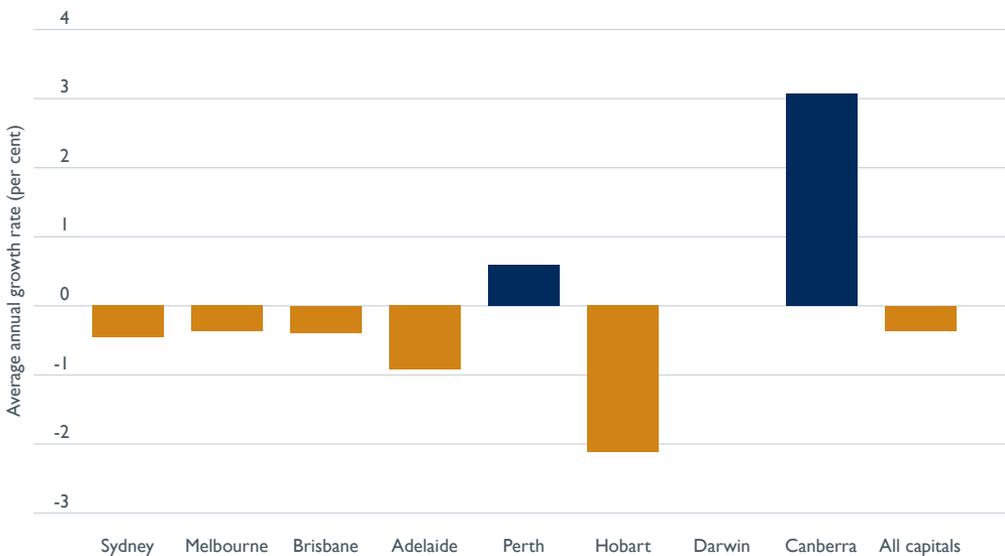

in Sydney was 832.9 million passenger trips and it decreased to 617.1 million passenger trips in 2010 (Figure 2.5a and Table 2.2). Similarly, metropolitan public transport trips in Melbourne were 630.6 million passenger trips in 1945 and decreased to 497.0 million passenger trips in 2010. However, metropolitan public transport trips were much lower in the smaller capital cities of Hobart, Darwin and Canberra (Figure 2.5b and Table 2.2).

There was a sharp increase in the public transport trips in Melbourne in recent years (see Figure 2.25a and Appendix A, Table A.1). This increase in public transport trips in Melbourne was mainly due to an increase in rail trips. From 2005 to 2010, the number of passenger trips on Melbourne’s heavy rail system grew by 51 per cent, from 145.1 million passenger trips to 219.3 million passenger trips (see Appendix A, Table A.1). A study by the Victorian Department of Transport (2008) highlighted many factors contributing to this growth, including high CBD employment growth and high petrol prices.

Over the period from 1945 to 2010, metropolitan public transport trips grew positively across the entire period only in Perth and Canberra (Figure 2.6 and Table 2.2). The average annual growth rate of total metropolitan public transport trips was negative, at -0.36 per cent per year. The capital city share of total metropolitan public transport trips between 1945 and 2010 increased in Perth and Canberra, while it decreased in Sydney, Adelaide and Hobart (Figure 2.7 and Table 2.3).

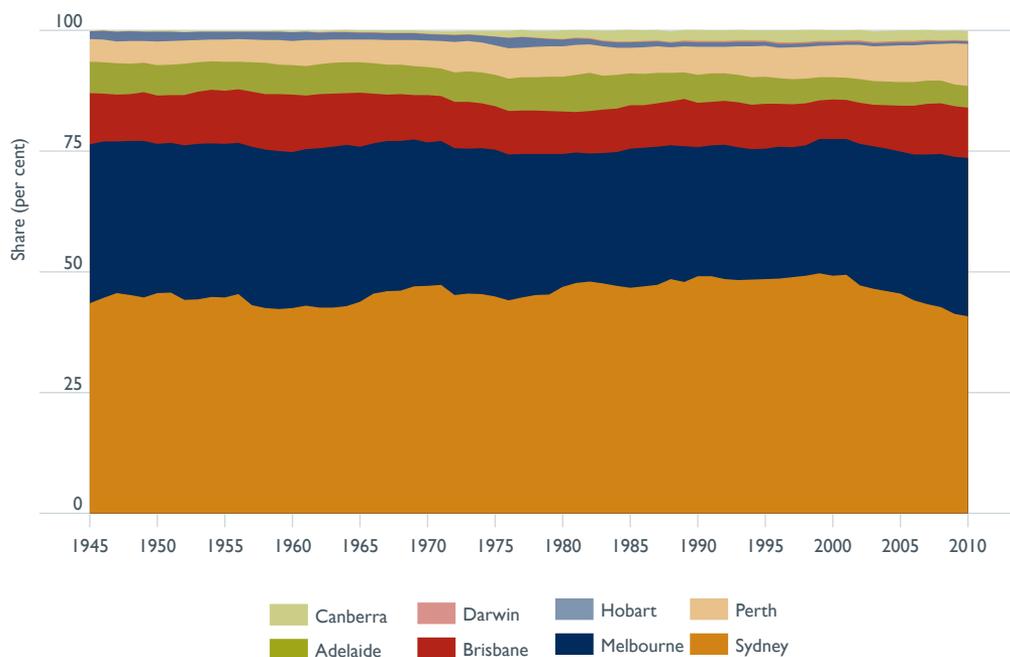

Capital city shares of total metropolitan public transport trips were very slow to change between 1945 and 2010, mainly because Sydney and Melbourne represented about 75 per cent of total metropolitan public transport trips.

Figure 2.6 Average annual growth rates (per cent) of metropolitan public transport trips by capital city, 1945–2010

Note: Not calculated for Darwin, due to no data in the earlier period.

Source: BITRE estimates (see Table 2.2).

2.2.3 Annual urban public transport trips per person, 1945–2010

The main drivers of passenger travel in our cities are increases in population and increases in per capita daily travel (Cosgrove and Gargett 2007).

The average number of annual public transport trips per person for all capital cities is shown in Figure 2.8, with data on the number of annual public transport trips per person for individual capital cities as well as total capital cities provided in Appendix B (see Table B.1).

Figure 2.8 Annual public transport trips per person, all capital cities, 1945–2010

Source: BITRE estimates.

Between 1945 and 2010, the average number of annual public transport trips per person for all capital cities reduced significantly, with patronage levels falling from 442 trips annually per person in 1945 to around 95 trips annually per person in 1994, and then increasing slightly to around 106 trips per person in 2010. These figures represent an overall average annual decline of 2.2 per cent between 1945 and 2010. Overall, there was a decline of 76 per cent in public transport trips during this period. This decline is mostly due to increasing car use, which may be associated with incomes growing faster than the costs of car use (ABS 2008c and ABS 2008d).

Similar reductions in public transport patronage were also observed internationally. For example, trips on Auckland's public transport system fell from 127 trips per person per year in 1960 to around 41 trips per person per year in 2006 (ARTA 2007), or a 68 per cent fall over the period.

2.3 Passenger transport task, personal vehicle travel and public transport travel, all capital cities, 1945–2010

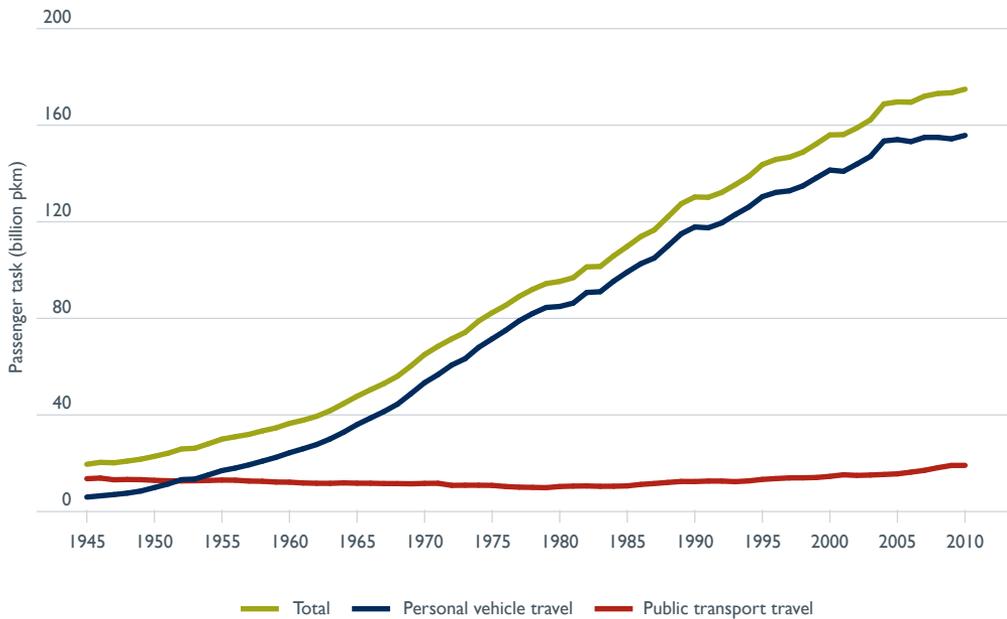

Cosgrove (2011) outlined long-term time-series for UPT usage patterns in terms of passenger-kilometres (pkm). The estimations were compiled for each Australian capital city from 1900 to 2010. This section details the long-term trends for the total metropolitan urban pkm transport task (the sum of both personal vehicle travel and public transport travel).

2.3.1 Total passenger transport task

Figure 2.9 shows the estimates of total passenger transport task, personal vehicle travel and public transport travel for all capital cities between 1945 and 2010. Figure 2.10 shows the

share of personal vehicle travel and public transport travel. The data underlying these figures is in Table 2.4.

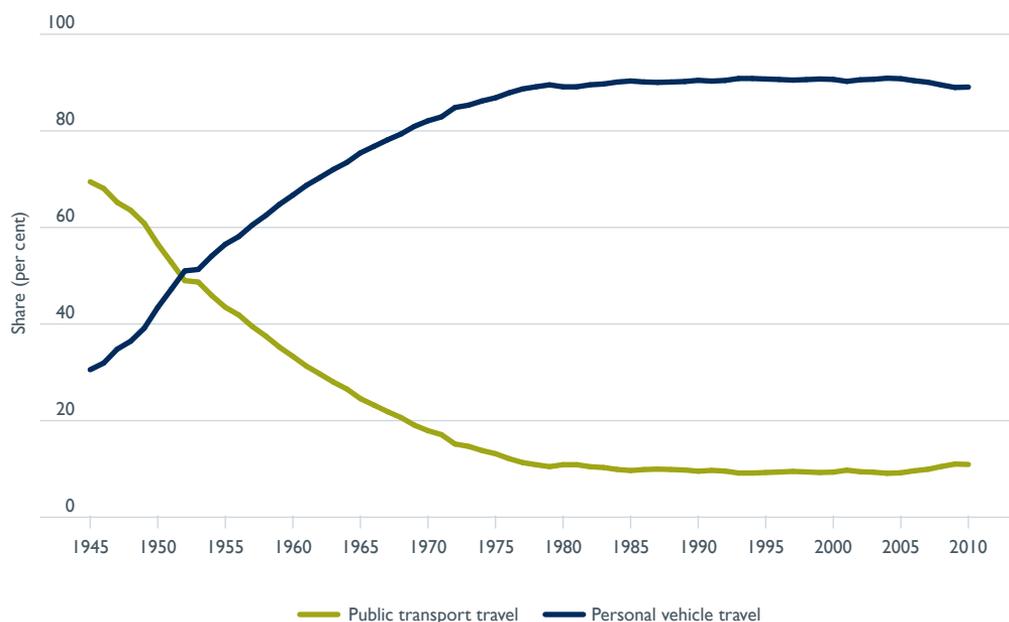

Figure 2.9 Passenger task (billion pkm), total personal vehicle travel and public transport travel, all capital cities, 1945–2010

Source: BITRE estimates (see Table 2.4).

Total passenger travel in Australian capital cities has grown almost nine-fold over the last 65 years, from 19.6 billion pkm in 1945 to 174.9 billion pkm in 2010, an average annual growth of 3.4 per cent (Figure 2.9 and Table 2.4). Since the 1950s, most of the growth in this passenger travel has been by personal vehicle. In 1945, the total distance travelled in personal vehicles was 6.0 billion passenger km, increasing to 155.8 billion passenger km in 2010, an average annual growth rate of 5.1 per cent. In comparison, the public transport task increased slightly, with an average annual growth rate of 0.5 per cent (Figure 2.9 and Table 2.4).

Between 1945 and 2010, personal vehicle travel share increased from 30.5 per cent to 89.1 per cent. UPT share decreased substantially from 69.5 per cent to 10.9 per cent, although there has been an increase in the mode share in recent years (Figure 2.10 and Table 2.4). This 10 per cent mode share for UPT is for all-day travel. When commuting travel is considered alone, the share of UPT is about 16 per cent nationally (BITRE 2009a). Recent increases in UPT mode share are due to growth in UPT passengers rather than to changes in the rate of growth in total travel (BITRE 2009a).

Source: BITRE estimates.

Personal vehicle travel, particularly by car, is characterised by its immediate availability, lower travel time, its predictability, flexibility and more convenient door-to-door characteristics. In contrast, public transport (notably train, bus and ferry) is characterised by higher travel times, relative inflexibility, unpredictability (reliability) and disconnectedness (Hensher 2000).

In a survey conducted by the ABS, it was found that people who usually took public transport to their place of work or study reported a variety of reasons for using public transport in the capital cities (ABS 2008b). The reasons for using public transport were convenience, comfort and lower stress levels compared to other modes of travel. Other reasons included price or cost considerations and parking concerns. The survey also determined the reasons for not using public transport included inconvenience, discomfort, lack of privacy, the length of travel time, preferences for walking or cycling, and the need for passengers to use their own vehicle before, during or after work or study hours.

Mackett (2009) identified three factors that make reducing the level of car use difficult: lack of motivation, lifestyle, and difficulties in walking, cycling, and using public transport.

2.3.2 Passenger transport task by mode, personal vehicle travel and public transport travel, 1945–2010

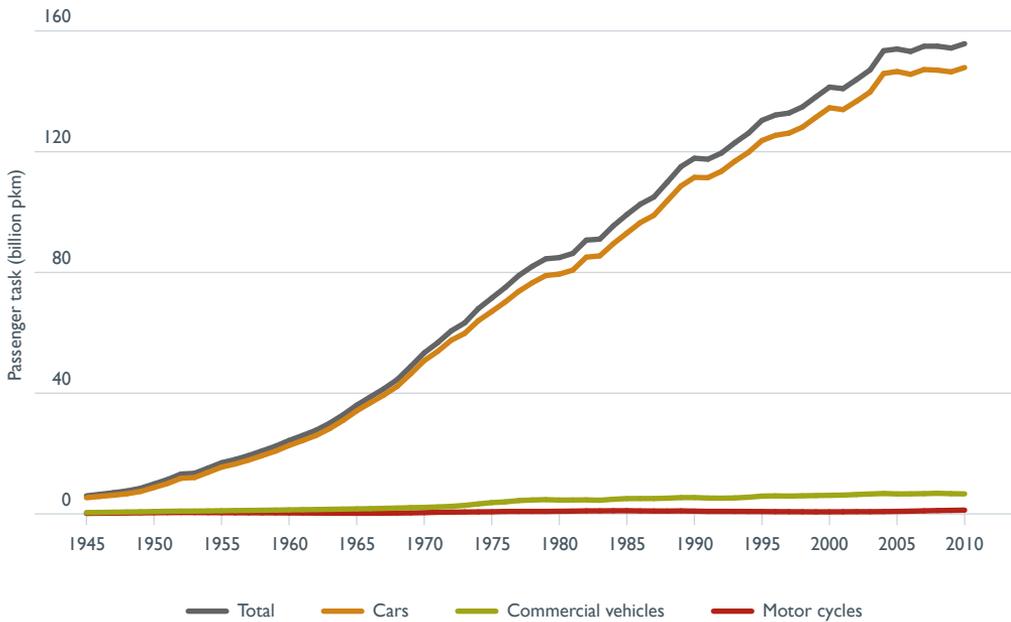

2.3.2.1 Passenger task by mode, personal vehicle travel

Analysis of data on passenger tasks for personal vehicle travel in Australian capital cities between 1945 and 2010 showed that the car was the main mode of transport, followed by light commercial vehicles and motor cycles (Figure 2.11). Data for this figure is presented in Table 2.5.

In 1945, passenger travel by car was 5.4 billion pkm and increased to 147.9 billion pkm in 2010, an average annual growth of 5.2 per cent (Figure 2.11, Figure 2.12 and Table 2.5). Passenger transport travel by light commercial vehicles was 0.45 billion pkm in 1945 and increased to 6.64 billion pkm in 2010, an average annual growth of 4.2 per cent. Passenger transport travel by motor cycles was 0.17 billion pkm in 1945 and it increased to 1.26 billion pkm in 2010, an average annual growth of 3.1 per cent (Figure 2.11, Figure 2.12 and Table 2.5).

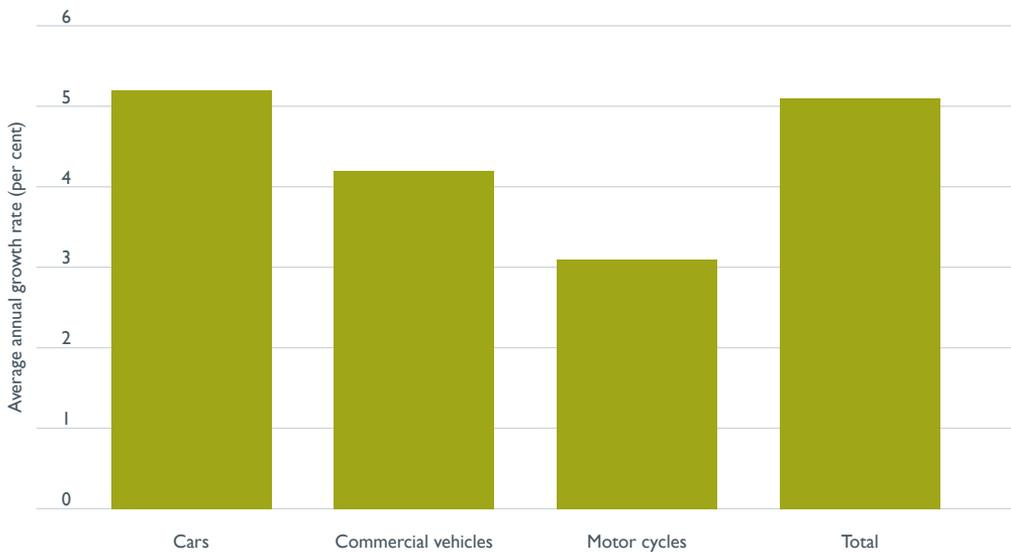

The strong growth in passenger travel by cars is linked to the dramatic increase in ownership of private cars (ABS 2005). In 1950, 769 000 cars and station wagons were registered cars (ABS 2005). This figure had increased to 12.3 million by 2010 (ABS 2011).

In Australia, car dependency has resulted in vehicle kilometres travelled increasing at a faster rate than population growth. Car dependency has created problems associated with high levels of traffic congestion, especially in the larger capital cities where infrastructure and public transport provision have not kept pace with growth rates (Commonwealth of Australia 2010).

Australia has the second highest level of car ownership per capita in the world. It has three to four times more road length per capita than Europe and seven to nine times more than Asia. Australia also has the third highest per capita rate of fuel consumption in the world. Perth, Adelaide and Brisbane are rated among the most car-dependent cities in the world, with Sydney and Melbourne close behind (Moving to Australia 2010).

BITRE (2012b) showed that car vehicle kilometres travelled (vkt) per person in Australia has saturated, and that the saturation effect is not only evident in Australia. For example, car ownership and use have also grown steadily in Great Britain over the last half a century, with only occasional interruptions to this long-term trend due to short periods of economic recession (Department of Transport 2008). However, the level of car use in Great Britain has stabilised (Le Vine et. al. 2009). Similar findings were also reported in the US and other industrialised nations (e.g. Puentes and Tomer 2008; Schipper 2009).

Among the private vehicle transport modes, car use in all Australian capital cities accounted for 90 per cent in 1945 and it increased gradually to 95 per cent in 2010 (Figure 2.13 and Table 2.6).

2.3.2.2 Passenger task by mode, public transport travel

Analysis of data on passenger tasks for public transport travel in the Australian capital cities between 1945 and 2010 showed that rail was the main mode of public transport used (Figure 2.14). Data for this figure is in Table 2.5.

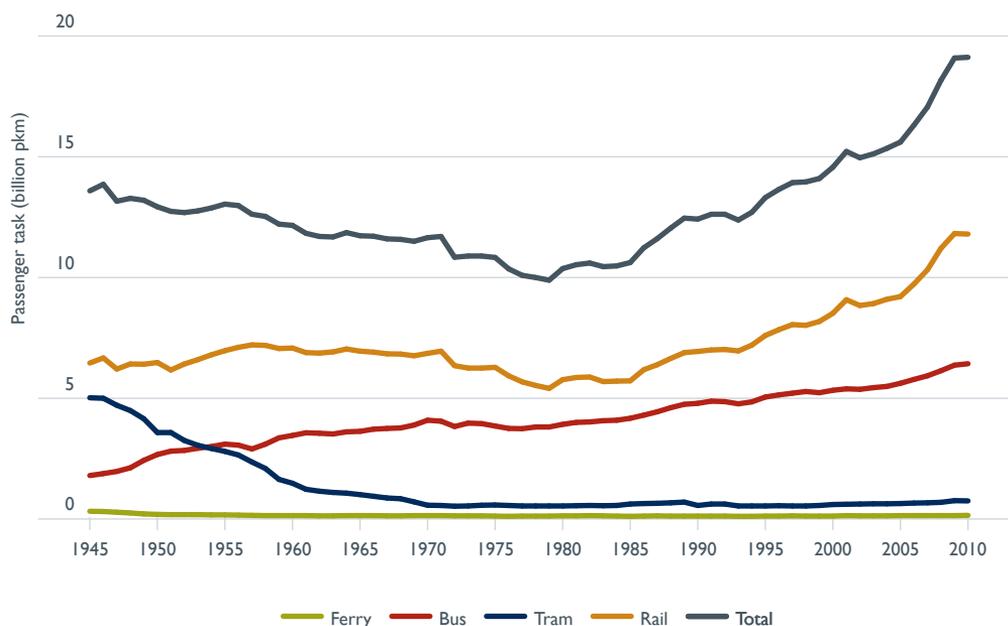

In 1945, passenger transport by rail was 6.5 billion pkm, increasing to 11.8 billion pkm by 2010, or an average annual growth of 0.9 per cent (Figure 2.14, Figure 2.15 and Table 2.5). Rail's UPT mode share was 47.5 per cent in 1945 and it increased to 61.7 per cent by 2010.

Passenger travel by bus increased gradually from 1.8 billion pkm in 1945 to 6.4 billion pkm by 2010, an average annual growth rate of 2.0 per cent. UPT mode share for buses also increased, from 13.2 per cent in 1945 to 33.6 per cent by 2010.

In the earlier years of the timeframe, trams were a more important form of public transport mode than buses. However, passenger travel by tram gradually declined until the 1970s and then remained relatively unchanged. Mode share decreased from 7.6 per cent to only 4.3 per cent by 2010.

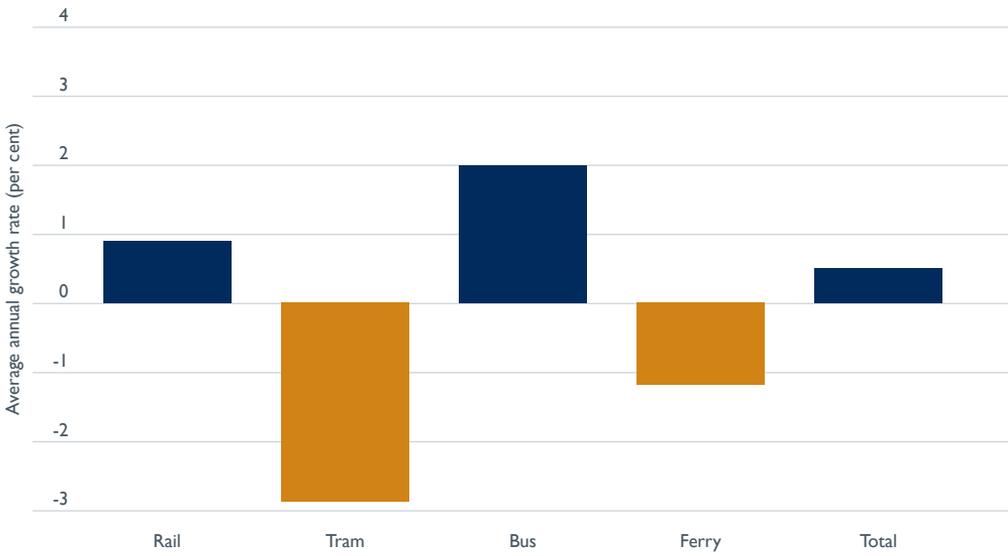

Passenger travel by ferry was the transport mode with lowest patronage. Between 1945 and 2010, average annual growth rates of passenger transport task by tram and ferry were negative (-2.9 per cent and -1.2 per cent, respectively) (Figure 2.15 and Table 2.5). Mode share for ferries decreased from 2.3 per cent in 1945 to 0.8 per cent by 2010 (Figure 2.16 and Table 2.6).

2.4 Passenger transport task, 1977–2010

2.4.1 By capital cities

Average annual growth rates of the passenger task for each capital city, as well as the total for capital cities between 1977 and 2010, are shown in Figure 2.17. Figure 2.18 to Figure 2.21 show the passenger transport task for each capital city during the same period. Data for these figures is in Appendix C, (Tables C.1 to Table C.4).

Between 1977 and 2010, personal vehicle travel grew fastest in Brisbane, Perth and Adelaide, while public transport travel grew faster in Darwin. Public transport travel fell in Hobart (Figure 2.17 and Tables C.1 to C.4).

Figure 2.17 Average annual growth rates (per cent) of passenger transport task by capital cities, 1977–2010

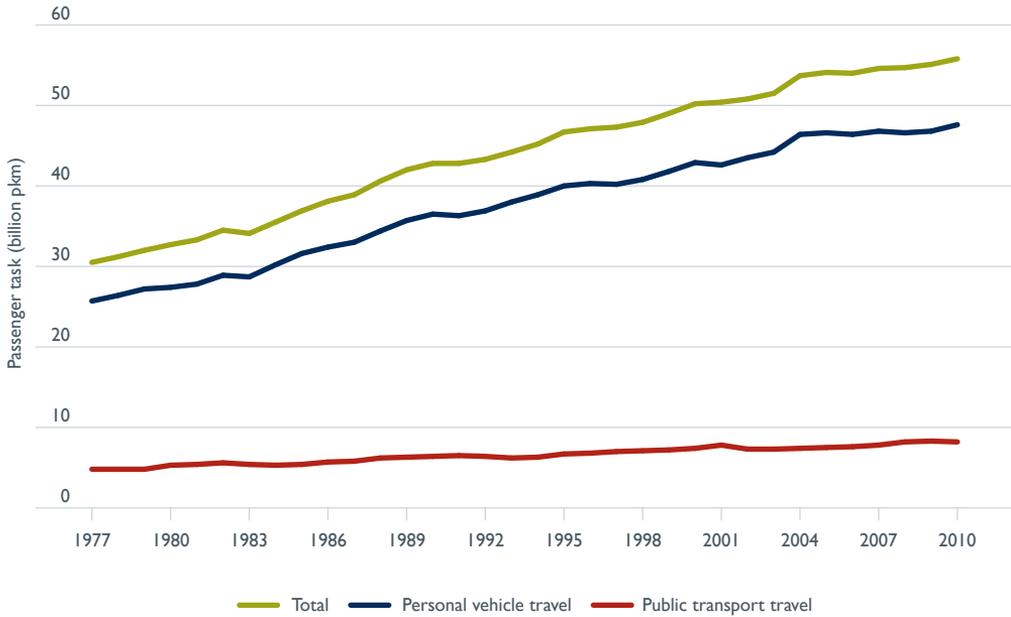

Source: BITRE estimates (see Appendix C, Tables C.1 to C4).

Sydney and Melbourne have similar levels of personal vehicle travel, but Sydney has higher UPT pkm travelled due, in part, to the longer rail distances per passenger on the Sydney rail system. Next in size, Perth and Brisbane also have similar overall motorised passenger travel, with Brisbane having more rail travel and less light vehicle travel. Adelaide has less travel than Perth and Brisbane, but it still has three times that of Canberra. Hobart and Darwin have the lowest travel levels, with only bus systems available for urban public transport.

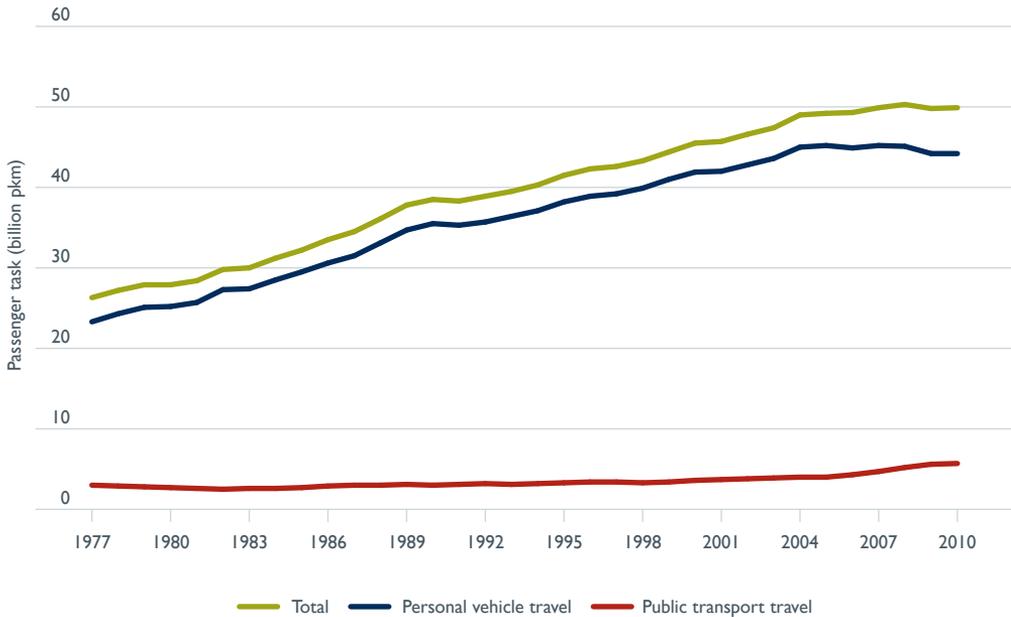

Passenger travel by personal vehicles represented more than 90 per cent of total travel in all capital cities, except Sydney where personal vehicle travel represented around 85 per cent (see Appendix C, Table C.1). However, the pattern of passenger transport task by both personal vehicle travel and public transport travel are very similar, although the magnitudes are different.

Figure 2.21 Passenger transport task (billion pkm), personal vehicle travel and public transport travel, Darwin and Canberra, 1977–2010

Darwin

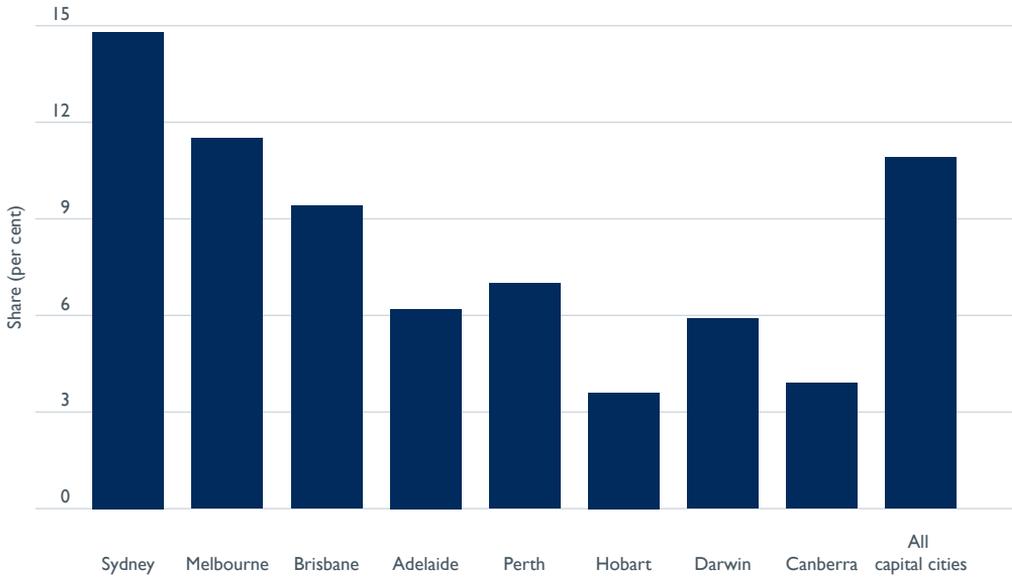

Canberra

Source: BITRE estimates (see Appendix C, Table C4).

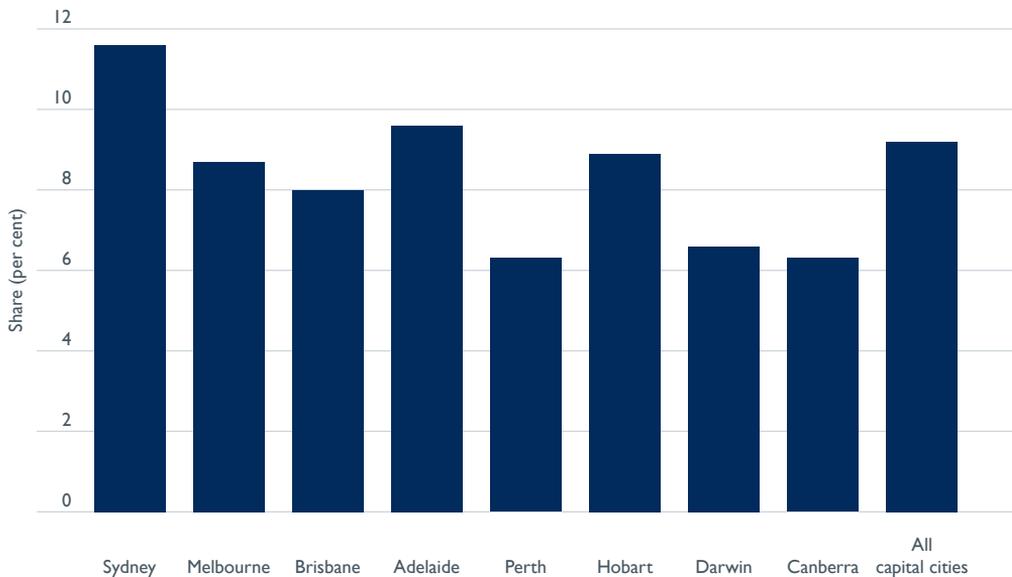

In 2010, Sydney had the highest usage of public transport of any capital city (14.8 per cent); followed by Melbourne (11.5 per cent); Brisbane (9.4 per cent); Perth (7.0 per cent); and Hobart (3.6 per cent). On average, approximately 11 per cent people used public transport in all capital cities (Figure 2.22).

Figure 2.23 Percentage of households with no car, capital cities, 2006

Source: ABS (2006).

2.4.2 Passenger transport task by transport mode

This section presents data for the passenger transport task by transport modes, between 1977 and 2010. However, comparisons between and across cities should be undertaken with caution given that the cities have different transport systems and travel patterns. Brisbane, for

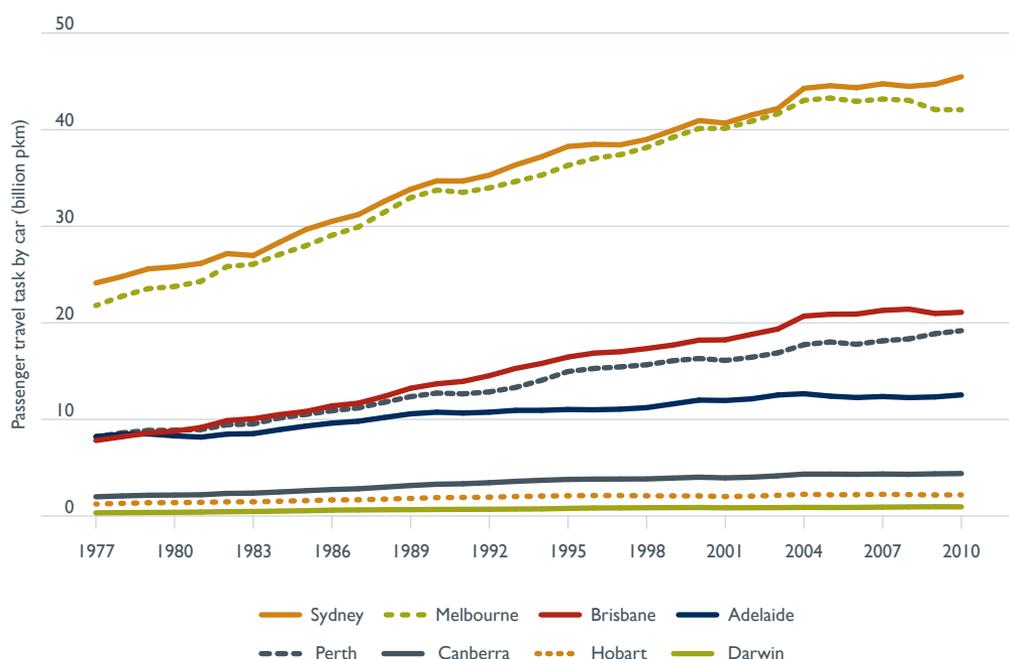

example, has an extensive bus, ferry and suburban train system, whereas Canberra is serviced only by a bus system.

2.4.2.1 Personal vehicle travel: car

Between 1977 and 2010, car travel was the dominant mode of transport for personal vehicle travel (more than 92 per cent of total personal vehicle travel in all capital cities except Darwin, which had more than 83 per cent). Data for car travel, as well as other personal vehicle travel modes (i.e. commercial vehicles and motorcycles), are presented in Appendix D (see Table D.1).

Car travel tasks were much higher in Sydney and Melbourne, followed by Brisbane, Adelaide and Perth, as shown in Figure 2.24.

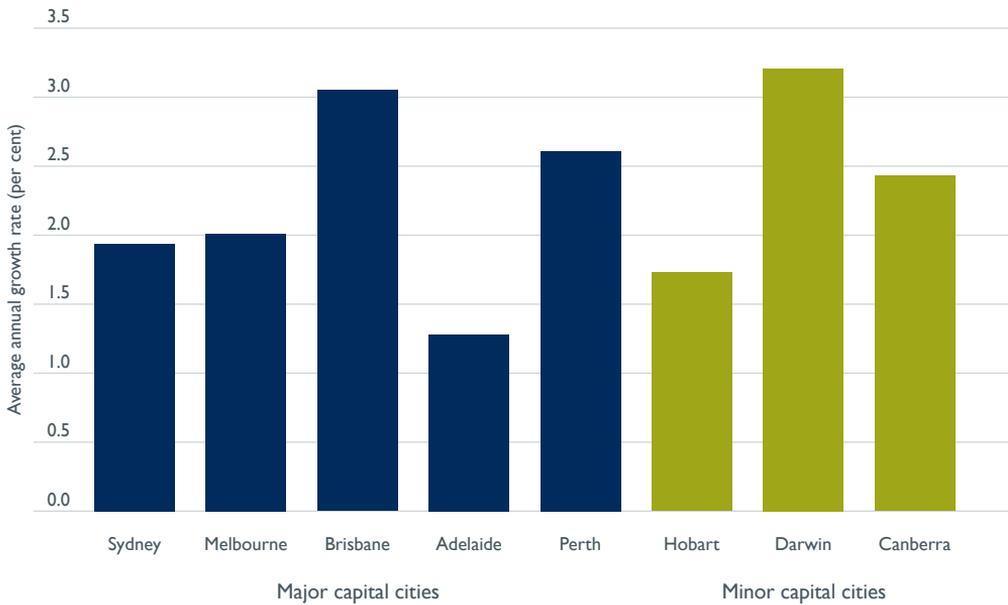

Figure 2.24 Personal vehicle travel task by car (billion pkm), all capital cities, 1977–2010

Source: BITRE estimates.

Among the five larger capital cities, the average annual growth rate of car travel between 1977 and 2010 was highest in Brisbane (3.05 per cent); followed by Perth (2.61 per cent); and lowest in Adelaide (1.28 per cent) (Figure 2.25). Sydney and Melbourne had similar average annual growth rates during this period (1.94 per cent and 2.01 per cent, respectively). Among the smaller capital cities, Darwin had the highest average annual growth rate of car travel, followed by Canberra, with the lowest growth rate in Hobart (Figure 2.25).

Figure 2.25 Average annual growth rate (per cent) of car travel, all capital cities, 1977–2010

Source: BITRE estimates.

2.4.2.2 Public transport travel: heavy rail and bus

Heavy rail is a public transport mode in Australia’s five larger capital cities; bus services are available in all eight capital cities. Data for these two modes, as well as other public transport modes (i.e. light rail, ferry), are presented in Appendix D (see Table D.2).

(a) *Public transport task by heavy rail: larger capital cities*

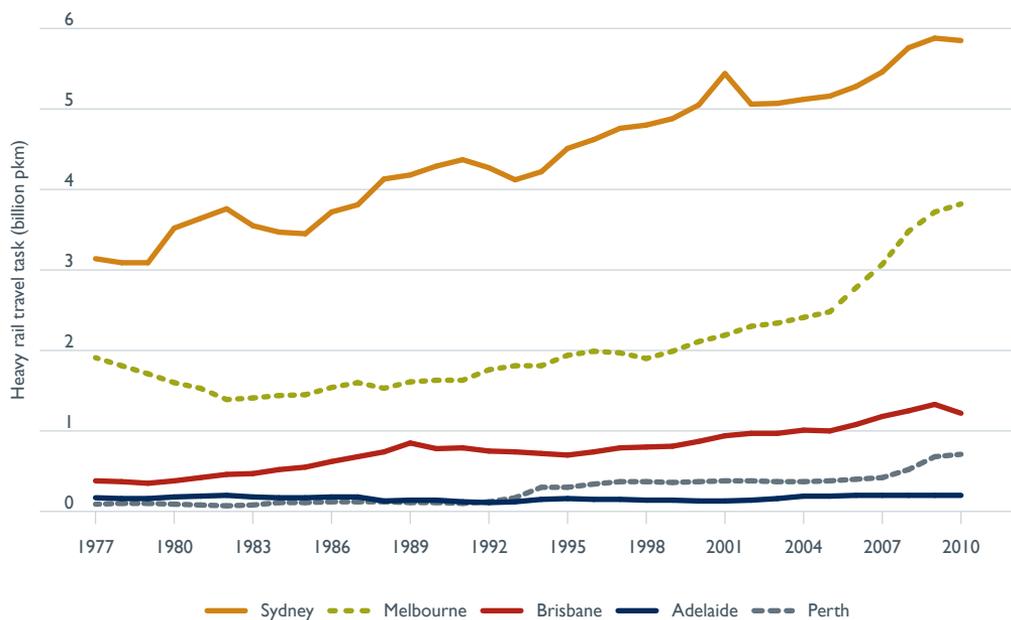

Among the five larger capital cities, total passenger kilometres travelled by heavy rail between 1977 and 2010 were the highest in Sydney, followed by Melbourne, Brisbane, Perth and Adelaide (Figure 2.26).

In Melbourne, there was a long-term decline in train trips until the early 1980s. Patronage gradually increased as a result of comfortable, new air-conditioned trains being introduced and the opening of the City Loop stations, with the last of the wooden-bodied ‘red rattler’ trains withdrawn in 1983 (Victorian Department of Transport 2012). The recession of the early 1990s caused rail patronage to decline in Melbourne, but it recovered quickly and continued to grow for the remainder of the decade. There was relatively modest growth in train patronage between 2000 and 2005, but in the second half of the decade a combination of population growth, employment growth, increasing petrol prices and pressure on household budgets created a strong period of growth (Victorian Department of Transport 2012).

The average annual growth rate of heavy rail travel between 1977 and 2010 was highest in Perth (6.41 per cent); followed by Brisbane (3.58 per cent); with the lowest average annual growth in Adelaide (0.54 per cent) (Figure 2.27). Sydney and Melbourne had similar average annual growth rates during this period (1.91 per cent and 2.13 per cent, respectively).

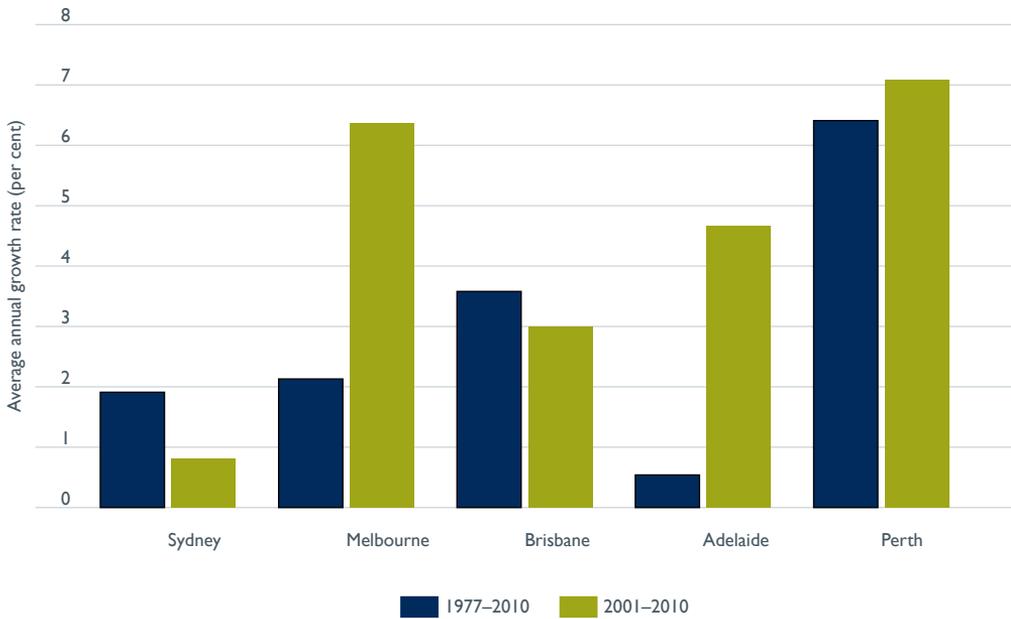

Figure 2.27 also compares average annual growth rates of heavy rail travel in the five larger capital cities between 1977–2010 and 2001–2010. During 2001–2010, heavy rail travel grew much faster in Melbourne, Adelaide and Perth.

Figure 2.26 Public transport tasks (billion pkm) by heavy rail, larger capital cities, 1977–2010

Source: BITRE estimates.

Figure 2.27 Comparison of average annual growth rates (per cent) by heavy rail, larger capital cities, 1977–2010 and 2001–2010

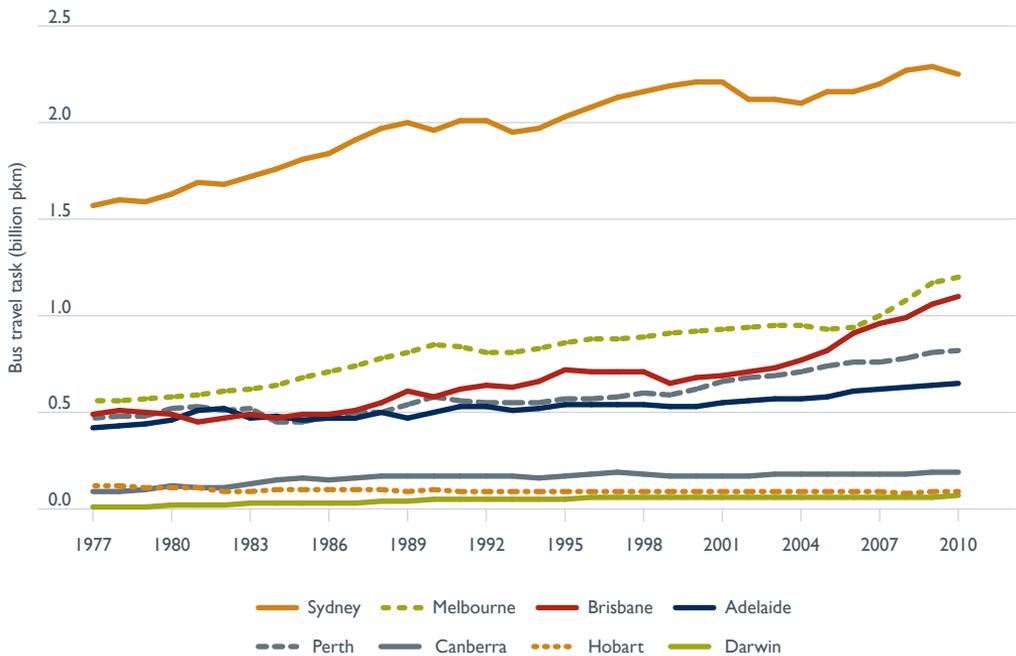

Source: BITRE estimates.

(b) *Public transport task by bus: all capital cities*

Although total bus boarding can be influenced by the degree of timetable integration between the various modes of public transport, bus passenger travel task between 1977 and 2010 was much higher in Sydney compared to other capital cities (Figure 2.28).

Figure 2.28 Bus transport passenger task (billion pkm), total capital cities, 1977–2010

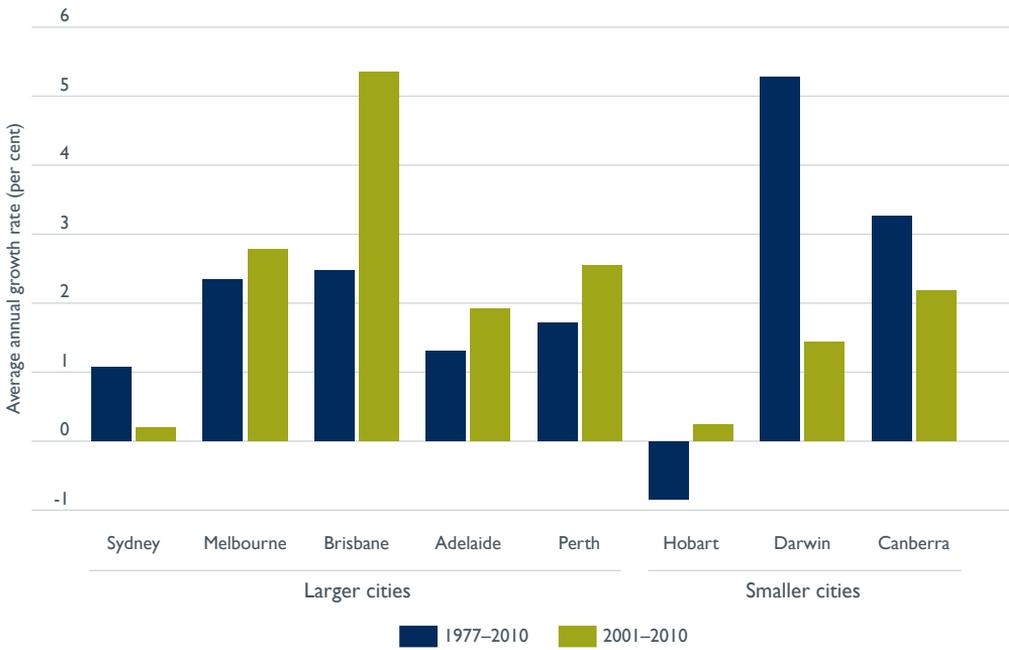

Source: BITRE estimates.

Among the five larger capital cities, the average annual growth rate of the bus passenger transport task between 1977 and 2010 was highest in Brisbane (2.47 per cent); followed by Melbourne (2.34 per cent); and was lowest in Sydney (1.08 per cent) (Figure 2.29). Among the smaller capital cities, Darwin had highest average annual growth rate of bus passenger transport task between 1977 and 2010, while Hobart experienced negative growth.

Since 2004, Brisbane and Melbourne experienced a sharp increase in bus pkm. The increase in bus passenger kilometres in Brisbane was due to the introduction of an integrated ticketing system in 2007 (TransLink 2007). Brisbane also relies significantly on an expansive bus network that use a system of dedicated bus ways, serviced by public and private operators. Brisbane's largest operator 'Brisbane Transport' is the corporate transport arm of Brisbane City Council. BITRE (2009b) also found that Brisbane recorded the highest growth (10.9 per cent) of in-service kilometres by buses between 2006 and 2007, followed by Melbourne (8.7 per cent).

The increase in bus passenger kilometres in Melbourne was enabled by extending bus operating hours, creating new bus routes, upgrading frequencies and extension or rerouting of some existing services (Victorian Department of Transport 2008; cited in BITRE 2009b).

Figure 2.29 Comparison of average annual growth rate (per cent) by bus, all capital cities, 1977–2010 and 2001–2010

Source: BITRE estimates.

Figure 2.29 shows the average annual growth rates of bus passenger transport task in all eight capital cities in two periods: 1977–2010 and 2001–2010. During 2001–2010, the bus passenger transport task grew much faster in Brisbane and more slowly in Melbourne, Perth and Adelaide, while Sydney experienced slow growth during 2001–2010.

CHAPTER 3

Modelling urban public transport passenger task by capital cities, 1977–2010

Summary

This chapter outlines the methodology and presents results of UPT mode share models for each of Australia's eight capital cities and also for the sum of all capital cities'. The key findings of this chapter are:

- The models relate UPT mode share to UPT fares, pressures on household budgets, and to various supply-side shocks (for example, the opening of the southern rail line in Perth).
- The models provide reasonably good predictions of UPT mode share across the different cities, generally accounting for about 90 per cent of the variation.
- The pattern of actual UPT share for the total of all capital cities is similar to the UPT share predicted by the model. Similarly, the pattern of the aggregate UPT task between 1977 and 2010 is largely as predicted by the model.
- The elasticities of the real UPT fares varied from -0.0762 (Sydney) to -0.6484 (Perth); an average for all capital cities was -0.3137. The fare elasticities are highly significant ($p < 0.001$) for Melbourne, Brisbane, Adelaide, Perth and Canberra, while the elasticities for Sydney, Hobart and Darwin are insignificant ($p > 0.05$). The average elasticity of the real UPT fares of the eight capital cities (-0.3137) is lower than a published mean fare elasticity of -0.4, which is based on eleven Australian studies of urban public transport demand (Webster and Bly 1980).
- The elasticities of the disposable income constraint variable varied from 0.0599 (Darwin) to 0.9587 (Melbourne). The average 'household disposable income constraint' elasticity for eight capital cities was 0.3855. The elasticities of disposable income constraint were highly significant for all capital cities ($p < 0.001$), except Darwin and Canberra ($p > 0.05$).

3.1 Background

Chapter 2 outlined the urban passenger transport task (pkm) in the eight Australian capital cities between 1977 and 2010. In this chapter, the focus shifts to considering UPT as a share of total urban passenger travel. Modelling was undertaken to explain 'UPT share'. UPT share is defined as the UPT task (pkm) as a percentage of the total transport task (pkm), i.e.:

$$\text{UPT share (per cent)} = (\text{UPT task} / \text{total transport task}) * 100$$

The determinants of the UPT task are important for understanding the needs for infrastructure development and investment as well as for congestion amelioration and road safety. Allsop (2008) stated that modelling transport systems has two main purposes:

1. to estimate features of an existing transport system and the way it is used that are difficult to observe
2. to estimate features of a transport system and the way it is used in circumstances that do not yet exist.

The parameters used in modelling UPT share include the household disposable income constraint and UPT fares. The disposable income constraint variable is a composite of several factors. These are costs of mortgage, rent, food, petrol and household savings.

3.2 Methodology

The data sources for each of these factors were:

- Nominal UPT Fare Index—sourced from the 'Urban Transport Fares' sub-index of the CPI (ABS 2012b)
- CPI sourced from the ABS *Consumer Price Index, Australia* publication (ABS 2012b)
- rents and house prices sourced from *Real estate market facts: a quarterly review of major residential property markets in Australia* (several issues) (Real Estate Institute of Australia)
- food prices sourced from the 'Food and Non-Alcoholic Beverages' sub-index of the CPI (ABS 2012b)
- petrol prices sourced BITRE (2012a)
- savings rates sourced from the *Australian National Accounts: National Income, Expenditure and Product* (ABS 2012c).

Modelling the urban public transport task in Australia's capital cities required two main variables: real fares and a disposable income constraint. How these two variables were calculated is described in Sections 3.2.1 and 3.2.2.

3.2.1 Calculation of the real UPT fare variable

The real UPT fare index for each capital city was calculated as follows:

$$\text{Real fare index} = \text{Nominal fare index} / \text{Consumer Price Index (CPI)} * 100$$

Nominal fares and CPI were indexed (1989–90 = 100). Estimates of the resulting real-fare indices for each capital city are provided in Appendix E.

3.2.2 Calculation of household disposable income constraint

Calculating the disposable income constraint variable used a number of different datasets, such as costs of petrol, food, rent and mortgage payments, savings rates and the CPI index.

The disposable income constraint in real \$/week/household for each capital city was calculated in three steps:

Step 1: Nominal weekly cost (nominal \$/week/household)

$$= PC + FC + ((RC + MC) / 2)$$

Step 2: Real weekly cost (real \$/week/household)

$$= (\text{Nominal weekly cost } (\$/\text{week}/\text{household}) / (\text{CPI} * 100))$$

Step 3: Weekly disposable income constraint (real \$/week/household)

$$= (\text{Real weekly cost } (\$/\text{week}/\text{household})) * (1 + SR / 100)$$

where

DIC = Disposable income constraint (real \$/week/household)

PC = Petrol cost (\$/week/household)

FC = Food cost (\$/week/household)

RC = Rent cost (\$/week/household)

MC = Mortgage cost (\$/week/household)

CPI = (GST/Medicare adjusted CPI)

SR = Savings rate (per cent).

Table 3.1 estimates the household disposable income constraint in real \$/week/household for Melbourne between 1977 and 2010, as an example. Estimates of disposable income constraint for each capital city, as well as all capital cities combined, are provided in Appendix F.

Table 3.1 Estimates of weekly budget or disposable income constraint (real \$/week/household), Melbourne, 1977–2010

Year	Cost (\$/week/household)				Weekly cost (nominal \$/week/household)	GST/Medicare adjusted CPI	Weekly cost (real \$/week/household)	Savings rate (per cent)	DIC ^a (real \$/week/household)
	Petrol	Food	Rent	Mortgage					
1977	5.9	44	59	61	110	35	315	15.5	363

a Disposable income constraint.

Sources: BITRE estimates.

3.2.3 Modelling the UPT task

For estimation, the UPT share, real fares and the disposable income constraint were transformed into logarithmic values. City-specific event dummy variables were included for each capital city. For example, an 'Olympic Games' dummy was included for Sydney (2000–01); a 'recession' dummy was included for Melbourne (from 1988–89 to 1990–91); a 'bicentennial celebration' (Expo88) dummy was included for Brisbane (1987–88 and 1988–89); and a 'rail' dummy was used for Perth (to capture the effect of the opening of the southern rail line). Due

to lags in supply expansion, a specific 'SupplyLag' dummy was used for Melbourne and Perth. Different time trends were also used for Brisbane, Adelaide, Hobart and Darwin. Depending on the nature of data, specific 'year' dummies were also used for each capital city.

Separate models were estimated for each capital city due to fundamental differences in the nature of each city's UPT travel demands. The eight models have the following forms:

For Sydney

$$\text{LnUPTS} = i + a_1 * \text{LnRF} + a_2 * \text{LnDIC} + a_3 * \text{OLYMDUM} + a_4 * \text{DUM}_{(77-83)} + a_5 * \text{DUM}_{(04-10)}$$

For Melbourne

$$\text{LnUPTS} = i + a_1 * \text{LnRF} + a_2 * \text{LnDIC} + a_3 * \text{DUM}_{(77-81)} + a_4 * \text{DUM}(\text{SupplyLag}) + a_5 * \text{Mel-DUM}_{(89-91)}$$

For Brisbane

$$\text{LnUPTS} = i + a_1 * \text{LnRF} + a_2 * \text{LnDIC} + a_3 * \text{BICENTDUM} + a_4 * \text{TIME}$$

For Adelaide

$$\text{LnUPTS} = i + a_1 * \text{LnRF} + a_2 * \text{LnDIC} + a_3 * \text{TIME} + a_4 * \text{DUM}_{(81-85)}$$

For Perth

$$\text{LnUPTS} = i + a_1 * \text{LnRF} + a_2 * \text{LnDIC} + a_3 * \text{RAILDUM} + a_4 * \text{DUM}(\text{SupplyLag}) + a_5 * \text{DUM}_{(89-91,97)}$$

For Hobart

$$\text{LnUPTS} = i + a_1 * \text{LnRF} + a_2 * \text{LnDIC} + a_3 * \text{TIME} + a_4 * \text{DUM}_{(77-81)}$$

For Darwin

$$\text{LnUPTS} = i + a_1 * \text{LnRF} + a_2 * \text{LnDIC} + a_3 * \text{TIME}$$

For Canberra

$$\text{LnUPTS} = i + a_1 * \text{LnRF} + a_2 * \text{DUM}_{(77-82)} + a_3 * \text{DUM}_{(96-98)}$$

where

LnUPTS = Log of UPT share in the capital city

i = Intercept

a₁ ... a₅ = Estimated coefficients

LnRF = Log of the real urban transport fare

LnDIC = Log of discretionary income constraint

OLYMDUM = Olympic dummy for Sydney

Mel-DUM = Recession dummy for Melbourne

BICENTDUM = Bicentennial celebration dummy for Brisbane

RAILDUM = Rail dummy (for Perth)

TIME = A time trend for Brisbane (77-78); Adelaide (77-10), Hobart (77-10) and Darwin (77-91, then kept same)

DUM (SupplyLag) = SupplyLag dummy (due to lag in supply expansion for Melbourne and Perth)

DUM = Year specific dummy, as mentioned in the equations.

The exact nature of the variables used for each capital city is set out in Appendix G (see Table G.1 to Table G.4), while Appendix H provides actual and estimated data for UPT share.

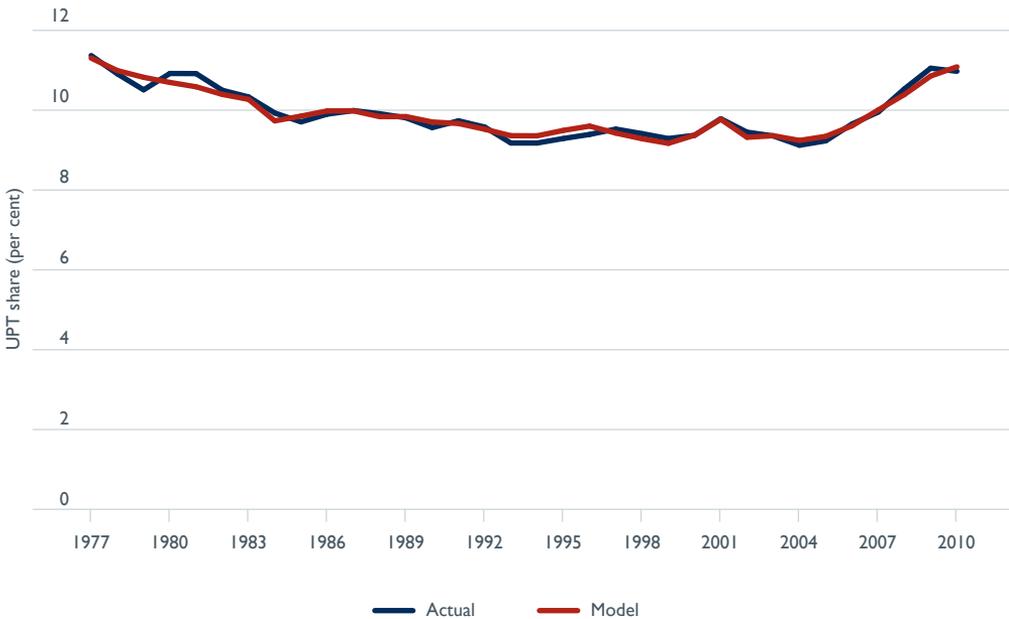

Using the equations from the regression analysis, the UPT task was estimated (modelled) and compared with the actual UPT task for each of the eight capital cities.

3.3 Modelling results

3.3.1 Total capital cities

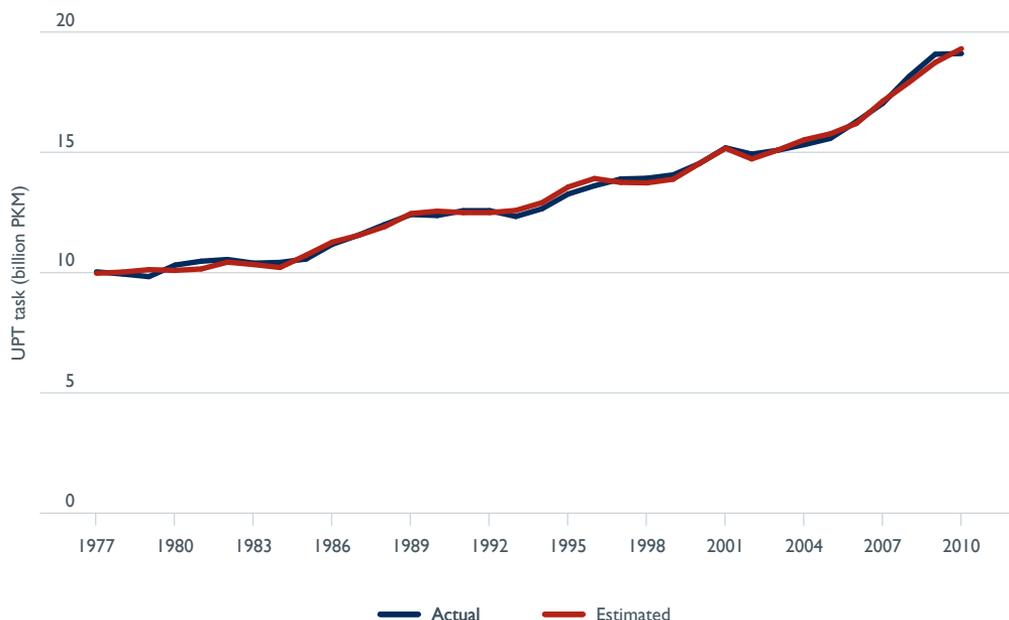

Figure 3.1 shows the model's estimate for the UPT share for all capital cities between 1977 and 2010. Figure 3.2 shows the actual and estimated UPT task in billion pkm during the same period. The estimates (both UPT share and task) were derived from an aggregation of the estimates of individual capital cities. The models used to drive these estimates are detailed below. Overall there is a downward trend in UPT mode share until 2004. After 2004, increasing pressure on household budgets and the effects of the GFC created an upward trend, which levelled out by 2010. The effects of the variables differ across capital cities.

Figure 3.1 Actual and estimated UPT share (per cent), total capital cities, 1977–2010

Source: BITRE estimates.

Figure 3.2 Actual and estimated UPT task (billion pkm), total (all) capital cities, 1977–2010

Source: BITRE estimates.

3.3.2 Individual capital cities

Sydney

Regression results for modelling the UPT share for Sydney are presented in Table 3.2. Actual and estimated UPT shares are shown in Figure 3.3, while actual and modelled UPT tasks (in terms of billion pkm) are shown in Figure 3.4.

As can be seen from Table 3.2, the results of the model show a significant effect for all independent variables, except real fares. The elasticity of the real fare variable for urban public transport in Sydney is estimated to be around -0.076 (t -statistics $= -2.019$; $p = 0.0532$).

Basically, the UPT share is high, but flat (i.e. unresponsive), ranging from 14 to 15 per cent, except for the late 70s and early 80s (around 16 per cent). Therefore a dummy (dummy 77-83) was used to capture this high share. However, from 2004 onward, there was a slight upward movement in UPT share, which is due to the disposable income constraint (see Figure 3.3). In addition, due to the significant effect of the Olympic dummy ($p = 0.0172$), the UPT task increased substantially in 2000–01, as shown in Figure 3.4.

Since the coefficient of determination (R^2) is only 0.78 (Table 3.2), the pattern of actual UPT share in Sydney is similar to the UPT share predicted by the model, as shown in Figure 3.3. Figure 3.4 shows that the pattern of the aggregate UPT task between 1977 and 2010 is largely as predicted by the model.

Figure 3.3 Actual and modelled UPT share (per cent), Sydney, 1977–2010

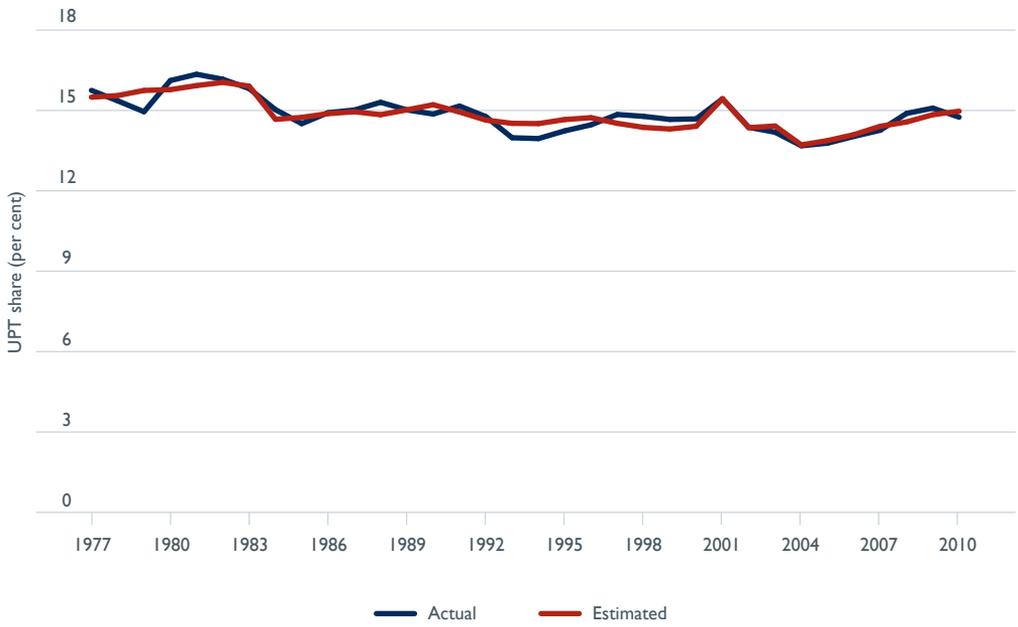

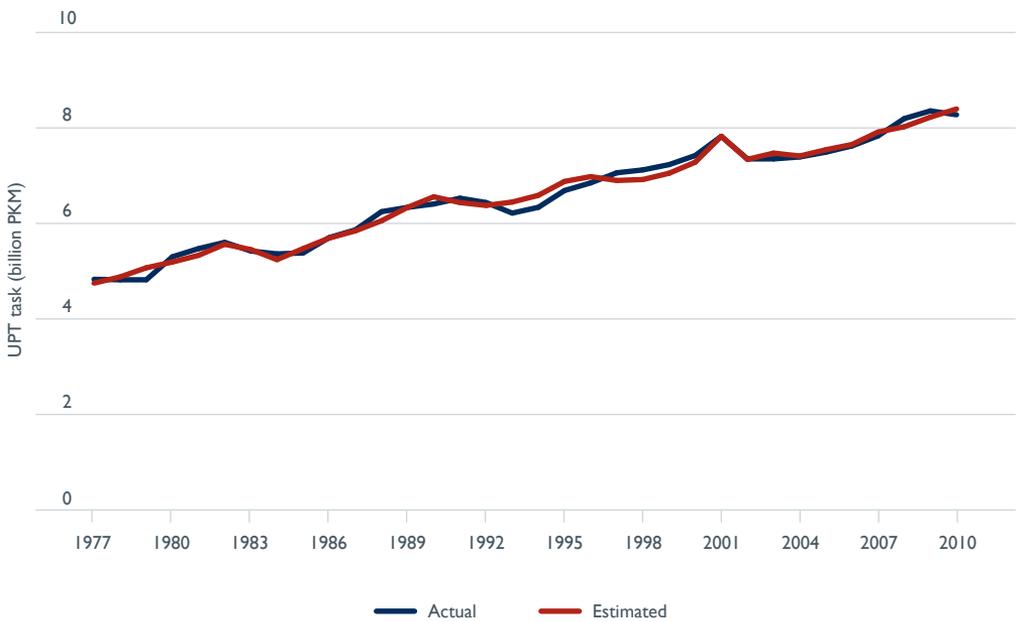

Figure 3.4 Actual and estimated UPT task (billion pkm), Sydney, 1977–2010

Melbourne

Regression results for modelling Melbourne’s UPT share are presented in Table 3.3. Actual and estimated UPT shares are shown in Figure 3.5, while actual and modelled UPT tasks are shown in Figure 3.6.

The downward trend in UPT mode share for Melbourne since the 1940s ended in 1983, where the UPT share sat at around eight per cent. However, this trend masks changes in fares and the disposable income constraint that balanced, except recently from 2005, when the disposable income constraint saw demand rise. There was, however, a lag in supply expansion, so the major increases in UPT share happened from 2007 to 2009.

As can be seen from Table 3.3, the results of the model show highly significant effects ($p = <0.001$) for all independent variables. The disposable income constraint coefficient for urban public transport in Melbourne is estimated to be around 0.959 (t-statistics = 21.931; $p = <0.001$). This high elasticity is due to the large average annual growth of jobs in metropolitan Melbourne in recent years (1.5 per cent per annum between 2001 and 2006). Between 2001 and 2006, 19 per cent of jobs growth was in the city area and 53 per cent of jobs growth was in outer Melbourne (BITRE unpublished data).

Since the coefficient of determination (R^2) is very high (0.97) (Table 3.3), the pattern of actual UPT share in Melbourne is very similar to the UPT share predicted by the model, as shown in Figure 3.5. Figure 3.6 shows that the modelling produced an accurate estimation of the aggregate UPT task in Melbourne between 1977 and 2010.

Figure 3.5 Actual and modelled UPT share (per cent), Melbourne, 1977–2010

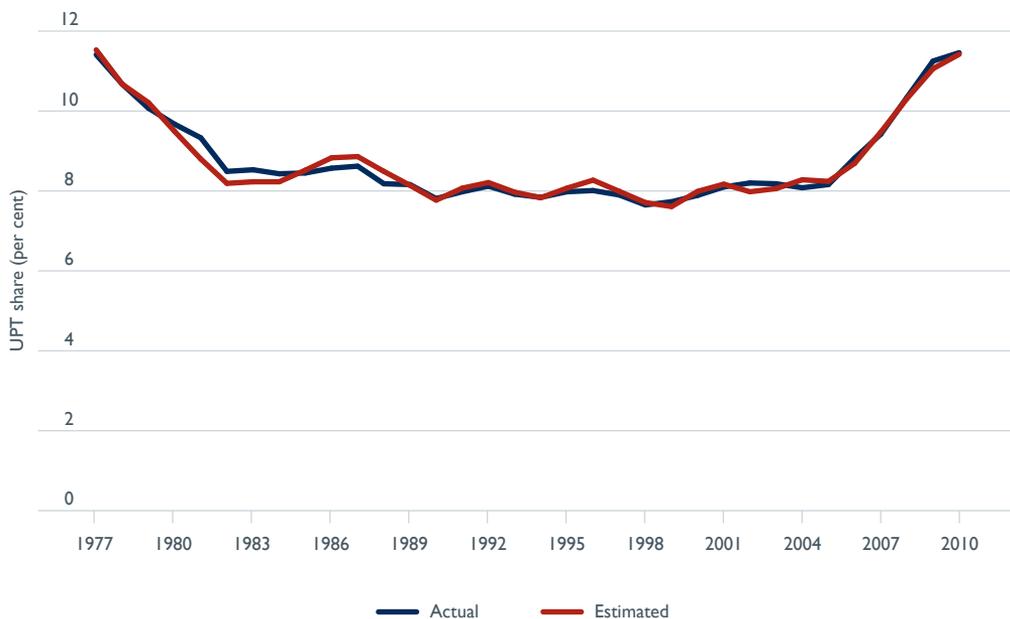

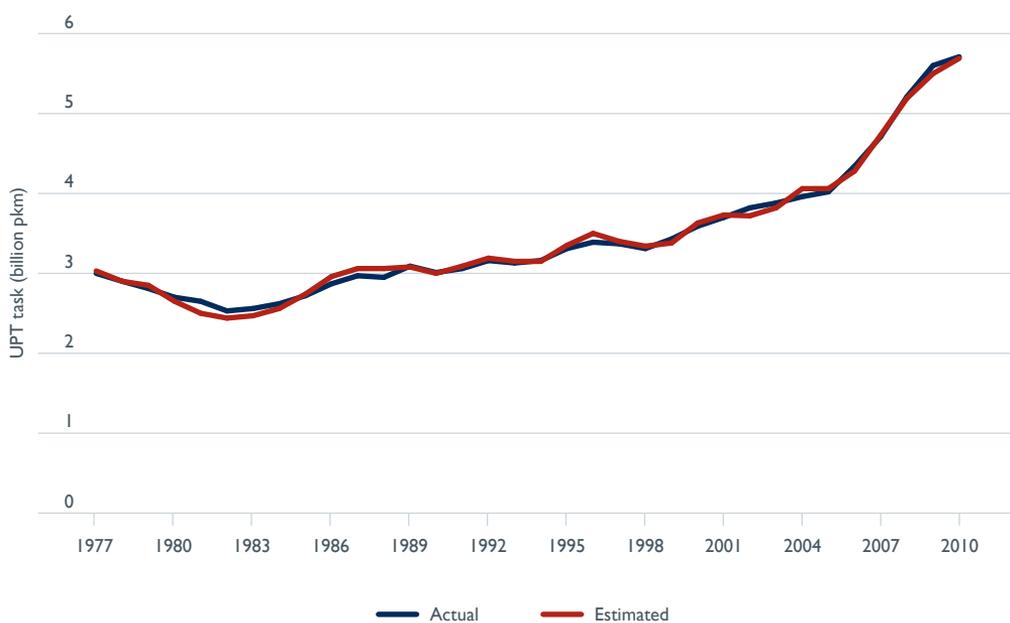

Figure 3.6 Actual and estimated UPT task (billion pkm), Melbourne, 1977–2010

Brisbane

Regression results for modelling Brisbane's UPT share are presented in Table 3.4. Actual and estimated UPT shares are shown in Figure 3.7, while actual and modelled UPT tasks are shown in Figure 3.8.

A negative time trend since the 1940s ended in 1979. As can be seen from Table 3.4, the results of the model show highly significant effects for real fares, the disposable income constraint, the bicentenary dummy and the time dummy (for all these variables, $p = <0.001$). Fare elasticity is low, while the disposable income constraint elasticity is moderate (Table 3.4).

Table 3.4 Regression results for modelling UPT share (per cent), Brisbane, 1977–2010

Note: Bicent. – Bicentenary.

The bicentenary effect is evident in 1987–88 and 1988–89, while the disposable income constraint is apparent in the expansion in UPT share from 2006 to 2009 (Figure 3.7). Since the coefficient of determination (R²) is high (0.87) (Table 3.4), the pattern of actual UPT share in Brisbane is similar to the UPT share estimated by the model, as shown in Figure 3.7. Figure 3.8 shows that the modelling also produced an accurate estimation of the aggregate UPT task in Brisbane between 1977 and 2010.

Figure 3.7 Actual and modelled UPT share (per cent), Brisbane, 1977–2010

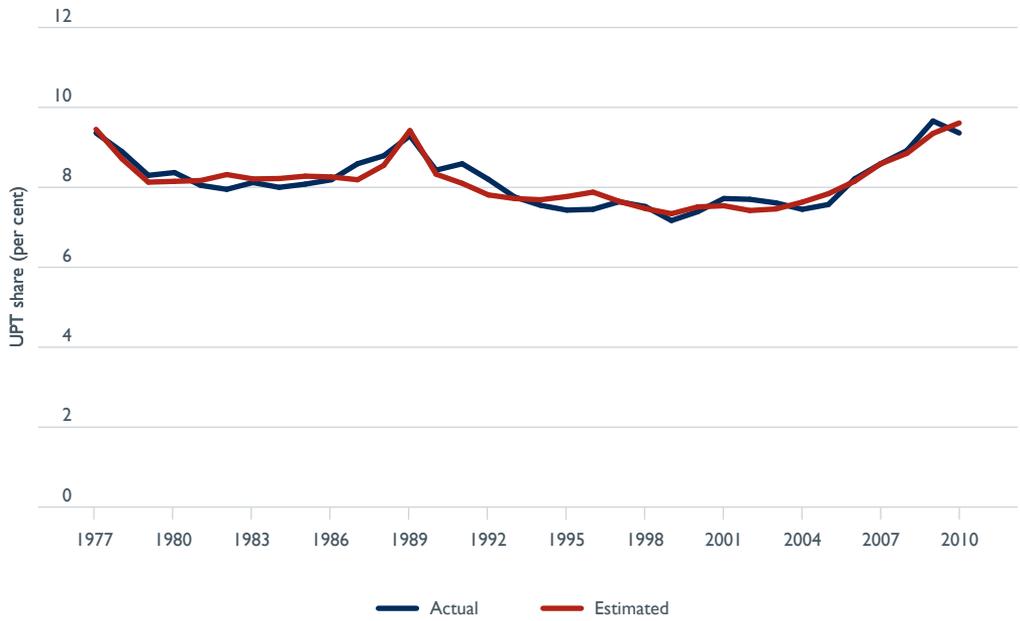

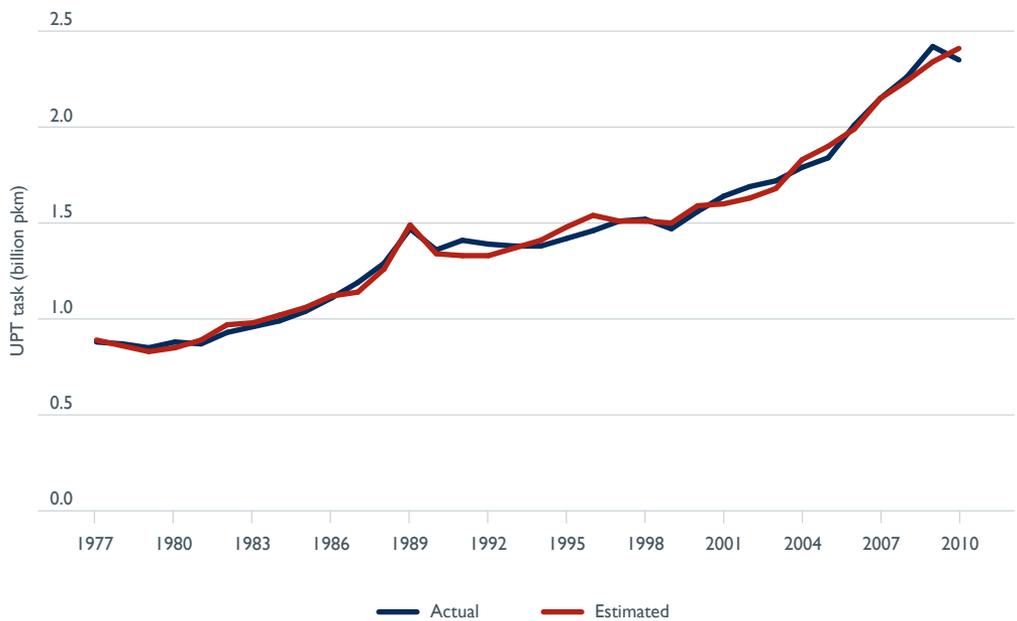

Figure 3.8 Actual and estimated UPT task (billion pkm), Brisbane, 1977–2010

Adelaide

Regression results for modelling Adelaide's UPT share are presented in Table 3.5. Actual and estimated UPT shares are shown in Figure 3.9, while actual and modelled UPT tasks are shown in Figure 3.10.

The downward time trend in Adelaide has continued for most of the period. However, the trend of UPT share was interrupted by a brief upward movement in 1981–1985 and by the effect of a rising disposable income constraint in 2005–2009 (Figure 3.9).

As can be seen from Table 3.5, the results of the model show a highly significant effect for all independent variables. Both fare and disposable income constraint elasticities are moderate.

Since the coefficient of determination (R^2) is high (0.87) (Table 3.5), the pattern of actual UPT share in Adelaide is similar to the UPT share predicted by the model, as shown in Figure 3.9. Figure 3.10 shows that the modelling produces an accurate prediction of the aggregate UPT task in Adelaide between 1977 and 2010.

Figure 3.9 Actual and modelled UPT share (per cent), Adelaide, 1977–2010

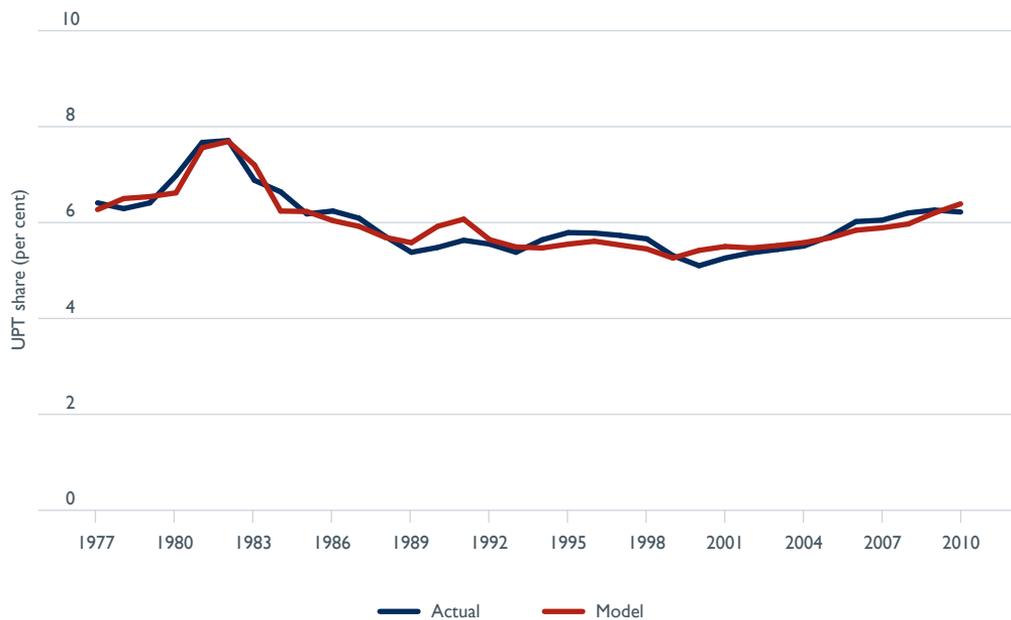

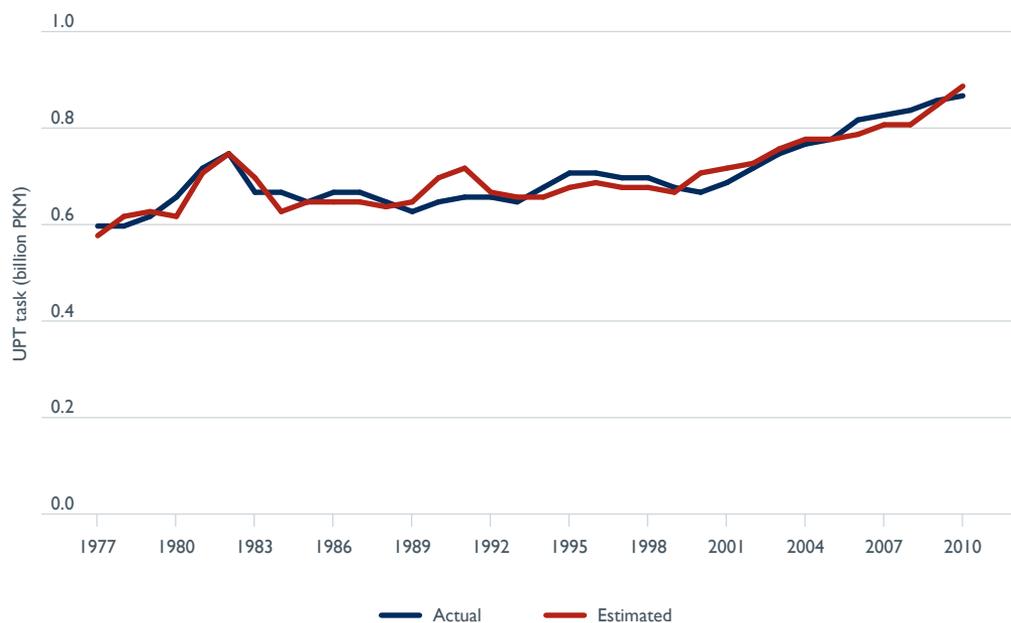

Figure 3.10 Actual and estimated UPT task (billion pkm), Adelaide, 1977–2010

Perth

Regression results for modelling Perth's UPT share are presented in Table 3.6. Actual and estimated UPT shares are shown in Figure 3.11, while actual and modelled UPT tasks are shown in Figure 3.12.

As can be seen from Table 3.6, the results of the model show highly significant effects for all independent variables (p -value = <0.001), except the SupplyLag dummy ($p = <0.01$). Fare and the disposable income constraint elasticities are moderate, with the rising disposable income constraint coming into effect in period 2007–2009, flowing through to the UPT share (after a supply lag) in the period 2008–2009. The opening of the Joondalup line in 1992, which links the north-west to Perth's central business district, followed by an extension to Currabmine in 1993 created an increase in UPT share from 4.5 per cent to 5.5 per cent.

Since the coefficient of determination (R^2) is very high (0.93) (Table 3.6), the pattern of actual UPT share in Perth is very similar to the UPT share estimated by the model, as shown in Figure 3.11. Figure 3.12 shows that the modelling also produced an accurate estimate of the aggregate UPT task in Perth between 1977 and 2010.

Figure 3.11 Actual and modelled UPT share (per cent), Perth, 1977–2010

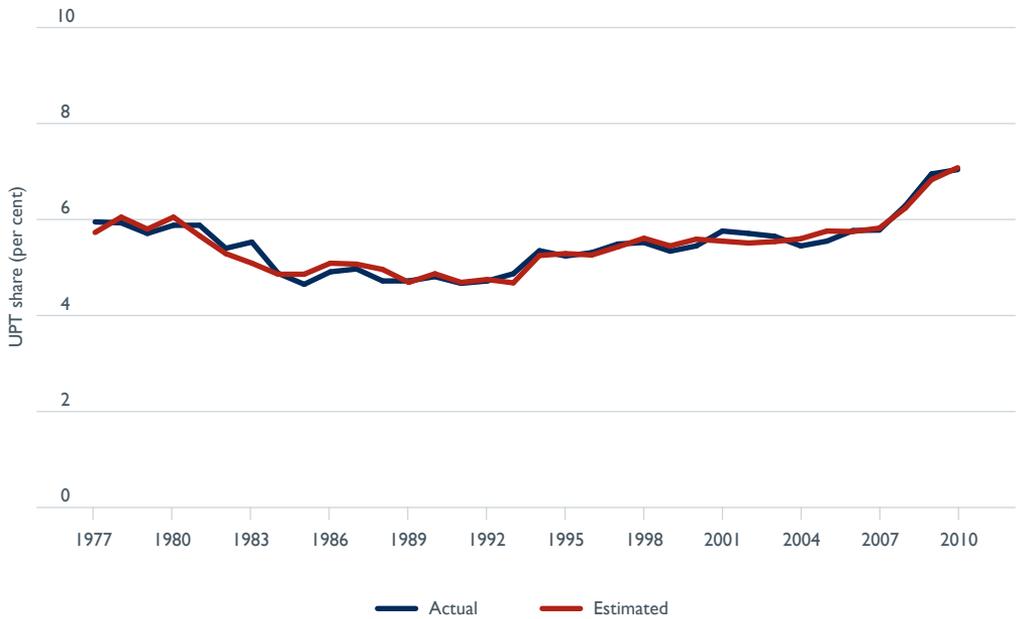

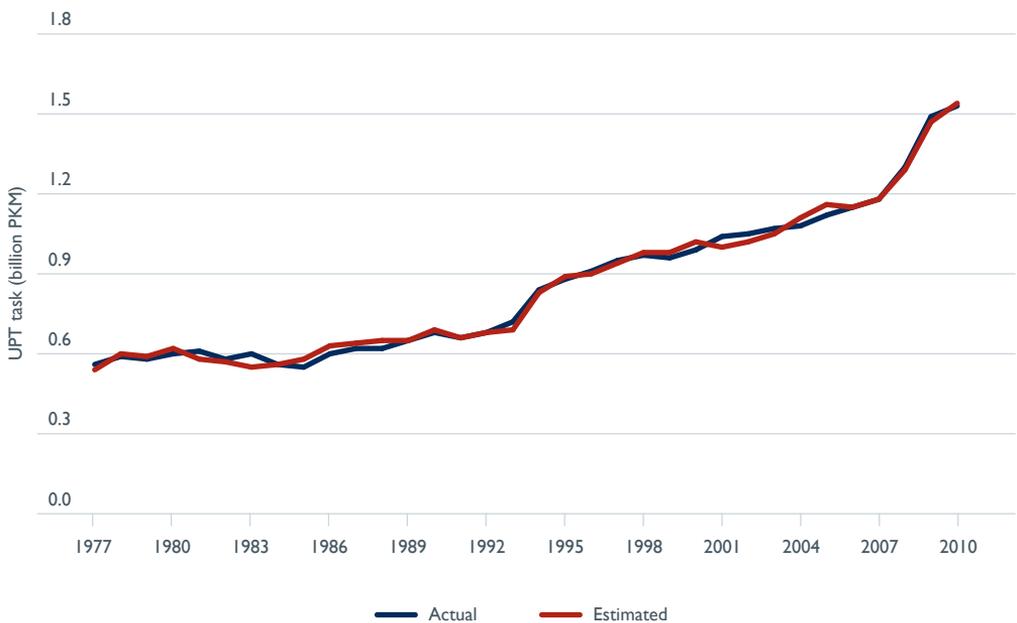

Figure 3.12 Actual and estimated UPT task (billion pkm), Perth, 1977–2010

Hobart

Regression results for modelling Hobart's UPT share are presented in Table 3.7. Actual and estimated UPT shares are shown in Figure 3.13, while the actual and modelled UPT tasks are shown in Figure 3.14.

The downward time trend in the UPT share since the 1940s slowed in 1982, but continued through until 2010. The levelling off of UPT share since 2005 is due to the disposable income constraint increase balancing the continuing underlying downward time trend.

As can be seen in Table 3.7, the results of the model show highly significant effects for all independent variables ($p = <0.001$), except real fares ($p = <10$ per cent).

Since the coefficient of determination (R^2) is very high (0.98) (Table 3.7), the pattern of actual UPT share in Hobart is very similar to the UPT share estimated by the model, as shown in Figure 3.13. Figure 3.14 shows that the modelling produces an accurate prediction of the aggregate UPT task in Hobart between 1977 and 2010.

Figure 3.13 Actual and modelled UPT share (per cent), Hobart, 1977–2010

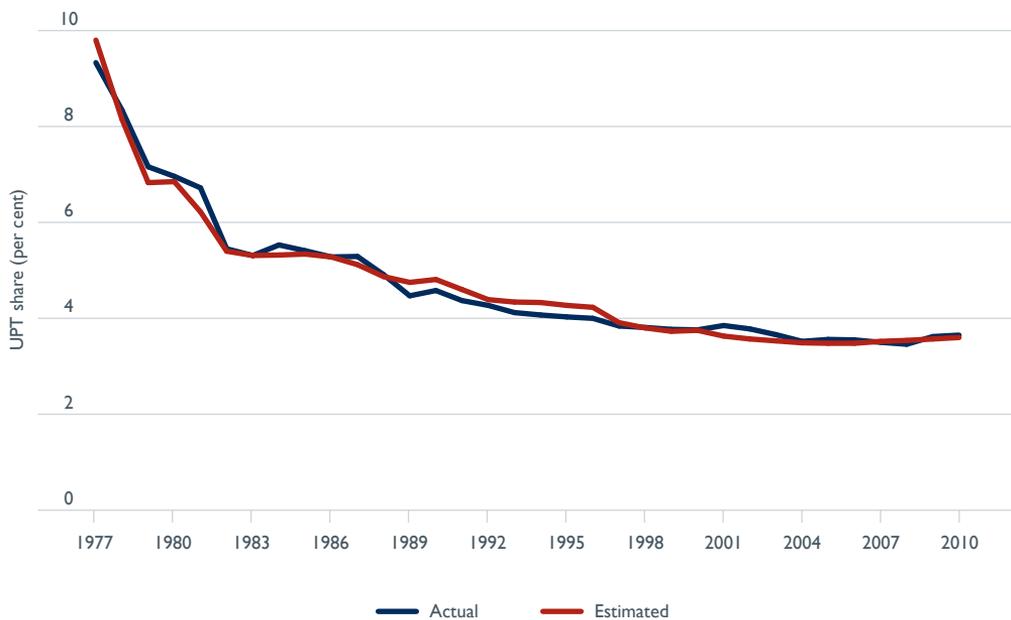

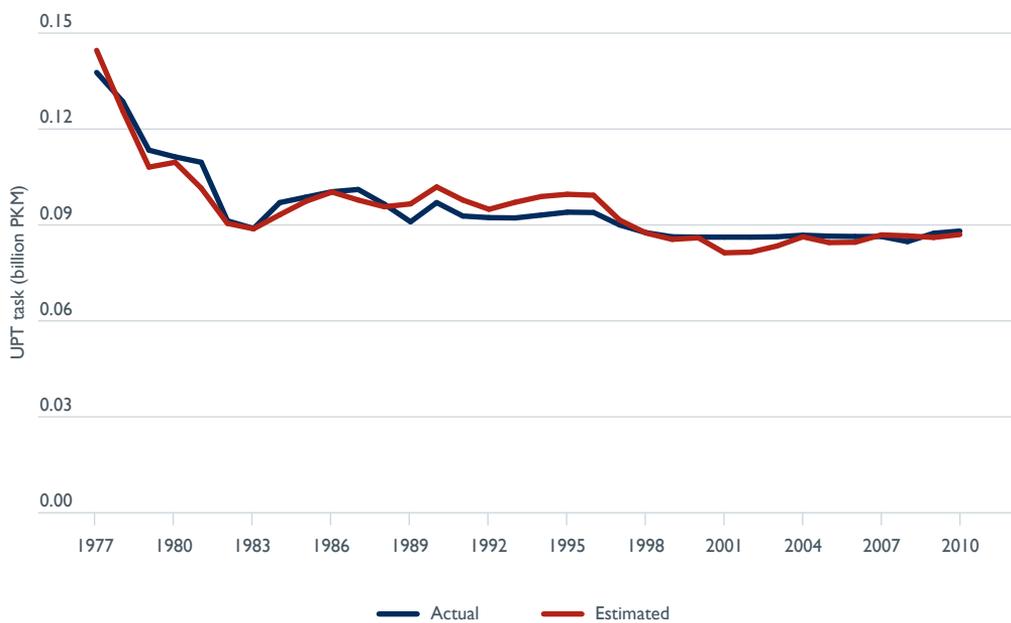

Figure 3.14 Actual and estimated UPT task (billion pkm), Hobart, 1977–2010

Darwin

Regression results for modelling Darwin's UPT share are presented in Table 3.8. Actual and estimated UPT shares are shown in Figure 3.15, while actual and modelled UPT tasks are shown in Figure 3.16.

Between 1977 and 2010, the trend for UPT in Darwin can be broken into two distinct phases: an upward trend to 1991, and flat thereafter. This trend is modelled with a time trend turning off in 1991. The fluctuations around the trend are minor, and therefore fares and the disposable income constraint, while of the expected sign, are not significant (Table 3.8).

Table 3.8 Regression results for modelling UPT share (per cent), Darwin, 1977–2010

Since the coefficient of determination (R^2) is very high (0.96) (Table 3.8), the pattern of actual UPT share in Darwin is very similar to the UPT share estimated by the model, as shown in Figure 3.15. Figure 3.16 shows that the modelling produces a similar prediction of the aggregate UPT task in Darwin between 1977 and 2010.

Figure 3.15 Actual and modelled UPT share (per cent), Darwin, 1977–2010

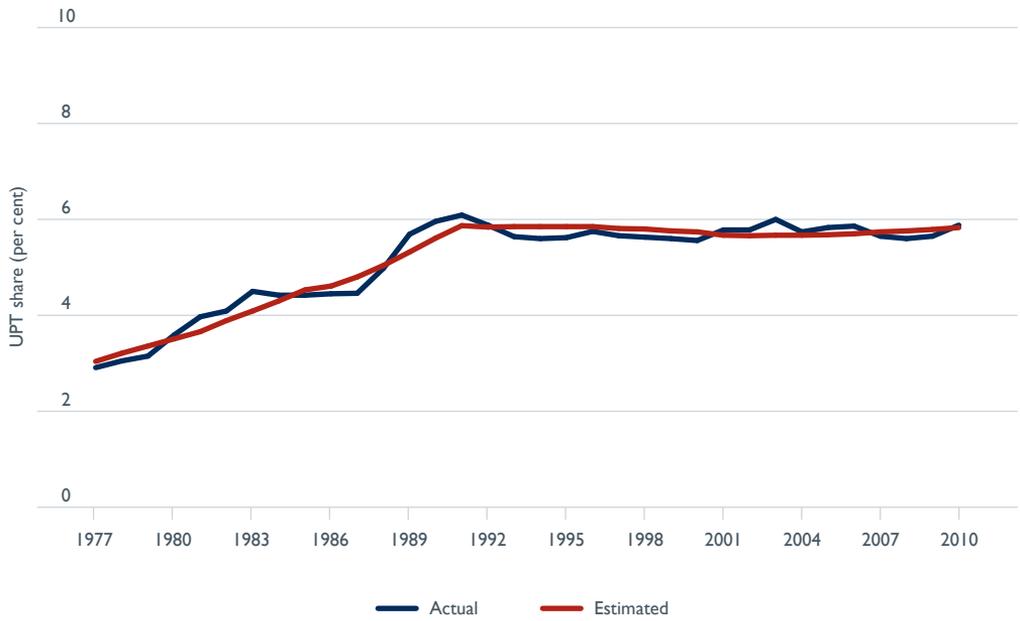

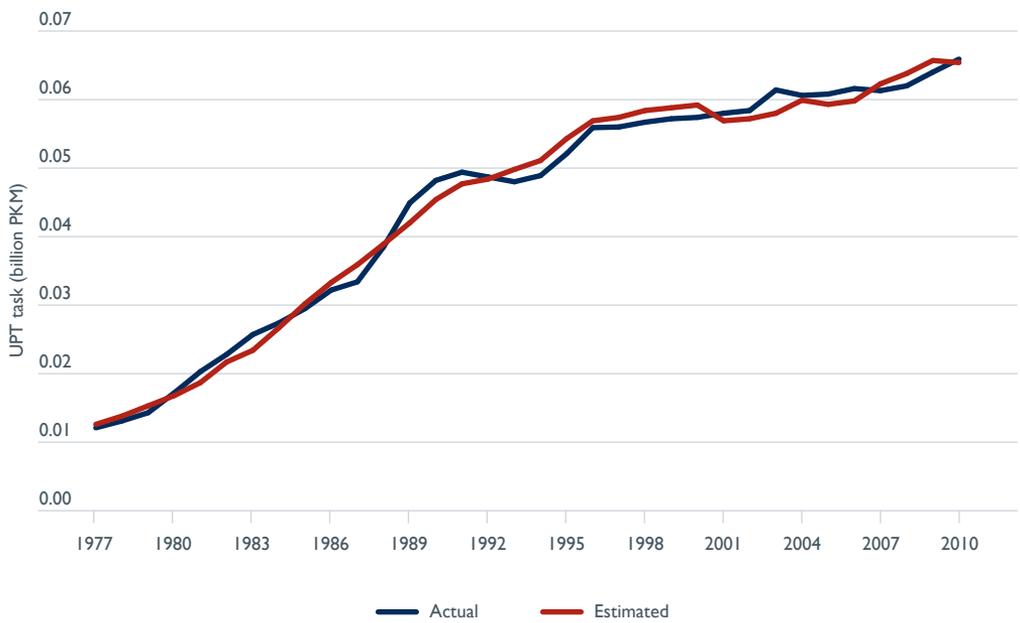

Figure 3.16 Actual and estimated UPT task (billion pkm), Darwin, 1977–2010

Canberra

Regression results for modelling Canberra’s UPT share are presented in Table 3.9. Actual and estimated UPT shares are shown in Figure 3.17, while actual and modelled UPT tasks are shown in Figure 3.18.

The share of UPT in Canberra has shifted twice: it shifted upward in 1983 from a low point in 1977–1982, and then upward again from 1996. The level of real fares was rising in the period 1977–1997. This increasing trend was matched by the decreasing UPT share, evident from 1985–1995. After 1997, fares were constant. After 1999, the underlying trend was flat. UPT share, however, slowly increased from 2005 due to the effect of a rising disposable income constraint.

As can be seen from Table 3.9, the results of the model show the highly significant effect for real fares. However, the fare elasticity is moderate. All other variables are highly significant ($p = <0.001$), except the disposable income constraint ($p = <11$ per cent).

Table 3.9 Regression results for modelling UPT share (per cent), Canberra, 1977–2010

In spite of the coefficient of determination (R^2) being relatively low (0.90) (Table 3.9), the pattern of actual UPT share in Canberra is quite similar to the UPT share estimated by the model, as shown in Figure 3.17. Figure 3.18 shows that the modelling produces a fairly accurate prediction of the aggregate UPT task in Canberra between 1977–2010.

Figure 3.17 Actual and modelled UPT share (per cent), Canberra, 1977–2010

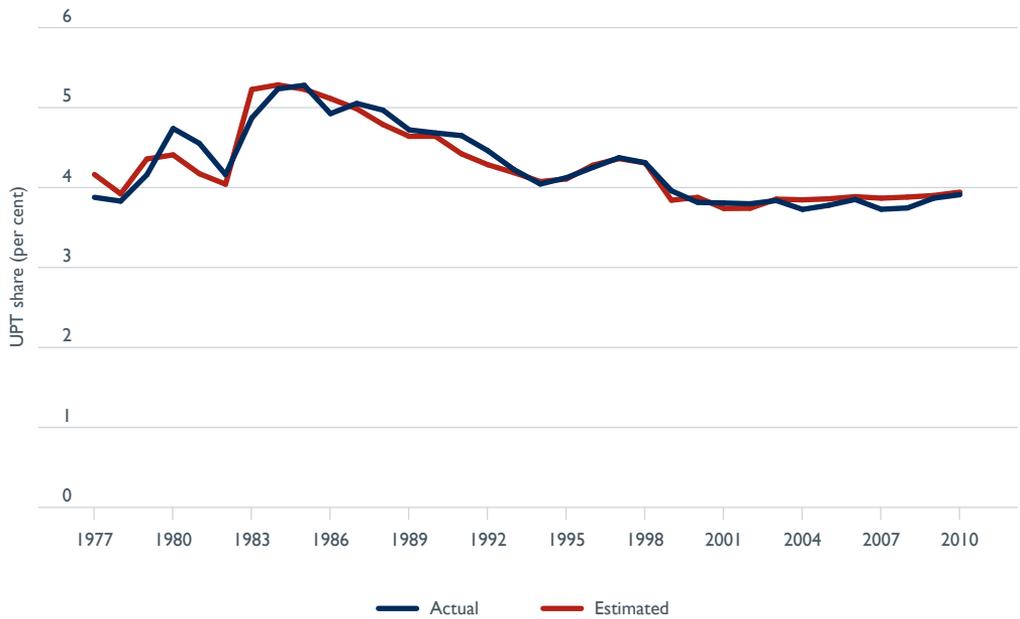

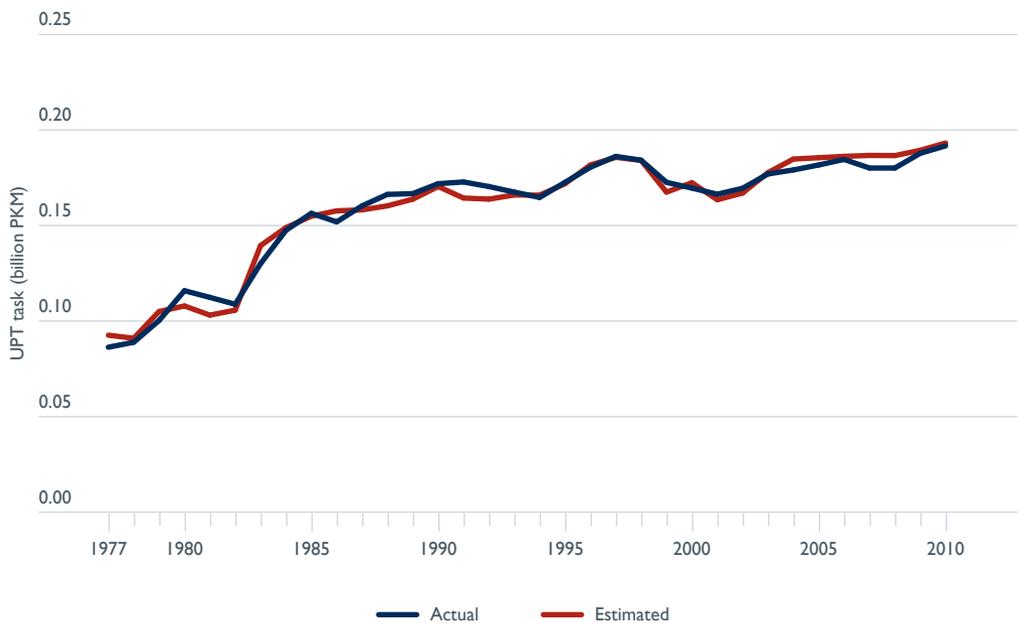

Figure 3.18 Actual and estimated UPT task (billion pkm), Canberra, 1977–2010

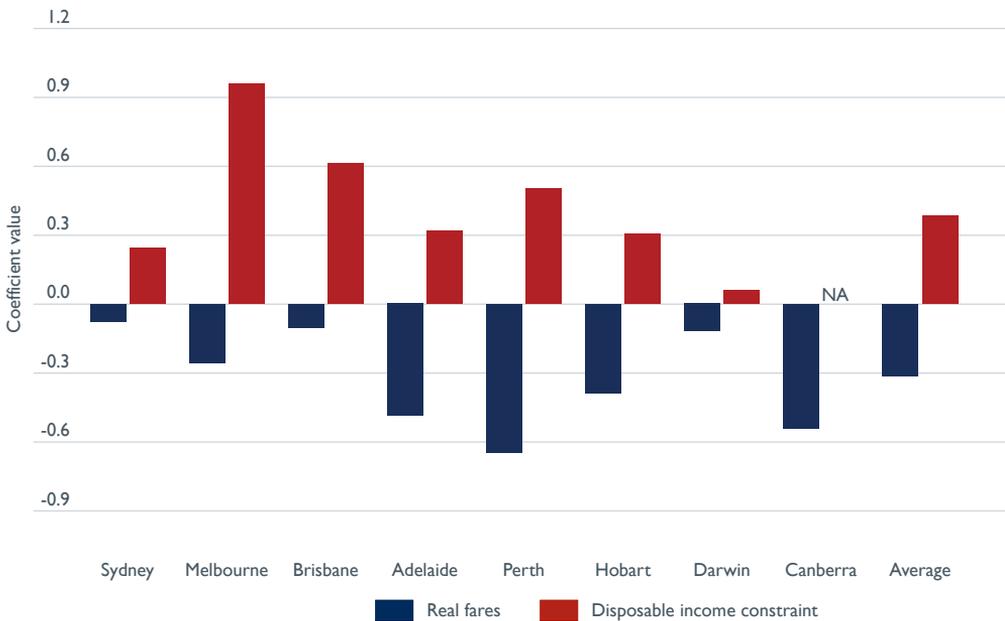

3.4 Real fare and disposable income constraint elasticities

This section compares the effects of real fares and the household disposable income constraint elasticities on the UPT shares in the various capital cities.

Because the regression equations are of a double-log form (see Table 3.2 to Table 3.9), the coefficients represent elasticities¹. The elasticities of the real UPT fares varied from -0.0762 (Sydney) to -0.6484 (Perth); an average for all capital cities was -0.3137 (Figure 3.19 and Table 3.10). The elasticities of the real UPT fares are highly significant ($p < 0.001$) for Melbourne, Brisbane, Adelaide, Perth and Canberra, while the elasticities for Sydney, Hobart and Darwin are insignificant ($p > 0.05$).

Figure 3.19 Coefficients of real fares and disposable income constraint, capital cities, 1977–2010

¹ Elasticity is defined as the percentage change in the dependent variable resulting from a one per cent change in the independent variable, all else held constant (Litman 2004). For example, a real fare elasticity of -0.4 means that each 1.0 per cent increase in transit fares, causes a 0.4 per cent reduction in ridership. So, a 10 per cent fare increase will cause ridership to decline by about 4 per cent.

Table 3.10 Coefficients and t-statistics of real fares and disposable income constraint, capital cities, 1977–2010

Capital city	Real fares			Disposable income constraint		
	Coefficient	t-statistics	p-value	Coefficient	t-statistics	p-value

Source: Table 3.2 to Table 3.9.

The average elasticity of the real UPT fares of the eight capital cities (-0.3137) (refer Table 3.10) is lower than the average fare elasticity of -0.4, which is based on eleven Australian studies of urban public transport demand cited in an earlier Transport and Road Research Laboratory (TRRL) report (Webster and Bly 1980). The influential review of public transport elasticities edited by Webster and Bly (1980) concluded that a reasonable rule of thumb for public transport fare elasticity was -0.3. This figure was widely acknowledged to be correct for much of the 1980s. However, towards the beginning of the 1990s, estimated fare elasticities increased slightly to somewhere in the range -0.3 to -0.4 or more (Hanly and Dargay 1999). International evidence was also cited in the TRRL report (Webster and Bly 1980). An average fare elasticity of -0.3 was reported for studies in Australia, France, Germany, Italy, the Netherlands, New Zealand, the UK and the USA. Hensher (2008) also compiled data from 40 publications, a number of which were reviews of the literature, and reported a mean estimate (elasticity) of -0.395 for fares, which is close to the -0.38 reported in Holmgren (2007) and other reviews, such as Goodwin (1992), Oum et. al. (1992) and Litman (2002).

The elasticities of the disposable income variables varied from 0.0599 (Darwin) to 0.9587 (Melbourne) (Figure 3.19 and Table 3.10). The elasticities of disposable income were highly significant for all capital cities ($p < 0.001$), except for Darwin ($p > 0.05$) and Canberra – where the variable was not used (Table 3.10). The average disposable income constraint elasticity for all eight capital cities combined was 0.3855 (moderate), ranging from 0.9587 (high) for Melbourne, to 0.0599 (low) for Darwin.

CHAPTER 4

Modelling and forecasting total passenger transport task by capital cities, 1965–2030

Summary

This chapter describes methodologies for modelling the total passenger-kilometre task (for both private vehicles and public transport) for each capital city in Australia. It provides regression results and the results on modelling estimates (1965–2010) and forecasts (2011–2030). Some key findings include:

- Growth in total passenger transport per person showed a saturating trend from 1965 to 2010.
- Between 1977 and 2010, the total passenger transport task was much higher in Sydney and Melbourne and lower in Hobart, Darwin and Canberra.
- The total metropolitan passenger transport task — that is the sum of all capital cities — is forecast to increase from 176.4 billion pkm in 2011 to 239.4 billion pkm in 2030, an average annual growth rate of 1.62 per cent.
- The total passenger transport task was 48 billion pkm in 1965, increasing to around 175 billion pkm by 2010, an average annual growth rate of 2.93 per cent. However, from 2005 to 2010, growth slowed (to 0.6 per cent per annum), mainly due to the effect of the GFC experienced from late 2008.
- Between 2011 and 2030, the total passenger transport task is forecast to grow fastest in Brisbane (2.41 per cent per annum) and slowest in Adelaide (0.69 per cent per annum), assuming the effect of the GFC diminishes.
- Between 2011 and 2030, Melbourne, Brisbane and Perth are expected to increase their share of the total metropolitan passenger transport task, while shares are forecast to decrease in other capital cities, except Darwin where the share is forecast to remain unchanged.

4.1 Background

Accurate forecasts of the future transport tasks in our cities are important for forward planning, particularly because investments in infrastructure are expensive and can have long lead times in project delivery (Gaymer 2010).

This chapter presents modelling results and estimates (1965–2010) of the total passenger transport task (pkm for both private vehicles and public transport) in each capital cities in Australia. The term 'metropolitan' is the sum of all eight capital cities. Forecasts to 2030 are also presented.

4.2 Methodology for modelling (1965–2010) and forecasting (2011–2030) total passenger transport task

To get the total predicted urban pkm per person (pkmpp) for the period 1965–2010 and to create forecasts for the period 2011–2030, pkm per person (sum of both private vehicles and public transport) from 1965 to 2010 was used as a dependent variable in linear regression models. Several independent variables, such as pre-1978 time, time, time squared, petrol price, unemployment, GFC and dummies, were used for the regression analysis. The equations were of the form:

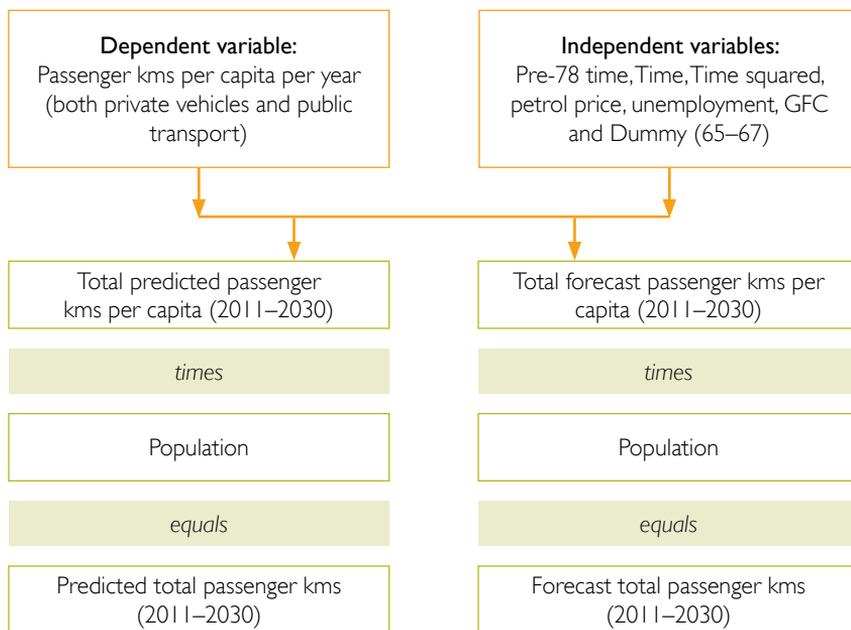

$$\text{Pkmpp} = f(\text{pre-1978time, time, time squared, petrol, unemployment, GFC, dummies})$$

Raw data for dependent and independent variables for each capital is presented in Appendix I.

For the forecast of the total passenger task in cities between 2011 and 2030, the models assumed that petrol prices and unemployment would not change, while the GFC effect would wear off by 2020.

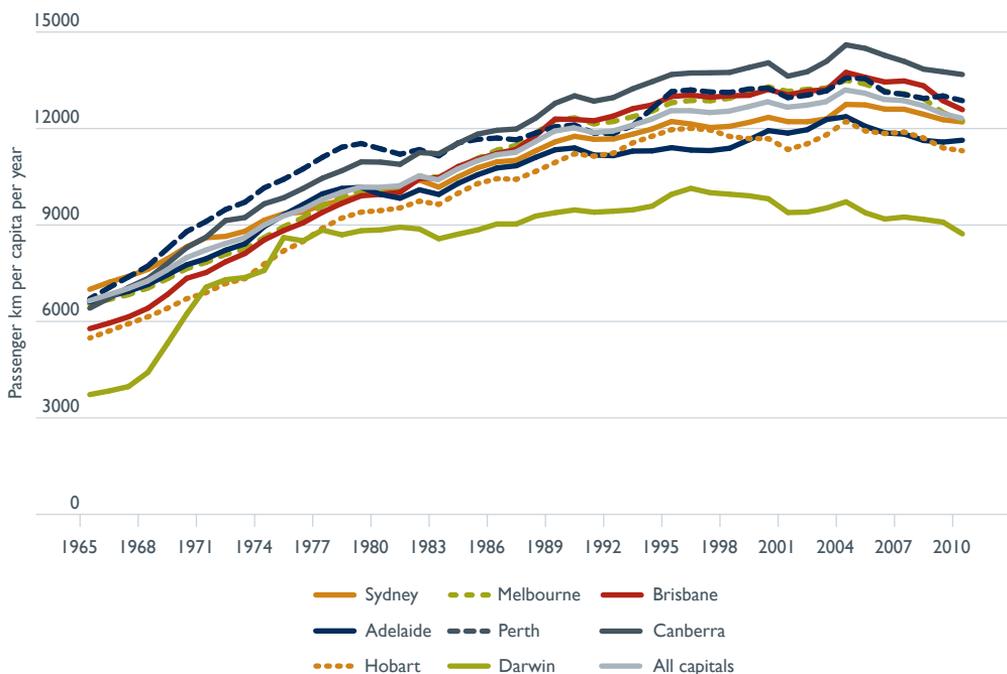

Figure 4.1 shows the schematic diagram for forecasting the total passenger transport task per capita.

Figure 4.1 Schematic diagram showing steps for modelling and forecasting total urban passenger transport task

The patterns of total urban passenger kilometres per capita in the eight capital cities as well as metropolitan Australia over the last 45 years from 1965 to 2010 are shown in Figure 4.2.

Figure 4.2 Patterns of total urban passenger kilometres per capita in Australian capital cities, 1965–2010

Fairly common to all individual capital cities is a period of faster growth in pkm from 1965 to 1978. This was taken into account in the regression analyses by including an extra 'time' trend that applies up to 1978 and is then turned off (by being held constant). For a short period from 1965–1967 higher levels of pkm per capita briefly occurred in all capital cities, except Perth. A dummy variable for this period was used in the analyses, and was important in allowing the 'time' and 'time squared' trends to concentrate on the period between 1967 and 2010.

Levels of unemployment and real petrol prices are important variables in determining the capital city passenger transport task. The unemployment rate and real petrol prices were kept constant in base case forecasting.

Further, the effect of the GFC on passenger levels is apparent in most states and territories (BITRE 2012a). This effect is independent of the effect associated with increased levels of unemployment, and has been modelled by a variable derived from the national consumer savings rate (a sudden increase in late 2008 and early 2009 taken to represent consumers' sudden switch to economizing, including economizing on travelling).

4.2.1 Total passenger transport task — Individual capital cities

Sydney

The growth in the total passenger transport task per person in Sydney over the last 45 years, from 1965 to 2010, is shown in Figure 4.3, together with the saturating trend fitted to 2030.

Using the independent variables, a model was fitted to the data, as detailed in Table 4.1, and illustrated in Figure 4.4. Several independent variables showed significant effects. First is the gradual trend toward saturation, which was reached in 2005. Second is the GFC from late 2008. Third is unemployment. Figure 4.5 shows the components of the Sydney total passenger transport task per person forecast.

Using the forecast total pkm per person and multiplying it by a series of the Sydney population, a forecast aggregate total pkm level was derived up to 2030, as shown in Figure 4.6. The fit is good and the total urban passenger task in Sydney is forecast to grow by 1.26 per cent per annum between 2011 and 2030, assuming the GFC effect diminishes.

Data for these four figures are presented in Appendix J (see Table J.1 and Table J.2).

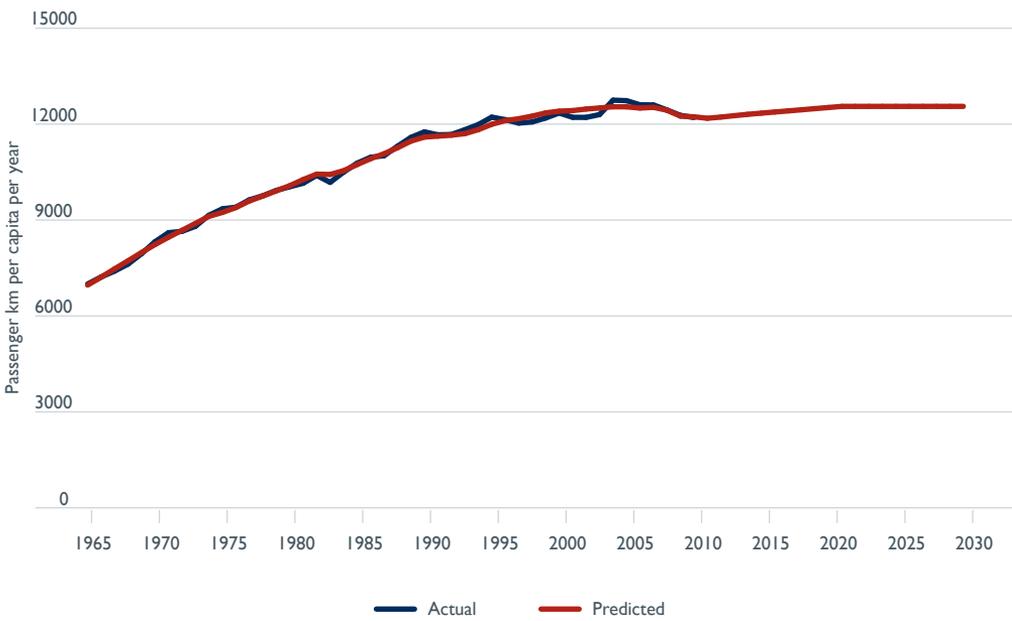

Figure 4.5 Components of predicted levels of total passenger transport task per person, Sydney, 1965–2030

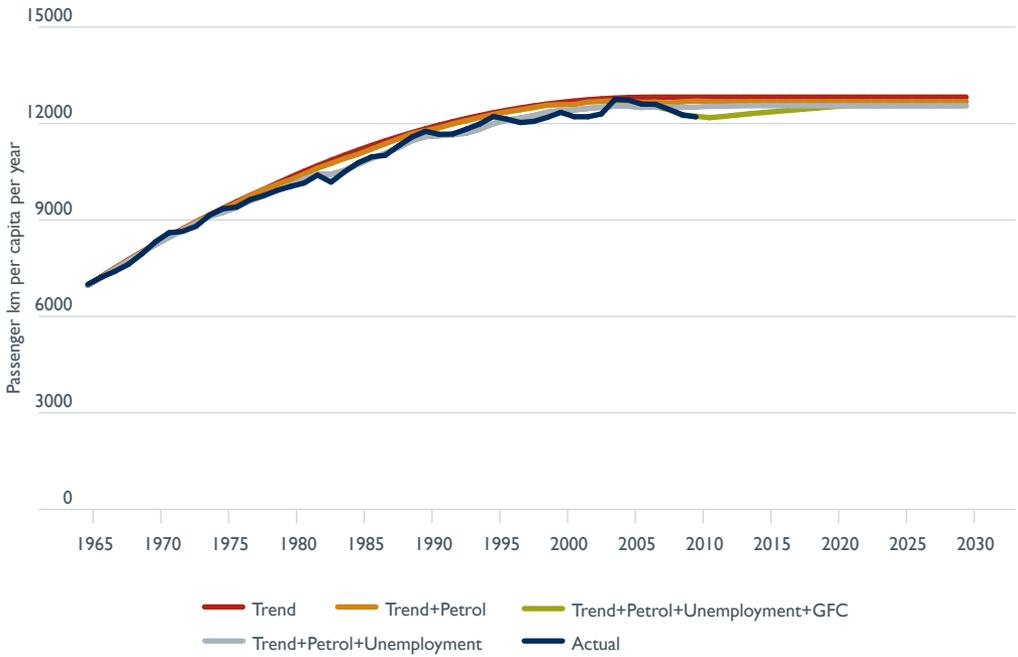

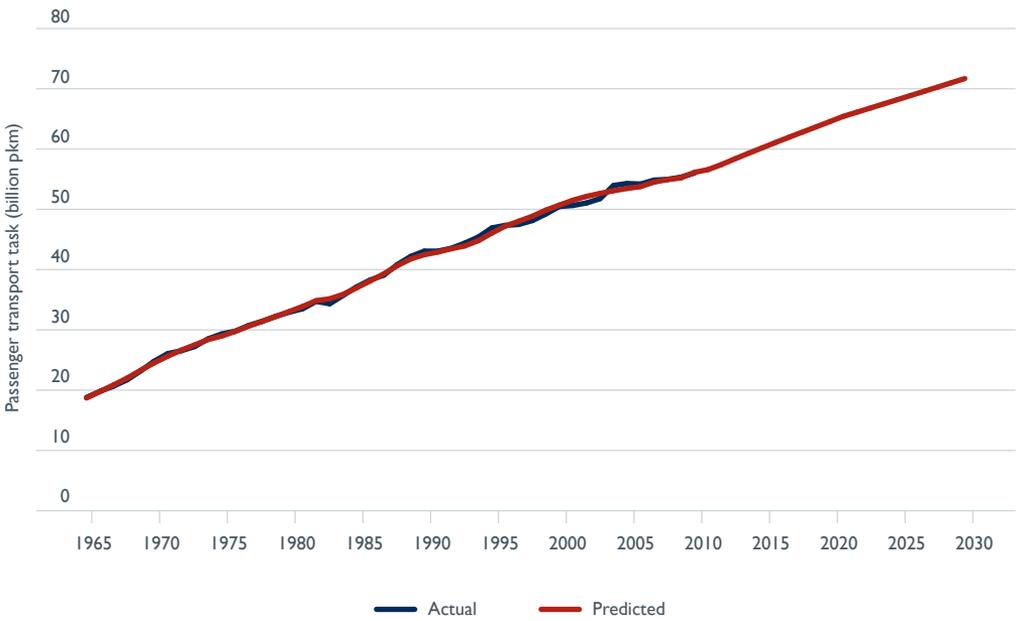

Figure 4.6 Aggregate total passenger transport task levels, Sydney, 1965–2030

Melbourne

The growth in the total passenger transport task per person in Melbourne over the last 45 years, from 1965 to 2010, is shown in Figure 4.7, together with the saturating trend fitted to 2030.

Using all the independent variables, a model was fitted to the data, as detailed in Table 4.2 and illustrated in Figure 4.8. All independent variables showed significant effects. First is the gradual trend toward saturation. Second is the petrol price. Third is unemployment. Finally, the GFC is significant from late 2008. Figure 4.9 shows the components of the Melbourne total passenger transport task per person forecast.

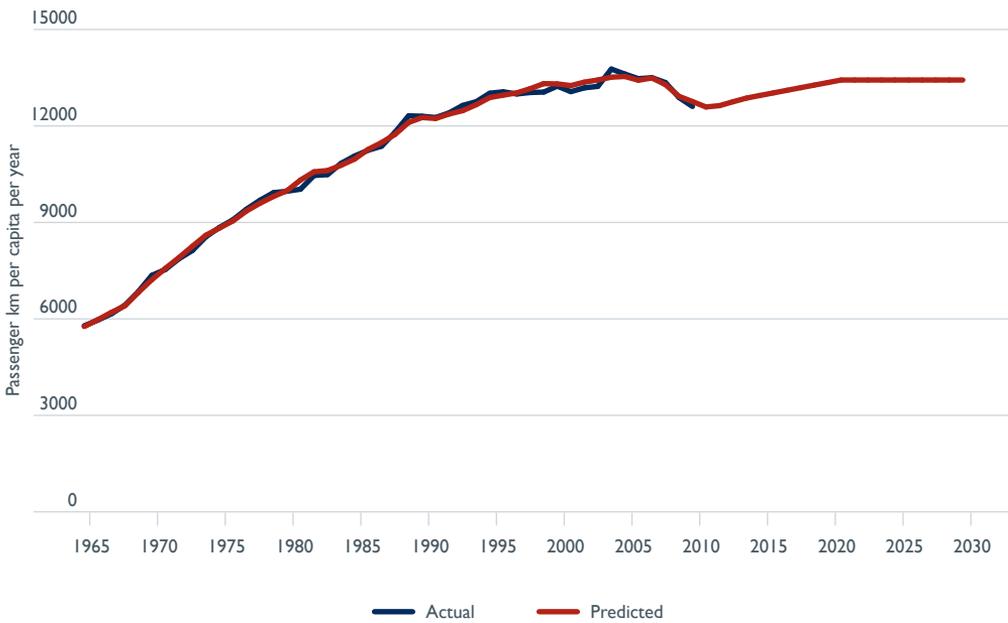

Figure 4.13 Components of predicted levels of total passenger transport task per person, Brisbane, 1965–2030

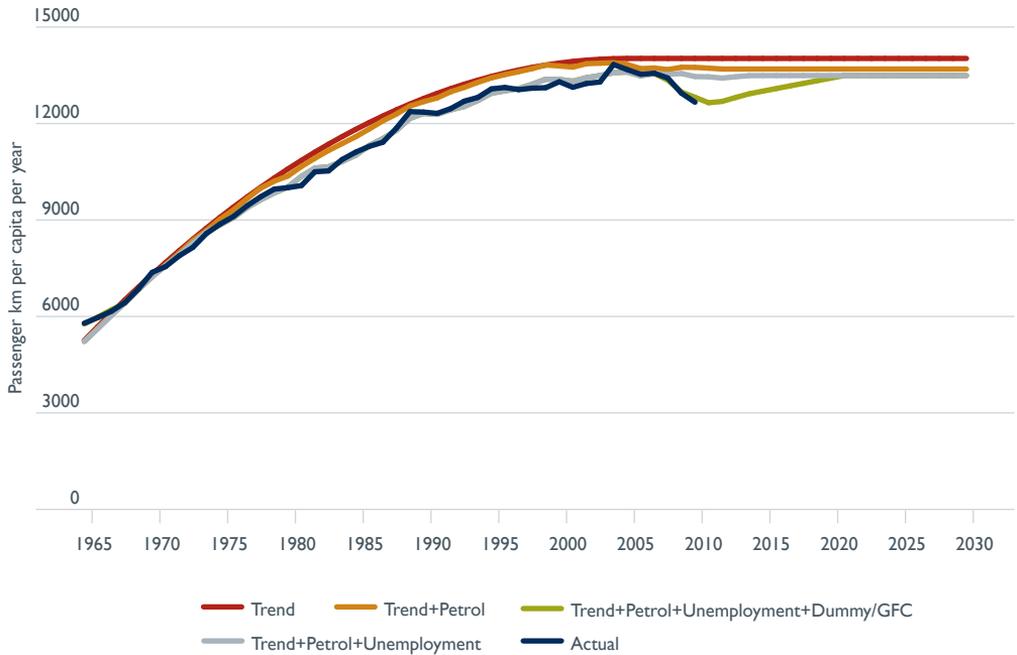

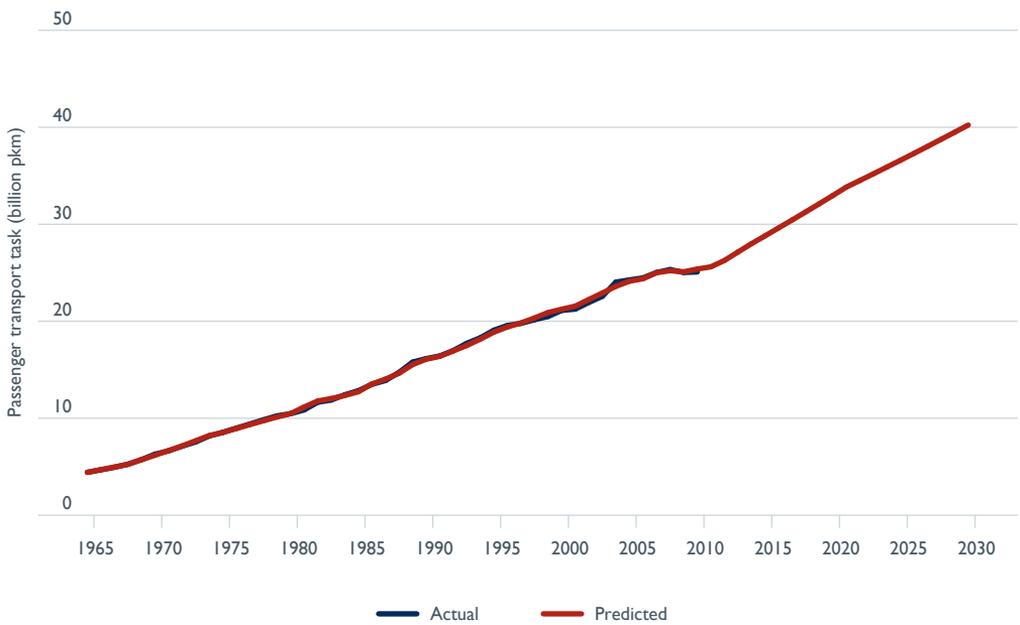

Figure 4.14 Aggregate total passenger transport task levels, Brisbane, 1965–2030

Adelaide

The growth in the total passenger transport task per person in Adelaide over the last 45 years, from 1965 to 2010, is shown in Figure 4.15, together with the saturating trend fitted to 2030.

Using all the independent variables, a model was fitted to the data, as detailed in Table 4.4, and illustrated in Figure 4.16. All independent variables showed significant effects. First is the gradual trend toward saturation. Second is petrol price (from 1979 to the mid-1980s and more recently), and third, the GFC from late 2008. Unemployment caused total pkm per person to dip below trend in the 1983 and early 1990's recessions. Figure 4.17 shows the components of the Adelaide total passenger transport task per person forecast.

Perth

The growth in the total passenger transport task per person in Perth over the last 45 years, from 1965 to 2010, is shown in Figure 4.19, together with the saturating trend fitted to 2030.

Using all the independent variables, a model was fitted to the data, as detailed in Table 4.5, and illustrated in Figure 4.20. All independent variables showed significant effects, except unemployment. First is the gradual trend toward saturation. Second is petrol price, and third, the GFC from late 2008. However, the Perth data is marked by a much higher growth trend from 1965 to 1978, after which there is a slowing in growth. Figure 4.21 shows the components of the Perth total passenger transport task per person forecast.

Note: The unemployment variable was not used.

Using the forecast total pkm per person and multiplying it by a series of the Hobart population, a forecast aggregate total pkm levels in the city was derived up to 2030. This is shown in Figure 4.26. The fit is good and the total urban passenger task in Hobart is forecast to grow by 0.97 per cent per annum between 2011 and 2030, assuming the GFC effect wears off.

Data for these four figures are presented in Appendix J (see Table J.11 and Table J.12).

² The unemployment variable was not used in the regression.

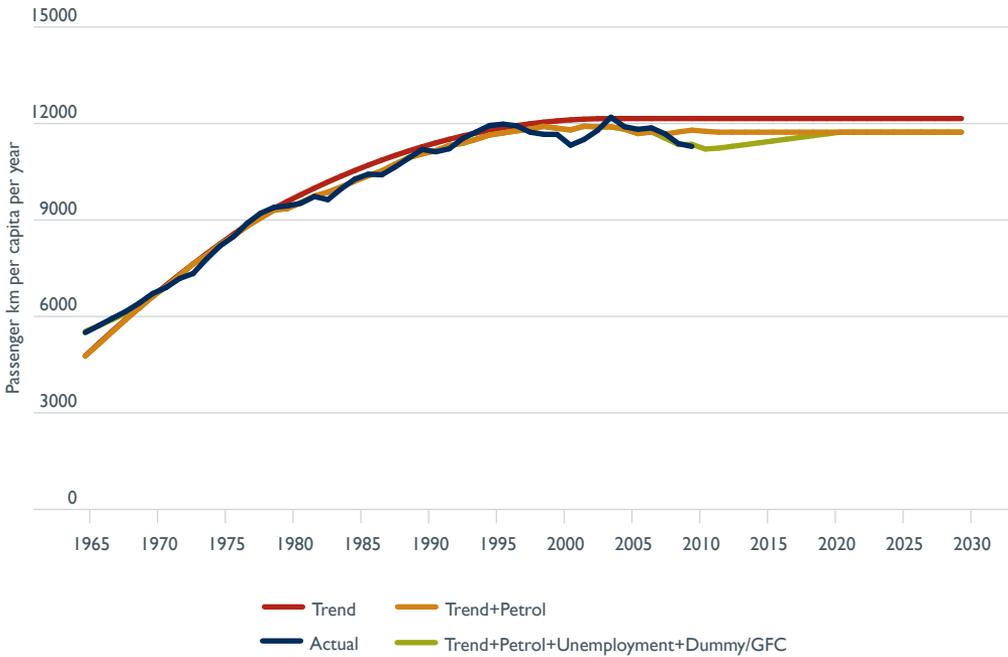

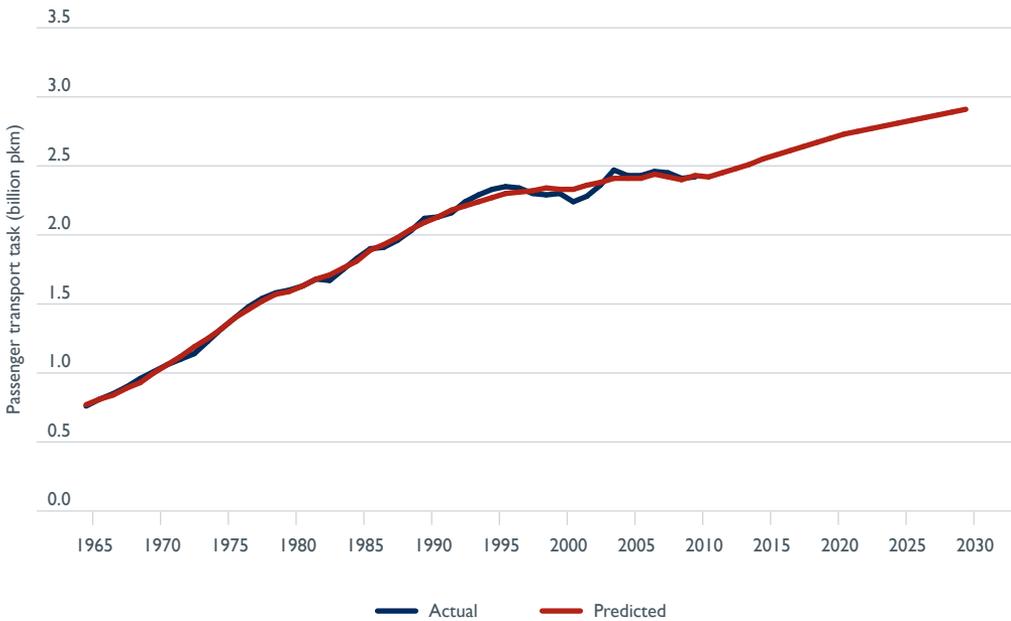

Figure 4.26 Aggregate total passenger transport task levels, Hobart, 1965–2030

Darwin

The growth in the total passenger transport task per person in Darwin over the last 45 years, from 1965 to 2010, is shown in Figure 4.27, together with the saturating trend fitted to 2030.

Using all the independent variables, a model was fitted to the data, as detailed in Table 4.7, and illustrated in Figure 4.28. All independent variables showed significant effects. First is the gradual trend toward saturation. Second is petrol price (from 1979 to the mid-1980s and more recently), thirdly unemployment, and finally, the GFC from late 2008. Overall, Darwin shows the most extreme break between pre- and post-1978 trends. There is a much higher trend between 1965 and 1978. After 1978, there is a marked slowing in trend growth. Figure 4.29 shows the components of the Darwin total passenger transport task per person forecast.

Using the forecast total pkm per person and multiplying it by a series of the Darwin population, a forecast of aggregate total pkm levels in the city was derived up to 2030. This is shown in Figure 4.30. The fit is good. The effect of Cyclone Tracy in late 1974 mainly shows in the subsequent temporary reduction in the population of Darwin, and shows up most starkly in the aggregate passenger level for 1975 (Figure 4.30). The forecast for the next two decades (2011–2030) is for the resumption of growth in total passenger travel, assuming the GFC effect diminishes.

Data for these four figures are presented in Appendix J (see Table J.13 and Table J.14).

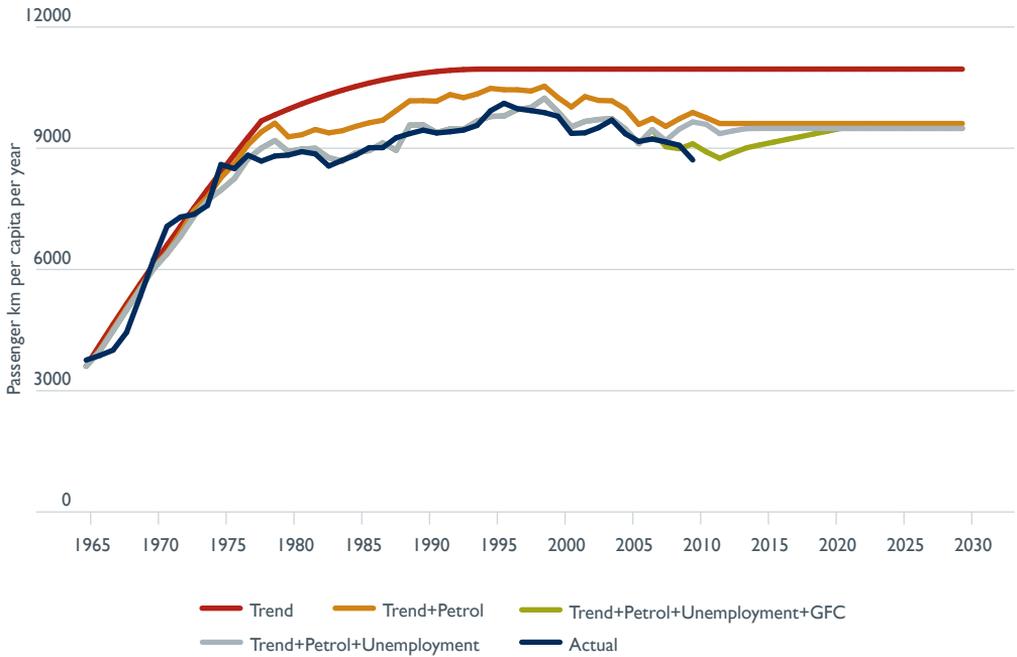

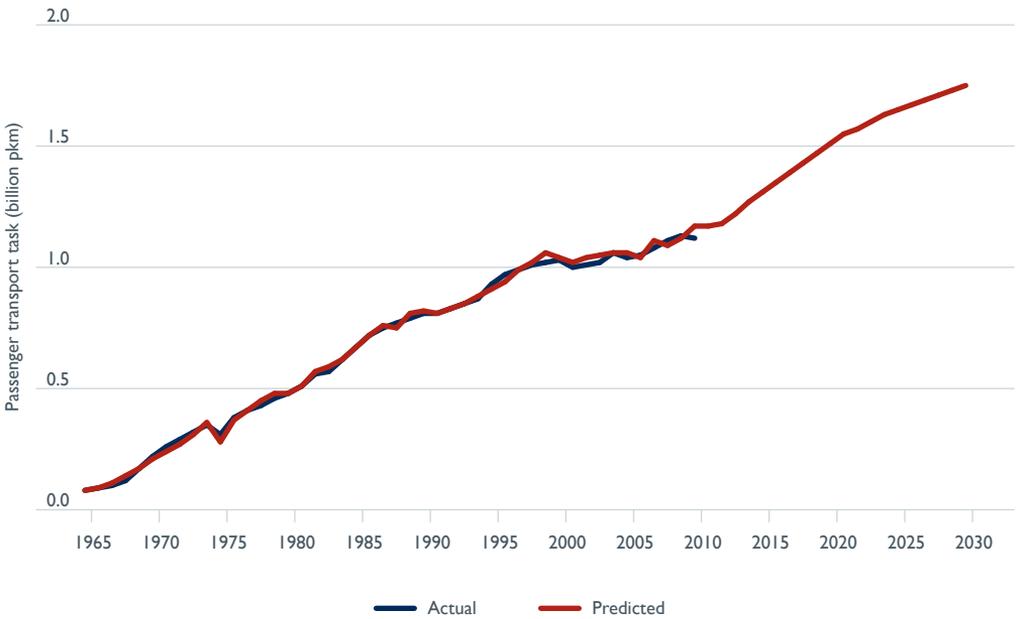

Figure 4.30 Aggregate total passenger transport task levels, Darwin, 1965–2030

Canberra

The growth in the total passenger transport task per person in Canberra over the last 45 years, from 1965 to 2010, is shown in Figure 4.31, together with the saturating trend fitted to 2030.

Using all the independent variables, a model was fitted to the data, as detailed in Table 4.8, and illustrated in Figure 4.32. All independent variables showed significant effects, except unemployment, which does not reach significance. The first significant variable is the gradual trend toward saturation. Second is petrol price, and finally, the GFC from late 2008. However, the Canberra data is marked by a much higher growth trend from 1965–1978, after which there is a slowing in trend growth. Figure 4.33 shows the components of the Canberra total passenger transport task per person forecast.

Using the forecast total pkm per person and multiplying by a series of the Canberra population, a series forecasting aggregate total pkm in the city is derived up to 2030. This is shown in Figure 4.34. The fit is good and the total urban passenger task in Canberra is forecast to grow by 1.35 per cent per annum between 2011 and 2030, assuming the GFC effect diminishes.

Data for these four figures are presented in Appendix J (see Table J.15 and Table J.16).

4.2.2 Total metropolitan passenger transport task

This section assembles various components of predicted levels of passenger task per person and data on the urban passenger transport task for all capital cities and presents data as ‘total metropolitan’ (see Figures 4.35 and 4.36).

Figure 4.35 Components of predicted levels of passenger task per person, total (sum of all) capital cities, 1965–2030

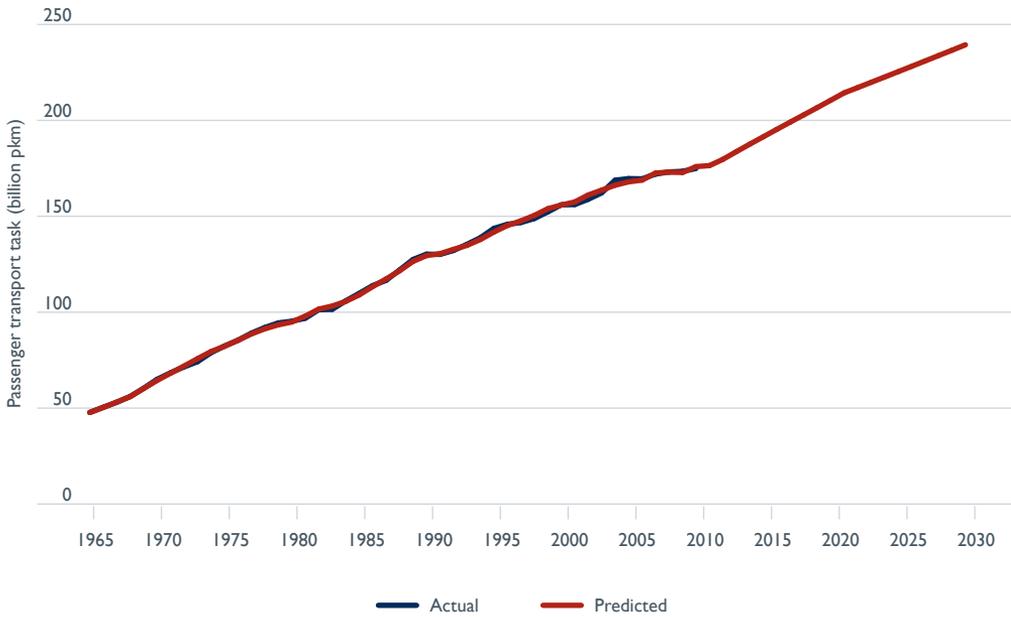

The various components of the predicted and forecast passenger-kilometres task per person for total capital cities showed the effects of variables on the growth trend (Figure 4.35). For example, unemployment lowered the level of passenger task per person, especially from late 1970s to 2010.

Using the sum of the forecast total passenger-kilometres for all the capital cities, a series forecasting ‘metropolitan’ total passenger-kilometre levels is derived up to 2030. This is shown in Figure 4.36. The fit is good and the total urban passenger task in metropolitan Australia is forecast to grow by 1.60 per cent per annum between 2011 and 2030, assuming the GFC effect diminishes.

Note that data for these four figures are presented in Appendix J (see Table J.17 and Table J.18).

Figure 4.36 Aggregate total urban passenger task levels, total (sum of all) capital cities, 1965–2030

4.3 Results on total passenger transport task by capital cities: estimates (1977–2010) and forecasts (2011–2030)

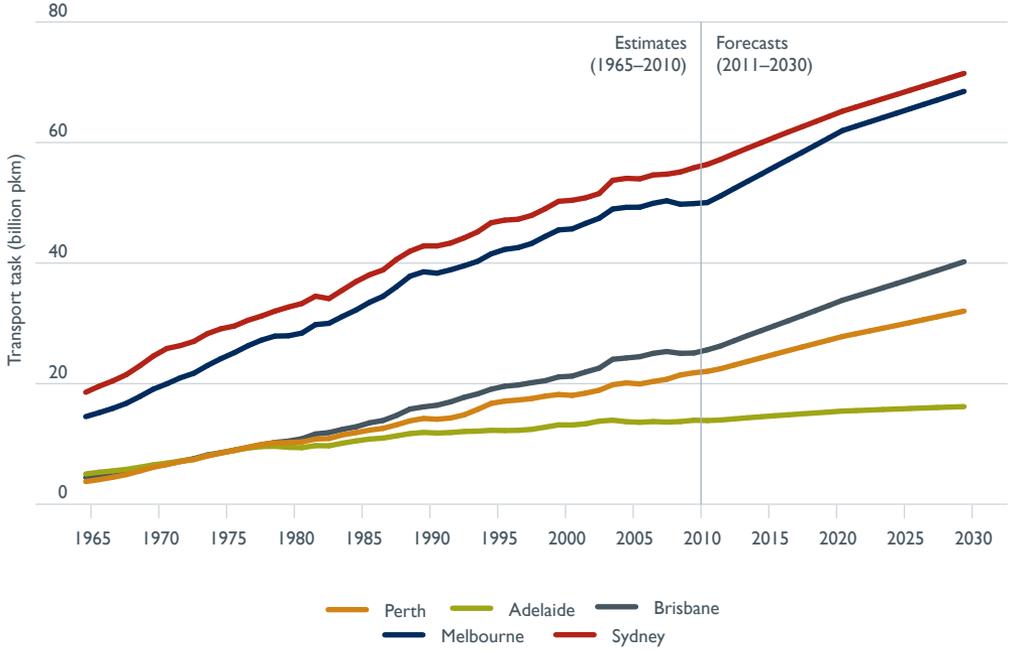

This section shows the results of the models' estimates of the total passenger transport task (1977–2010) as well as forecasts (2011–2030) the total urban passenger transport task for each capital city, as well as for the metropolitan urban passenger transport task.

4.3.1 Individual capital cities

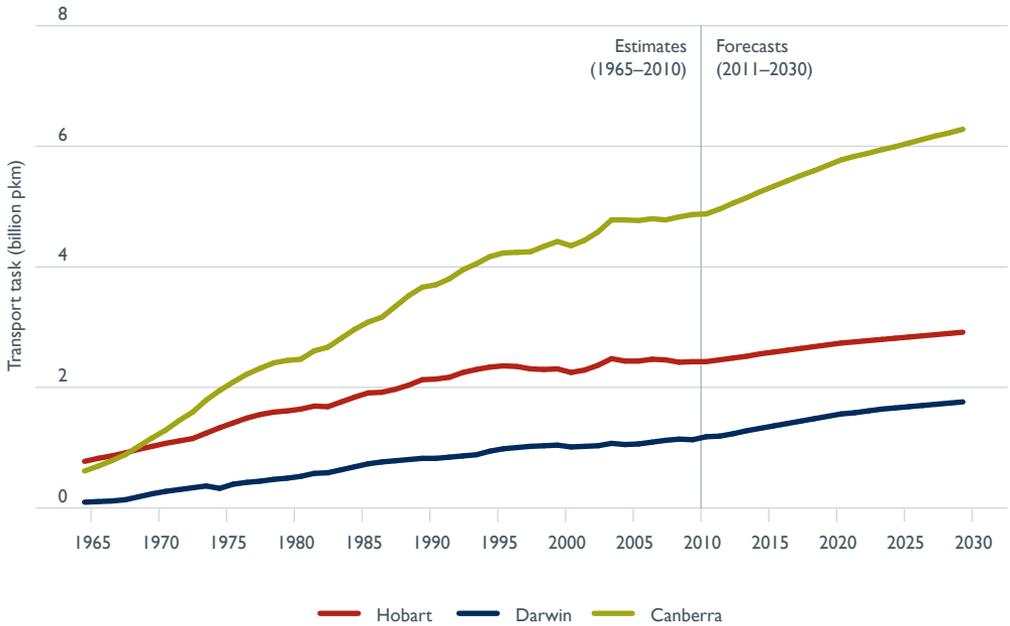

Figure 4.37 shows the forecasts (2011–2030) of the total urban passenger transport task for each capital city, as well as the estimates (1977–2010) for showing trends. Data for this figure is presented in Table 4.9.

Figure 4.37 Estimates and forecasts of total urban passenger transport task, capital cities, 1977–2030

(a) Major capital cities

(b) Minor capital cities

Between 2011 and 2030, the total urban passenger transport task is forecast to grow from 56.4 billion pkm to 71.5 billion pkm in Sydney, from 50.0 billion pkm to 68.5 billion pkm in Melbourne, from 25.6 billion pkm to 40.2 billion pkm in Brisbane, from 13.9 billion pkm to 16.2 billion pkm in Adelaide and from 22.0 billion pkm to 32.0 billion pkm in Perth (Figure 4.37a and Table 4.9). The total urban passenger transport task is forecast to grow from 2.4 billion pkm to 2.9 billion pkm in Hobart, from 1.2 billion pkm to 1.8 billion pkm in Darwin and from 4.9 billion pkm to 6.3 billion pkm in Canberra during the same period (Figure 4.37b and Table 4.9).

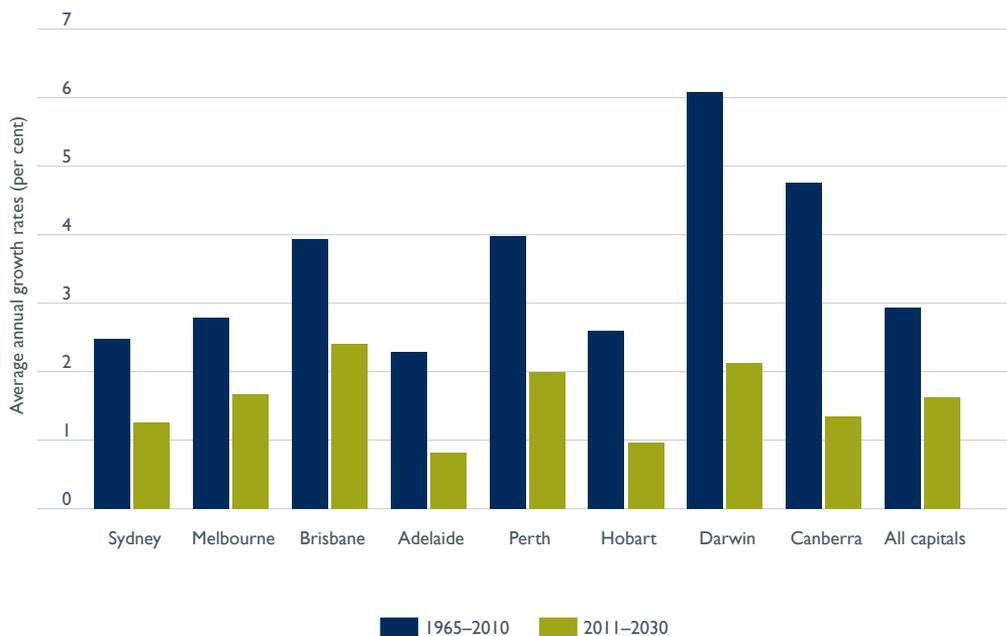

Between 2011 and 2030, among the five larger capital cities, the average annual growth rates of total urban passenger transport task are expected to be highest in Brisbane (2.41 per cent); followed by Perth (1.99 per cent); and lowest in Adelaide (0.82 per cent). Sydney and Melbourne will have average annual growth rates of 1.26 per cent and 1.67 per cent, respectively (Figure 4.38 and Table 4.9). Among three smaller capital cities, the average annual growth rate of total urban passenger transport task is expected to be higher in Darwin (2.12 per cent); followed by Canberra (1.35 per cent); and lowest in Hobart (0.97 per cent) (Figure 4.38 and Table 4.9).

Between 2011 and 2030, the city share of the total metropolitan passenger transport task is forecast to increase in Melbourne (from 28.4 per cent to 28.7 per cent); increase in Brisbane (from 14.5 per cent to 16.8 per cent); and increase in Perth (from 12.5 per cent to 13.4 per cent). Shares of the total passenger transport task are forecast to decrease in other capital cities, except Darwin where the share is forecast to remain unchanged (Figure 4.39 and Table 4.10).

Between 1977 and 2010, among the capital cities, total urban passenger transport tasks were much higher in Sydney and Melbourne, while total urban passenger transport tasks were much lower in Hobart, Darwin and Canberra (Figure 4.37 and Table 4.9).

Between 1977 and 2010, the average growth rates of total urban passenger transport task among the five larger capital cities show that Perth had the highest growth rate (3.98 per cent per annum), followed by Brisbane (2.93 per cent per annum), with the lowest growth rate in Adelaide (2.29 per cent per annum) (Table 4.9). The average annual growth rate of total urban passenger transport task in the three smaller capital cities was highest in Darwin (6.08 per cent per annum), followed by Canberra (4.76 per cent per annum) and lowest in Hobart (2.59 per cent per annum) (Table 4.9). The average annual growth rates of total urban passenger transport task for each of the eight capital cities, as well as for the total (sum of all) capital cities between 1977 and 2010, are shown graphically in Figure 4.38.

Figure 4.38 Average annual growth rates (per cent) of estimates (1965–2010) and forecasts (2011–2030) of total urban passenger transport task, capital cities

Over the period (1977–2010), the city share of the total urban passenger transport task increased in Brisbane, Perth, Darwin and Canberra, while it decreased in Sydney, Melbourne, Adelaide and Hobart (Table 4.10).

4.3.2 Total (sum of all) capital cities

Figure 4.39 Estimates (1965–2010) and forecasts (2011–2031) of total passenger transport task, sum of all capital cities

In 1965, the total passenger transport task totalled 47.8 billion pkm and it increased to around 174.9 billion pkm by 2010 (Figure 4.39 and Table 4.9). Over the last 45 years, the urban passenger transport task has grown at an average annual rate of 2.93 per cent per year. This growth has been driven by increases in population, vehicle ownership, increasing incomes and urban decentralisation. However, during the last decade (2001–2010), the growth slowed to an average annual growth rate of 1.14 per cent per year. This slower growth is mainly due to the effect of the GFC experienced in 2008–09.

The total passenger transport task is forecast to increase by more than 35 per cent over the next two decades, from 176.4 billion pkm in 2011 to 239.4 billion pkm in 2030 (Figure 4.39 and Table 4.9). The average annual growth rate over this period is forecast to be 1.62 per cent per year. Catering for this forecast increase in the total passenger transport task in capital cities will present a significant challenge within urban areas.

CHAPTER 5

Forecasting the public transport passenger task, capital cities, 2011–2030

Summary

This chapter describes the methodology used in this report for forecasting the UPT passenger task in capital cities between 2011 and 2030. It also provides forecast results, which are base case forecasts of future trends for UPT passenger task in each capital city, as well as for the sum of all capital cities. Estimates of the UPT passenger task between 1977 and 2010 are also presented for comparison purposes, to show the accuracy of the model for estimating. Several key findings emerged including:

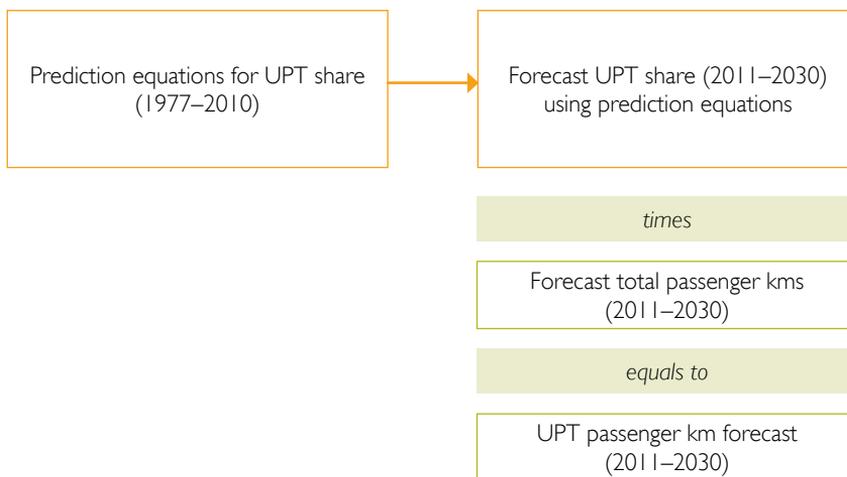

- Between 2011 and 2030, the total UPT passenger task is forecast to grow from 19.71 billion pkm to 25.34 billion pkm, an average annual growth rate of 1.33 per cent.
- Among the five larger capital cities, the UPT passenger task is forecast to grow fastest in Brisbane, followed by Perth, Melbourne, Sydney and Adelaide.
- Among the three smaller capital cities, the average annual growth rate of the UPT passenger task is expected to be highest in Darwin (1.78 per cent) followed by Canberra (1.04 per cent) and Hobart (0.73 per cent).
- Among the five larger capital cities, the city share of the total metropolitan UPT passenger task is forecast to increase in Brisbane and Perth, while the shares are forecast to decrease in Sydney, Melbourne and Adelaide. Among the three smaller capital cities, the city shares of the total metropolitan UPT passenger task will remain largely unchanged.

5.1 Methodology for forecasting UPT tasks

Forecasts of the volume of passengers that will be using public transport form an important base for policy development. This section describes the methodologies used for forecasting the UPT task for each capital city in Australia between 2011 and 2030. The total metropolitan UPT task is calculated as the sum of all eight capital cities.

Forecast UPT shares between 2011 and 2030 were obtained from the predicted equations for UPT share (1977–2010) combined with real fares unchanged. The disposable income constraint (DIC) components were also assumed not to change. The exception was the GFC. The effects of the GFC were assumed to wear off by 2020 and the savings rate to decline to 3 per cent of GDP. This resulted in a decrease in the DIC and a decrease in UPT share across most cities. The resulting forecast UPT shares were then multiplied by total forecast pkm (2011–2030), which gave the UPT task forecasts in passenger kilometres. The schematic diagram for forecasting the UPT passenger task between 2011 and 2030 is shown in Figure 5.1.

Figure 5.1 Schematic diagram showing steps for forecasting the urban public transport (UPT) passenger task in capital cities

Forecasting the UPT task can be calculated from the following equation:

$$UPT_{\text{Forecast}} = \text{Task}_{\text{Forecast}} * UPT_{\text{Share}} / 100$$

where UPT_{Forecast} = UPT passenger task (billion pkm)

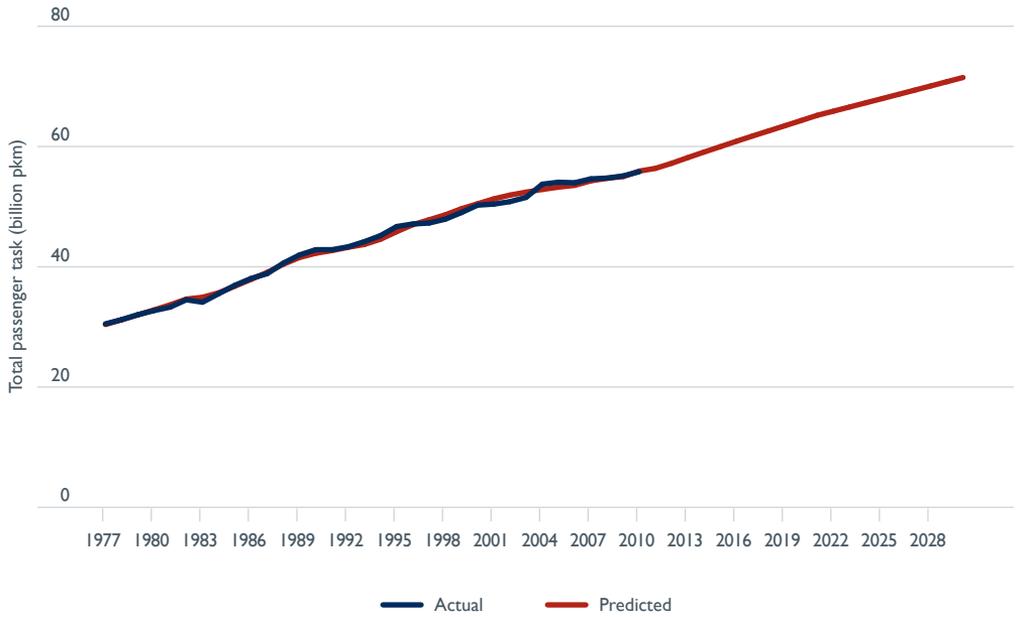

$\text{Total}_{\text{Forecast}}$ = Total passenger task (billion pkm)

UPT_{Share} = UPT share (per cent).

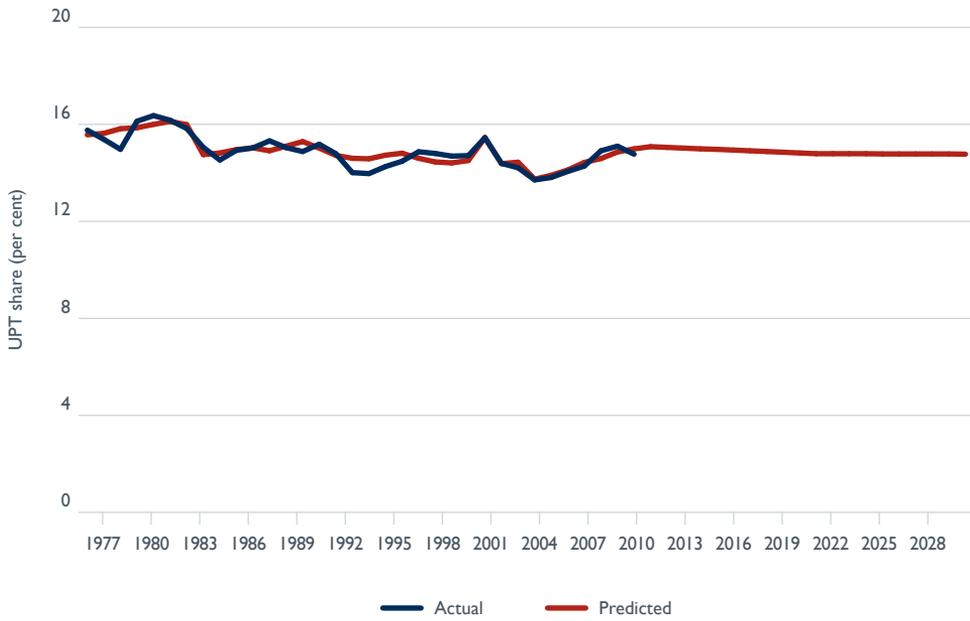

The actual and predicted (modelled) Total passenger task, UPT share and UPT pkm fit well in each capital city, as shown in Figure 5.2 to Figure 5.9. Data for these figures are presented in Appendix K (see Table K.1 to Table K.8).

5.2 UPT passenger task, estimates (1977–2010) and forecasts (2011–2030)

This section examines the forecasts (2011–2030) of the UPT passenger tasks for each of the eight capital cities as well as the total metropolitan Australia task.

5.2.1 Individual capital cities

Figure 5.11 shows the forecasts (2011–2030) of the UPT for the eight capital cities, as well as the modelled estimates (1977–2010) for showing trends and demonstrating the reliability of the model. Data for this figure is presented in Table 5.1.

Between 2011 and 2030, the UPT passenger task in the larger capital cities is forecast to increase from:

- 8.49 billion pkm to 10.55 billion pkm in Sydney
- 5.83 billion pkm to 7.35 billion pkm in Melbourne
- 2.48 billion pkm to 3.71 billion pkm in Brisbane
- 0.89 billion pkm to 0.99 billion pkm in Adelaide
- 1.50 billion pkm to 2.14 billion pkm in Perth (Figure 5.10a and Table 5.1).

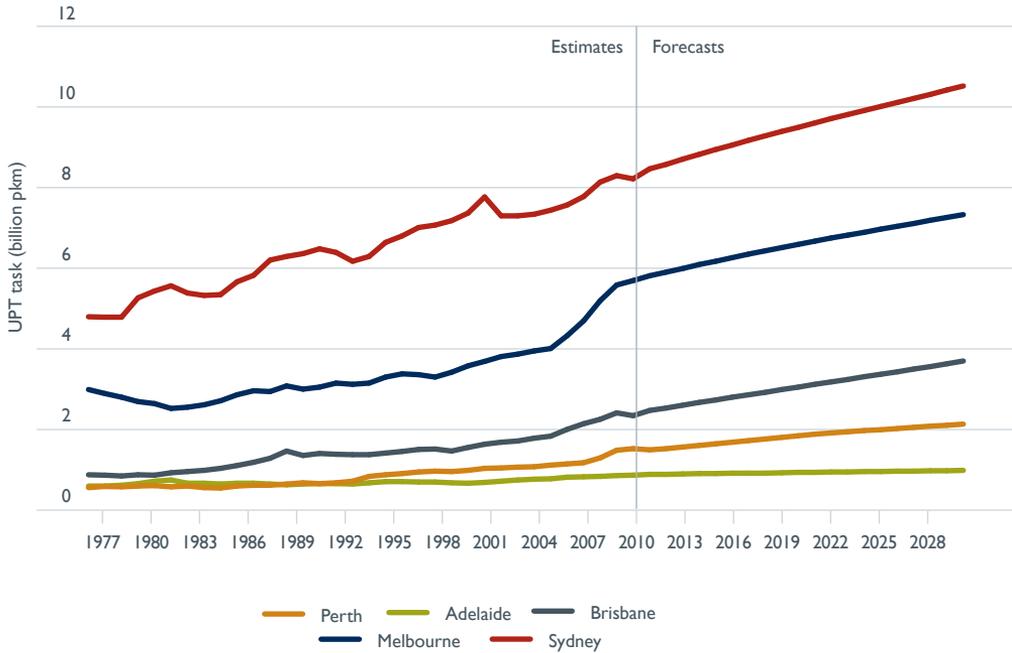

In the three smaller capital cities, the UPT passenger task is forecast to grow from:

- 0.08 billion pkm to 0.10 billion pkm in Hobart
- 0.07 billion pkm to 0.10 billion pkm in Darwin
- 0.26 billion pkm to 0.33 billion pkm in Canberra. (Figure 5.10b and Table 5.1).

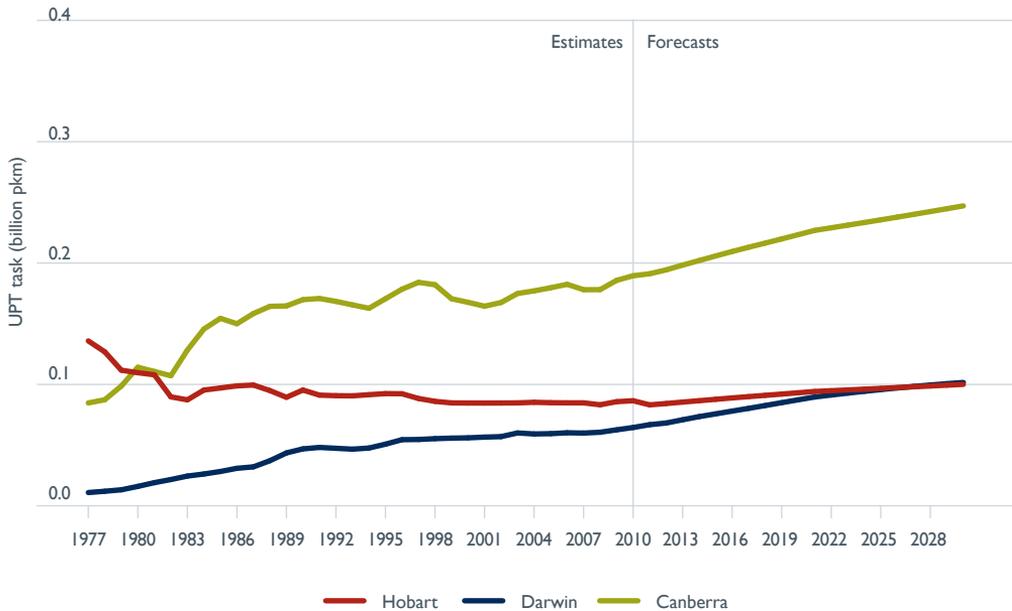

Between 2011 and 2030, among the five larger capital cities, the average annual growth rate of the UPT passenger task is expected to be highest in Brisbane (2.14 per cent); followed by Perth (1.90 per cent); and lowest in Adelaide (0.55 per cent). Sydney and Melbourne will have average annual growth rates of 1.15 per cent and 1.23 per cent respectively (Table 5.2 and Figure 5.11). Among the three smaller capital cities, the average annual growth rate of UPT passenger task is expected to be higher in Darwin (2.20 per cent); followed by Canberra (1.34 per cent); and lowest in Hobart (0.97 per cent). The average annual growth rates of UPT passenger task for each of the eight capital cities, as well as sum of all capital cities, from 2011–2030 are shown in Figure 5.12.

Figure 5.11 UPT passenger task, estimates (1977–2010) and forecasts (2011–2030), capital cities

(a) Larger capital cities

(b) Smaller capital cities

Source: Table 5.1.

Note: Data from 1977 to 2010 are estimates, while from 2011 to 2030 are forecasts.

Figure 5.12 Average annual growth rates (per cent) of UPT passenger task, estimates (1977–2010) and forecasts (2011–2030), capital cities

Source: Table 5.2.

Note: Data from 1977 to 2010 are estimates, while from 2011 to 2030 are forecasts.

Between 2011 and 2030, the city share of the total metropolitan UPT passenger task is forecast to increase in Brisbane (from 12.6 per cent to 14.6 per cent) and Perth (from 8.0 per cent to 8.6 per cent). Shares are forecast to decrease in Sydney (from 43.1 per cent to 41.7 per cent); Melbourne (from 29.7 per cent to 29.1 per cent); and Adelaide (4.5 per cent to 3.9 per cent) (Table 5.3). On the other hand, the city shares of the UPT passenger task will be more or less similar in the smaller capital cities.

Over the historical period (1977–2010), the city share of the total metropolitan UPT passenger task increased in Brisbane, Perth, Darwin and Canberra, while it decreased in Sydney, Adelaide and Hobart. Hobart experienced a sharp decline, from 1.4 per cent to 0.5 per cent (Table 5.3). Melbourne experienced a flat UPT city share during this period.

5.2.2 Total metropolitan UPT passenger task

Over the next 20 years, the total UPT passenger task is forecast to grow from 19.59 billion pkm to 25.28 billion pkm, with an average annual growth rate of 1.35 per cent (Figure 5.13 and Table 5.4). This forecast increase in the UPT task is largely due to the projected population growth in the capital cities. However, the UPT task as a share of the total passenger transport task is forecast to decline slightly, from 11.1 per cent in 2011 to 10.6 per cent in 2030. Forecast UPT shares between 2011 and 2030 were obtained from the predicted equations for UPT share (1977–2010) assuming unchanged real fares. The disposable income constraint components were also assumed not to change. The exception was the GFC. The effects were assumed to wear off by 2020, causing the savings rate to decline. This resulted in a decrease in the DIC and a decrease in UPT share across most cities.

Figure 5.13 UPT passenger task and UPT share as total public transport task, sum of all capital cities, 1977–2030

Note: Data from 1977 to 2010 are estimates, while from 2011 to 2030 are forecasts.

CHAPTER 6

Sensitivity Analysis

Summary

Due to uncertainty in future petrol prices, UPT fares and the effect of the GFC, this chapter outlines the results of a sensitivity analysis that analysed the possible impact of high and low petrol prices, high UPT fares and persistent effects of the GFC on the future UPT tasks in all capital cities as well as the total metropolitan UPT transport task.

Results of the sensitivity analyses indicate that:

- The total metropolitan UPT task over 2011–2030 would slightly increase under a 'low petrol price' scenario and slightly decrease under the 'high petrol price' and 'ongoing GFC effect' scenarios, compared to the base case scenario. This result would also be true for all capital cities, but the magnitude and trend would vary.
- The only significant change in predicted UPT task would come under the 'high UPT fares' scenario. The UPT tasks in Melbourne, Adelaide, Perth, Hobart and Canberra under the 'high UPT fares' scenario show a large decrease compared to the base case.
- The size of the UPT task depends on two components: the total passenger task in the capital city and UPT's share of this total task. Paradoxically, the decrease in the total passenger task with a high petrol price outweighs the increase in UPT's share with a high petrol price, which results in a slightly lower UPT task with high petrol price, and a slightly higher UPT task with a low petrol price.

6.1 Background

The forecasts of future trends (2011–2030) for UPT passenger tasks in each capital city in Chapter 5 were obtained from:

1. the equations for UPT share (1977–2010) and assumed constant independent variables (i.e. the household disposable income constraint³ and real fares)
2. the total passenger task equations (1977–2010) and assumed constant petrol prices and unemployment, plus an assumption that the GFC effect would fade by 2020.

These forecasts are considered to be base case scenarios. The base case is defined as a medium scenario that reflects the economic conditions as at 2010.

³ The household disposable income constraint is a derivative of several cost factors, such as mortgage, rent, food, petrol and household saving.

The aim of this chapter is to examine how the future UPT tasks might vary due to fluctuations in petrol prices, UPT fares and a persistent GFC effect. Therefore, a sensitivity analysis was carried out to assess the possible impact of these scenarios on the UPT passenger tasks in each capital city.

6.2 Methodology

The sensitivity analysis consisted of four alternative scenarios. These four scenarios are based on increases and decreases in petrol prices and real UPT fares, as well as an ongoing GFC effect. The assumptions considered under the alternative scenarios were:

- Scenario 1: 'high petrol price' — Australian-level real petrol price rises from \$1.27 per litre in 2010 to \$2.04 per litre in 2030.
- Scenario 2: 'low petrol price' — Australian-level real petrol price falls from \$1.27 per litre in 2010 to \$1.05 per litre in 2030.
- Scenario 3: 'high UPT fares' — assumed to increase by 50 per cent until 2030, from 2010 base, making the fares higher than in the base case.
- Scenario 4: 'ongoing GFC effect' — was assumed to persist for the whole forecast period.

A 'low UPT fare' scenario was not considered due to the already low cost recovery of UPT expenditures by governments.

The high and low petrol prices to 2030 for each capital city were generated from the Australian real petrol price, presented in BITRE Report 128 (BITRE 2012b). The real petrol price for Australia was derived using USDA forecasts of real exchange rates (USDA ERA 2011). Excise was assumed to remain constant in nominal terms at the 2011 estimated amount, with inflation assumed to average 2.8 per cent per year (Deloitte Access Economics 2011). Sales tax rates were held constant at estimated 2011 values (for details, see BITRE 2012b).

Data for the assumptions and for the calculated UPT passenger tasks under the various scenarios and the base case for each capital city is in Appendix L (see Table L.1 to Table L.8).

The results of the sensitivity analysis are presented Section 6.3.

6.3 Results

6.3.1 Total metropolitan task

The predicted UPT share and the total metropolitan UPT task for each of the five scenarios until 2030 are shown in Figure 6.1 and Figure 6.2. The data underlying Figure 6.2 is presented in Table 6.1. UPT tasks by scenarios for total capital cities in Figure 6.1 and Table 6.1 are the sum of all capital cities. Table 6.1 also provides data for the change in UPT tasks from base case in 2030 as well as average annual growth rates between 2011 and 2030 for the various scenarios.

Figure 6.1 Total UPT share (per cent) by scenarios, all capital cities, 2010–2030

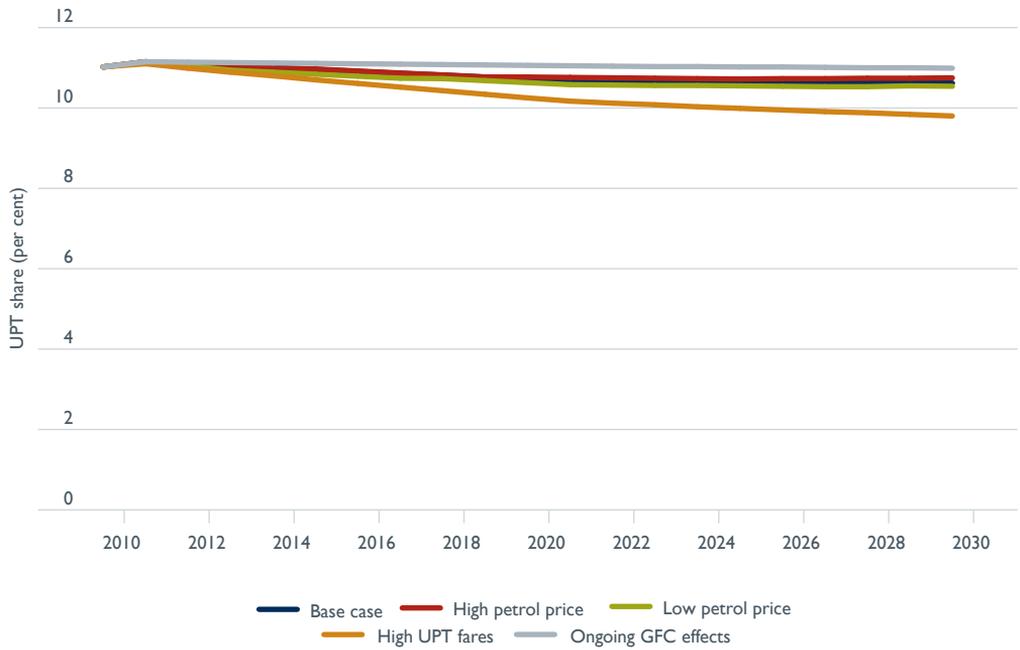

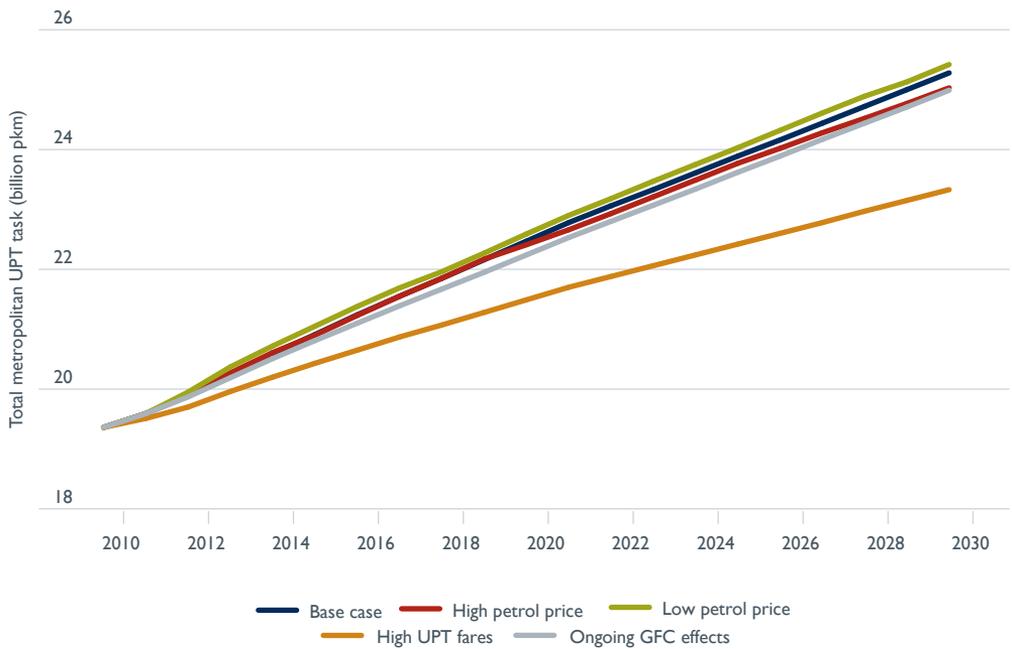

Figure 6.2 Total metropolitan UPT task (billion PKM) by scenarios, all capital cities, 2010–2030

Results of the sensitivity analysis indicated that, compared to the base case, the total UPT tasks in all capital cities between 2011 and 2030 would be slightly higher under the 'low petrol price' scenario, slightly lower under the 'high petrol price' and the 'ongoing GFC effect' scenarios and substantially lower under the 'high UPT fares' scenario (Figure 6.1 and Figure 6.2). This implies that the total metropolitan UPT tasks would increase by 0.14 billion pkm under the 'low petrol price' scenario over the next 20 years compared to the base case, but would experience lower growth under the other scenarios (Table 6.1).

Table 6.1 Total metropolitan UPT task (billion PKM) by scenarios, all capital cities, 2010–2030

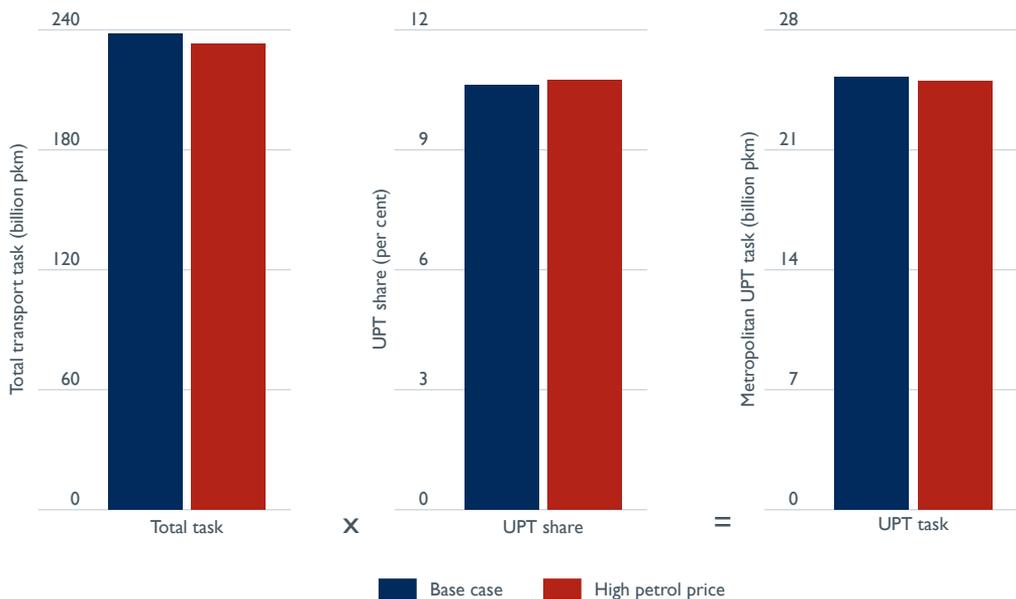

<i>Total metropolitan UPT task (billion PKM) by scenarios</i>					
Year	Base case (Scenario 1)	High petrol price (Scenario 2)	Low petrol price (Scenario 3)	High UPT fares (Scenario 4)	Ongoing GFC effect (Scenario 5)
2010	19.36	19.36	19.36	19.36	19.36
2011	19.59	19.59	19.59	19.51	19.59
2012	19.90	19.91	19.95	19.70	19.87
2013	20.25	20.27	20.37	19.96	20.19
2014	20.59	20.61	20.72	20.20	20.51
2015	20.91	20.90	21.05	20.43	20.81
2016	21.24	21.23	21.38	20.65	21.10
2017	21.55	21.55	21.69	20.87	21.39
2018	21.85	21.85	21.96	21.07	21.67
2019	22.16	22.17	22.27	21.28	21.95
2020	22.47	22.41	22.59	21.49	22.24
2021	22.78	22.66	22.90	21.70	22.53
2022	23.06	22.93	23.18	21.88	22.80
2023	23.33	23.21	23.47	22.06	23.07
2024	23.61	23.49	23.75	22.24	23.34
2025	23.89	23.77	24.03	22.42	23.62
2026	24.16	24.02	24.32	22.60	23.89
2027	24.44	24.28	24.61	22.78	24.17
2028	24.72	24.52	24.89	22.97	24.44
2029	25.00	24.77	25.13	23.15	24.71
2030	25.28	25.03	25.42	23.33	24.99
Change in UPT task (billion PKM) from 'Base case' scenario, 2030		-0.25	0.14	-1.95	-0.29
Change in UPT task (per cent) from 'Base case' scenario, 2030		-1.00	0.53	-7.70	-1.13
Average annual growth rates (per cent), 2011–2030	1.35	1.30	1.38	0.95	1.29

The total metropolitan UPT task under the base case is forecast to increase to 25.28 billion pkm. Total metropolitan UPT tasks over the forecast period (2011–2030) would:

- decrease by 1.00 per cent to 25.03 billion pkm under the 'high petrol price' scenario
- increase by 0.53 per cent to 25.42 billion pkm under the 'low petrol price' scenario
- decrease by 7.70 per cent to 23.33 billion pkm under the 'high UPT fares' scenario
- decrease by 1.13 per cent to 24.99 billion pkm under the 'ongoing GFC effect' scenario (Table 6.1).

The size of the metropolitan UPT task depends on two components: the total passenger task in the city and the UPT's share of this total task. Paradoxically, the decrease in total passenger task with a high petrol price outweighs the increase in UPT's share with a high petrol price. The result is a slightly lower UPT task with high petrol price, and a slightly higher UPT task with a low petrol price. The effect of high petrol price on the size of the UPT task for total capital cities in 2030 is shown in Figure 6.3. Similar petrol price effects are also apparent in the high and low petrol price scenarios for all individual capital cities.

Figure 6.3 Effects of high petrol price on the size of the UPT task, total capital cities, 2030

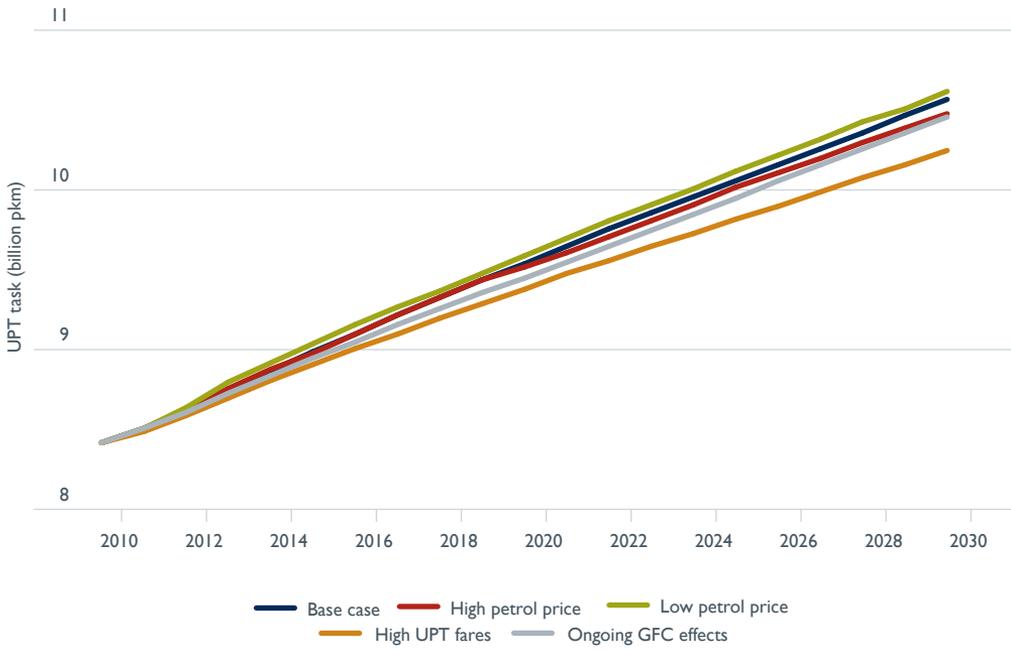

6.3.2 By capital city

Sensitivity analyses by capital city show a very similar pattern, but different magnitudes and trends, as seen in Figure 6.4 to Figure 6.7. The data for these figures is in Appendix L (see Table L.1 to Table L.8).

In each capital city, the UPT task under the 'low petrol price' scenario would increase slightly, while under all other scenarios, the UPT task would shrink. However, the total UPT task in Melbourne, Adelaide, Perth, Hobart and Canberra under the 'high UPT fares' scenario would show a large decrease compared to other scenarios, including the base case.

CHAPTER 7

Discussions and concluding remarks

7.1 Background

This chapter summarizes the modelling and long-term forecasting results of UPT use in Australia's capital cities. Modelling was undertaken on UPT from 1977–2010, while forecasts were undertaken from 2011–2030.

The major objectives of this study were:

- to model capital city public transport tasks in Australia between 1977 and 2010
- to produce long-term forecasts of these modelled estimates from 2011–2030.

7.2 Methodology

A number of methods and procedures were developed to estimate and forecast UPT tasks. The models are specified in terms of household disposable income constraints and real fares. A disposable income constraint variable was used that was a derivative of several costs, such as mortgage, rent, food, petrol and household savings.

Due to uncertainty of future petrol prices, UPT fares and the GFC effect, sensitivity analyses were carried out to examine the possible effects of these drivers on future UPT tasks.

7.3 Results of the study

The methods used in the study to model and forecast the UPT task in the capital cities were complex, but the ultimate results are important to various researchers and policy makers. Briefly, the key results are:

1. Modelling the UPT passenger task by capital cities between 1977 and 2010 showed that the overall trend across all capital cities in Australia was a downward drift in UPT mode share until 2004. After 2004, increasing household cost constraints and the effects of the GFC imparted an upward trend in the UPT mode share, which levelled out by 2010. The effects of various drivers of demand differ across capital cities. However, the pattern of actual UPT share in all capital cities is quite similar to the UPT share predicted by the models. Similarly, the aggregate levels of the UPT passenger tasks between 1977 and 2010 are roughly as predicted by the models.

2. Estimates (1977–2010) of the public transport passenger task by capital city showed that total estimated metropolitan UPT task increased at an average annual growth rate of 1.96 per cent, rising from 10.1 billion pkm to 19.1 billion pkm, a total increase of 9.0 billion pkm. Among the five larger capital cities, the UPT share of the total passenger task grew in Brisbane and Perth, while the share decreased in Sydney, Melbourne and Adelaide. Among the three smaller capital cities, the UPT shares increased in Darwin and Canberra, but decreased in Hobart.
3. UPT forecasts (2011–2030) showed that the total metropolitan UPT passenger task is forecast to grow from 19.6 billion pkm to 25.3 billion pkm, giving a forecast UPT task growth of 5.7 billion pkm. This figure equates to an average annual growth rate of 1.35 per cent. Among the five larger capital cities, the city share of the total metropolitan passenger task is forecast to increase in Brisbane and Perth, while the city share is forecast to decrease in Sydney, Melbourne and Adelaide. Among the three smaller capital cities, the city share will be more or less unchanged.
4. The sensitivity analysis showed that the level of the UPT task in metropolitan Australia over 2011–2030 would increase slightly under a 'low petrol price' scenario and decrease slightly under a 'high petrol price' and an 'ongoing GFC effect' scenario, compared with the base case. However, the major decrease would be associated with a 'high UPT fares' scenario. These trends were also apparent in each capital city, but the magnitudes and the trends were different.

7.4 Potential use of the UPT task data

UPT in Australia's capital cities has been undergoing a resurgence for the last half decade. The modelling presented in this report shows that this higher growth was as a result of population growth, lower UPT fares and increasing household disposable income constraints. The forecasting done using the models also shows that this higher growth rate is unlikely to persist. Nevertheless, the base-case forecast still has UPT demand growing by about one-third over the 20 years from 2010 to 2030.

The results of the research have a wide range of potential uses. It is important for policymakers across the country, including local, state and federal government agencies, investors, transport regulators and city planners, to understand the drivers of future UPT growth.

Although UPT comprises only a small component of total city passenger transport, the results of this research may assist in developing policies for areas such as infrastructure planning, urban transport reform and energy efficiency policy. The results can also provide insight into new and emerging policy issues relating to the development of urban infrastructure, congestion amelioration and road safety.

APPENDIX A

Metropolitan public transport journeys by capital city by transport mode, 1945–2010

This Appendix provides data on metropolitan public transport journeys in terms of million passenger journeys by capital city by transport mode between 1945 and 2010.

APPENDIX B

Annual public transport journeys per person by capital cities, 1945–2010

Appendix B presents data on the number of annual public transport trips per person for individual Australian capital cities as well as all total capital cities between 1945 and 2010.

Table B.1 Public transport journeys per person per year by capital cities, 1945–2010

Financial year	Number of public transport journeys per person per annum								
	Sydney	Melbourne	Brisbane	Adelaide	Perth	Hobart	Darwin	Canberra	All capitals
1945	471.2	485.0	450.8	296.7	310.3	383.7	0.0	200.8	442.2

APPENDIX C

Public/private passenger transport task and shares by capital cities, 1977–2010

This Appendix provides underlying data presented as figures in Chapter 2 (see Figures 2.10 to 2.14) which is passenger transport task in terms of billion pkm and average annual growth rates and shares as per cent for each of the eight capital cities between 1977 and 2010.

Table C.1 Public/private passenger transport task and share, Sydney and Melbourne, 1977–2010

Financial year	Sydney						Melbourne					
	Passenger task (billion pkm)			Share (per cent)			Passenger task (billion pkm)			Share (per cent)		
	Personal vehicle travel	Public transport travel	Total	Personal vehicle travel	Public transport travel	Total	Personal vehicle travel	Public transport travel	Total	Private transport travel	Public transport travel	Total
1977	25.7	4.8	30.5	84.2	15.8	100.0	23.3	3.0	26.3	88.6	11.4	100.0
1978	26.4	4.8	31.2	84.6	15.4	100.0	24.3	2.9	27.2	89.3	10.7	100.0
1979	27.2	4.8	32.0	85.0	15.0	100.0	25.1	2.8	27.9	89.9	10.1	100.0
1980	27.4	5.3	32.7	83.9	16.1	100.0	25.2	2.7	27.9	90.3	9.7	100.0

APPENDIX D

Personal vehicle and public transport task by type of vehicle, all capital cities, 1977–2010

This appendix provides personal vehicle travel and public transport travel task by type of vehicle and average annual growth rates for each of the eight capital cities between 1997 and 2010.

Table D.1 Personal vehicle transport task (billion PKM) by transport mode, capital cities, 1977–2010

Note: Different capital cities have different transport modes. Darwin and Canberra have only bus as public transport mode.

APPENDIX E

Estimates of real fares by capital cities, 1977–2010

Real fare indices for each of the eight capital cities have been calculated from nominal fare indices which were adjusted with Consumer Price Index (CPI), using the simple equation:

Real fare index = Nominal fare index / Consumer Price Index (CPI) * 100

In this exercise, nominal fares and CPI were indexed (1989–90 = 100).

Estimates of real fare indices for each of the eight capital cities are provided in this Appendix (see Table E.1).

Table E.1 Estimates of real fare indices by capital cities, 1977–2010

Year	Sydney			Melbourne			Brisbane			Adelaide		
	Fares	CPI	Real fares	Fares	CPI	Real fares	Fares	CPI	Real fares	Fares	CPI	Real fares

APPENDIX F

Estimates of household disposable income constraint by capital cities, 1977–2010

This Appendix provides estimates of disposable income constraint (or real weekly budget cost in dollars per week per household) for each of the eight capital cities as well as all capital cities between 1977 and 2010. The methodology for calculating disposable income constraint is provided in Chapter 3 (see Section 3.2.2).

Table F.1 Estimates of petrol and food cost (\$/week/household) by capital cities, 1977–2010

APPENDIX G

Modelling data by capital cities, 1977–2010

This appendix presents modelling data for each of the eight capital cities (Tables G.1 to G.4) between 1977 and 2010. Due to the nature of the data, urban public transport (UPT) share, real fares and disposable income constraint were transformed into logarithmic values for the regression analysis. In addition, different dummies were used, depending on the capital city. Note that passenger transport task in terms of billion PKM and shares as per cent for each of the eight capital cities between 1977 and 2010 are provided in Appendix C (see Tables C.1 to C.4).

Table G.1 Data used for regression analysis, Sydney and Melbourne, 1972–2010

APPENDIX H

Actual and estimated urban public transport share and passenger task by capital city, 1977–2010

This appendix presents actual and predicted urban public transport task as a proportion of total transport task (per cent) as well as actual and modelled urban public passenger task (billion PKM) for metropolitan Australia (Table H.1) and also as for each capital city (Table H.2 to Table H.5) between 1977 and 2010. Data in Table H.1 was presented graphically in Figure 3.1 and Figure 3.2 (see Chapter 3), while data in Table H.2 to Table H.5 was shown graphically in Figures 3.3 to 3.18 (see Chapter 3).

Table H.1 Actual and estimated UPT share (per cent) and passenger task (billion PKM), all capital cities, 1977–2010

Year	UPT share (per cent)		UPT Task (billion PKM)	
	Actual	Estimate	Actual	Estimate
1977	11.32	11.27	10.09	10.03
1978	10.87	10.94	10.00	10.08
1979	10.47	10.75	9.89	10.18
1980	10.88	10.68	10.37	10.15
1981	10.88	10.58	10.53	10.21
1982	10.46	10.37	10.60	10.49
1983	10.29	10.24	10.45	10.39

APPENDIX I

Regression data for forecasting total passenger task, capital cities, 1965–2010

This appendix provides raw regression data for forecasting the total (private plus public) motorised passenger transport task for each capital city between 1965 and 2010.

Table I.1 Regression data for forecasting total (private plus public) motorised passenger task, Sydney, 1965–2010

Year	PKM per person	Pre-78 time	Time	Time squared	Petrol	Unemployment	GFC
1965	6 999	1	1	1	48.30	1.48	0
1966	7 219	2	2	4	51.06	1.72	0
1967	7 403	3	3	9	50.79	1.84	0
1968	7 622	4	4	16	51.34	1.89	0
1969	7 947	5	5	25	50.12	1.79	0
1970	8 322	6	6	36	49.08	1.77	0
1971	8 604	7	7	49	50.78	1.75	0
1972	8 646	8	8	64	49.37	2.23	0
1973	8 804	9	9	81	46.67	2.67	0
1974	9 149	10	10	100	50.17	2.14	0
1975	9 350	11	11	121	51.50	4.05	0
1976	9 402	12	12	144	54.40	4.87	0
1977	9 631	13	13	169	49.14	5.18	0

APPENDIX J

Actual and predicted metropolitan traffic per person, individual capital city and total capital cities, 1965–2030

This appendix provides actual traffic per person, predicted components, and actual and predicted levels of passenger traffic task for each capital city as well as total (sum of all) capital cities between 1965 and 2030.

The details of predicted variables use to estimate passenger traffic task in terms of kilometres per person are as follows:

1. Trend = Trend
2. + Petrol = Trend+Petrol
3. + Petrol+Unemployment = Trend+Petrol+Unemployment
4. + Petrol+Unemployment+GFC = Trend+Petrol+Unemployment+GFC
5. Actual = Actual.

Table J.1 Actual traffic per person and predicted components, Sydney, 1965–2030

APPENDIX K

Actual and predicted total transport task, urban public transport (UPT) share and UPT task, capital cities

This appendix provides actual and predicted total passenger task, urban public transport (UPT) share and UPT task for each eight capital cities as well as total capital cities. These data have been presented as figures in Chapter 5 (refer section 5.2).

Table K.1 Actual and predicted total passenger task (billion PKM), UPT share (per cent) and UPT task (billion PKM), Sydney

APPENDIX L

Sensitivity analysis data and calculated UPT task by capital cities

This Appendix presents the assumptions made and the calculated urban public passenger (UPT) tasks, for the five scenarios for each of Australia's capital cities.

Details of the assumptions and five scenarios are given earlier (see Chapter 6).

Table L.1 Assumptions made and UPT task by scenarios, Sydney

Year	Assumptions					UPT task (billion PKM)				
	Petrol price (cents/litre)			High UPT fares (cents)	Ongoing GFC effect	Petrol price			High UPT fares	Ongoing GFC effect
	Base	High	Low			Base	High	Low		
2010	123.5	123.5	123.5	135.0	8.8	8.40	8.40	8.40	8.40	8.40
2011	132.5	132.5	132.5	138.4	8.0	8.49	8.49	8.49	8.47	8.49
2012		127.2	112.1	141.8	8.0	8.60	8.61	8.62	8.57	8.59
2013		124.5	87.6	145.1	8.0	8.73	8.74	8.78	8.68	8.71
2014		123.6	86.7	148.5	8.0	8.85	8.86	8.90	8.79	8.82
