The Transportation Research Forum, founded in 1958, is an independent, nonprofit organization of transportation professionals who conduct, use, and benefit from research. Its purpose is to provide an impartial meeting ground for carriers, shippers, government officials, consultants, university researchers, suppliers, and others seeking exchange of information and ideas related to both passenger and freight transportation. More information on the Transportation Research Forum can be found on the Web at [www.trforum.org](http://www.trforum.org).

# Relationship Between Perceived In-Cabin Air Quality and Truck Drivers' Self-Reported Health and Alertness

by Richard Tay, Zhongchao Tan and Xiaoying Cheng

*This study surveyed 253 truck drivers and found that many drivers scored poorly on the Stanford and Epworth sleepiness scales indicating that they may not be as alert as they should be while driving. Moreover, those who rated the air in their truck cabins as fresh reported less irritation to their eyes, noses, throats, and skin, scored better in both sleepiness scales, and reported fewer sleep-related medical symptoms. Finally, the results of the ordinal logistic model indicate that drivers' perceptions of the air quality in their truck cabins are significantly related to their alertness during a trip.*

## INTRODUCTION

Trucking is one of the most important industries in North America. There were over three million truck drivers in the U.S. in 2004 and 1.3 million of them were long-haul heavy-duty truck drivers (American Trucking Associations 2005). Over the next 10 years, economic growth will give rise to a need for a 2.2% average annual increase in the number of long-haul heavy-duty truck drivers, or an additional 320,000 jobs overall in the U.S. Moreover, there were 13.4 million two-way trips made across the Canada-U.S. border in 2004 and this traffic is also expected to grow by about 2.2% per year (Transport Canada 2004).

Since a significant share of the truck traffic involves long-haul trips, drivers accumulate very high mileage on the roads. It is not surprising, therefore, that crashes involving trucks are a major concern in road safety. In Canada, for example, crashes involving commercial vehicles account for approximately 20% of all traffic fatalities each year and are one of the explicitly targeted areas in the national road safety strategy (Transport Canada 2002). Similarly, truck drivers accounted for 5,375 deaths (17.6 per 100,000 full-time equivalent workers) in the United States between 1992 and 2001, the highest number and rate for any single occupation (NIOSH 2004).

Although the factors contributing to commercial truck crashes are complex, driving while fatigued is widely accepted as one of the main contributing factors (Dingus et al. 2006, Gander et al. 2006; Hanowski et al. 2003; Williamson et al. 2001; Häkkänen and Summala 2001; Baas et al. 2000; Arnold et al. 1997; Feyer et al. 1997; Williamson et al. 1996). The factors influencing driver fatigue in the general driving population, and among commercial trucking in particular, have been a topic of research interest in road safety. Most studies on truck drivers thus far have focused on biological factors such as the overall health of the drivers and circadian rhythm or organizational factors such as work hours and incentives. Little research, however, has been done on examining the effects of vehicular and environmental factors, especially environmental factors within truck cabins, on the health and safety of occupants and other road users.

An environmental factor that merits further investigation is air quality in truck cabins. Since drivers spend most of their working hours, as well as large portions of their sleeping hours, in trucks, in-cabin air quality is expected to have a significant impact on their overall health, sleepiness, and fatigue levels (Gillberg et al. 2003; Dingus et al. 2001). If the concentration of air pollutants is high

enough within this limited space, it could impair the driver's health and sleep quality. The driver may not feel as refreshed even after an overnight sleep. The purpose of this study, therefore, is to examine the perceptions of truck drivers of in-cabin air quality and correlate these perceptions with their general alertness and health status. The knowledge gained will lay the foundation for future research that may eventually establish a causal link between in-truck air quality and the health and alertness of truck drivers.

## LITERATURE REVIEW

The linkages between air quality and fatigue have been well-documented in other areas of research (Norbäck et al. 1990; Thibeault 1997; Gander et al. 1998; Wargocki 1999; Akerstedt 2000). However, little attention has been devoted to the influence of in-vehicle air quality on drivers' health in general and alertness in particular, which is also likely to affect their driving performance and the safety of all road users. Among the likely pollutants found in vehicles, several are expected to have effects on drivers' health and alertness. Besides carbon dioxide (CO<sub>2</sub>) which could be produced by the driver's respiration or as a part of vehicle emission, other gases like carbon monoxide (CO) and nitrogen dioxide (NO<sub>2</sub>), which are also common gases in emissions, may have detrimental effects on a driver's health and alertness (Sato 2005; Cheng et al. 2006; Penney 2007). In addition, particulate matter (PM) is an important health-threatening pollutant.

CO<sub>2</sub> has obvious health effects in humans at various levels. At the concentration level of 700 parts per million (ppm) or lower, its adverse effect is negligible, but people start feeling uncomfortable when its concentration reaches 800 ppm (MDH 2004). In an environment where CO<sub>2</sub> concentration reaches 5,000 ppm, people feel fatigued and lose concentration (OSHA 1995); and, at 20,000 ppm, they breathe at 150% of the normal rate. When the concentration of CO<sub>2</sub> increases to 30,000 ppm, the heart rate and blood pressure increase (Schwarzberg 1993), hearing can be impaired, and most people feel dizzy.

When subjects are exposed to CO concentrations above 90 ppm for a long time, they may experience adverse effects on their hearts and brains and it could lead to low children's birth weights. Angina, impaired vision, and reduced brain function may also result (Townsend and Maynard 2002). When exposed to 200 ppm of CO, most people experience slight headaches, tiredness, dizziness, and nausea after two to three hours. At 400 ppm, frontal headache occurs within one to two hours, and life can be threatened after three hours. At 800 ppm, people experience dizziness, nausea, and convulsions within 45 minutes, are unconscious within two hours, and die in two to three hours. At 1,600 ppm, headache, dizziness and nausea occur within 20 minutes and death within an hour.

Simoni et al. (2002) showed that there is a close relationship between indoor NO<sub>2</sub> levels of 33 ppm in winter and increased occurrence of acute respiratory symptoms in non-smoking adults. At higher NO<sub>2</sub> levels, bronchitic and asthmatic symptoms are significantly more prevalent. They also reported that these health effects were associated with the duration of the exposure. Similar results were obtained when subjects were exposed to a low dose of NO<sub>2</sub> of 10 parts per billion (ppb) for a longer duration (five hours) and to a higher NO<sub>2</sub> concentration (i.e., 50 ppb) for a short duration (one hour). Exposure to NO<sub>2</sub> of 200 ppm or greater immediately endangers life. At levels of 50 to 100 ppm, NO<sub>2</sub> impairs lung function and irritates the eyes, nose, and throat (Alberts 1994). Moreover, there is evidence that NO<sub>2</sub> may cause lung damage at concentrations of 300 ppb or higher (Samet and Cushing 1997).

Besides these gases, indoor particulate matter presents a risk to public health (Cheng et al. 2006; Wallace and Smith 2007). Particles smaller than one micrometer (submicron particles) pose more threat to indoor occupants because they can penetrate deeply into the respiratory system. A recent workshop organized by The Royal Society concluded that there was some evidence that submicron particles, especially nanoparticles, translocated from the lungs to the brain and blood causing increased blood coagulation and inflammogenic effects (Dreher 2004). In addition, particulate matter in a truck cabin is likely to contain several toxic substances that may be harmful

to the human body. The main sources of particulate matter in truck cabins are road dust, emissions, and cigarette smoke, which may contain chemicals such as lead, barium, magnesium, cobalt, and manganese (Tan and Tay 2008).

In one of the few studies that examined engineering and other environmental effects, Galatsis et al. (2000) linked in-cabin air quality in cars with fatigue and indirectly with road safety. They found that it was necessary to install gas sensors in enclosed spaces such as inside cars where air quality can be improved by controlling the ventilation system. When the concentrations of pollutants monitored are high, an alarm will be activated to inform the occupants to open the ventilation system, thereby keeping the air quality in the cabin as good as the ambient air. Sato (2002) suggested that further studies focusing on the effects of air quality on safe and comfortable driving should be conducted.

Several studies have also been conducted to understand the effect and mechanisms of self-pollution in transportation vehicles such as school buses and passenger cars (Chan and Chung 2003; Park et al. 1998; Rodes et al. 1998). In these vehicles, some of the engine exhaust can enter the cabin through open windows and the ventilation systems and degrade the quality of the air inside the cabin. Although no study has been conducted on heavy trucks, it is expected that this self-pollution mechanism also exists for these types of vehicles.

In a recent review of the literature, Cheng et al. (2006) found no publicly available reports documenting in-cabin air quality in trucks. Tan et al. (2006a) developed and tested a portable air quality monitoring system, which was then deployed in an urban short-haul truck during the summer to measure gaseous pollution inside truck cabins. In a separate study, Tan et al. (2008) deployed an improved system during winter in an intercity truck to measure the same gaseous pollution and particulate matter as they did in the summer. Overall, their results indicated that gaseous concentrations (carbon monoxide, carbon dioxide, and nitrogen dioxide) were within the values recommended by the U.S. National Ambient Air Quality Standards most of the time, but thermal comfort levels (temperature and relative humidity) were outside the values recommended by the American Society for Heating, Refrigeration, Air-conditioning Engineers for a significant portion (93%) of the time. They also found that readings for particulate matter (PM<sub>2.5</sub>) were one to 12 times higher than the recommended values for the entire period monitored. Overall, the limited physical data available on in-cabin air quality in trucks suggest that probably the air quality is not as good as it should be.

The above review shows limited information on drivers' perception of in-cabin air quality. If most truck drivers perceive the air in their cabins as clean and fresh, they would not raise any concern nor will they demand actions to be taken to improve it. On the other hand, drivers may perceive the air quality to be poor but little attention has been paid to this issue and thus, no data are available to support their concerns. Due to the limited knowledge available on the actual or perceived relationships between in-cabin air quality, health, and driver performance, there is currently no government or industry guideline to use.

## **METHODOLOGY**

### **Procedure**

The most logical method to examine the effects of in-cabin air quality on truck drivers' health and alertness is to physically measure in-cabin air quality and their state of alertness on trips. However, since in-cabin air quality is significantly affected by the outside environment, it has to be measured over an entire trip. To obtain such measurements for a relatively large sample of drivers, however, is beyond the scope of this study. Moreover, no simple measurement method is currently available to assess driver fatigue and alertness with an acceptable degree of reliability or validity. Therefore, the most appropriate method of collecting these data is by driver survey. Moreover, the use of subjective measures, as adopted in this study, has a strong foundation in the behavioral sciences, especially with respect to risk-taking behavior and road safety. It is important to point out that most

of the drivers' decision making (especially the decision to continue driving or stopping for fresh air) is based on their perceptions of the environment and their mental states as opposed to the actual physical measurements of air quality.

A questionnaire was therefore designed to gather information on drivers' perception of air quality in their cabins and their self-reported health and alertness status. The part of the questionnaire survey focusing on health and alertness was designed using mostly standardized questions and measurement scales adopted from the literature (sleepiness scales or medical condition checklist). However, we were not able to find any standardized questionnaire or scales to use to measure perceived air quality. Hence, questions were developed to capture drivers' perception of in-cabin air quality. These questions were designed with the assistance of two managers from a trucking company in the City of Calgary, Alberta, Canada, and several researchers in road safety as well as environmental engineering.

The questionnaire was then pilot tested using a sample of graduate students in air quality and road safety as well as drivers from the same trucking company. To increase the response rate, the questionnaire was deliberately kept short so that it could be completed in less than 10 minutes because it was designed to be administered to the drivers while they were refueling their trucks in the middle of the Canadian winter. The survey was approved by the University of Calgary research ethics committee and conducted in accordance with its guidelines. Participation in the survey was strictly voluntary and participants were informed of their rights to withdraw at any time. They were also assured that the information collected would be kept confidential and only aggregate data would be published.

### **Sample and Profile of Participants**

The revised questionnaire was subsequently administered to 253 truck drivers at two popular truck stops (gas stations with rest areas and eateries for trucks) in the city between January and March 2006, with the approval and support of the station managers. Less than 10% of the drivers approached declined to participate. The majority of the respondents were long-haul truck drivers and thus did not reside in Calgary. They came from as far as Tennessee and Connecticut in the United States. Although the sample was taken at truck stops, there is no reason to expect any systematic biases in the responses received. The profile of the respondents is very similar to that of drivers in the North American trucking industry (American Trucking Association 2005).

As shown in Table 1, the sample is dominated by middle-aged males (79.2% aged between 35 and 65) with over 10 years of driving experience (70.8%). Most drivers drive alone (85.7%) and drive on long-haul trips (73.7%). They work long hours, with 91.2% working between nine and 15 hours per day and three-quarters working more than five days per week. Almost a quarter of the drivers sleep for six hours or less a day, which is less than the desired amount of sleep per day. Most of the drivers sleep in their trucks regularly, with 43.9% sleeping in the sleeper berth every day. These results suggest that they spend a very significant amount of their time in the truck cabins.

**Table 1: Truck Driver Profile**

Driving Experience	
5 years or less	14.6%
6 - 10 years	14.6%
Over 10 years	70.8%
Usual Driving Mode	
Alone	85.7%
Co-driver	9.5%
Passenger	4.8%
Type of Trips	
Mostly Long Haul	73.7%
Very Mixed	21.4%
Mostly Short Haul	4.9%
Working Days per Week	
4 days or less	4.4%
5 days	20.5%
6 days	40.6%
7 days	34.5%
Working Hours per Day	
8 hrs or less	5.6%
9-11 hrs	51.2%
12-15 hrs	40.0%
16 hrs or more	3.2%
Sleeping Time per Day	
6 hrs or less	24.3%
7-9 hrs	61.9%
10 hrs or more	13.8%
Sleeping in Truck	
Less than 3 times per week	9.0%
3-4 times per week	12.3%
5-6 times per week	34.8%
Every day	43.9%

### Questionnaire and Material

The questionnaire was designed to collect information on the drivers' perception of in-cabin air quality as well as their health profiles and self-reported driving performance. In addition to the standard questions on driving experience, work schedules, and time spent sleeping in the truck, the first section of the questionnaire gathered some information on drivers' perceptions of the usefulness of the 12 measures in helping them stay alert while driving (Table 2). Examples are "Taking a power nap," "Drinking coffee," and "Cooling the truck cabin." Data for these items were collected using a five-point scale ranging from 1 = "not useful at all" to 5 = "very useful."

**Table 2: Perceived Usefulness of Measures to Help Stay Alert (Percent)**

Measures	Not At All Useful	Slightly Useful	Moderately Useful	Fairly Useful	Very Useful	Mean
Taking a power nap	10.9	7.1	15.1	26.8	40.2	3.78
Stopping for fresh air & stretching	6.0	10.6	18.7	31.1	33.6	3.76
Stopping to eat or drink	10.1	8.0	20.2	28.6	33.2	3.67
Cooling the truck cabin	4.6	12.9	21.6	36.5	24.5	3.63
Listening to music on cassette or CD	9.8	13.2	24.3	26.0	26.8	3.47
Listening to radio	11.6	14.5	22.3	26.0	25.6	3.40
Talking on CB	16.2	14.0	29.8	23.7	16.2	3.10
Drinking coffee	18.2	17.4	28.0	19.5	16.9	3.00
Singing or humming	38.7	20.9	21.3	12.2	7.0	2.28
Using tobacco products	48.4	10.7	18.1	12.6	10.2	2.26
Using over the counter drugs or stimulants	83.3	3.8	5.3	4.8	2.9	1.40
Using prescription drugs	84.9	6.8	1.4	2.7	4.1	1.34

Note: Mean computed using 1 = “not at all useful,” 2 = “slightly useful,” 3 = “moderately useful,” 4 = “fairly useful” and 5 = “Very Useful.”

The second section of the questionnaire gathered information on drivers’ perception of in-cabin air quality and their self-reported alertness levels during their current trips. Self-reported alertness is measured by the widely used Stanford Sleepiness Scale which has been shown to have high reliability and validity (Hoddes et al. 1973; Russo et al. 2003; Pizza 2004; Contardi et al. 2004; Bailes et al. 2006). Alertness was measured by “How did you feel when you were most tired while you were driving?” and the choices provided were the same as in the Stanford Sleepiness Scale. A standard eight-point coding system was also used and it ranged from 1 = “Feeling active, vital, alert or wide awake” to 8 = “Asleep.”

Driver’s perception of air quality was measured primarily using the item: “Do you think that the air in the cabin is fresh?” and was measured using a three-point categorical scale with 1 = “Yes,” 2 = “No,” and 3 = “Not sure.” In addition, three secondary items were used to supplement the perception scores: “How do you quantify the irritation to your eyes, nose, throat, and skin, etc. during this trip?,” “After how many hours did you feel that the air was not fresh?” and “How do you keep the air fresh?” The first item was measured using a five-point scale ranging from 1 = “None” to 5 = “Very Often.” The second item was measured using four categories ranging from “less than four hours” to “10 hours or more.” For the third item, respondents were asked to choose from different ventilation modes: “Natural (open windows),” “Recirculation,” “Fresh air intake,” or “Combination of the above.”

In addition to the standard demographic data (e.g., age, gender), the final section gathered data on relevant health indicators from the respondents. First, the Epworth Sleepiness Scale was used to capture the general level of sleepiness and fatigue (Chervin 2003; Miletin and Hanly 2003; Kotterba et al. 2004; Bailes et al. 2006). Respondents were asked to rate the likelihood of falling asleep under seven nonphysical activities such as “sitting and reading” and their responses were coded from 0 = “no chance” to 3 = “high chance.” In addition, they were asked to indicate if they experienced any of the 20 common sleep-related medical symptoms or conditions, which could indicate they might be suffering from some kind of sleep disorder. These symptoms included snoring, choking, stopped breathing, forgetfulness, kicking legs, irresistible urge to sleep during the day, difficulty concentrating, forgetfulness, and morning headaches and are in Figure 5.

## Statistical Analyses

To determine if perceived air quality was associated with the health and alertness of drivers, the respondents were sub-divided into two groups: those who felt that the air was fresh and those who felt that the air was not fresh. Those who indicated that they were not sure of the air quality were excluded from further analyses. One Way Analysis of Variance was then performed using SPSS v11.5 (2002) to determine if significant differences existed between the two groups in terms of their Stanford Sleepiness Score, Epworth Sleepiness Score, number of sleep-related symptoms, and number of existing medical conditions.

Finally, an ordinal logit analysis was used to model the relationship between driver alertness during the trip and the two more pertinent perceived air quality indicators. The first is qualitative: “Do you think that the air in the cabin is fresh?” The second is physiological: “How do you quantify the irritation to your eyes, nose, throat, and skin, etc. during this trip?” Poor in-cabin air quality is likely to be associated with a driver experiencing these minor physiological symptoms. In addition to air quality indicators, some general driver information, such as age and gender, were included in the model. The model was estimated using SPSS v11.5 (2002) and because the program treats every independent variable as categorical, two simple dichotomous variables were created for the air quality indicators to simplify the analysis.

## DISCUSSION OF THE RESULTS

As shown in Table 2, the most useful measure reported by drivers to help them stay alert while driving was taking a power nap, followed by stopping for fresh air and stretching, and stopping to eat and drink. A majority of the respondents also felt that cooling the truck cabin helped them stay alert. Other measures that were deemed to be useful (mean  $\geq 3.0$ ) included listening to music and radio, and drinking coffee. Singing, and using tobacco products and drugs were not rated as useful by most truck drivers.<sup>1</sup> Of these measures, stopping for fresh air and cooling the cabin are expected to be highly correlated with drivers’ attempts to improve air quality and increase their alertness. Hence, it is encouraging to note that these were rated as useful by the majority of the drivers.

Drivers’ perceptions of air quality in their trucks are reported in Figure 1. About half (50.8%) felt that the air was fresh whereas about a quarter (24%) said it was not. Moreover, 12.1% of the drivers reported they often or very often experienced irritations to their eyes, noses, throats, and skin as compared to 20.3% who reported experiencing irritations sometimes, 31.3% who reported rarely experiencing them, and 27.3% who reported no irritation. The most frequent mode of ventilation used was opening the window, which was reported by almost half (49.6%) of the sample. The fresh air intake and recirculation mode of the vehicle ventilation system were used exclusively by only a small percentage (8%) of the drivers while the rest (42.4%) preferred using a combination of the different modes.

Drivers’ self-rating of their state of alertness (sleepiness) during their trip was also elicited and reported in Figure 2. Only about 43.7% of the drivers reported that they were (1) “Feeling active, vital, alert, or wide awake” or (2) “Functioning at high level, but not at peak; able to concentrate” while 28.2% reported that they were (3) “Awake, but relaxed; responsive but not fully alert.” More importantly, about 28.2% reported that they were clearly fatigued, with scores ranging from (4) “Somewhat foggy” to (8) “Asleep” while they were driving. These results suggest that a fairly large portion of truck drivers often continued to drive even when they felt tired and sleepy, a result that is consistent with several previous studies (Williamson et al. 1996; Arnold et al. 1997; Bass 2000; Häkkinen and Summala 2001; Hanowski et al. 2003; Dingus et al. 2001, 2006).

The results of administering the Epworth Sleepiness Scale (ESS) are reported in Figure 3. To simplify the analysis, the scores for the seven items in the ESS were added to obtain a composite score. Respondents were then classified by the following approach: a total score of nine or higher was considered to be poor and a score of six or less was considered to be good.<sup>2</sup> Only 35.5% of

**Figure 1: Drivers' Perceptions of Air Quality**

**Figure 2: Stanford Sleepiness Scale**

**Figure 3: Epworth Sleepiness Scale**

**Figure 4: Self-Reported Sleep Disorders**

**Figure 5: Self-Reported Medical Conditions**

**Table 3: Self-Reported Medical Conditions in Drivers**

Medical Conditions	Rates
None	32.1%
High blood pressure	15.9%
Depression	6.9%
Asthma & Bronchitis	6.1%
Heart problems	4.5%
Chronic pain that interferes with sleep	2.8%
Thyroid problems	1.6%
Chronic fatigue syndrome	1.2%
Liver problems	0.8%
Alcohol or drug addiction	0.8%
Kidney problems	0.4%

the drivers reported a good score on ESS which implied that they probably did not suffer from any sleep-related problems. In contrast, nearly half (48.2%) scored poorly on this scale, which indicated that they might have problems staying alert under normal circumstances and might suffer from poor quality of sleep.

To further examine their sleep-related problems, the numbers of disorders reported by the drivers are shown in Figure 4. A very large share (85.1%) of the drivers reported experiencing at least one of the common symptoms showing they might be suffering from some form of sleep disorder. In addition, in Table 3, less than one-third (32.1%) of the respondents reported that they did not have any existing medical conditions while a total of 41% reported having one of the conditions listed, which implies that at least 26.9% had some other medical conditions that were not included in the list. Of the medical conditions, 15.9% had high blood pressure, 6.9% experienced depression, 6.1% had asthma or bronchitis, and 4.5% suffered from heart problems.

To determine if perceived air quality in the truck cabin was associated with the drivers' health and alertness, the Analysis of Variance procedure was performed between those who rated the air as

fresh and those who rated the air as not fresh. First, truck drivers who rated the air as fresh reported less irritation to their eyes, noses, throats, skin, etc. (Mean,  $M = 1.9$ ) than those who rated the air as not fresh ( $M = 2.9$ ) and the difference was statistically significant ( $p < 0.01$ ). Second, drivers who rated the air in their cabins as fresh reported a better score on the Stanford Sleepiness Scale ( $M = 2.69$ ) than those who rated the air as not fresh ( $M = 3.74$ ) and the difference in the two means was statistically significant ( $p = 0.022$ ). Third, those who rated the air as fresh scored better on the Epworth Sleepiness Scale ( $M = 8.1$ ) than those who rated the air as not fresh ( $M = 9.6$ ), and this difference was also statistically significant ( $p = 0.038$ ). Finally, drivers who rated the air as fresh also reported fewer sleep-related symptoms ( $M = 2.2$ ) than those who rated the air as not fresh ( $M = 3.2$ ) and this difference was statistically significant ( $p = 0.010$ ). The perception of in-cabin air quality, however, was not related to the number of medical conditions that the drivers had. The last result is not surprising because, unlike the other four health indicators, most of the medical conditions surveyed are not directly related to in-cabin air quality but are included in the survey for completeness.

Finally, an ordinal logit model was estimated to examine the effects of perceived air quality on driver alertness during the trip. This particular performance indicator is chosen because it has the greatest direct impact on road safety among all the health and alertness measures examined. The estimation results are reported in Table 4. With one exception, all other thresholds ( $\mu$ ) delineating the different levels of alertness were found to be statistically significant whereas demographic variables, such as age and gender, were found to be insignificant. The latter results are not surprising, since age and gender are likely to have greater impacts on long-term health outcomes than on alertness during a single trip. Our results show that drivers' alertness during a trip is negatively and significantly correlated with their qualitative perception of in-cabin air quality not being fresh and their self-reported physiological symptoms (irritation to eyes, nose, throat, skin, etc).

**Table 4: Estimation Results**

Number of Observations	235	
Chi-Square	18.23	
P-value	<0.0001	
Variables	Coefficients	Standard Errors

None/Rarely *	-0.59*	0.20

Note: \* denotes statistically significant at  $\alpha = 0.05$  level

## CONCLUDING REMARKS

Despite its importance to the Canadian and American economies, little research has been conducted to examine the quality of the air in truck cabins which are workplaces for over three million people. Additionally, there is currently no regulation requiring minimum air quality at this important workplace. Previous studies have found that air quality in commercial truck cabins may not be clean and comparable to standards for other workplaces and indoor environments (Tan et al. 2006a, b).

In this study, a questionnaire survey was administered to 253 truck drivers to gather information on their perception of air quality in their cabins. The results were related to their self-reported health and alertness. Only about half of the drivers surveyed rated the air in their cabins as fresh. More importantly, those who rated the air as fresh reported less irritation to their eyes, noses, throats, and skin, scored better in both the Stanford Sleepiness Scale and the Epworth Sleepiness Scale, and reported fewer sleep-related medical symptoms. Multivariate analysis using an ordinal logistic model found that drivers' alertness during a trip is significantly correlated with their qualitative assessment of the air quality in their cabins and their self-reported symptoms of breathing poor quality air (irritations to nose, throat, eyes, and skin).

This study establishes only a correlation between perceived air quality and self-reported health and alertness with two limitations. First, it does not establish a causal relationship between perceived air quality and self-reported health and alertness. Therefore, more comprehensive studies are needed to establish the underlying causal relationship and the strength of this relationship. Second, it relies on drivers self-report of health and alertness and not on actual medical records which are extremely difficult to obtain. It also examines drivers' perception of air quality. Although physical measurement of air quality is possible, it is beyond the scope of this study. Given these limitations, care should be exercised in generalizing the results. Nevertheless, the results raise questions about the quality of the air in truck cabins and the need for further research.

## APPENDIX

### Survey on Air Quality in Trucks

There is no right or wrong answer and the survey is completely confidential, so please tick the box that best represents your view.

#### Section One: (General Driving)

1. How long have you been driving a truck?  
 0-2 yrs     3-5 yrs     6-10 yrs     10 yrs or more
2. Are you primarily a short haul or long haul driver?  
 Mostly short haul     Very mixed     Mostly long haul
3. How many days do you usually drive for work in a week?  
 3 days or less     4 days     5 days     6 days     7 days
4. How many hours do you usually drive for work in a day?  
 0-3 hrs     4-8 hrs     9-11 hrs     12-15 hrs     16-19 hrs     20 hrs or more
5. Do you usually drive alone?  
 Yes     No, I usually have a passenger     No, I usually have a co-driver
6. How many hours of sleep do you usually get in a 24 hour period?  
 4 hrs or less     4-6 hrs     7-9 hrs     10 hrs or more
7. How often do you sleep in the sleeper berth in the truck?  
 Less than once a week     1-2 times a week     3-4 times a week     5-6 times a week  
 everyday
8. How useful do you think the following measures are in helping you stay alert while driving?  
 (1 = not useful at all, 2 = slightly useful, 3 = moderately useful, 4 = fairly useful, 5 = very useful)
 

a. Cooling the truck cabin	1	2	3	4	5
b. Drinking coffee	1	2	3	4	5
c. Listening to AM/FM radio	1	2	3	4	5
d. Listening to music on cassette or CD	1	2	3	4	5
e. Stopping to eat, drink or stretching	1	2	3	4	5
f. Stopping for fresh air	1	2	3	4	5
g. Using tobacco products	1	2	3	4	5
h. Using over the counter drugs	1	2	3	4	5
i. Talking on CB	1	2	3	4	5
j. Singing or humming	1	2	3	4	5
k. Taking a power nap or short nap	1	2	3	4	5

**Section Two: Information on Current Trip**

Route: From \_\_\_\_\_ To \_\_\_\_\_  
Time: Start \_\_\_\_\_ End \_\_\_\_\_

1. How many stops or breaks (including sleeping) from driving did you take during the trip?  
 Never     1-2     3-4     5-6     7 or more
  
2. How long did you sleep during the trip?  
 less than 4 hrs     4-6 hrs     6-8 hrs     8-10 hrs     10 hrs or more
  
3. When did you sleep?     daytime only     evening only     a bit of both
  
4. How did you feel when you were the most tired while you were driving?  
 Feeling active, vital, alert, or wide awake  
 Functioning at high levels, but not at peak; able to concentrate  
 Awake, but relaxed; responsive but not fully alert  
 Somewhat foggy, let down  
 Foggy; losing interest in remaining awake; slowed down  
 Sleepy, woozy, fighting sleep; prefer to lie down  
 No longer fighting sleep, sleep onset soon; having dream-like thoughts  
 Asleep
  
5. How do you keep in-truck air fresh?  
 Natural ventilation (open windows)  
 Recirculation mode  
 Fresh-air intake mode  
 Combined all the above
  
6. Do you think that the air in the cabin is fresh?  
 Yes             No     Not sure  
If No, please specific why:
  
7. After how many hours, do you feel in-truck air is not fresh enough and you have to open windows?  
 less than 4 hrs     4-6 hrs             6-8 hrs             8-10 hrs             10 hrs or more
  
8. How do you quantify the irritation to your eyes, nose, throat, skin etc. during this trip?  
 None     Rarely             Sometimes             Often             very often

**Section Three: General Health**

1. Age:     under 25     25-34     35-44     45-54     55-64     65 & over
  
2. Sex:     Male                     Female
  
3. Do you smoke?                     No     Light     Moderate     Heavy
  
4. Do you drink (alcohol)?             No     Light     Moderate     Heavy

5. How likely are you to doze off or fall asleep in the following situations, in contrast to feeling just tired? This refers to your usual way of life in recent times. Even if you have not done some of these things recently try to work out how they would have affected you.

(0= no chance; 1 = slight chance; 2 = moderate chance; 3 = high chance)

a. Sitting and reading	0	1	2	3
b. Watching TV	0	1	2	3
c. Sitting inactive in a public place (e.g. a theatre or a meeting)	0	1	2	3
d. As a passenger in a vehicle for an hour without a break	0	1	2	3
e. Lying down to rest in the afternoon when circumstances permit	0	1	2	3
f. Sitting and talking to someone	0	1	2	3
g. Sitting quietly after a lunch without alcohol	0	1	2	3
h. In a vehicle, while stopped for a few minutes in traffic	0	1	2	3

6. Please check any of the following that you have experienced (or anyone else like your spouse or driving partners has reported about you) on regular basis related your sleep.

- |  |  |
|--|--|
| <input type="checkbox"/> Snoring that disturbs others              | <input type="checkbox"/> Waking with coughing fits   |
| <input type="checkbox"/> Choking                                   | <input type="checkbox"/> Throat dry when wake up     |
| <input type="checkbox"/> Stopped breathing                         | <input type="checkbox"/> Forgetfulness               |
| <input type="checkbox"/> Tightness in chest                        | <input type="checkbox"/> Sleep-walking               |
| <input type="checkbox"/> Sputtering or gagging                     | <input type="checkbox"/> Sleep-talking               |
| <input type="checkbox"/> Difficulty breathing                      | <input type="checkbox"/> Severe recurrent nightmares |
| <input type="checkbox"/> Difficulty concentrating                  | <input type="checkbox"/> Grinding teeth              |
| <input type="checkbox"/> Irresistible urge to sleep during the day | <input type="checkbox"/> Kicking and twitching legs  |
| <input type="checkbox"/> Gasping                                   | <input type="checkbox"/> Acting out your dreams      |
| <input type="checkbox"/> Morning headaches                         | <input type="checkbox"/> Congested nose or allergy   |

7. Please indicate any of the following medical conditions that you have.

- |  |  |
|--|--|
| <input type="checkbox"/> High blood pressure | <input type="checkbox"/> Alcohol or drug addiction               |
| <input type="checkbox"/> Liver problems      | <input type="checkbox"/> Chronic fatigue syndrome                |
| <input type="checkbox"/> Kidney problems     | <input type="checkbox"/> Chronic pain that interferes with sleep |
| <input type="checkbox"/> Thyroid problems    | <input type="checkbox"/> Seizures                                |
| <input type="checkbox"/> Heart problems      | <input type="checkbox"/> Asthma or Bronchitis                    |
| <input type="checkbox"/> Depression          | <input type="checkbox"/> None                                    |

8. If you have any comments or suggestions, please add in below.

## Endnotes

1. It should be noted that this question only asked for the drivers' perception of the usefulness of using over the counter drug, which is legal, and not on its use. Therefore, social desirability bias is not expected to be significant.

## Acknowledgements

Financial support for the project was provided by the Natural Science and Engineering Research Council of Canada, the Alberta Motor Association and the Centre for Transportation Engineering and Planning. However, the views expressed by the authors do not necessarily reflect those of the sponsors. The authors also thank the management and staff of Economy Carrier Limited and the Road King and Husky truck stops for their kind assistance.

**Dr. Richard Tay**, P.Eng., is the AMA chair and professor in road safety in the Department of Civil Engineering at the University of Calgary. He graduated with a B.S. from Texas Tech University, a M.S. from Stanford University and a Ph.D. from Purdue University. His research focuses on the analysis and prevention of road crashes. He serves on the editorial board of several journals including *Accident Analysis and Prevention*, *Journal of the Australian College of Road Safety* and *Journal of Advanced Transportation*.

**Dr. Zhongchao Tan**, P.Eng., is an assistant professor of environmental engineering at the Department of Mechanical Engineering at the University of Calgary. He received his B.S. and M.S. from Tsinghua University and his Ph.D. from the University of Illinois at Urbana-Champaign. His research focuses on aerosol/particulate air pollution characterization and control and waste management. He won first place in the Ph.D. student research award from ASAE in 2004 and ASABE superior paper award in 2006. He is the associate editor of two journals.

**Ms. Xiaoying Cheng**, P.Eng., is an air quality specialist with Jacque Whitford Ltd. She received her B.S. from Taiyuan Institute of Technology and her M.S. from the University of Calgary. She has extensive experience in air dispersion modeling and indoor air quality.
