The Virginia Institute of Marine Science (VIMS) conducted a sea scallop survey in the Nantucket Lightship Closed Area (NCLA) during July 2009. The survey was funded by the Sea Scallop Research Set-Aside Program (RSA). The results of the survey indicated an exploitable scallop biomass of 11,017 metric tons or 25.3 million lbs with an average meat count of 10.1 MPP. This is more than sufficient for an opening in 2010. The survey also encountered a limited number of yellowtail flounder which still may present the possibility that the scallop fishery could prematurely reach the yellowtail TAC during the opening. The survey was conducted aboard the *F/V Celtic* towing a NMFS 8 foot survey dredge along with a 15 foot commercial dredge with a 10 inch diamond mesh twine top with a 1.76 hanging ratio (60 meshes, 34 rings) and 8.5 meshes on the side.

The abundance and distribution of sea scallops and yellowtail flounder are presented in Table 1 and Figures 1- 2. In Figure 3, the shell height frequency distribution is presented. One can easily discern the peak abundance of scallops at 120 mm (4.8 inches) which represent the strong 2003 year class. These scallops will be around 5.5 inches in 2010. The other peak to the right represents older scallops in the area that are reaching their maximum size. This information is based on the catch data obtained from the commercial dredge during a 15 minute tow at 3.8 kts with a 3:1 scope. We present this data so that the scallop industry can target fishing effort to areas where there may be less yellowtail bycatch. We recognize that this data is from the 2009 survey, but may provide some guidance as to the distribution of yellowtail but accurate information as to the distribution and abundance of sea scallops.

VIMS conducted several research trips aboard the *F/V Celtic* within the boundaries of the Georges Bank Access Areas during 2006 and 2007 to test the effects of altering the twine top ratio on finfish bycatch. The results indicated that there was a significant reduction in yellowtail by catch and no loss of scallops when a twine top hanging ratio of 1.76 (60 meshes, 34 rings) was used compared to a 2.64 hanging ratio (90 meshes, 34 rings) Both dredges had twine tops with 8.5 meshes on the side and 7 rings to the clubstick.

Another experiment was conducted using a short twine top (5.5 meshes on the side) with an apron of 13 rings compared with a standard twine top with 8.5 meshes on the side and a 7 ring apron. The results showed that the short twine top configuration caught more yellowtail flounder than the standard configuration. Dredges rigged with short twine tops and high hanging ratios are not useful for the reduction of yellowtail flounder. This is an important consideration for the opening of the NLCA in 2010 flounder bycatch.

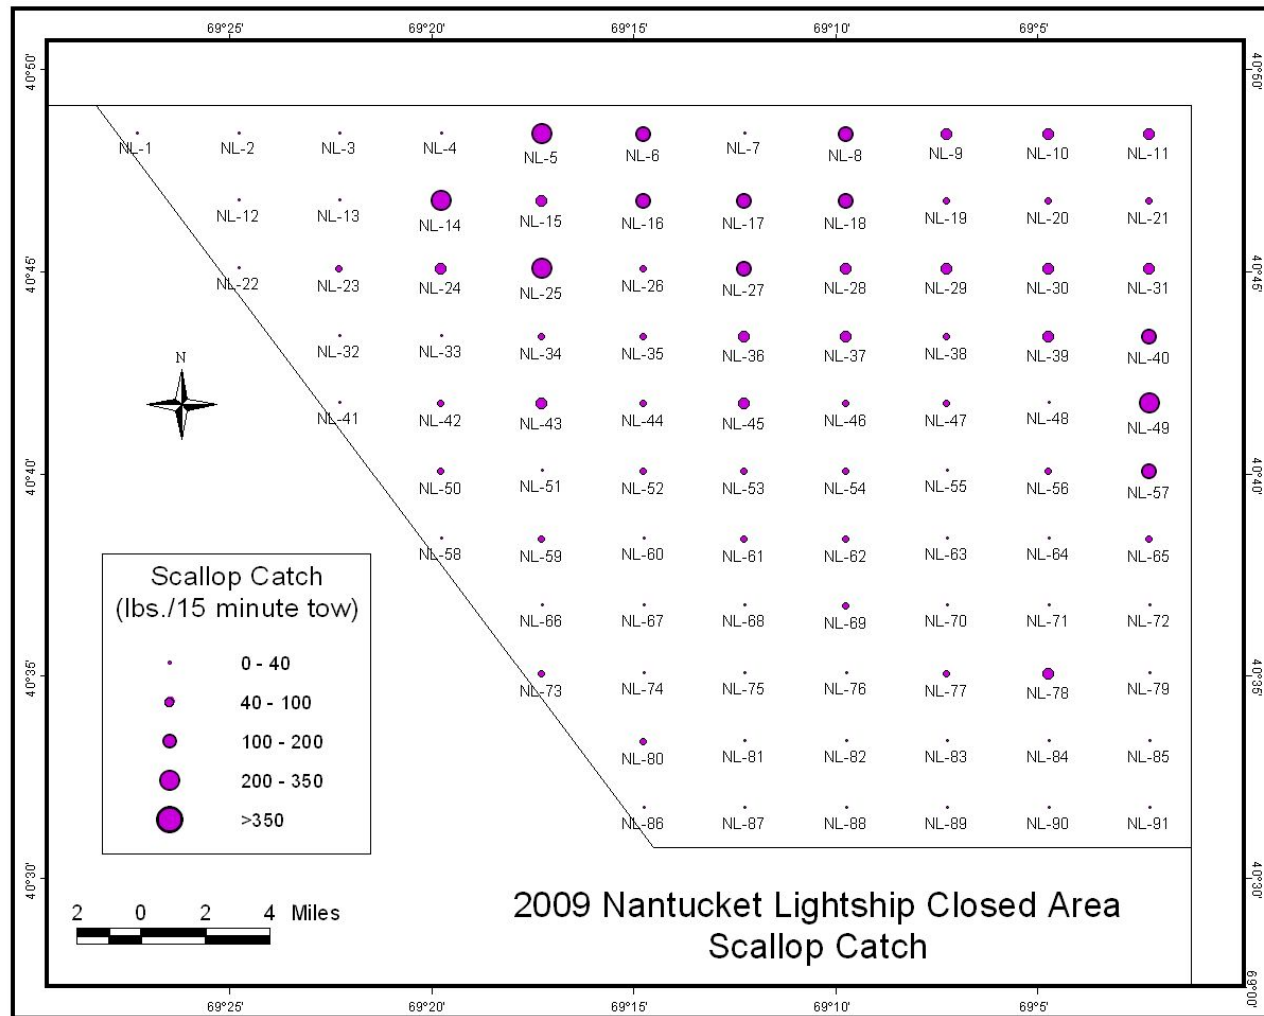

**Table 1** Catch data for the VIMS/Industry cooperative survey of the access area of Nantucket Lightship Closed Area during July 2009.
