Abstract

A special book-keeping method was developed to allow computers with limited random access memory but sufficient hard-disk space to feasibly solve large banded matrix equations by using the Gaussian Elimination method with Partial Pivoting. The computation time for this method is excellent because only a minimum number of disk read/write is required, freeing processor time for number crunching.

INTRODUCTION

Numerical solutions of elliptic partial differential equations with high resolution or large domains are typically approached through iteration methods, e.g., Successive-Over-Relaxation (SOR) (Roache 1972), Multi-Grid (MG) (Brandt 1984), etc. This is primarily because direct approaches such as the Gaussian Elimination method cannot feasibly solve large sets of linear algebra equations (or matrix equations) with limited computer memory. For example, a square two dimensional domain with 200 grids per side will generate a banded coefficient matrix with a dimension of 400 x 40000. If four bytes are used to represent real numbers, a computer would require approximately 64 megabytes (MB) of memory to store this matrix alone. If 16 bytes are used to represent complex numbers with improved accuracy, the memory requirement could easily increase to 256 MB. This memory requirement is typically too large for general computers.

Using the Gaussian Elimination method for solving a partial differential equation, however, has two advantages: (1) The numerical scheme is simple and has been available for more than 20 years; (2) The computation time is not affected by the type and complexity of boundary conditions. In contrast, the convergence rate for iteration methods typically degrades with Neumann type boundary conditions or complex boundary geometries.

In order to practically implement the Gaussian Elimination method, however, the enormous memory requirements must be addressed. With today's advances in hard-disk storage, computer

hard-disks on the order of gigabytes(GB) or more have become standard and commonplace. It has also become a standard practice for many operating systems to automatically satisfy an application's memory requirements with virtual memory, swapping random access memory with hard-disk storage. This built-in virtual memory, however, has very low efficiency because it was never designed for computations with matrices of very large orders. In this study, a method for solving large banded matrix equations by systematically swapping the contents of a high order matrix between memory and hard-disk is presented. This report will detail the construction of the banded matrix equation, and compare the original Gaussian Elimination method of solution, versus the thrifty banded matrix solver method of solution. Computer source codes are listed in the Appendices and are also available on disk for registered user.

METHODOLOGY

A simple two dimensional elliptic Laplace equation (Eq. 1) is used to demonstrate the construction of a banded matrix equation.

For simplicity, we are using Dirichlet boundary conditions in this study. The boundary conditions are specified at the border of a square domain, from 0 to π , are as follows: $p = 2$ at $x = 0$; $p = 1$ at $y = 0$; and $p = 0$ at both $x = y = \pi$. For this example,

we can find the analytical solution to compare the results obtained from each approach.

Using an S-transform on the y component yields the analytical solution:

$$p = \sum_{n=1}^{\infty} \frac{2}{n\pi} \left\{ [1-2(-1)^n] \cosh(nx) - [[1-2(-1)^n] \coth(n\pi) + \text{csch}(n\pi)] \sinh(nx) + 1 \right\} \sin(ny) \dots \dots \dots \quad (2)$$

The analytical solution (with n=4000) is plotted in Fig. 1. The MATLAB program that calculated Eq. 2 can be found in Appendix V. Notice that the analytical solution does not exactly meet the boundary condition $\phi = 1$ at $y = 0$. This is because the solution is in the form of Fourier series, which converges to the average, i.e., zero, at the boundary $y = 0$. In the neighborhood of this boundary, however, ϕ increases sharply and approaches 1 when $y > 1 \times 10^{-3}$. Two selected profiles of the analytical solution demonstrate this situation in Fig. 2. In Fig. 2a, a linear scale on the y-axis indicates that $p \rightarrow 1$ in the neighborhood of $y = 0$. In Fig. 2b, a semi-log scale on the y-axis indicates that $P = 0$ at $y = 0$, but p increases very fast to approach 1 when $y > 0.001$. The contour plot in Fig. 1 was generated with a spatial resolution of $\Delta x = \Delta y = 0.03141592$, which is not high enough to show the significant change of p for $0 < y < 0.001$. Thus the P values at $y = 0.001$ instead of $y = 0$ were used with other p values to construct the contour plot (Fig. 1).

SIMULTANEOUS LINEAR ALGEBRA EQUATIONS

Using the central finite difference method, Eq. 1 can be rewritten as

$$p_{i-1,j} + r p_{i,j-1} - 2(1+r) p_{i,j} + r p_{i,j+1} + p_{i+1,j} = 0 \quad \dots \dots \dots \quad (3)$$

where $r = (\Delta x / \Delta y)^2$, and Δx and Δy are the grid sizes selected in the x and y directions, respectively. This equation is typically referred to as a five-point-approximation because only five points are involved in one iteration loop of an iteration method (e.g., SOR or MG) or to build a band matrix equation.

To demonstrate the construction of the banded matrix e points in both the x and y directions, is initially chosen. See

$$\begin{array}{ccccccccc} 2 & + & 1 & - & 4 & p_1 & + & p_2 & + & p_{11} & = & 0 \\ 2 & + & p_2 & - & 4 & p_3 & + & p_4 & + & p_{12} & = & 0 \\ 2 & + & p_3 & - & 4 & p_4 & + & p_5 & + & p_{13} & = & 0 \\ \cdot & \cdot \\ \cdot & \cdot \\ 2 & + & p_8 & - & 4 & p_9 & + & p_{10} & + & p_{19} & = & 0 \\ 2 & + & p_9 & - & 4 & p_{10} & + & 0 & + & p_{20} & = & 0 \\ p_1 & + & 1 & - & 4 & p_{11} & + & p_{12} & + & p_{21} & = & 0 \\ p_2 & + & p_{11} & - & 4 & p_{12} & + & p_{13} & + & p_{22} & = & 0 \\ p_3 & + & p_{12} & - & 4 & p_{13} & + & p_{14} & + & p_{23} & = & 0 \\ \cdot & \cdot \\ \cdot & \cdot \\ \cdot & \cdot \\ p_{79} & + & p_{88} & - & 4 & p_{89} & + & p_{90} & + & p_{99} & = & 0 \\ p_{80} & + & p_{89} & - & 4 & p_{90} & + & 0 & + & p_{100} & = & 0 \\ \cdot & \cdot \\ \cdot & \cdot \\ \cdot & \cdot \\ p_{88} & + & p_{97} & - & 4 & p_{98} & + & p_{99} & + & 0 & = & 0 \\ p_{89} & + & p_{98} & - & 4 & p_{99} & + & p_{100} & + & 0 & = & 0 \\ p_{90} & + & p_{99} & - & 4 & p_{100} & + & 0 & + & 0 & = & 0 \end{array} \quad \dots \dots \dots \quad (4)$$

Fig. 3. The solutions are the p values at each intersection point. In Fig. 3, they are marked as $p_1, p_2, p_3, \dots, p_{99}, p_{100}$.

Application of Eq. 3 at these intersection points (from p_1 to p_{100}) generates the following simultaneous linear equations.

The constants in the above equations can be moved to the righthand side, and the simultaneous linear equations can be written as a band matrix equation:

where \mathbf{A} is a banded coefficient matrix, \mathbf{P} is a column matrix that contains the unknown variable p in the study domain, and \mathbf{B} is a column matrix that contains the given boundary conditions.

$$A = \begin{bmatrix} 0 & 0 & 0 & \dots & 0 & 1 & 1 & \dots & 1 & 1 & 1 & \dots & 1 & 1 \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ \cdot & \cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \cdot & \cdot \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ 0 & 1 & 1 & \dots & 1 & 1 & 1 & \dots & 1 & 1 & 1 & \dots & 1 & 1 \\ -4 & -4 & -4 & \dots & -4 & -4 & -4 & \dots & -4 & -4 & -4 & \dots & -4 & -4 \\ 1 & 1 & 1 & \dots & 1 & 1 & 1 & \dots & 1 & 1 & 1 & \dots & 1 & 0 \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ \cdot & \cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \cdot & \cdot \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ 1 & 1 & 1 & \dots & 1 & 1 & 1 & \dots & 1 & 1 & 0 & \dots & 0 & 0 \end{bmatrix} \quad \dots \dots \dots \quad (6)$$

$$P^T = [P_1 \ P_2 \ P_3 \ P_4 \ \dots \ P_{i-1} \ P_i \ P_{i+1} \ \dots \ P_{98} \ P_{99} \ P_{100}] \ \dots \dots \dots \quad (7)$$

$$B^T = [-3 \ -2 \ -2 \ \dots \ -2 \ -1 \ 0 \ 0 \ \dots \ 0 \ 1 \ 0 \ \dots \ 0 \ 1 \ 0 \ \dots \ 0 \ 0] \ \dots \dots \dots \quad (8)$$

Matrix A has a dimension of $M \times N$, (21×100), where M is the band width and N is the total number of unknown points within the study domain. The band width is the sum of the upper band width, M_U , the lower band width, M_L , and the unit width of diagonal elements, i.e., $M = M_U + M_L + 1$. The upper band width, M_U , is the maximum count of the element $P_{i+1,j}$ from the diagonal element, $P_{i,j}$. Here the count represents the number of grid points between $P_{i,j}$ and $P_{i+1,j}$. The measurement begins in the i _th column and $j+1$ _th row and continues with increasing row number until the maximum row number or the upper boundary is reached, and then continues on the first grid point (or the lower boundary) on the $i+1$ _th column, and ends at the j _th row. Similarly, M_L is the maximum count between element $P_{i-1,j}$ and $P_{i,j}$.

GENERAL BANDED MATRIX EQUATION

In general, the coefficient matrix, A , can be written as follows. Note that in Eq. 2, r need not be 1. Also in Eq. 8,

$$\mathbf{A} = \begin{bmatrix}
 0 & 0 & 0 & \dots & 0 & a_{1,u} & \dots & a_{1,n-L} & a_{1,n-L-1} & \dots & a_{1,n-1} & a_{1,n} \\
 0 & 0 & 0 & \dots & 0 & 0 & \dots & 0 & 0 & \dots & 0 & 0 \\
 \cdot & \cdot & \cdot & \dots & \cdot & \cdot & \dots & \cdot & \cdot & \dots & \cdot & \cdot \\
 0 & 0 & 0 & \dots & 0 & 0 & \dots & 0 & 0 & \dots & 0 & 0 \\
 0 & a_{d-1,2} & a_{d-1,3} & \dots & a_{d-1,u-1} & a_{d-1,u} & \dots & a_{d-1,n-L} & a_{d-1,n-L-1} & \dots & a_{d-1,n-1} & a_{d-1,n} \\
 a_{d,1} & a_{d,2} & a_{d,3} & \dots & a_{d,u-1} & a_{d,u} & \dots & a_{d,n-L} & a_{d,n-L-1} & \dots & a_{d,n-1} & a_{d,n} & \dots \quad (9) \\
 a_{d+1,1} & a_{d+1,2} & a_{d+1,3} & \dots & a_{d+1,u-1} & a_{d+1,u} & \dots & a_{d+1,n-L} & a_{d+1,n-L-1} & \dots & a_{d+1,n-1} & 0 \\
 0 & 0 & 0 & \dots & 0 & 0 & \dots & 0 & 0 & \dots & 0 & 0 \\
 \cdot & \cdot & \cdot & \dots & \cdot & \cdot & \dots & \cdot & \cdot & \dots & \cdot & \cdot \\
 0 & 0 & 0 & \dots & 0 & 0 & \dots & 0 & 0 & \dots & 0 & 0 \\
 a_{m,1} & a_{m,2} & a_{m,3} & \dots & a_{m,u-1} & a_{m,u} & \dots & a_{m,n-L} & 0 & \dots & 0 & 0
 \end{bmatrix}$$

$a_{1,u}$, $a_{1,u+1}$, ..., and $a_{1,n}$ are not necessarily all in the same row, i.e., row 1. In this example, however, they are all in the same row because of the simple boundary geometry. If the boundary geometry was irregular, then these elements would not be in the same row. Similarly, $a_{m,1}$, $a_{m,2}, \dots$, and $a_{m,L}$ are not necessarily all in row M.

A problem arises when the above stated approach is used to solve an elliptic partial differential equation when the required resolution is high, or the study domain is large, i.e., the banded matrix equation is large. To illustrate this problem, the previous example will be solved by both the original Gaussian Elimination method with Partial Pivoting and the thrifty banded matrix solver developed for this study.

FULL BANDED MATRIX EQUATION SOLVER

To solve Eq. 1 using the full banded matrix, A, a program P_BANDED.FOR (see Appendix I), which use the FORTRAN subroutines (CGBFA and CGBSL) from Linpack (Dongarra et al. 1979), was established. This program performs adequately on a personal computer (PC) with the coarse grid. Fig. 4 plots the results using a MATLAB program, P_PLOT.M (see Appendix IV), which reads the output generated by P_BANDED.FOR directly. From Fig. 4, it is obvious to see that a higher resolution is required. When the grid size is increased to 102 x 102, however, the program P_BANDED.FOR would require approximately 42 MB of memory to execute. While a Windows 3.1/95 based PC would use virtual memory to execute the program, the computing time would be very long because Windows would be constantly swapping between memory and hard-disk. Because of this reason, we changed to a Unix workstation SUN SPARC II computer with 32 MB of memory to do the job. It is still very slow for this size because of disk and memory swap. But we eventually got the results, which is identical to Fig. 1.

The input data for the program P_BANDED.FOR was generated using another FORTRAN program, ID.FOR, given in Appendix III. The input file generated by ID.FOR was as general as possible so users could easily modify the input file for different equations. Notice, however, that this program was only programmed for a Dirichlet boundary value problem. For Neumann type boundary conditions, the routine that formulates the banded coefficient

matrix would be quite different. The solution procedure for the banded matrix equation, however, would remain essentially the same.

A THRIFTY BANDED MATRIX EQUATION SOLVER

Notice that there are many zero elements in \mathbf{A} , especially when the band width is large. Eq. 2 indicates that only the diagonal terms ($a_{d,j}$ with $j=1, N$), the two immediate off-diagonal terms ($a_{d-1,j}$ and $a_{d+1,j}$ with $j=1, N$), the upper border terms ($a_{1,j}$ with $j=1, N$), and the lower border terms ($a_{m,j}$ with $j=1, N$) are possibly non-zero terms. All other elements are zero. The entire banded matrix \mathbf{A} , therefore, can be stored in two much smaller matrices, \mathbf{v} and \mathbf{T} , each with a dimension of $N \times 5$. Matrix \mathbf{v} stores the five rows that contain possible non-zero elements as $v_{i,k}$ with $k = 1$ to 5 and $i = 1$ to N . Their locations (all integer values) in the original banded matrix \mathbf{A} are stored in matrix \mathbf{T} . In this way, \mathbf{A} can be stored more compactly. For comparison, the band matrix presented in the introduction would only require 1.2 MB as opposed to the original 64 MB of memory to store.

In solving Eq. 2, the two small matrices, \mathbf{v} and \mathbf{T} , are recalled one block at a time to construct a working matrix, \mathbf{w} , with dimensions of $(M+ML) \times (NK+M)$, where NK is determined by the available computer memory.

$$W = \begin{bmatrix} 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ \cdot & \cdot & \cdot & \dots & \cdot & \cdot & \cdot & \dots & \cdot & \cdot \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ 0 & 0 & 0 & \dots & 0 & a_{1,u} & a_{1,u+1} & \dots & a_{1,nk+m-1} & a_{1,nk+m} \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ \cdot & \cdot & \cdot & \dots & \cdot & \cdot & \cdot & \dots & \cdot & \cdot \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ 0 & a_{d-1,2} & a_{d-1,3} & \dots & a_{d-1,u-1} & a_{d-1,u} & a_{d-1,u+1} & \dots & a_{d-1,nk+m-1} & a_{d-1,nk+m} \\ a_{d,1} & a_{d,2} & a_{d,3} & \dots & a_{d,u-1} & a_{d,u} & a_{d,u+1} & \dots & a_{d,nk+m-1} & a_{d,nk+m} \\ a_{d+1,1} & a_{d+1,2} & a_{d+1,3} & \dots & a_{d+1,u-1} & a_{d+1,u} & a_{d+1,u+1} & \dots & a_{d+1,nk+m-1} & a_{d+1,nk+m} \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ \cdot & \cdot & \cdot & \dots & \cdot & \cdot & \cdot & \dots & \cdot & \cdot \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 \\ a_{m,1} & a_{m,2} & a_{m,3} & \dots & a_{m,u-1} & a_{m,u} & a_{m,u+1} & \dots & a_{m,nk+m-1} & a_{m,nk+m} \end{bmatrix} \quad (10)$$

Notice that in the working matrix, the original banded matrix was shifted ML rows downward. This is just following the approach used in Linpack. Also notice that some data were excluded after column NK+M when fetch a block (length NK) of data from \mathbf{V} and \mathbf{T} to construct \mathbf{W} . These data will be recovered in the construction of next \mathbf{W} to maintain data integrity.

$$\begin{aligned}
W = & \left[\begin{array}{ccccccccc}
0 & 0 & 0 & \dots & 0 & 0 & u_{1,M} & \dots & u_{1,NK+M} \\
0 & 0 & 0 & \dots & 0 & u_{2,M-1} & u_{2,M} & \dots & u_{2,NK+M} \\
0 & 0 & 0 & \dots & u_{3,M-2} & u_{3,M-1} & u_{3,M} & \dots & u_{3,NK+M} \\
\cdot & \cdot & \cdot & \dots & \cdot & \cdot & \cdot & \dots & \cdot \\
\cdot & \cdot & \cdot & \dots & \cdot & \cdot & \cdot & \dots & \cdot \\
0 & 0 & 0 & \dots & \cdot & \cdot & \cdot & \dots & \cdot \\
0 & 0 & 0 & \dots & \cdot & \cdot & \cdot & \dots & \cdot \\
0 & 0 & 0 & \dots & \cdot & \cdot & \cdot & \dots & \cdot \\
0 & 0 & 0 & \dots & \cdot & \cdot & \cdot & \dots & \cdot \\
0 & 0 & u_{M-2,3} & \dots & \cdot & \cdot & \cdot & \dots & \cdot \\
0 & u_{M-1,2} & u_{M-1,3} & \dots & u_{M-1,M-2} & u_{M-1,M-1} & u_{M-1,M} & \dots & u_{M-1,NK+M} \\
d_{M,1} & d_{M,2} & d_{M,3} & \dots & d_{M,M-2} & d_{M,M-1} & d_{M,M} & \dots & d_{M,NK+M} \\
m_{M+1,1} & m_{M+1,2} & m_{M+1,3} & \dots & m_{M+1,M-2} & m_{M+1,M-1} & m_{M+1,M} & \dots & m_{M+1,NK+M} \\
m_{M+2,1} & m_{M+2,2} & m_{M+2,3} & \dots & m_{M+2,M-2} & m_{M+2,M-1} & m_{M+2,M} & \dots & m_{M+2,NK+M} \\
\cdot & \cdot & \cdot & \dots & \cdot & \cdot & \cdot & \dots & \cdot \\
\cdot & \cdot & \cdot & \dots & \cdot & \cdot & \cdot & \dots & \cdot \\
m_{M+ML-2,1} & m_{M+ML-2,2} & m_{M+ML-2,3} & \dots & \cdot & \cdot & \cdot & \dots & m_{M+ML-2,NK+M} \\
m_{M+ML-1,1} & m_{M+ML-1,2} & m_{M+ML-1,3} & \dots & \cdot & \cdot & \cdot & \dots & m_{M+ML-1,NK+M} \\
m_{M+ML,1} & M_{M+ML,2} & m_{M+ML,3} & \dots & \cdot & \cdot & \cdot & \dots & m_{M+ML,NK+M}
\end{array} \right] . \quad (11)
\end{aligned}$$

In general, the larger the NK, the smaller the number of disk I/O, thereby reducing the processing time, however, this speed reduction is only marginally because the number of disk I/O is already minimized in this process. As a rule of thumb, NK should be at least $4 \times M$.

After applying the procedure of Gaussian Elimination Method for a banded matrix on w (Dongarra et al. 1979), the results were saved in the first M rows (row 1 to M). The space from row M+1 to M+ML is used to save the multipliers. This is also the typical approach used in Linpack. In this study, however, only

the first M row, from column 1 to NK, was written into hard disk as a temporary file. The multipliers in row M+1 to M+ML were ignored because there is no use for a single column matrix B. Only for those cases that matrix B is a rectangular matrix, we then need to store these multipliers.

After writing a disk file, data in the block from column NK+1 to NK+M is then moved to the beginning of the working matrix, i.e., column 1 to column M. The data ignored when expending the first block of V and T into W is then retrieved, and the second block (also length of NK) of V and T is then expanded into the working matrix. Some data at the end of this block must again be ignored due to a lack of space in W. This process repeats until the entire V and T have been processed. During this forward elimination process, many temporary files will have been written into the hard-disk. These files are written in binary form to improve I/O times and to conserve disk space.

The backward substitution method implemented in the FORTRAN subroutine CGBSL from Linpack is then used to find the solution, P, also one block at a time. This routine is relatively simple: the last disk file was read first (and deleted), and the backward substitution routine is used to calculate the solutions for this block. This process also repeated for all the blocks to find out P.

Using the finite difference method with $dx = dy = 0.031105$, i.e., a grid size of 102×102 . With the thrifty banded matrix solver, we only need a working matrix that has a size of $310 \times$

400. Thus, the size of executable codes reduces to about 2 MB. Of course, one needs about 40 MB of disk space for writing temporary files, which were deleted at the end. Under this condition, the example problem given previously can be solved using a personal computer with reasonable time. For example, the computer time for solve the same problem using a Pentium 75 MHz PC was about 160 sec. The results are identical to that given in Fig. 1.

Source list of this thrifty banded matrix solver, a FORTRAN program, P_THRIFT.FOR, is given in Appendix II. The input data file is the same as that used for the program P_BANDED.FOR, and the results were also plotted using the MATLAB program P_PLOT.M. Some of the subroutines (e.g., DOMAIN, ICAMAX, CAXPY, CSCAL, IDISTR, and IDISTL) used in this program are identical to those used in the program P_BANDED.FOR. But they are put together to have a complete file.

DISCUSSION AND CONCLUSIONS

The Gaussian Elimination method involves two steps: forward elimination and backward substitution. Mathews (1987) pointed out that the number of computations involved in the forward elimination is proportional to N^3 , where N is the order of the coefficient matrix. In contrast, the number of computations involved in backward substitution is proportional to N^2 . Computation time, therefore, is mostly spent in forward elimination. If there are many linear systems (all with the same

coefficient matrix) to be solved, then the forward elimination should only be calculated once, and the results, multipliers, should be saved for different B matrices. While the book-keeping procedure developed in this study could easily be adapted to solve multiple linear systems, the details are out of the scope of this study.

For very large banded matrix equations, i.e., a large N, the round-off error may become significant. To improve accuracy, it may become necessary to use double precision (8 bytes for real numbers). This increase in precision, however, does not significantly increase the memory requirement because the size of the executable code is small to begin with, and sufficient hard-disk space is not difficult to obtain.

While only a simple application was presented in this note, this method can be used in many applications, especially when there are Neumann boundary conditions and an irregular boundary geometry. For those situations, the formulation of the banded matrix equation may differ, but the banded matrix solver remains the same.

The use of the Gaussian Elimination Method with Partial Pivoting, the development of a special book-keeping procedure, and the high availability of large hard-disks allow the practical solution of large banded matrix equations. The feasibility of efficiently calculating the solution of an elliptic partial differential equation with large study domain and/or high resolution on a personal computer was demonstrated. While

developed for computers with limited resources, however, this method could easily compute domains on a global scale when processed on computers with large memory and/or disk resources.

SUBROUTINE CGBFA(LDA, N, ML, MU, INFO)
C
C Original Date of WRITTEN Aug. 14 1978 by MOLER, C. B.,
C PURPOSE Factors a COMPLEX band matrix by Gaussian elimination
C and partial pivoting.
C
C CGBFA is usually called by CGBCO, but it can be called
C directly with a saving in time if RCOND is not needed.

```

```

C
C On Entry
C
C ABD COMPLEX(LDA, N), contains the matrix in band storage. The
C columns of the matrix are stored in the columns of ABD and
C the diagonals of the matrix are stored in rows ML+1
C through 2*ML+MU+1 of ABD. See comments below for details.
C
C LDA INTEGER, the leading dimension of the array ABD .
C           LDA must be .GE. 2*ML + MU + 1 .
C
C N     INTEGER, the order of the original matrix.
C
C ML    INTEGER, number of diagonals below the main diagonal.
C           0 .LE. ML .LT. N .
C
C MU    INTEGER, number of diagonals above the main diagonal.
C           0 .LE. MU .LT. N. More efficient if ML .LE. MU
C
C On Return
C
C ABD an upper triangular matrix in band storage and the
C multipliers which were used to obtain it. The
C factorization can be written  $A = L \cdot U$  where L is a
C product of permutation and unit lower triangular matrices
C and U is upper triangular.
C
C IPVT INTEGER(N), an integer vector of pivot indices.
C
C INFO INTEGER
C   = 0 normal value.
C   = K if  $U(K,K) = 0.0$ . This is not an error condition,
C       but it does indicate that CGBSL will divide by zero if
C       called. Use RCOND in CGBCO for a reliable indication
C       of singularity.
C
C This uses rows ML+1 through 2*ML+MU+1 of ABD. In addition, the
C first ML rows in ABD are used for elements generated during
C the triangularization. The total no. of rows needed in ABD is
C 2*ML+MU+1. The ML+MU by ML+MU upper left triangle and the ML
C x ML lower right triangle are not referenced.
C
C LINPACK. This version dated 08/14/78 .
C Cleve Moler, University of New Mexico, Argonne National Lab.

C
SUBROUTINE CGBSL(LDA, N, ML, MU, zb)
C
C Original written on Aug. 14, 78, revised on Aug. 1, 82
C   AUTHOR MOLER, C. B., (U. OF NEW MEXICO)
C
C DESCRIPTION
C
C   CGBSL solves the complex band system
C   A * X = B or CTRANS(A) * X = B
C   using the factors computed by CGBCO or CGBFA.
C
C On Entry
C
C   ABD  COMPLEX(LDA, N), the output from CGBCo or CGBFA,
C         passed by common block.
C   LDA  INTEGER,      the leading dimension of the array ABD .
C   N    INTEGER,      the order of the original matrix.
C   ML   INTEGER,      number of diagonals below the main diagonal.
C   MU   INTEGER,      number of diagonals above the main diagonal.
C   IPVT INTEGER(N), the pivot vector from CGBCO or CGBFA.
C                   passed to this subroutine by common block.
C   zB    COMPLEX(N), the right hand side vector.
C
C On Return
C
C   zB      the solution vector X .
C
C Error Condition
C
C   A division by zero will occur if the input factor contains a
C   zero on the diagonal. Technically this indicates singularity
C   but it is often caused by improper arguments or improper
C   setting of LDA . It will not occur if the subroutines are
C   called correctly and if CGBCO has set RCOND .GT. 0.0 or CGBFA
C   has set INFO .EQ. 0 .
C
C LINPACK. This version dated 08/14/78 .

C           conjugate of first vector
C***DESCRIPTION
C
C           B L A S  Subprogram
C           Description of Parameters
C
C           --Input--
C           N  number of elements in input vector(s)
C           CX  complex vector with N elements
C           INCX storage spacing between elements of CX
C           CY  complex vector with N elements
C           INCY storage spacing between elements of CY
C
C           --Output--
C           zCDOTC  complex result (zero if N .LE. 0)
C
C           Returns the dot product for complex CX and CY, uses
C           CONJUGATE(CX)
C           zCDOTC=SUM for I=0 to N-1 of CONJ(CX(LX+I*INCX))*CY(LY+I*INCY)
C           where LX = 1 if INCX .GE. 0, else LX = (-INCX)*N, and LY is
C           defined in a similar way using INCY.

Appendix II. Source List of FORTRAN Program P_THRIFT.FOR

```
program p_thrify
c
c This program solves the Laplace equation (p) in the area
c 0.0 <= x <= 3.1416, 0.0 <= y <= 3.1416.
c using the thrifty band matrix solver
c This method was first developed by Li, C. (1995), and later,
c improved and documented by Jerome P.-Y. Maa
c
c The Govern Equation is d^2(p)/dx^2 + d^2(p)/dy^2 = 0
c The finite difference equation is:
c p(i-1,j) +r*p(i,j-1) -2*(1+r)*p(i,j) +r*p(i,j+1) +p(i+1,j) = 0
c
c The boundary conditions are:
c p = 2 at x = 0
c p = 1 at y = 0
c p = 0 at x = y = pi
c
c INFILE and OUTFILE : to store input and main output data.
c RECFILE is used to store routine checking information. If the
c program run O.K., it can be deleted.
c A MATLAB program PHIPLT.M has been developed to plot the
c output results. It uses Matlab version 4.01 for windows, and
c read output data from the OUTFILE directly.
c
c Data in the file INFILE are generated by another program
c ID.FOR for the examples given in this program.
c
c In this example, there is no need to use complex variable.
c But, it was used anyway for general applications.
c
c Jerome P.-Y. Maa      Virginia Institute of Marine Science.

C
C
*****
*
C
      subroutine BMsolver(ierr_code)
C
c It solves a complex banded matrix equation ZAF * ZX = ZB
c where ZAF is a complex band matrix with dimension (m * n)
c     ZX and ZB are two complex column matrices with length (n).
c
c Because of the huge size of ZAF, e.g., (300 x 50000), it is
c designed to solve this problem using the following two steps.
c
c First, don't use the full size of ZAF, instead, uses two small
c matrices: ZA & IA that each only uses 50000 x 5 to save space.
c
c ZA : a complex matrix (n * 5) to store the coefficient matrix in
c a matrix equation ZAF*ZX= ZB. Because of using the finite
c difference method to solve an elliptic equation, there are
c only 5 elements to be saved for the coefficient matrix.
c     The band width, however, is much much large than 5 with a
c     lot of "zero." By doing so, we need another matrix
c IA : to save the corresponding locations.
c
c Second, uses a working matrix, ZW(IW,JW), and do a systematical
c
c swap between a hard disk and memory. For this reason, be sure
c that you do have enough space in your hard disk. For example, a
c complex matrix with size of (300 x 50000) requires 120 MB for
c storage, if using 4 byte for a real number. If using 8 bytes,
c then, 240 MB is needed.
c
c IW,JW: IW should be >= m+ml, where ml is the lower band width.
c     The size of JW depends on the available computer memory.
c     In general, the larger the JW, the less the disk IO, and
c     thus, the faster the computing speed. As a rule of
c     thumb, you may select JW = 2*IW and tried to see if your
c     computer has enough memory to run the program.
c
c The procedures follows that given in the subroutine CGBFA &
c CGBSL from LINPACK. The major difference is just doing it one
c block at a time, stores the results in hard disk sequentially.
c After forward elimination, reverse the process by reading the
c data from hard disk and do back substitute for the solution.
c
      parameter (iq=110, jq=110, iw=310, jw=560, kq=10000)
