## **INFORMATION TO USERS**

**This manuscript has been reproduced from the microfilm master. UMI films the text directly from the original or copy submitted. Thus, some thesis and dissertation copies are in typewriter face, while others may be from any type of computer printer.**

**The quality of this reproduction is dependent upon the quality of the copy submitted. Broken or indistinct print, colored or poor quality illustrations and photographs, print bleedthrough, substandard margins, and improper alignment can adversely affect reproduction.**

**In the unlikely event that the author did not send UMI a complete manuscript and there are missing pages, these will be noted. Also, if unauthorized copyright material had to be removed, a note will indicate the deletion.**

**Oversize materials (e.g., maps, drawings, charts) are reproduced by sectioning the original, beginning at the upper left-hand corner and continuing from left to right in equal sections with small overlaps. Each original is also photographed in one exposure and is included in reduced form at the back of the book.**

**Photographs included in the original manuscript have been reproduced xerographically in this copy. Higher quality 6" x 9" black and white photographic prints are available for any photographs or illustrations appearing in this copy for an additional charge. Contact UMI directly to order.**

## ACKNOWLEDGEMENTS

The support and guidance of my Advisory Committee is greatly appreciated, with special thanks to my major professor, Dr. 'Jack' Musick. I also wish to thank students and aides who worked on the VIMS sea turtle project and contributed to this project; R. Blaylock, J. Brown, R. Byles, S. Bellmund, W. Jones, R. Klinger, M. Lutcavage, S. McLeod, B. Sauls, L. Sweeny, and M. Thompson. In addition I thank S. White, K. O'Hara (and the rest of the gang at the CMC), personnel from the Back Bay Wildlife Refuge, Columbus Zoo, and Virginia Marine Science Museum, L. Hagan, L. Haydu, J. Jones, D. Lee, and J. Younger. I thank all Virginia's stranding cooperators who checked out and reported turtles, as well as all the folks along the east coast who shared their tagging and recapture data. Gratitude goes to the fishermen who supplied live turtles, especially the Jetts. I could not have completed this without the constant support and encouragement of my close friends (you know who you are), and especially my parents. Above all, I wish to thank my wife, Deb, for the continuous support, encouragement, and help with field, laboratory, and computer work.

This project was funded by the Virginia Department of Game and Inland Fisheries, Virginia Highway Department, the Department of the Navy, the U.S. Fish and Wildlife Service, the National Marine Fisheries Service, the Columbus Zoo, the Virginia Marine Science Museum, and the Minerals Management Service.

## ABSTRACT

Flipper-tagging, aerial surveys, and satellite telemetry was used to investigate the occurrence, migratory routes, distances traveled, swimming speeds, diving behavior, and the relation of water temperature to movements and timing of migration of wild loggerhead (Caretta caretta) and Kemp's ridley (Lepidochelys kempii) sea turtles. The behavior and movements of head-started loggerhead turtles was investigated with satellite telemetry and compared to wild turtles.

Flipper-tagged loggerhead and Kemp's ridley turtles inhabit Chesapeake Bay during the warm months and many return in subsequent seasons. Aerial surveys showed that loggerhead turtles migrate from south of Cape Hatteras to northern waters during May and June, and return to the south of Cape Hatteras in the autumn, usually during October or November. Satellite telemetry supported aerial survey data, and showed that loggerhead and Kemp's ridley turtles migrate nearshore to the south of Cape Hatteras in the autumn, although one loggerhead became pelagic in the North Atlantic. Kemp's ridleys and some loggerheads migrate as far south as Florida for the winter months, while some loggerheads overwinter in the Gulf Stream off North Carolina. Loggerheads which returned to Chesapeake Bay used similar migratory routes during the northerly and southerly migrations.

Loggerhead and Kemp's ridley turtles spent up to 94% of 12 h periods submerged (ridley mean = 81%, loggerhead mean = 88%), and mean dive durations ranged from 13 to 124 min (ridley mean = 66 min, loggerhead mean = 74 min), making 13 to 38 dives over a 12 h period (ridley mean = 25, loggerhead mean = 25). Temperatures measured by satellite transmitters attached to Kemp's ridley turtles ranged from 13 - 23 C (mean = 17 C), while loggerhead temperatures ranged from 6 - 33 C (mean = 20 C). Movements of turtles appear to be mitigated by temperatures about 15 C.

Movements and diving behavior of head-started loggerheads were different than wild turtles. Some head-started turtles entered the Gulf Stream and traveled eastward across the Atlantic, while others wandered in various directions. Head-started loggerheads made more (mean = 69) and shorter dives (mean = 21 min) over a 12 hr period than wild turtles, and spent significantly less time submerged (mean = 54%) than wild turtles.

**MOVEMENTS AND BEHAVIOR OF WILD AND HEAD-STARTED SEA TURTLES**

## INTRODUCTION

Sea turtles are the most migratory extant reptiles. Leatherbacks (*Dermochelys coriacea*) travel over 3000 km between Caribbean breeding grounds and temperate feeding areas (Bleakney, 1965; Boulon et al., 1988; Goff and Lien, 1988; Keinath and Musick, 1990; Lambie, 1983; Lazell, 1980; Pritchard, 1976; Rhodin and Schoelkopf, 1982). Green turtles (*Chelonia mydas*) migrate from Ascension Island nesting beaches to South American feeding areas and from Costa Rican nesting beaches to Caribbean feeding grounds (Carr, 1967). These point to point migrations were discovered by flipper tagging, yet virtually nothing else is known of sea turtle migration, especially juvenile turtle movements.

Chesapeake Bay is an important foraging habitat for juvenile loggerhead (*Caretta caretta*) and Kemp's ridley (*Lepidochelys kempii*) sea turtles during warmer months (Byles, 1988; Bellmund et al., 1987; Keinath and Musick 1991a, 1991b; Keinath et al., 1987, 1991; Lutcavage, 1981; Lutcavage and Musick, 1985; Musick et al., 1985a). Aerial survey data (Barnard et al., 1989; CeTAP, 1982a, 1982b; Keinath et al., 1987, 1992; Shoop, 1987; Shoop and Kenney, 1992; Shoop et al., 1981) suggested loggerheads migrate nearshore to and from south of Cape Hatteras, North Carolina each spring and fall: Turtles enter the bay in May and June and exit the bay when water temperature undergoes a pronounced decrease,

usually caused by northeastern storms which occur in October or November (Bellmund et al., 1987; Keinath et al., 1987; Lutcavage and Musick, 1985; Musick, 1988; Musick et al., 1985b).

Flipper tags have traditionally been used to track sea turtles over long periods of time, and the remarkable navigational abilities of Ascension Island green turtles were revealed via this method. But flipper tagging only discloses point to point movement, and usually only nesting females are studied. Chesapeake Bay is one of the few areas where juvenile loggerhead and Kemp's ridley sea turtles have been tagged in any numbers, and subsequently recaptured (Byles, 1988; Sauls et al., 1990).

Aerial surveys have been flown by VIMS personnel since 1982 to estimate loggerhead turtle populations in Chesapeake Bay. Results from the surveys indicate that up to 9,000 loggerheads inhabit the bay each summer (Byles, 1988; Keinath et al., 1987). Surveys have also been flown over coastal Virginia and North Carolina since 1985 (Keinath et al., 1987, 1992; Musick, 1986; Musick et al., 1987, 1989). In addition, surveys were flown between Oregon Inlet and Hatteras Inlet during 1991-1992.

Recently, satellite telemetry has been used to track sea turtles, and concurrently collect information on swimming behavior and ambient water temperature (Byles, 1988; Keinath, 1991; Keinath et al., 1989). Satellites receive signals from transmitters and relay the data to earth stations. The satellite determines position of the transmitter by doppler shift, and other parameters can be measured by sensors in the transmitter.

#### Wild sea turtles

The coastal area from Cape Hatteras, North Carolina to Virginia is

a major migratory pathway for loggerhead, leatherback, and Kemp's ridley sea turtles (CeTAP, 1982a, 1982b; Shoop and Kenney, 1992; Shoop et al., 1981). During spring, turtles migrate from the south past Cape Hatteras to summer in northern waters. Juvenile loggerheads and ridleys enter estuaries such as Chesapeake Bay, Long Island Sound, and Cape Cod Bay, while the leatherbacks travel as far north as Newfoundland and possibly farther (Bleakney, 1965; Danton and Prescott, 1988; Keinath and Musick, 1991a, 1991b; Keinath et al., 1987, 1989, 1991; Goff and Lien, 1988; Lazell, 1980; Lutcavage and Musick, 1985; Morreale and Standora, 1989; Morreale et al., 1992; Musick, 1988; Musick et al., 1985a, 1985b, 1987; Shoop, 1980). When water temperatures fall in the autumn, turtles return to south of Cape Hatteras to overwinter.

#### Head started turtles

Egg and hatchling sea turtle predation is very high, with an estimated 0.01 to 0.1% of hatchlings surviving to reproduce (Frazer, 1986). Raising sea turtles in captivity to a size larger than can be taken by most marine predators (head-starting) may increase the probability that turtles may survive to reproduce. Until relatively recently, head-starting sea turtles has been an accepted and encouraged practice throughout the coastal southeast states (Allen, 1992; Frazer, 1992; Taubes, 1992; Woody, 1990, 1991).

The best example is the Kemp's ridley head-start program. The primary (20 km) nesting beach was unknown to science until in 1950 when a film made in 1947 was made available and showed over 40,000 turtles nesting in one day (Hildebrand, 1963). By the 1960's egg, meat, and leather poachers drastically reduced the nesting population. In 1966 a joint Mexican/US team started collecting and incubating eggs in protected areas. The steady decline of nesting females (presently less

than 500 per year) persuaded the US National Marine Fisheries Service and US Fish and Wildlife Service (USFWS) to initiate a head-start program in Galveston, Texas which is still in operation. Approximately 1500 eggs per year are hatched, raised for one year, and the dinner plate size turtles are released into the Gulf of Mexico. Although tremendous time, effort, and money has been spent on this and many other head-start projects, not one head-started turtle has been observed nesting in the wild, and little effort has been expended to study the behavior of the turtles after release. Suggested reasons why head-started turtles do not return to nest are varied, including lack of antipredator response, no navigational abilities, and altered homing response; all of which are possible products of the unnatural environment inherent in the head-starting process. Conversely for loggerhead turtles, most of the head-started turtles may not have yet reached sexual maturity which may not occur for 15 to 30 years (Klinger, 1988). Because of the lack of observations of nesting head-started sea turtles (and potential failure of the procedure), most US head-start projects have been discontinued (Taubes, 1992), although the reasons for this lack of observed nesting has not been addressed.

## OBJECTIVES

The objectives of the present study were:

- 1) To describe the occurrence, migratory routes, distances traveled, swimming speeds, diving behavior, and the relation of water temperature to movements and timing of migration of wild loggerhead (Caretta caretta) and ridley (Lepidochelys kempji) sea turtles off the coast of the south-east United States utilizing 1) recaptures of flipper tagged turtles from 1979 - 1992, 2) aerial surveys, and 3) satellite telemetry.
  
- 2) To compare diving behavior and movements, measured with satellite telemetry, of head-started loggerheads to wild loggerheads to gain insight into the effectiveness of head-starting in producing viable sea turtles.

## MATERIALS AND METHODS

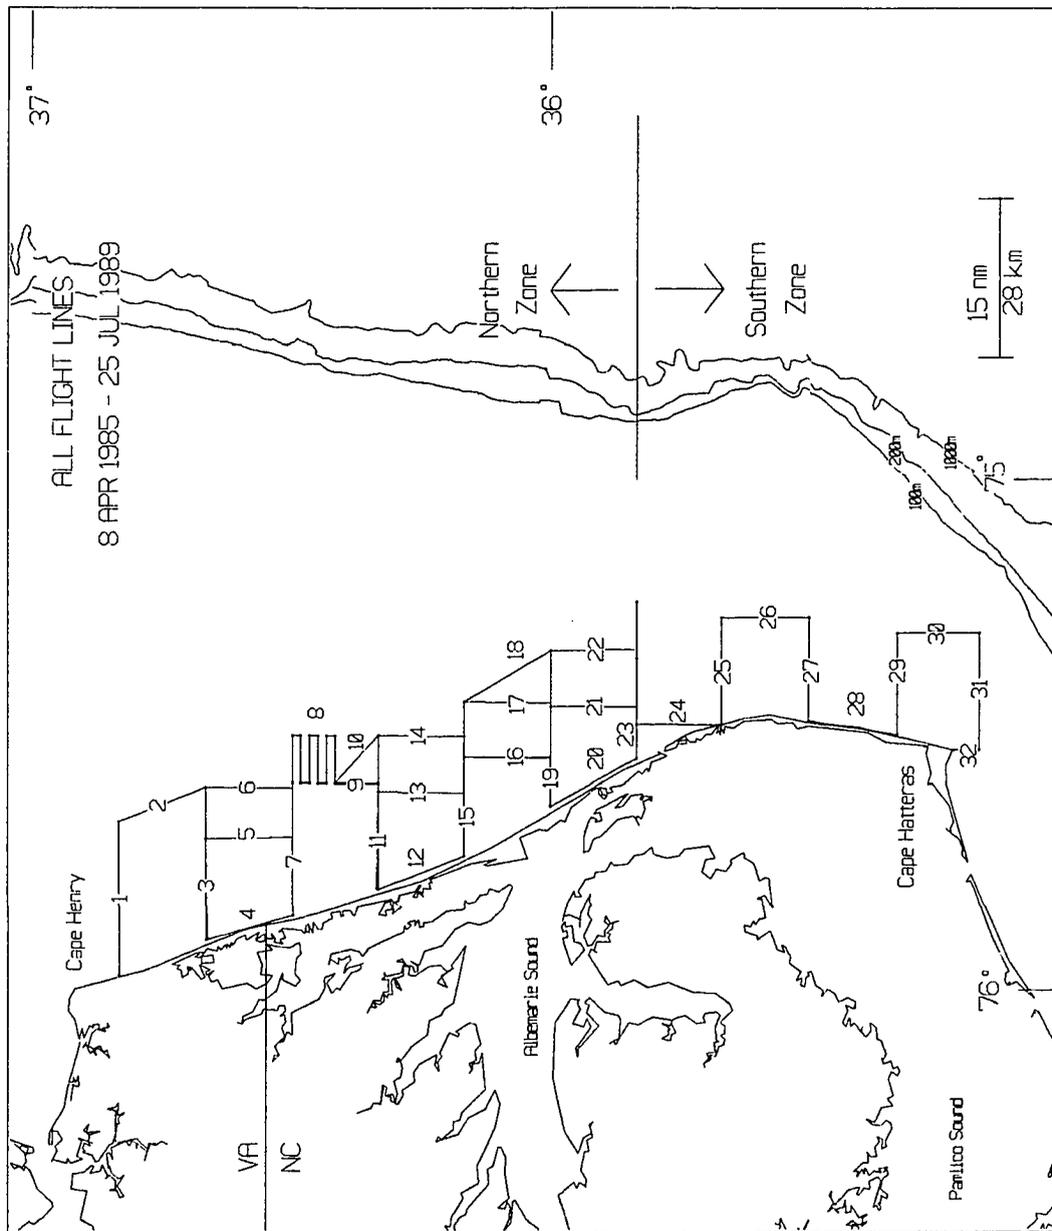

### Flipper tagging

Live turtles were obtained from various sources: cooperating pound net fishermen, recreational fishermen who inadvertently catch turtles, cold stunned individuals, nesting females, and from VIMS trawl surveys. Turtles were flipper-tagged (with metal tags supplied by the University of Florida or the National Marine Fisheries Service), weighed, measured, and released (some of these individuals were also fitted with satellite transmitters). Turtles were either recaptured in subsequent seasons in Virginia and reported to the VIMS stranding program or recaptured in other areas and reported to the NMFS's Sea Turtle Stranding and Salvage Network (STSSN), who relayed the information to VIMS.

### Aerial surveys

The VIMS Sea Turtle Research Project has conducted aerial surveys covering the area between Cape Henry to Cape Hatteras since 1985 (Figure 1) to estimate density of loggerhead turtles in the area (Keinath et al., 1987). In 1991 surveys were initiated from approximately Oregon Inlet to Hatteras Inlet. Three areas were surveyed; from 55.5 km to 18.5 km north of Cape Hatteras (northern zone), from 18.5 north to 18.5 km south of Cape Hatteras (middle zone), and from 18.5 to 55.5 km south

Figure 1. Aerial survey transects flown during 1985 - 1989. Various lines were surveyed on each flight. The transects were divided into northern and southern zones. Numbered lines correspond to data presented in Appendix 1.

of Cape Hatteras (southern zone) (Figures 2 and 3). Following our established protocol (Bellmund et al., 1987; Byles, 1988; Keinath et al., 1987; Musick et al., 1985a, 1985b) surveys were flown at an altitude of 152 m, and at a speed of 130 km/hr. Two observers, one on each side of the plane, scanned the sea surface for turtles and other sea creatures. When an animal was sighted, the following data were taken:

- 1) Sighting angle from the transect line
- 2) Time of observation
- 3) Species

The sighting angle was used to determine the distance each animal was from the transect line. Since turtles are rarely sighted under the airplane (0-50 m) and sighting efficiency drops off dramatically beyond 300 m (Figure 4), the effective visual swath being surveyed is 250 m on each side of the plane. Thus density of turtles can be calculated as:

$$D = N / A$$

where  $D$  = density of turtles observed

$N$  = number of turtles observed

$A$  = area surveyed

and:

$$A = (O * W) * L$$

where  $O$  = number of observers (2 in the present study)

$W$  = survey strip width (250 m in this study)

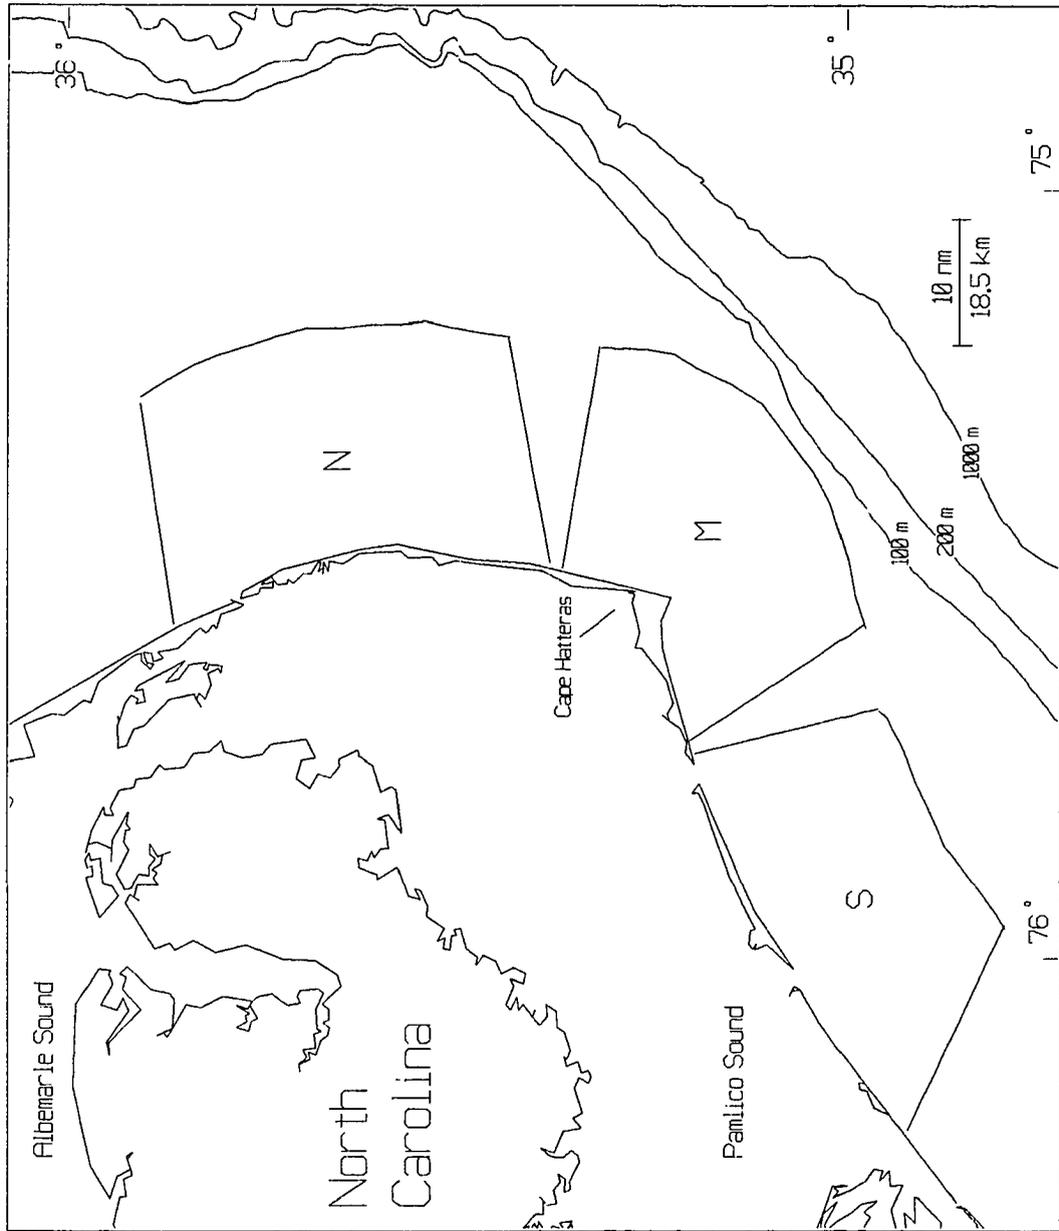

$L$  = length of survey line

Thus, for this study

$$D = N / (0.5 \text{ km} * L)$$

Byles (1988) compared this method to a more complicated Hermite polynomial function (Burnham et al., 1980) which accounts for turtles at

Figure 2. Aerial survey zones flown during 1991 - 1992. Attempts were made to survey all three zones on each flight. N = northern zone, M = middle zone, S = southern zone.

**Figure 3. Aerial survey transects flown during 1991 - 1992.**

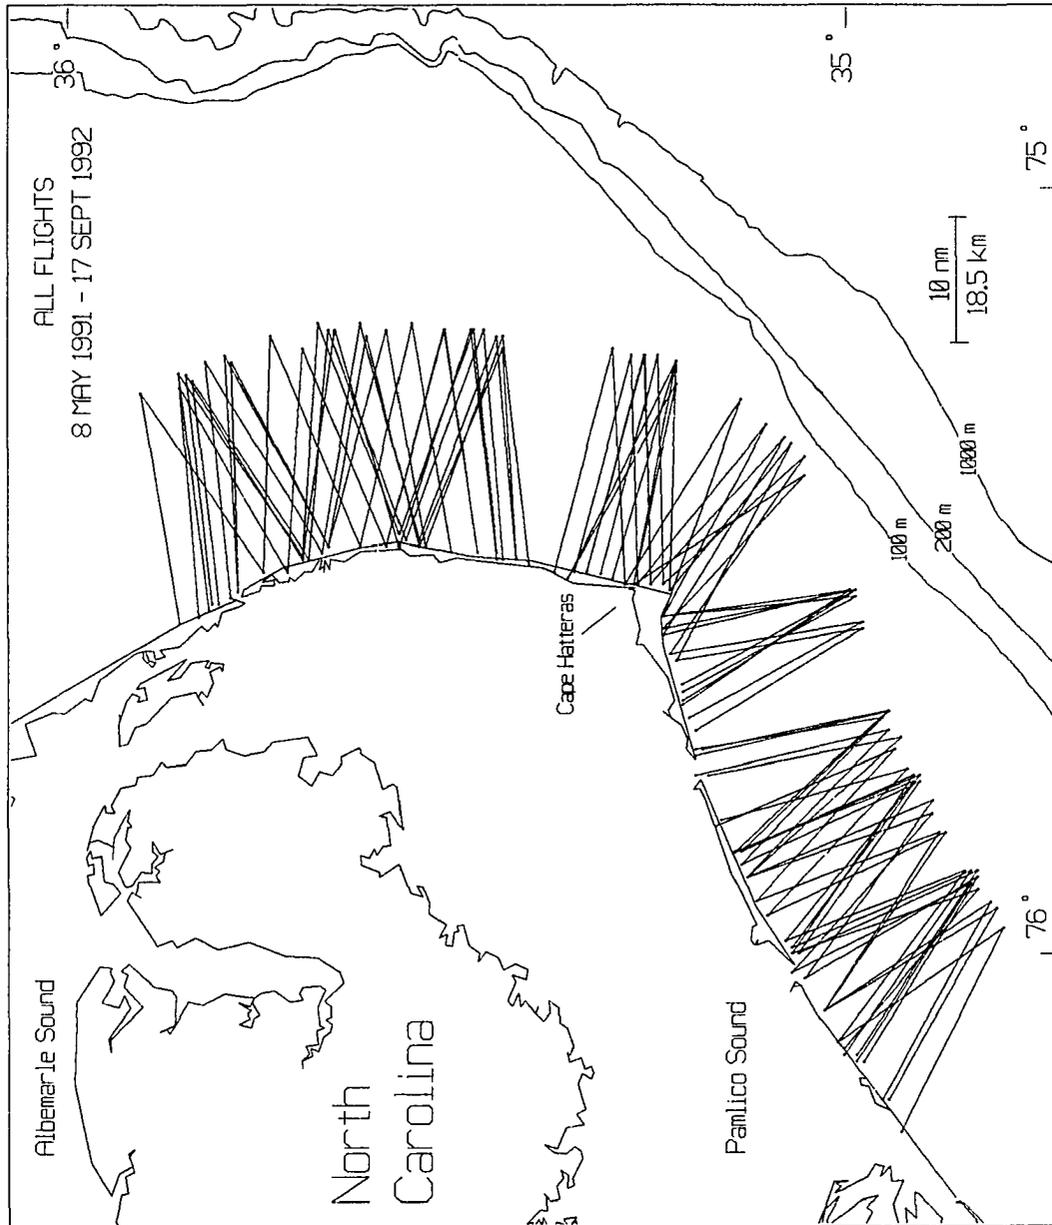

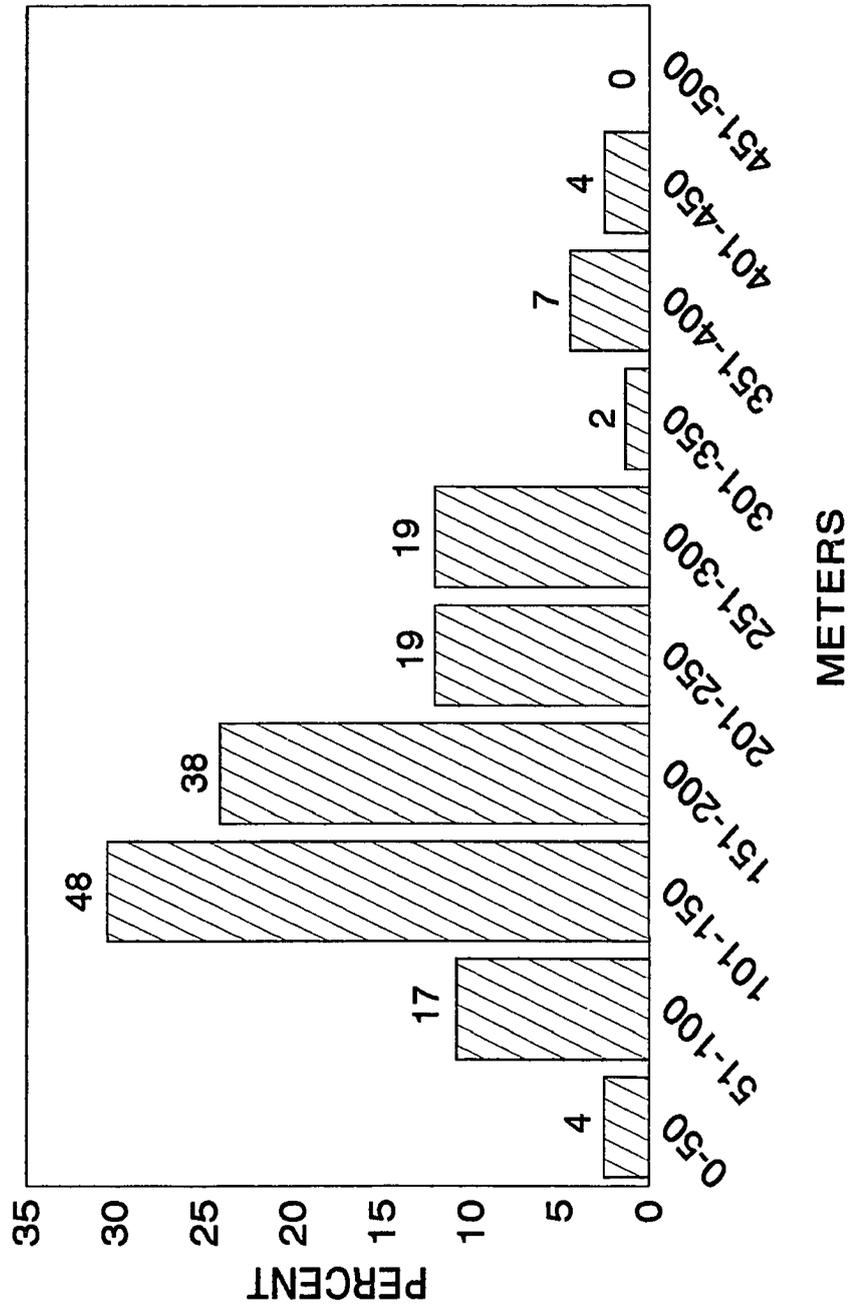

Figure 4. Percentage of sea turtles observed as a function of distance from the flight path on 1991 - 1992 surveys. Leatherback turtles excluded. Number of turtles observed over bars.

# Turtles Observed By Distance From Flight Line

the surface but not seen by observers, and found that both methods produced similar results (eg. means of 423 vs 372 turtles in his study area). Thus I chose to use this simpler method to calculate turtle densities. Each of the six lines in each zone was used to calculate the mean and standard deviation of densities by flights flown in 1991 - 1992.

Since only turtles at the surface of the water are observed on aerial surveys, a correction factor must be used to account for submerged turtles (Bellmund et al., 1987; Byles, 1988; Keinath, 1986; Keinath et al., 1987; Musick et al., 1985a, 1985b, 1992; Standora et al., 1984). If the amount of time a turtle spends at the surface is known, an adjustment factor can be calculated as the inverse of the proportion of time spent at the surface (Keinath, 1986; Musick et al., 1985a). By multiplying this factor by the relative density values for the submerged turtles, an estimated population density may be obtained. The diving data required to calculate the adjustment factor were obtained from satellite telemetry. Estimated standing stocks were calculated for each of the zones by multiplying the estimated population densities by the areas of each zone (north = 1527.4 km<sup>2</sup>, middle = 891.9 km<sup>2</sup>, south = 1216.0 km<sup>2</sup>)

#### Satellite telemetry

Satellite telemetry uses UHF transmitters which transmit signals to a satellite which in turn relays them to an earth station. The Argos satellite telemetry system utilizes NOAA Tiros satellites to calculate transmitter location by doppler shift of the transmitter's radio frequency (Kenward, 1987), and also allows transmission of digital data collected by transmitter sensors. Data collected by on board sensors included water temperature and diving data: mean dive duration in a 12 h

period and number of dives in that 12 h period (Byles, 1989; Byles and Dodd, 1989; Keinath, 1991; Keinath et al. 1989). A salt water switch was used to determine these dive parameters, and the switch also served to turn off the transmitter while underwater (UHF radio waves do not travel through seawater) to extend the battery life from 25 - 30 days to up to a year of operation. Because waves breaking over the sea water switch would give erroneous dive data, submersions under one minute were disregarded. Data was transmitted from satellites to ground stations, and processed and disseminated by Argos (Byles and Keinath, 1991). Data was accessed via computer and modem, and back up diskettes or print-outs of monthly data were available from Argos. Location, parameters sent by the transmitter, day and time of reception, and probability of location accuracy are among data received. From this dive data the duration of time spent submerged and percentage of time spent submerged in each 12 h segment was calculated.

In contrast to radio and sonic telemetry which can provide continuous data, the Argos system provides only a limited number of daily fixes, depending on latitude (Kenward, 1987). Since Tiros satellites are polar orbiting, more fixes are possible at higher latitudes (up to 15 per day) than at the equator (up to seven per day), and since the transmitter is below the surface most of the time, probability of receiving a location is decreased further. Up to two fixes per day were received from wild loggerhead turtles tracked off the east coast of the US, although there were occasions when no positions are recorded for days. The Argos system was used to track three wild Kemp's ridley, eight wild loggerhead, and seven head-started loggerhead sea turtles (one 3 yr and six 2 yr olds; see Swingle et al., 1991).

Argos compatible satellite transmitters were attached to selected

wild and head-started turtles following established protocol. Migration routes were plotted and distances traveled and speeds were calculated. Temperatures obtained from the transmitters were used to identify temperature tolerance, preferred temperature, and the temperature ranges which mitigated movement. For turtles which made significant north-south migrations, latitude and transmitter temperature versus date were graphed. Diving parameters were compared between the two wild species and between wild and head-started loggerheads utilizing analysis of variance if the data met parametric statistical assumptions, otherwise Kruskal Wallis nonparametric analysis of variance was utilized. Significant differences were further analyzed with multiple range comparisons (SPSS, 1986, Siegel and Castellan, 1988).

## RESULTS

### Flipper tagging

Between 1979 and 1992, 421 loggerheads from Virginia's waters were flipper-tagged. Four loggerheads were subsequently recaptured outside Virginia (Table 1), while 48 were recaptured in Virginia in subsequent (but not necessarily consecutive) seasons (Table 2). Thirteen loggerheads tagged outside Virginia were recovered in Virginia's waters (Table 3). Although the majority of loggerheads tagged in Virginia were only recovered in one subsequent season, some loggerheads have been observed for up to four seasons (Table 2, Figure 5).

Of 57 Kemp's ridleys tagged from Virginia's waters, two were recaptured in Virginia's waters in subsequent seasons, and three were recovered outside Virginia. Three ridleys tagged elsewhere were captured in Virginia (Table 4).

### Aerial surveys

Eleven surveys were flown during 1985, nine in the northern zone and two in the southern zone (Table 5, Figure 6, Appendix 1). During the end of April, more loggerheads were observed in the southern than the northern zone. Of all the surveys, most loggerheads were observed during early May in the northern zone, but by late May few turtles were observed in the northern zone. During August, loggerheads became more abundant in the northern zone, but became less abundant by September. During October and November turtles again became more abundant in the northern zone than in September, and in November, abundance decreased in the northern zone while abundance in the southern zone increased.

Twenty surveys were flown during 1986, 15 in the northern zone and five in the southern zone (Table 5, Figure 7, Appendix 1). On 30 April both zones were surveyed and more loggerheads were observed in the southern zone, while on 7 May turtles were more abundant in the northern zone. Turtles became very abundant in the northern zone during late May, and few were observed in mid-June. Throughout the rest of the year abundance fluctuated.

From 1987 through 1989 ten surveys were flown, eight in the northern zone and two in the southern zone (Table 5, Figure 8, Appendix 1). Turtles were observed in the northern zone on 16 September 1987, but no turtles were seen in the southern zone on 3 December. During 1988 turtle abundance was high in early June, then decreased until late July when a large concentration of turtles was observed in the area. Turtle abundance again decreased in August and October. Two surveys were flown in 1989, one each in the northern and southern zone on 25 July. Although few, equal numbers of turtles were observed in each zone.

Table 5. Estimated density of loggerhead turtles in the two zones surveyed during 1985 - 1989 (Figure 1), in turtles km<sup>-2</sup>. ESD = estimated surface density; EPD = estimated population density.

Figure 9. Density of surfaced loggerhead turtles observed in each of the three zones (Figure 2) surveyed in 1991 - 1992. Only the northern and middle zones were surveyed on 8 May 1991. All three zones were surveyed on other dates.

# Aerial Surveys

1991 - 1992

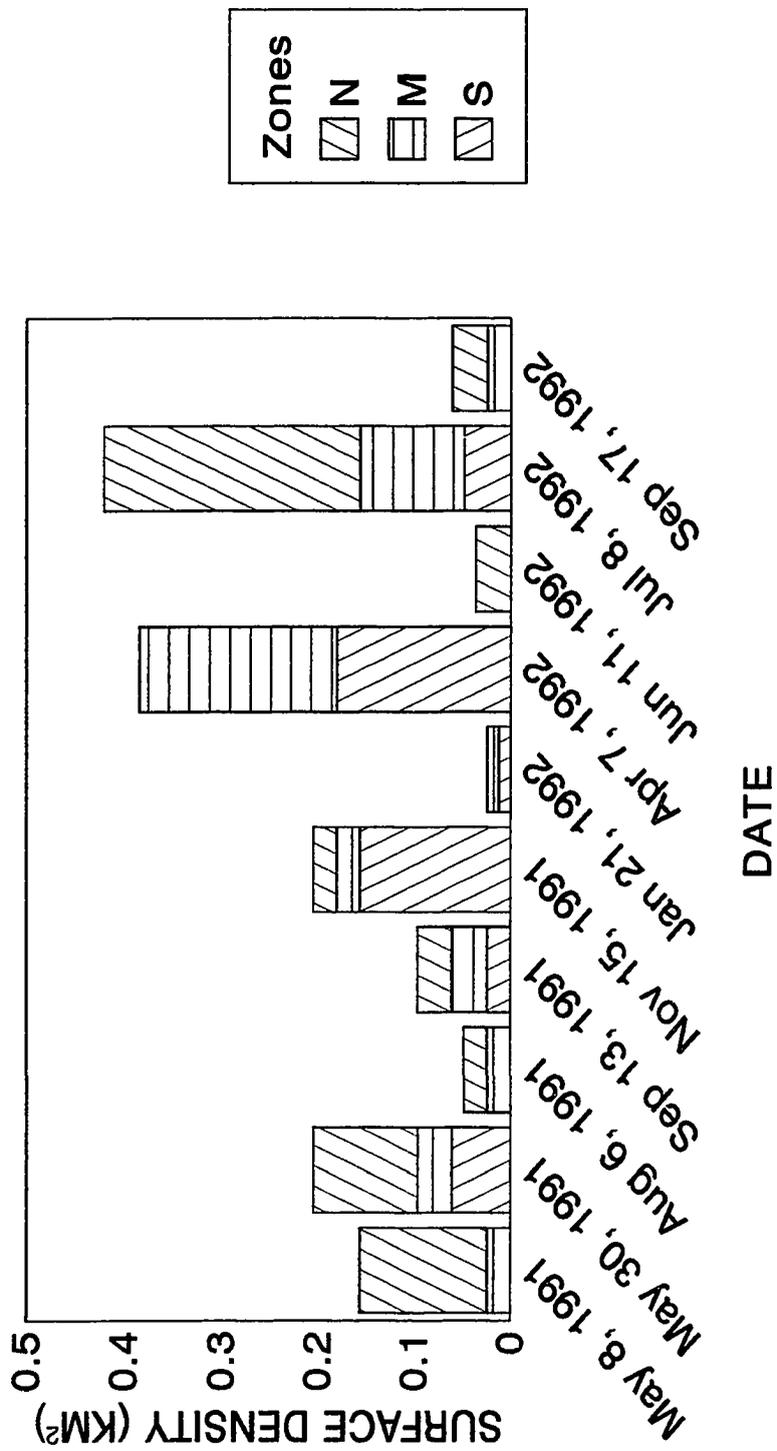

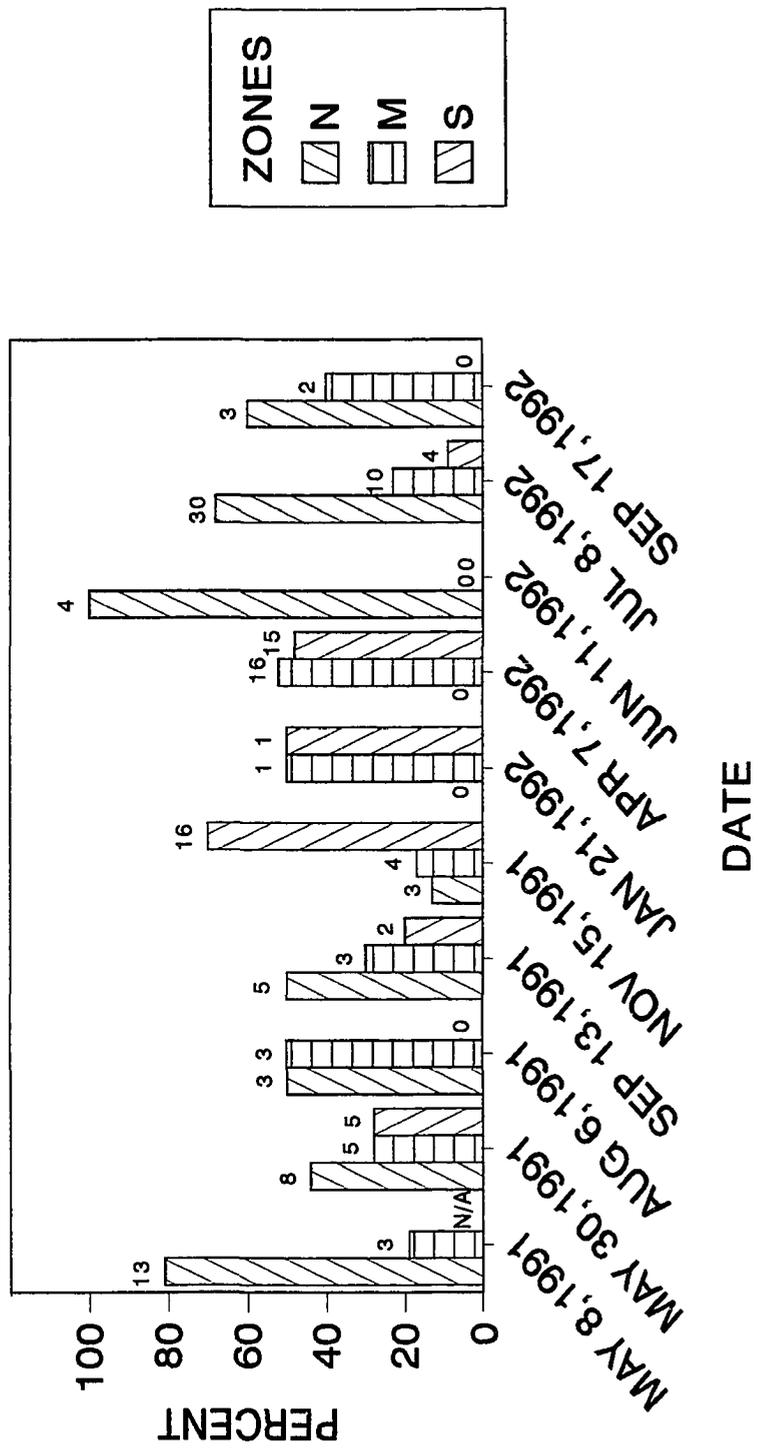

Figure 10. Percentage of loggerhead turtles observed in each of the three zones (Figure 2) surveyed in 1991 - 1992. Number of turtles observed over bars. N/A = not surveyed.

# Aerial Surveys

1991 - 1992

In 1991 and 1992 attempts were made to survey each of the three zones (Table 6, Figures 9 - 10) on each day. On the first survey, the sea state deteriorated and the southern zone was not surveyed. In May 1991 most turtles were observed in the northern zone, then turtles became less abundant but approximately equally distributed throughout the summer. During November 1991 most turtles were observed in the southern zone. No turtles were observed in the northern zone in January 1992, and one turtle was seen in each of the other zones. In April 1992 no turtles were observed in the northern zone, and equal numbers were seen in the middle and southern zones. In June turtles were only observed in the northern zone. In July and September most turtles were seen in the northern zone, followed by the middle and southern zones.

Density estimates of surfaced loggerheads for the 1985 - 1989 surveys ranged from 0 (in December) to 1.261 turtles  $\text{km}^2$  (in early May; Table 5, Figures 6 - 8). Diving data from three satellite telemetered loggerheads showed that the turtles migrating south along the North Carolina coast stayed at the surface 10.6% of the time, providing an adjustment factor of 9.4. Applying the adjustment factor yields population density estimates for loggerheads up to 11.853 turtles  $\text{km}^2$ . In general, highest densities were observed in the spring (May and June), and lowest in late summer and autumn, while during the summer months, densities fluctuated.

Discounting zero counts, mean density estimates of surfaced loggerheads in the 1991-1992 study ranged from 0.024 to 0.264 turtles  $\text{km}^2$  (Table 6). In the northern zone the estimates ranged from 0 (in January and early April) to the maximum of 0.264 turtles  $\text{km}^2$  (in early July). Except for the high observed in early July, the greatest densities were observed in May. In the middle zone, observed mean

estimates ranged from 0 (in June) to 0.204 turtles km<sup>-2</sup> (in early April), the survey conducted earliest in the presumed migratory time frame (Table 6). In the southern zone estimates ranged from 0 (in June and August) to 0.180 turtles km<sup>-2</sup> (in early April). Applying the adjustment factor of 9.4 yields population density estimates up to 2.48 turtles km<sup>-2</sup> in the northern zone, 1.92 km<sup>-2</sup> in the middle zone, and 1.47 km<sup>-2</sup> in the southern zone. Standing stocks in the northern zone ranged from 0 to 3787.98 turtles, from 0 to 1712.47 in the middle zone, and from 0 to 1240.32 in the southern zone (Table 6).

#### Satellite telemetry

The movements and temperatures of eight wild loggerheads, seven head started loggerheads, and three Kemp's ridleys were successfully tracked since 1986 (Table 7). Of these turtles, six wild loggerheads and all the ridleys and head-started loggerheads were instrumented with transmitters capable of measuring diving behavior. Instrumented turtles were released in the autumn either in the Chesapeake Bay or along the coast between Cape Henry, Virginia and Cape Hatteras, North Carolina. Duration of tracks were from 26 d to over 8 mo, when either the transmitters became detached from the turtles or ceased transmitting because of failure or the turtles died.

#### MOVEMENTS - Kemp's ridleys

Kemp's ridley 01229 was released at Back Bay National Wildlife Refuge (BBNWR), Virginia Beach on 23 October 1991 (Table 7). The turtle traveled south nearshore, and rounded Cape Hatteras the last week of October (Figures 11 - 12, Appendix 2). The turtle continued south, farther offshore, but in water less than 100m deep, and arrived off Cape Lookout early in the first week of November, then started to travel

Figure 11. Positions of Kemp's ridley sea turtle 01229 determined by satellite telemetry. The turtle was released at Back Bay National Wildlife Refuge, Virginia Beach, Virginia on 23 October 1991 and the last location was received on 13 November 1991. Numbered points correspond to "POINT NO" in Appendix 2.

Figure 12. Latitude (squares) and selected temperatures (triangles) as a function of date of Kemp's ridley sea turtle 01229 determined by satellite telemetry.

01229

south later that week (Figures 11 - 12, Appendix 2). The last position was obtained on 13 November, when the turtle was nearshore between Cape Lookout and Cape Fear. The turtle moved at speeds up to 4 km/h, with a mean speed of 1.30 km/h (Table 8, Appendix 2).

Kemp's ridley 04938 was released at BBNWR on 28 October 1991 (Table 7). The turtle traveled south nearshore, and rounded Cape Hatteras the first week of November (Figures 13 - 14, Appendix 3). The turtle continued south and rounded Cape Fear 10 - 12 November, arriving at the South Carolina - Georgia boarder during the end of December, and transmission ceased on 18 January 1992 when the turtle was off the Georgia - Florida boarder (Figures 13 - 14, Appendix 3). The turtle moved at speeds up to 3 km/h, with a mean speed of 1.07 km/h (Table 8, Appendix 3).

Kemp's ridley 04939 was released at BBNWR on 28 October 1991 (Table 7). The turtle traveled south farther offshore than the previous two ridleys, and rounded Cape Hatteras the first week of November (Figures 15 - 16, Appendix 4). The turtle continued south and rounded Cape Fear 17 - 19 November, arriving at the South Carolina - Georgia boarder during the second week of December, and continued to travel south to Cape Canaveral when transmission ceased on 4 January 1992 (Figures 15 - 16, Appendix 4). The turtle moved at speeds up to 6 km/h, with a mean speed of 1.53 km/h (Table 8, Appendix 4).

#### MOVEMENTS - Wild loggerheads

Loggerhead 05783 was released in the York River on 5 October 1986 (Table 7). The turtle traveled south nearshore and rounded Cape Hatteras between 18 - 31 October and continued south (Figures 17 - 18, Appendix 5). On 31 October the transmitter began transmitting continually, indicating the transmitter was adrift and not attached to

Table 8. Summary statistics on swimming speeds (km/h) of satellite telemetered sea turtles. TAG NUMBER = satellite identification code, SD = standard deviation of the mean, N = sample size, MIN = minimum value, MAX = maximum value.

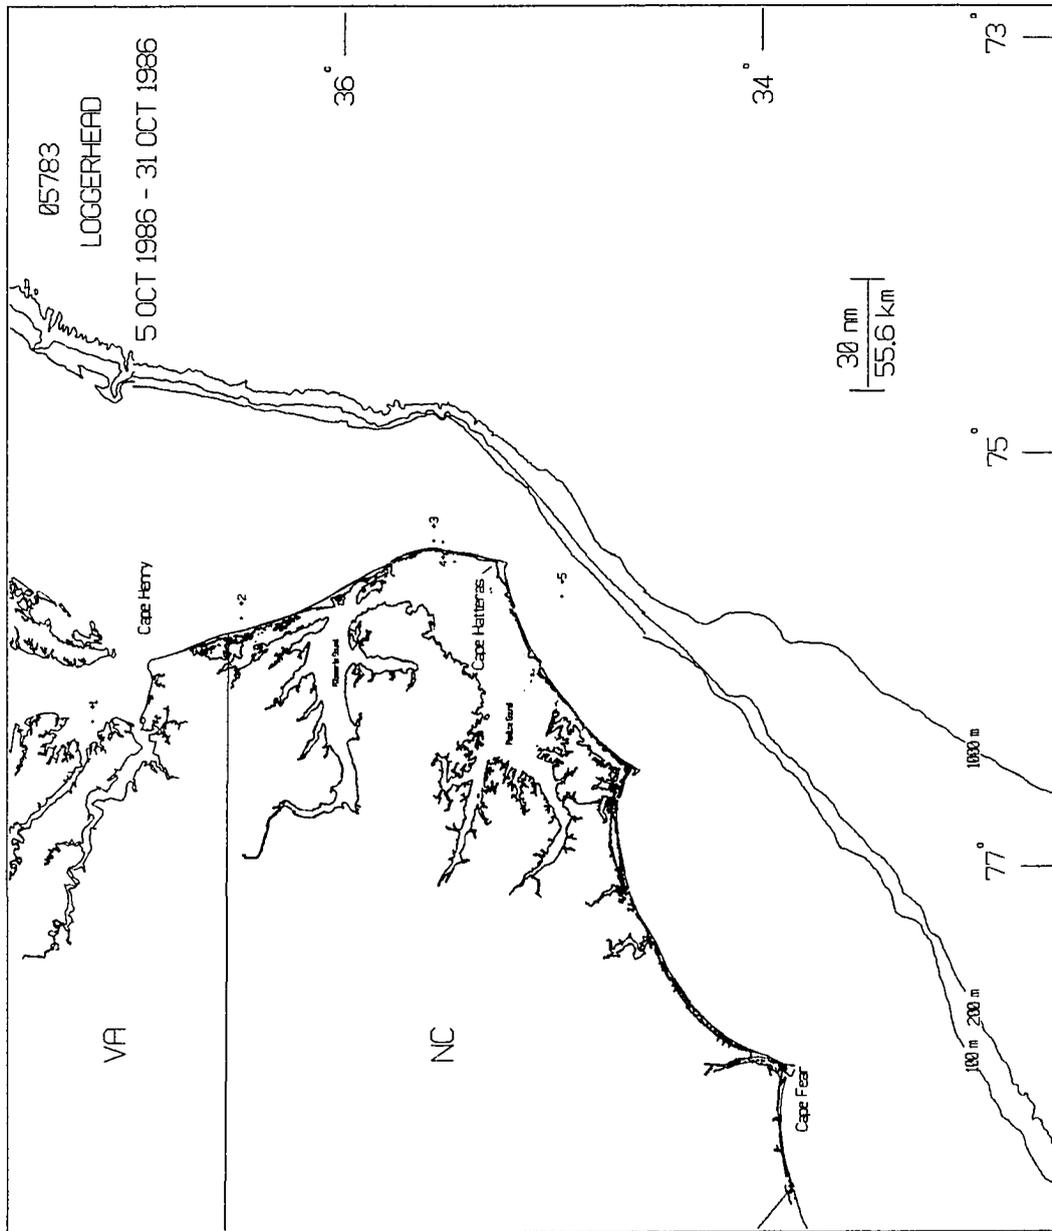

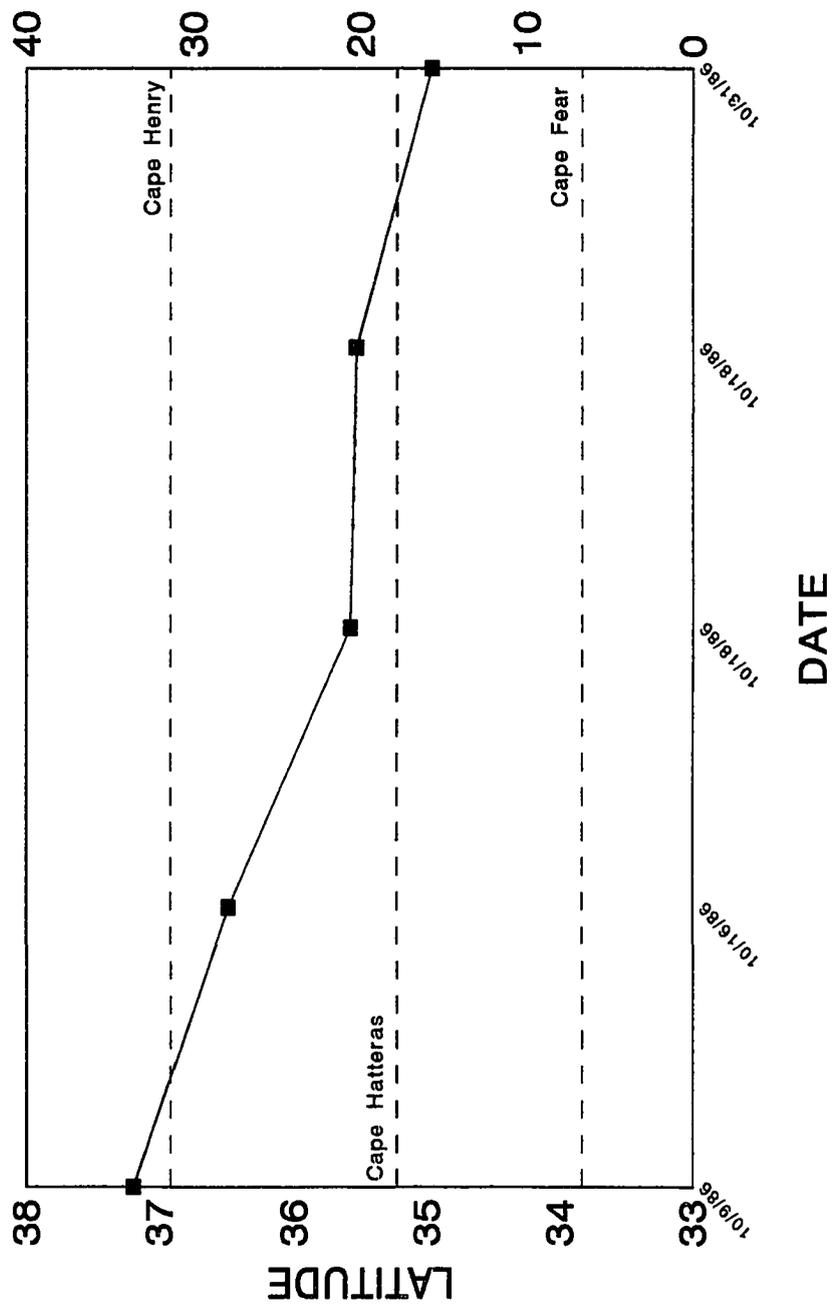

Figure 18. Latitude as a function of date of loggerhead sea turtle 05783 determined by satellite telemetry.

05783

the turtle. Heavy trawling activities were occurring in the area, and it was surmised that the turtle was captured in a trawl and the fisherman detached the transmitter from the turtle and set it adrift. The turtle moved at speeds up to 3 km/h, with a mean speed of 1.38 km/h (Table 8, Appendix 5).

Because of cold temperatures farther north, loggerhead 05784 was released off Oregon Inlet on 3 December 1987 (Table 7). The turtle entered the Gulf Stream and traveled to the north of Bermuda in the Atlantic Ocean (Figures 19 - 20, Appendix 6). The first week of January 1988 the turtle began swimming southwest and again entered the Gulf Stream and traveled north during late April. In early May the turtle began swimming southeast in deep water, and transmissions ceased on 31 May 1988 (Figures 19 - 20, Appendix 6). The turtle moved at speeds up to 5 km/h, with a mean speed of 1.62 km/h (Table 8, Appendix 6).

Loggerheads 04932 and 04933 were released at BBNWR on 9 November 1989 (Table 7). Both turtles traveled south nearshore and rounded Cape Hatteras the last week of November (Figures 21 - 24, Appendices 7 - 8). The turtles continued south nearshore and were off Savannah Georgia by mid-December, and off Cape Canaveral by Mid-January 1990. Loggerhead 04932 continued south to the eastern Florida Keys, where it remained until the transmitter ceased transmitting on 10 June (Figures 21 - 22, Appendix 7). The turtle moved at speeds up to 6 km/h, with a mean speed of 1.08 km/h (Table 8, Appendix 7). Loggerhead 04933 remained off Cape Canaveral until the middle of March when it began travelling north. The turtle passed Cape Fear and Cape Hatteras in early May, and entered the Chesapeake Bay in the second week of May (Figures 23 - 24, Appendix 8). The turtle moved at speeds up to 5 km/h, with a mean speed of 1.44 km/h (Table 8, Appendix 8).

Figure 19. Positions of loggerhead sea turtle 05784 determined by satellite telemetry. The turtle was released off Oregon Inlet, North Carolina on 3 December 1987 and the last location was received on 31 May 1988. Numbered points correspond to "POINT NO" in Appendix 6.

049333

Loggerheads 04934 and 04937 were released at VIMS on 22 October 1991 (Table 7), and both had tail and carapace lengths indicating the turtles were either mature or nearly mature males. The turtles traveled south and rounded Cape Hatteras the last week of October (Figures 25 - 28, Appendix 9 - 10). The turtles overwintered over the continental shelf between Cape Fear and Cape Lookout. The turtles began migrating north in mid-April to early May 1992, rounded Cape Hatteras in late May, and entered the Chesapeake Bay in early June (Figures 25 - 28, Appendices 9 - 10). Loggerhead 04934 moved at speeds up to 6 km/h, with a mean speed of 1.44 km/h (Table 8, Appendix 9), while turtle 04937 reached speeds up to 4 km/h with a mean speed of 1.12 km/h (Table 8, Appendix 10).

Loggerhead 04935 was released at BBNWR on 28 October 1991 (Table 7). The turtle traveled south and rounded Cape Hatteras the last week of October (Figures 29 - 30, Appendix 11). The turtle overwintered over the continental shelf just to the south of Cape Hatteras, and entered Pamlico Sound during March 1992. The turtle began migrating north in early May and transmissions ceased on 24 May when the turtle was off Kittyhawk North Carolina (Figures 29 - 30, Appendix 11). The turtle reached speeds up to 5 km/h with a mean speed of 1.63 km/h (Table 8, Appendix 11).

Loggerhead 01235 was telemetered while nesting at BBNWR on 30 July 1992 (Table 7). The turtle immediately traveled south, rounding Cape Hatteras on 9 August, and continued south. The turtle arrived off Florida on 29 August, and remained off northern Florida until 8 September, when transmissions ceased (Figures 31 - 32, Appendix 12). The turtle moved at speeds up to 6 km/h, with a mean speed of 2.10 km/h (Table 8, Appendix 12).

Figure 25. Positions of loggerhead sea turtle 04934 determined by satellite telemetry. The turtle was released at Gloucester Point, Virginia on 22 October 1991 and the last location was received on 15 June 1992. Numbered points correspond to "POINT NO" in Appendix 9.

# 01235

### MOVEMENTS - Head-started loggerheads

Head-started loggerhead 04931 was released at BBNWR on 4 October 1989 (Table 7). The turtle traveled offshore and south, and entered the Gulf Stream on 9 October (Figures 33 - 34, Appendix 13). The turtle traveled north-east in the Gulf Stream until 15 October, when it started heading north-west until the turtle was close to Cape May, New Jersey on 31 October. The turtle then started following the shoreline south, crossing the mouth of Chesapeake Bay on 13 November. The turtle continued south, and rounded Cape Hatteras on 24 November, and Cape Lookout on 10 December. The turtle continued south to off Cape Fear, when the transmitter ceased transmitting on 5 January 1990 (Figures 33 - 34, Appendix 13). The turtle moved at speeds up to 6 km/h, with a mean speed of 1.39 km/h (Table 8, Appendix 13).

Head-started loggerheads 01228, 01230, 01231, 01233, and 01234 were released at BBNWR on 18 September 1991 (Table 7). Turtle 01228 traveled east and entered the Gulf Stream, where it was carried eastward into the North Atlantic. From 29 September to 3 October the turtle was entrained in a cold core ring south of Cape Cod, then it continued east until the transmitter ceased on 14 October (Figure 35, Appendix 14). The turtle moved at speeds up to 9 km/h, with a mean speed of 3.48 km/h (Table 8, Appendix 14).

Head-started loggerhead 01230 traveled north and entered Chesapeake Bay on 19 September. The turtle continued west and entered Back Creek off the York River mouth on 21 September where it remained for 2 days, then the turtle began to swim east, exiting the Bay on 23 September. The turtle then traveled south along the coast to the Virginia - North Carolina boarder until 27 September, when it headed north-east. The signal ceased on 12 October, when the turtle was off

Figure 33. Positions of head-started loggerhead sea turtle 04931 determined by satellite telemetry. The turtle was released at Back Bay National Wildlife Refuge, Virginia Beach, Virginia on 4 October 1989 and the last location was received on 5 January 1990. Numbered points correspond to "POINT NO" in Appendix 13.

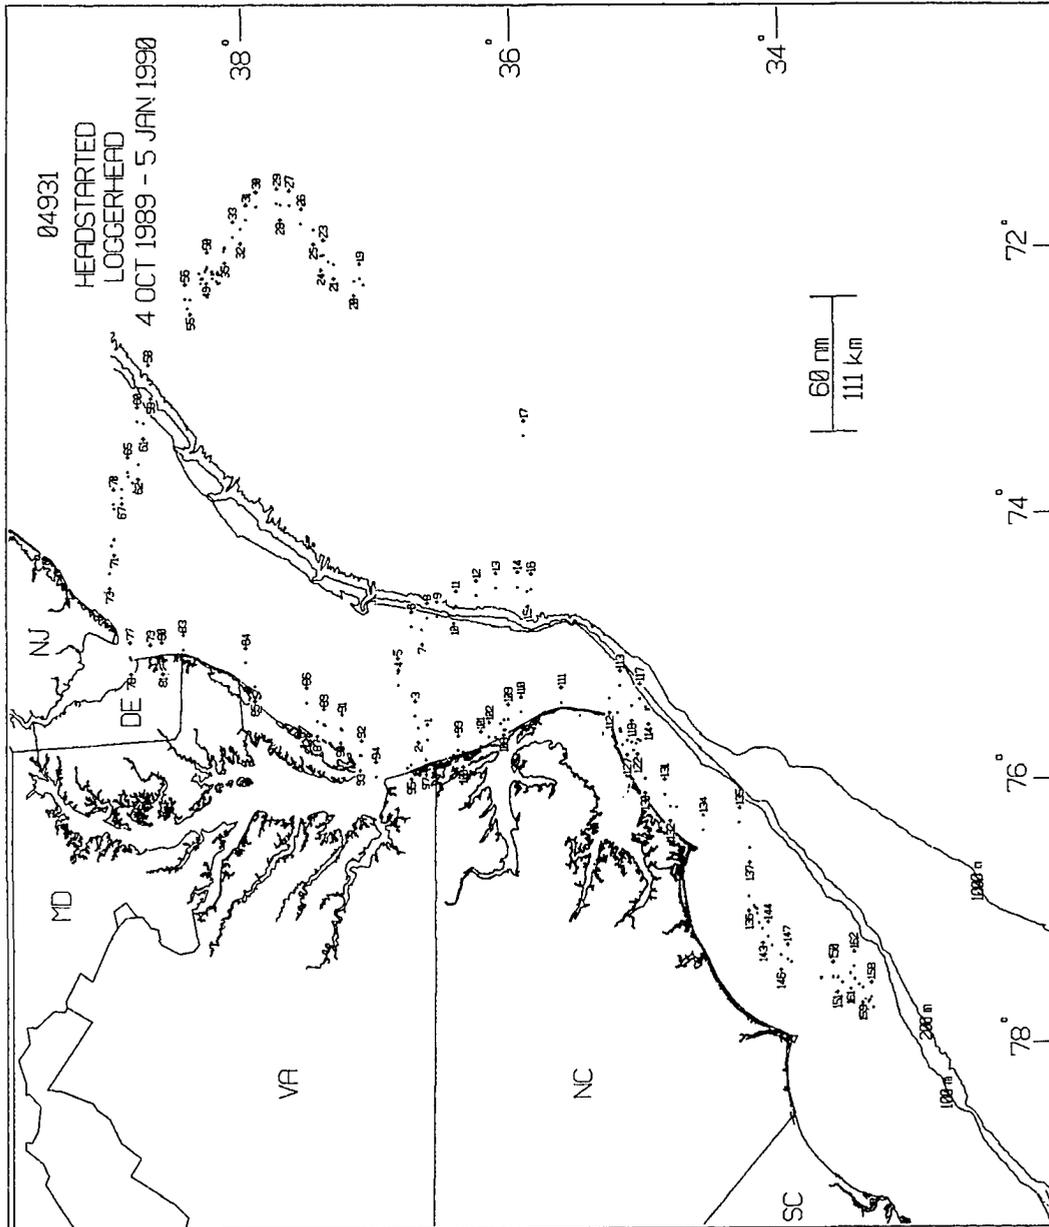

Figure 34. Latitude (squares) and selected temperatures (triangles) as a function of date of loggerhead sea turtle 04931 determined by satellite telemetry.

04931

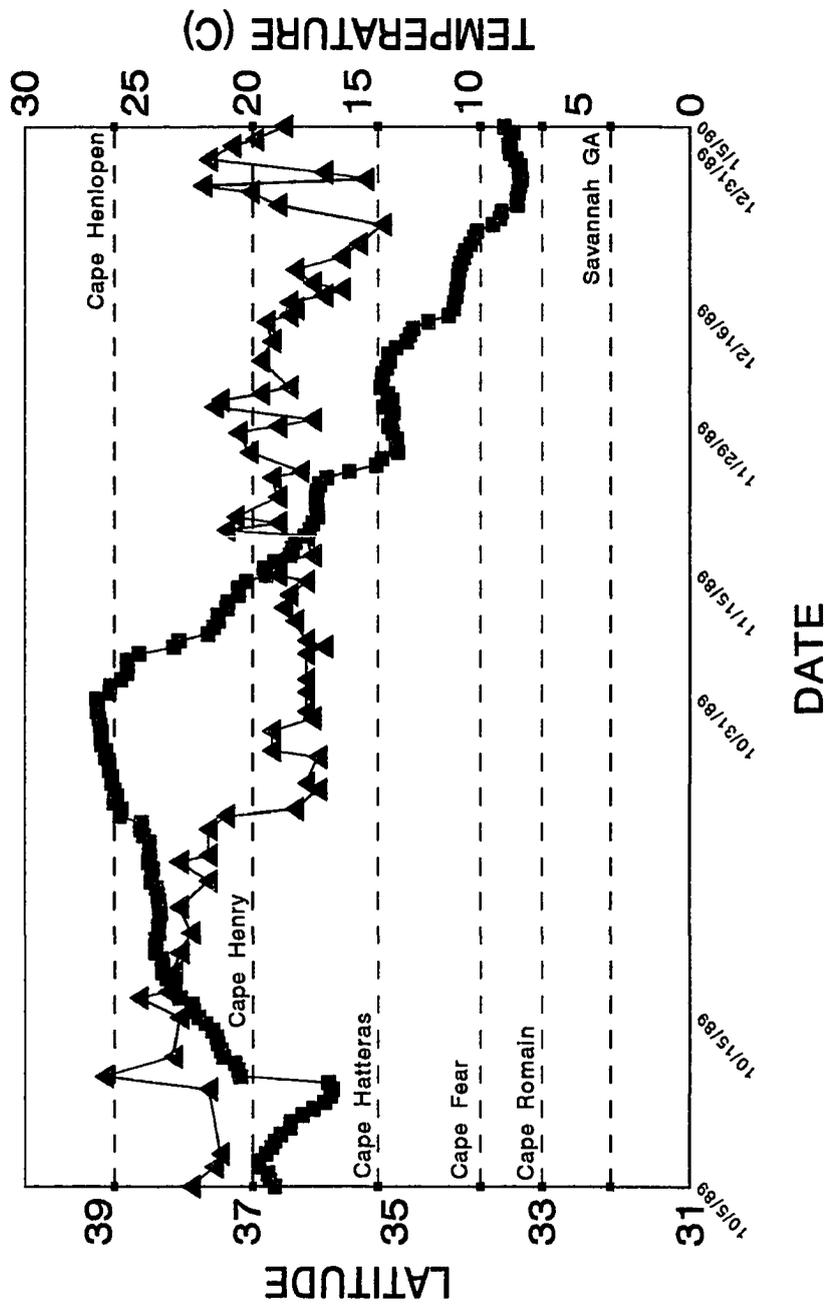

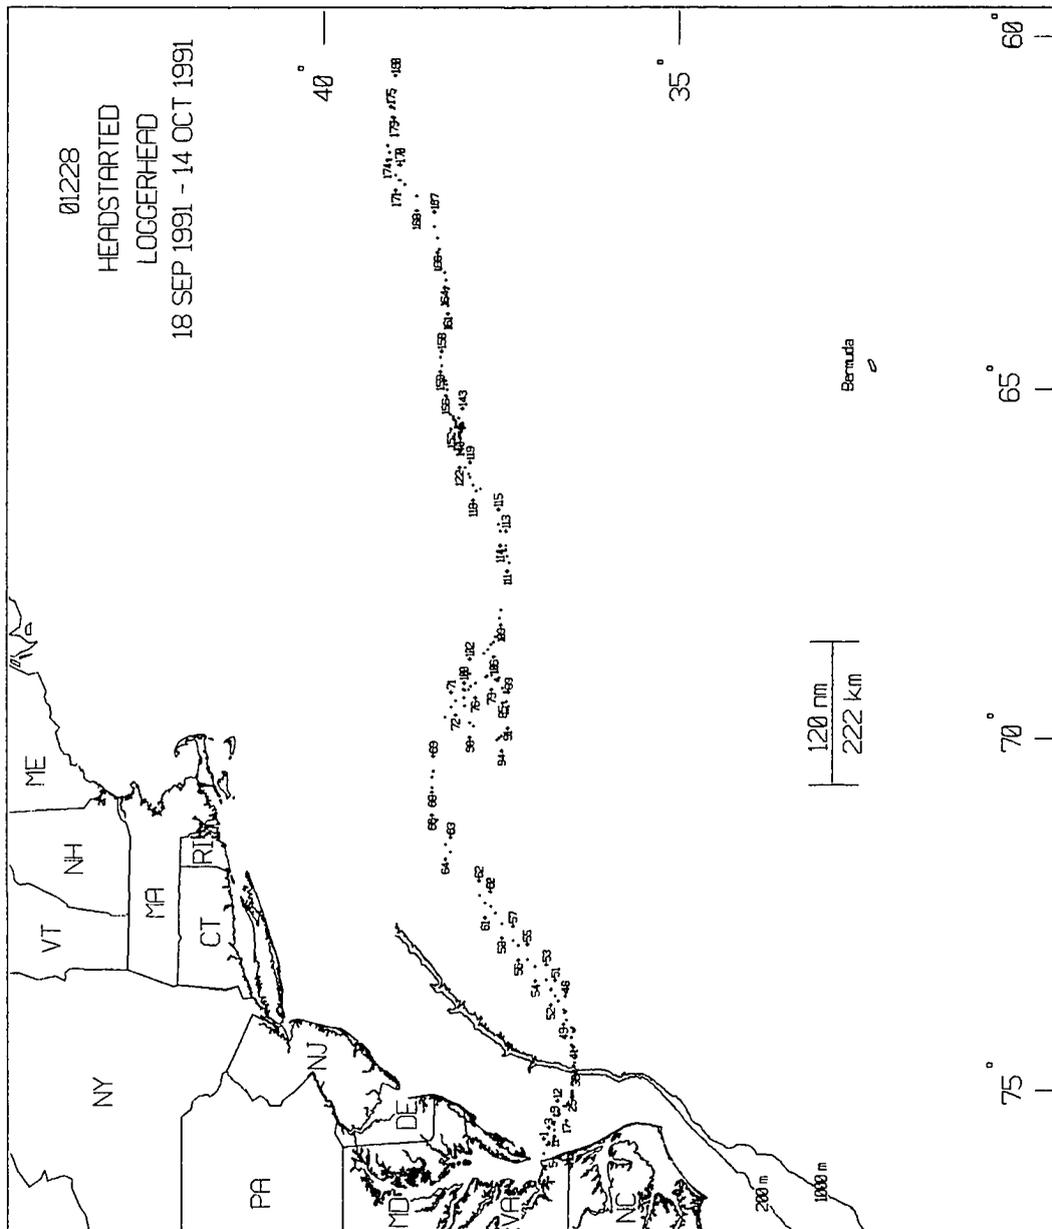

Figure 35. Positions of head-started loggerhead sea turtle 01228 determined by satellite telemetry. The turtle was released at Back Bay National Wildlife Refuge, Virginia Beach, Virginia on 18 September 1991 and the last location was received on 14 October 1991. Numbered points correspond to "POINT NO" in Appendix 14.

the Eastern Shore of Virginia (Figure 36, Appendix 15). The turtle moved at speeds up to 7 km/h, with a mean speed of 1.25 km/h (Table 8, Appendix 15).

Head-started loggerhead 01231 moved offshore, then headed in a southerly direction, entering Pamlico Sound through Oregon Inlet on 22 september. The turtle traveled south-westerly in the sound, and signals ceased on 5 October (Figure 37, Appendix 16). The turtle moved at speeds up to 5 km/h, with a mean speed of 1.48 km/h (Table 8, Appendix 16). The turtle subsequently became trapped in a pound net on 14 October 1991. The turtle was released, and the fishermen reported that the turtle seemed in 'bad shape'.

Head-started loggerhead 01233 traveled south along shore until 10 October, when like turtle 01228, it entered the Gulf Stream and headed across the North Atlantic. Transmission ceased on 17 October, when the turtle was south-east of Cape Cod (Figure 38, Appendix 17). The turtle moved at speeds up to 8 km/h, with a mean speed of 2.01 km/h (Table 8, Appendix 17).

Head-started loggerhead 01234 traveled south, nearshore to Oregon Inlet. The turtle remained in the Oregon Inlet vicinity from 23 September to 25 September when transmissions ceased (Figure 39, Appendix 18). The turtle moved at speeds up to 7 km/h, with a mean speed of 1.64 km/h (Table 8, Appendix 18).

Head-started turtle 04936 was released at BBNWR on 23 October 1991 (Table 7). The turtle traveled south, near shore and rounded Cape Hatteras on 4 November. The turtle reached Ocracoke Inlet on 10 November, then started travelling north-east until 27 November when the turtle was offshore of the Virginia - North Carolina boarder. The turtle then swam north-west until 9 december when it was off the Eastern

Shore of Virginia. The turtle then began a southerly course, and the transmissions ceased on 11 December when the turtle was off Cape Henry, Virginia (Figure 40, Appendix 19). The turtle moved at speeds up to 8 km/h, with a mean speed of 2.00 km/h (Table 8, Appendix 19).

Figure 36. Positions of head-started loggerhead sea turtle 01230 determined by satellite telemetry. The turtle was released at Back Bay National Wildlife Refuge, Virginia Beach, Virginia on 18 September 1991 and the last location was received on 12 October 1991. Numbered points correspond to "POINT NO" in Appendix 15.

Figure 37. Positions of head-started loggerhead sea turtle 01231 determined by satellite telemetry. Numbered points correspond to "POINT NO" in Appendix 18.

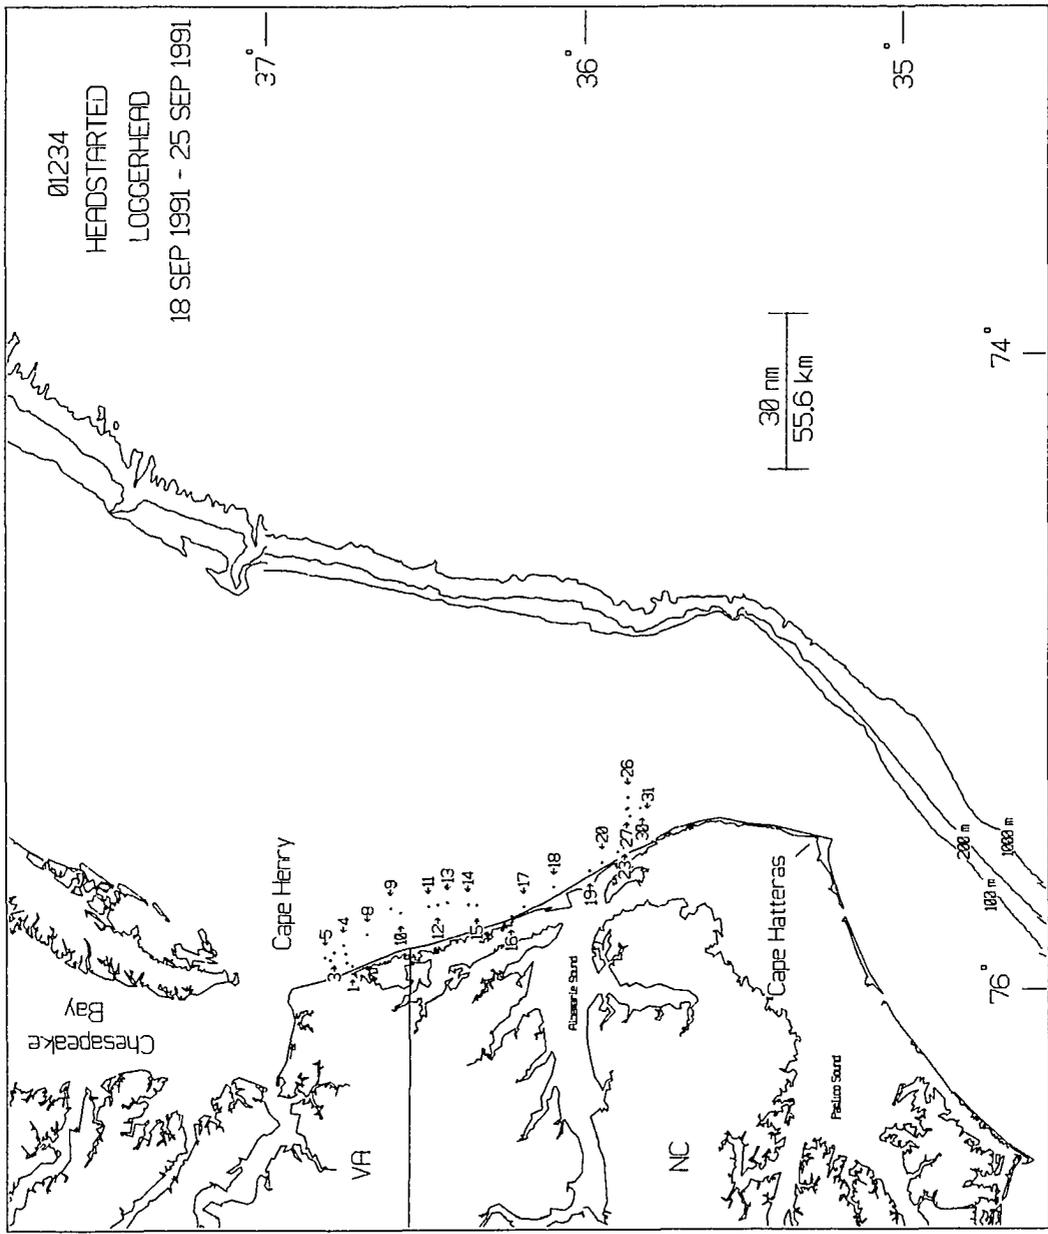

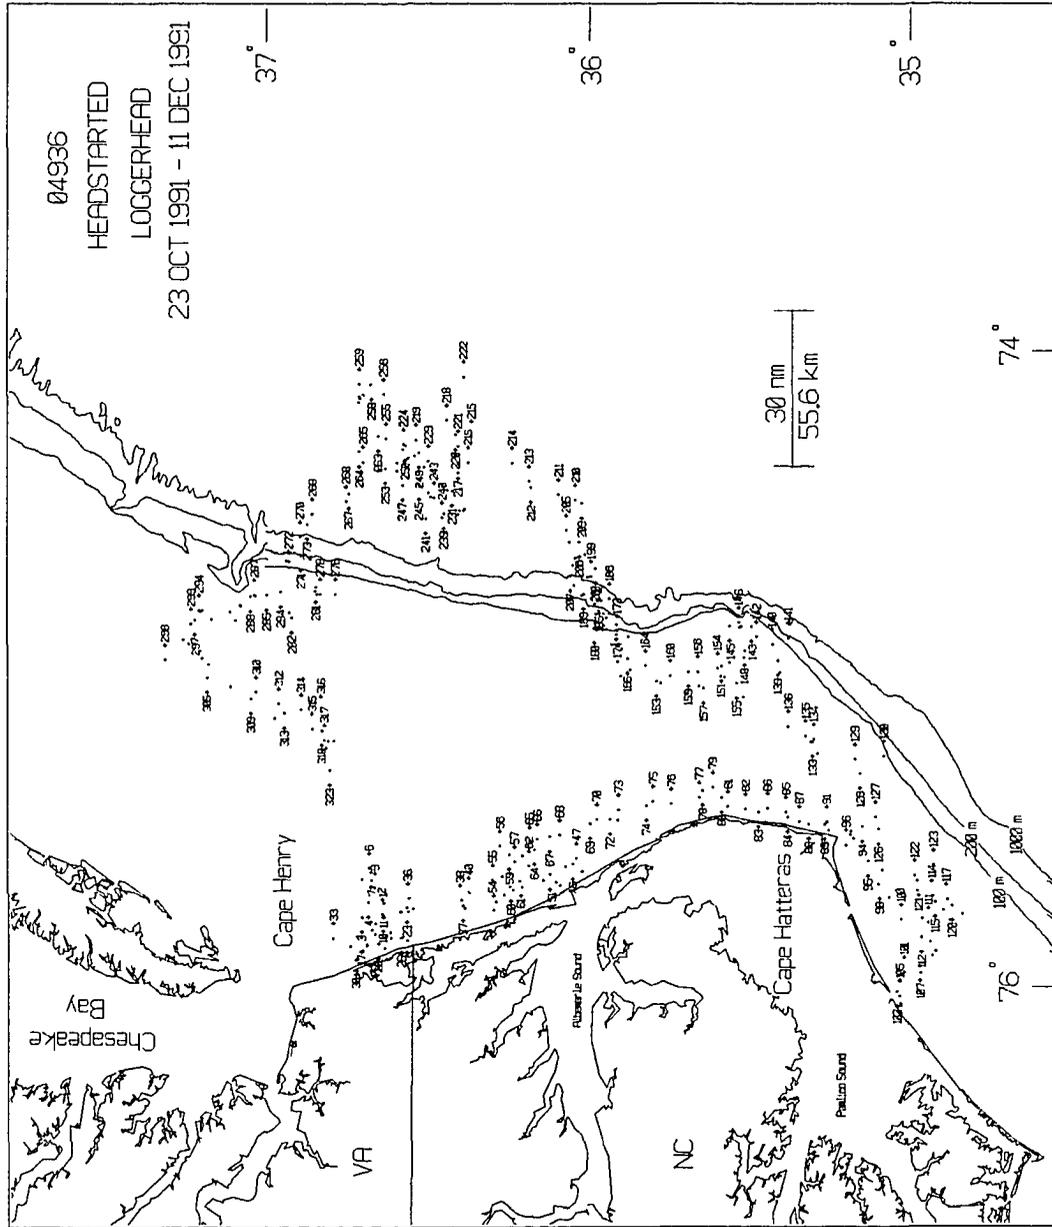

Figure 40. Positions of head-started loggerhead sea turtle 04936 determined by satellite telemetry. The turtle was released at Back Bay National Wildlife Refuge, Virginia Beach, Virginia on 23 October 1991 and the last location was received on 11 December 1991. Numbered points correspond to "POINT NO" in Appendix 19.

## TEMPERATURES

Kemp's ridley 1229 traveled from Virginia to north of Cape Fear in 22 days (Table 7, Figures 11 - 12, Appendix 2). During that time the turtle encountered water ranging from 13 - 19 C, and the average temperature was 16.6 C (Table 9, Appendix 20). The temperature increased after the turtle rounded Cape Hatteras, then levelled to approximately 16 C as the turtle traveled south, decreasing to less than 15 C as the turtle approached Cape Fear (Figure 12).

Kemp's ridley 4938 traveled from Virginia to Florida in 83 days (Table 7, Figures 13 - 14, Appendix 3). The turtle encountered temperatures from 14 - 21 C, with an average temperature of 16.7 C (Table 9, Appendix 21). In general, temperatures ranged from 15 - 18 C, with two instances when temperatures were above 20 C (Figure 14). These high temperatures were most likely due to solar input during basking.

Kemp's ridley 4939 traveled from Virginia to Florida in 69 days (Table 7, Figures 15 - 16, Appendix 4). Temperatures ranged from 15 - 23 C, averaging 16.9 C (Table 9, Appendix 22). In general, temperatures were between 15 - 20 C (Figure 16).

Wild loggerhead 4932 traveled from Virginia to southern Florida in 214 days (Table 7, Figures 21 - 22, Appendix 7). Temperatures ranged from 15 - 33 C, averaging 23.1 C (Table 9, Appendix 23). Temperatures remained about 15 - 20 C until the turtle entered Florida's waters, then temperatures steadily increased, up to 30 C (Figure 22).

Wild loggerhead 4933 traveled from Virginia to Florida and back in 226 days (Table 7, Figures 23 - 24, Appendix 8). Temperatures ranged from 9 - 25 C, averaging 18.3 C (Table 9, Appendix 24). As the turtle traveled south into Florida's waters, temperature dropped steadily from 30 C to 18 C, then as the turtle approached Cape Canaveral, temperatures

increased to ca. 20 C, and the turtle remained in water >18 C until the transmitter ceased transmitting when the turtle was in Chesapeake Bay (Figure 24).

Wild loggerhead 4934 traveled from Virginia, overwintered off Raleigh Bay, and returned to Virginia in 238 days (Table 7, Figures 25 - 26, Appendix 9). Temperatures ranged from 9 - 32 C, averaging 20.4 C (Table 9, Appendix 25). In general, temperatures ranged from 20 - 25 C, until March 1992, when the turtle started on a northerly course to Cape Hatteras and the turtle encountered waters down to 15 C (Figure 26). The turtle then traveled south, to Cape Fear, where the waters warmed to > 20 C. In mid April the turtle again headed north, and again encountered water temperatures to 10 C, however the turtle remained in the Cape Hatteras area until heading north into Chesapeake Bay (Figure 26).

Wild loggerhead 4937 also overwintered off Raleigh Bay, and returned to Virginia in 271 days (Table 7, Figures 27 - 28, Appendix 10). Temperatures ranged from 12 - 26 C, averaging 19.9 C (Table 9, Appendix 26). Temperatures fluctuated from ca. 14 - 22 C throughout the autumn and winter months, until early June, when the turtle started moving north, encountering water temperatures which increased to 25 C (Figure 28).

Wild loggerhead 4935 overwintered in Onslow Bay, returning to Virginia in 210 days (Table 7, Figures 29 - 30, Appendix 11). Temperatures ranged from 6 - 24 C, averaging 14.5 C (Table 9, Appendix 27). Temperatures fluctuated dramatically during the winter months, reaching a low of 6 C in early February. Even when the turtle started its northward migration, temperatures remained below 18 C, down to ca. 12 C (Figure 30).

Nesting loggerhead 1235 immediately traveled south to Florida in 41 days (Table 7, Figures 31 - 32, Appendix 12). Throughout the trip temperatures remained from 24 - 27 C, averaging 25.6 C (Table 9, Figure 32, Appendix 28).

Of the head-started loggerheads, only the 3 yr old turtle (4931) traveled in significant north-south directions (Figures 33 - 34), over 94 days (Table 7, Appendix 13). Temperatures ranged from 14 - 30 C, averaging 19.8 C (Table 9, Appendix 29). As the turtle traveled north in the Gulf Stream, temperatures remained over 20 C, however, as the turtle swam inshore toward Delaware Bay (Figure 33), temperatures dropped to ca. 18 C (Figure 34). Although the turtle began travelling south in early November, temperatures did not increase dramatically. Temperatures remained in the 15 - 20 C range throughout the remainder of the track (Figure 34).

All of the 2 yr old turtle's tracks were of limited duration and geographic range. Temperatures ranged from 15 - 28 C, with averages ranging from 19.5 to 24.7 C (Table 9, Appendices 30 - 35).

Temperatures of Kemp's ridley turtles were the lowest of the three groups, averaging 16.8 C, and also exhibited the smallest variability (Table 9). Wild loggerhead temperatures averaged 19.6 C, with the highest variability, while head-started loggerhead temperatures were the highest, averaging 21.0 C, with intermediate variation (Table 9). This data did not meet parametric assumptions, and a Kruskal Wallis nonparametric analysis of variance (SPSS, 1986) tested significantly ( $\chi^2 = 196.8$ ,  $N = 1617$ ,  $P < 0.0001$ ). A multiple comparison test (Siegel and Castellan, 1988) showed all three groups significantly different from each other at  $\alpha = 0.05$ .

## DIVING BEHAVIOR

Kemp's ridley turtles spent an average of 25.8 to 88.1 minutes submerged per dive in a 12 h period, up to an average of 356 minutes per dive in a 12 h period (Table 10, Appendices 20 - 22). The turtles dove from once during the 12 h period, up to 182 dives per 12 h, with an average of 13.3 to 36.7 dives in a 12 h period (Table 11, Appendices 20 - 22). During these 12 h periods, the turtles spent up to 98.8 percent of the time submerged, with averages ranging from 25.5 to 91.8 percent (Table 12).

Wild loggerhead turtles spent an average of 13.2 to 124.8 minutes submerged per dive in a 12 h period, up to an average of 358 minutes per dive in a 12 h period (Table 10, Appendices 23 - 28). The turtles dove had from 1 to 269 dives per 12 h, with an average of 14.6 to 38.3 dives in a 12 h period (Table 11, Appendices 23 - 28). During these 12 h periods, the turtles spent up to 99.5 percent of the time submerged, with averages ranging from 70.7 to 94.3 percent (Table 12).

Head-started loggerhead turtles spent an average of 8.6 to 47.5 minutes submerged per dive in a 12 h period, up to an average of 237 minutes per dive in a 12 h period (Table 10, Appendices 29 - 35). The turtles dove from once during the 12 h period, up to 291 dives per 12 h, with an average of 25.8 to 116.3 dives in a 12 h period (Table 11, Appendices 29 - 35). During these 12 h periods, the turtles spent up to 99.9 percent of the time submerged, with averages ranging from 36.9 to 74.7 percent (Table 12).

Mean dive duration, transformed by  $\log_{10}$ , was the only dive parameter which met parametric assumptions, and ANOVA was used to test for differences between wild loggerheads, head-started loggerheads, and Kemp's ridleys. A nonparametric Kruskal Wallis test was used on the

other variables. Significant differences were observed at the  $\alpha = 0.05$  level on all tests (Table 13). The appropriate multiple range tests showed mean dive durations and number of dives in a 12 h period of head-started turtles different from wild loggerheads and Kemp's ridleys, which were not significantly different from each other. Significant differences between percentage of time spent submerged in a 12 h period were observed for all groups (Table 13).

## DISCUSSION

### Wild turtles

Hatchling loggerheads and Kemp's ridleys enter major oceanic currents (such as the North Atlantic gyre) for the first few years of their lives (Carr, 1986a, 1986b). At approximately 40 cm carapace length (CL), loggerhead turtles (and smaller Kemp's ridleys) adopt benthic habits in lagoon, estuaries, and mouths of bays and rivers (Dodd, 1988; Ogren, 1989) which are rich in food resources. Although Morreale et al. (1992) suggested that Kemp's ridleys found in Long Island Sound are of a single year class (this may be the beginning of the benthic habit for Kemp's ridley), and do not return in subsequent seasons, flipper tagging showed that individuals of both Kemp's ridley and loggerheads utilize Chesapeake Bay for more than one season. This is reflected in the large size ranges of individuals found in Virginia's waters (35 - 105 cm CL for loggerheads, 20 - 60 cm CL for Ridleys, Bellmund et al., 1987; Musick et al., 1985a).

In general, population densities of loggerheads reached a maximum from Cape Hatteras south in April with a secondary peak in November. North of Cape Hatteras population densities were highest in May with a secondary peak in November. The high density estimates observed on 6 August 1985, 4 July 1986, 29 July 1988, and 8 July 1992 may have been due to changes in the turtles' surfacing behavior rather than to real increases in standing stocks. The coastal region from Cape Hatteras to New Jersey is subject to periodic upwelling caused by prolonged

southwesterly winds in July and August (Hicks and Miller, 1980; Ingham and Eberwine, 1984; Norcross and Austin, 1988; Wells and Gray, 1960). This phenomenon pulls in cold bottom water from offshore and establishes a strong thermocline. Loggerheads tend not to swim through a strong thermocline, and may spend more time on the surface (Keinath and Musick, Unpub. data).

Standing stocks of turtles in the 1991 - 1992 study areas during the spring migration were between 2000 - 3000 turtles, while less than 1000 turtles were observed during the southward fall migration. The large number of turtles observed during the northward migration probably reflects turtles concentrated behind fronts of cool water to the north. Although lower than the standing stock of the lower Chesapeake Bay (ca. 7000) calculated by Byles (1988), the number of turtles estimated travelling through these three zones are a significant number of turtles which overwinter in Chesapeake Bay. Shoop and Kenney (1992) estimated >7000 loggerheads inhabit the offshore waters of the continental shelf from Nova Scotia to Cape Hatteras during summer months, with fewer turtles present during spring (ca. 1500) and fall (ca. 3000), with virtually no turtles present during the winter. These numbers are much lower than estimated in the present study, and may reflect temporal and geographic differences in sampling coverage and differences in survey methods and standing stock calculations (Shoop and Kenney, 1992 did not account for submerged turtles). Accounting for submerged turtles, Shoop and Kenney's (1992) data suggested numbers of loggerheads (ca. 7000 - 15,000) present from Virginia to Cape Hatteras during the spring and autumn which are larger than (but comparable to) the numbers estimated in the present (small) study area.

Aerial surveys and satellite telemetry showed that loggerheads

migrated south from waters north of Cape Hatteras in the autumn, rounding Cape Hatteras during October and November. Once south of Hatteras, telemetered loggerheads either became pelagic in deep oceanic waters (one loggerhead), traveled nearshore to Florida (two loggerheads), over-wintered off North Carolina in the west side of the Gulf Stream (three loggerheads), or transmissions ceased shortly after rounding the Cape. One loggerhead which overwintered off Florida and three which overwintered off North Carolina returned to the Chesapeake Bay the following year, rounding Cape Hatteras during May. Aerial surveys also detected a northerly spring migration past Cape Hatteras in May. These migratory patterns are consistent with data collected on other aerial surveys (CeTAP, 1982a, 1982b; Shoop et al., 1981; Shoop and Kenney, 1992).

Byles (1988) satellite tagged two loggerhead turtles in 1985. One turtle which was released off the mouth of the Chesapeake Bay traveled south nearshore, similarly to the turtles in this study, but then entered Pamlico Sound through Oregon Inlet when the transmitter detached from the turtle after 36 days. The other turtle was released off Oregon Inlet on 21 November. Like the turtles tracked in this study, the turtle traveled south, near shore, past Cape Lookout, but became pelagic in the Gulf Stream during mid-December, travelling north until transmissions ceased. This behavior is similar to turtle number 5784, which became pelagic in the Gulf Stream. Because of the large size of these early transmitters, the instrumented turtles were of a relatively large size (> 80 cm). The pelagic behavior was initially thought to be related to near adult-sized turtles, but latter tracks of large turtles (4934, 4937) refuted that hypothesis. It may be possible that the release sites of the turtles (far from their original capture site in

Chesapeake Bay) accounted for the pelagic behavior, or that the presence of the large, trailing transmitters affected their behavior. However, open ocean movement of a juvenile loggerhead has been reported (Eckert and Martins, 1989).

Two other overwintering strategies were observed in loggerheads: migrating south to warm water, or offshore to warm Gulf Stream waters over reef habitats (Newton et al., 1971). The former strategy was exhibited by two juveniles, and was similar to the migratory route presumably taken by a juvenile loggerhead which I flipper tagged in Rhode Island and latter washed up dead on Cumberland Island, Georgia (Shoop and Ruckdeschel, 1989). The latter strategy was displayed by two (near?) adult males and an average-sized juvenile, discounting a migratory destination preference due to differing age classes. Bowen (pers. com.) found genetic differences between the loggerhead nesting population in Florida and nesters to the north, and if a genetic difference exists, one would expect turtles hatched in the north to overwinter off the northern beaches, and conversely turtles hatched in Florida to overwinter off Florida. However, if there were a difference in overwintering strategies due to genetic differences (birthplace), one would not expect the loggerhead satellite tagged while nesting in Virginia to migrate to Florida. Conversely meteorological conditions may dictate migratory destinations. If winter temperatures are moderate, it would be energetically advantageous to overwinter off North Carolina instead of swimming to Florida. Alternately, rapid onset of cold weather may dictate migration: If the autumn temperatures are mild over a long period turtles would have sufficient time to migrate south close to shore. But if temperatures drop quickly, turtles may respond by swimming to warm offshore waters. In this scenario, it would be

energetically advantageous to remain in warm Gulf Stream waters rather than swim south against the northerly current. The paucity of flipper tag returns from the south suggests that overwintering off North Carolina may be a prevalent strategy.

Two of the three Kemp's ridleys were tracked south to Florida in the autumn, consistent with flipper tag returns. It is unlikely that Kemp's ridleys would overwinter in deeper offshore waters, since this species is characterized as a shallow water benthic forager (< 50 m; Shaver, 1991). Although Kemp's ridleys are hard to detect by aerial survey, relative temporal and geographic trends in ridley population abundance probably closely reflect those of loggerheads (but absolute abundance is much lower). The tracking data suggest that ridleys migrate through the Hatteras migration corridor at the same time as loggerheads.

All the turtles which migrated to Florida (three loggerheads and two ridleys) remained inshore of the Gulf Stream, reducing energetic output. Surface water drift south of Cape Fear is southerly (Barans and Roumillat, 1976), and turtles may obtain an energetic advantage by utilizing these currents for southerly transport. However, the loggerhead which migrated north to Chesapeake Bay from Florida in the spring (4933) utilized the same routes in both directions. If the currents are consistent seasonally, no net advantage would have been realized.

Speeds attained by both wild loggerheads and Kemp's ridleys were relatively consistent. Speeds up to 6 km/h were attained by both species, possibly due to local currents, although long term mean speeds were 1 - 2 km/hr. These speeds probably underestimate speeds attained while actively migrating, since turtles appear to "stop and rest" at

certain areas. These areas may be inlet channels, preferred feeding areas, or simply areas which possess elevated temperatures adequate for foraging. Swimming speeds of loggerheads and Kemp's ridleys are comparable to leatherbacks, although leatherbacks can attain faster burst speeds (Keinath and Musick, in press).

During autumn and winter, Kemp's ridley turtles remained in water temperatures consistently between 15 and 20 C, while loggerheads experienced temperatures ranging both higher and lower. In many instances, turtles were relatively sedentary when temperatures dropped, and in response the animals traveled south to warmer waters. The two loggerheads which migrated to Florida experienced the coolest temperatures from the beginning of their migration until late December or early January, when the turtles were between Savannah, Georgia and Cape Canaveral, Florida. Upon reaching Cape Canaveral, water temperatures increased to over 18 C.

The two loggerheads which overwintered off Cape Fear experienced temperatures consistently between 15 - 25 C, while the turtle which overwintered off Cape Hatteras experienced more widely fluctuating temperatures around 15 C. During March and April, all three turtles made northerly excursions, experiencing cold water temperatures, and in response the animals traveled south into warmer waters.

Although temperatures as low as 6 C were recorded, it appears that turtles move south into warmer waters in response to temperatures which approach 15 C, lower than that (18 C) suggested by Lutcavage and Musick (1985) and substantially lower than the temperature (22 C) where most loggerheads were observed on offshore aerial surveys (Shoop and Kenney, 1992). Although 15 C is generally accepted as a lower limit for occurrences of wild sea turtles, the lower temperatures experienced are

close to lethal. Schwartz (1978) reported that prolonged exposure to 5.0 - 6.5 C is lethal to loggerheads and ridleys, and that turtles bob to the surface when exposed to water temperatures below 10 C. Barco and Pitchford (1990) reported four loggerheads and one Kemp's ridley which stranded in response to 10 C water temperatures in Virginia waters. However, Anonymous (1992) reported turtle sightings off North Carolina in waters as cold as 6 C, and trawled turtles in waters 10 C, all with no apparent signs of cold stunning. It appears that at least some turtles can tolerate temperatures as low as 6 C, although 10 C may be marginal. However, although temperatures experience by wild turtles fluctuated between 6 - 30 C at certain times, overall the temperatures remained within a range of 15 - 25 C.

Loggerhead and Kemp's ridleys exhibited a wide range of dive durations and number of dives per 12 h period. Byles (1988) reported mean dive durations of ridleys in Chesapeake Bay of 12.7 min, and 18.9 min for loggerheads, and Keinath (1986) reported dive durations of 2 - 5 min for loggerheads off Rhode Island. Because of the need for increased oxygen exchange due to swimming activity, one would expect migrating turtles to exhibit shorter dive times than exhibited by the sedentary turtles studied by Byles (1988). However, with the exception of one Kemp's ridley and the nesting loggerhead, turtles spent 80 - 94% of the time submerged, or 6 - 20% of the time at the surface, more than the 5% reported by Byles for summer resident loggerheads in Chesapeake Bay. This data may be further confounded since some turtles which migrated south subsequently became sedentary for the winter months. Turtle 1235, which immediately migrated south showed lower mean submergence duration and percentage of time submerged than reported by Byles (1988) for sedentary loggerheads and may be more representative of turtles in

active migration.

The respiratory behavior of one Kemp's ridley (1229) was dramatically different from the other ridley's, spending more time at the surface, and this lack of underwater activity contributed to the short duration of the track. This turtle had one front flipper missing, presumably from a large fish attack, and had been rehabilitated at VIMS for the previous few years. Perhaps this physical challenge contributed to the abnormal diving behavior, however the movements and, surprisingly speed, of the turtle were consistent with the other ridleys.

#### Head-started turtles

Movements and diving behavior of head-started loggerheads were different than wild loggerheads. Head-started loggerheads which remained in the coastal area exhibited swimming speeds comparable to wild loggerheads, however speeds of turtles which entered the Gulf Stream were greater, probably reflecting the movement of that system. Two year old loggerheads which inhabit the Gulf Stream spend a majority of the time at the surface, foraging on infauna, and although the size of the head-started turtles in this study were representative of 7 - 10 year old turtles (Klinger and Musick, 1992), it appears that the head-started turtles acted more like two year olds: number of dives per 12 h period was greater than wild turtles, and dive durations and amount of time spent submerged was small compared to wild turtles. Like Kemp's ridley 1229, the small amounts of time spent submerged probably contributed to the short track durations because of battery drain.

The track of one head-started turtle (4931) was significantly longer than the other turtles, and this was the only 3 yr old turtle studied. Initially this turtle moved into the Gulf Stream but after moving in-shore, it began to migrate south, similar to wild turtles. In

addition, this turtle made less frequent dives and spent more time submerged per dive than the 2 yr olds, although the percent of time spent submerged per 12 hr period was similar among most of the head-started turtles. Perhaps the switch from a pelagic to benthic habitat of wild loggerheads occurs between 2 and 3 years of age. Additional (and longer term) studies of 2 and 3 yr old head-started loggerheads may reveal the abilities of head-started turtles to adapt to the wild, and the timing of adoption of benthic habitats.

Because of the short durations of tracks of the other 2 yr old turtles, the longer term movements of these turtles is unknown, but the two turtles which entered the North Atlantic gyre certainly could not have returned to a near-shore migratory pattern. Three of the other head-started turtles may have begun a southerly migration after cessation of signals. Conversely, the time between the two age classes may be the time when pelagic turtles begin a benthic habit, but longer duration experiments must be undertaken.

The final result of head-starting sea turtles, to increase the populations of nesting females, has not been realized, and the present study suggests that head-starting may be a futile process. Head-started loggerheads do not appear to behave as wild turtles and seem to lack migratory or navigational skills exhibited by wild loggerheads of similar size. The fast growth rates (compared to wild turtles) exhibited by head-started turtles confounds the practice. Head-started turtles are released in areas where neither their size (or age) cohorts are found. If head-starting continues, studies into locations of wild turtles of similar size and ages should be initiated, and head-started turtles should be released in those areas. However, it remains uncertain that those turtles would survive. The time and funds

presently appropriated for head-starting would be better allocated for protecting nests and nesting beaches, along with protecting larger sized individuals (Crouse et al., 1987), and implementation of conservation oriented fishing practices (Committee on Sea Turtle Conservation, 1990).

Appendix 2. Data from Kemp's ridley 1229 tracked via satellite in 1991. POINT NO. corresponds to numbered points in Figure 11. TIME in Greenwich mean time, LAT = north latitude, LONG = west longitude, TSLL = time since last location in minutes, DSLL = distance since last location in km, SPEED = speed since last location in km/h.

POINT NO.	DATE	TIME (GMT)	LAT	LONG	TSLL (m)	DSLL (km)	SPEED (km/h)
1	24-Oct-1991	9:21:42	36.674	75.903

Appendix 3. Data from Kemp's ridley 4938 tracked via satellite in 1991 - 1992. POINT NO. corresponds to numbered points in Figure 13. TIME in Greenwich mean time, LAT = north latitude, LONG = west longitude, TSLL = time since last location in minutes, DSLL = distance since last location in km, SPEED = speed since last location in km/h.

POINT NO.	DATE	TIME (GMT)	LAT	LONG	TSLL (m)	DSLL (km)	SPEED (km/h)

Appendix 4. Data from Kemp's ridley 4939 tracked via satellite in 1991 - 1992. POINT NO. corresponds to numbered points in Figure 15. TIME in Greenwich mean time, LAT = north latitude, LONG = west longitude, TSLL = time since last location in minutes, DSSL = distance since last location in km, SPEED = speed since last location in km/h.

POINT NO.	DATE	TIME (GMT)	LAT	LONG	TSLL (m)	DSSL (km)	SPEED (km/h)

Appendix 8. Data from loggerhead 4933 tracked via satellite in 1989 - 1990. POINT NO. corresponds to number points in Figure 23. TIME in Greenwich mean time, LAT = north latitude, LONG = west longitude, TSLL = time since last location in minutes, DSLL = distance since last location in km, SPEED = speed since last location in km/h.

POINT NO.	DATE	TIME (GMT)	LAT	LONG	TSLL (m)	DSLL (km)	SPEED (km/h)

Appendix 9. Data from loggerhead 4934 tracked via satellite in 1991 - 1992. POINT NO. corresponds to number points in Figure 25. TIME in Greenwich mean time, LAT = north latitude, LONG = west longitude, TSLL = time since last location in minutes, DSLL = distance since last location in km, SPEED = speed since last location in km/h.

Appendix 10. Data from loggerhead 4937 tracked via satellite in 1991 - 1992. POINT NO. corresponds to number points in Figure 27. TIME in Greenwich mean time, LAT = north latitude, LONG = west longitude, TSLL = time since last location in minutes, DSLL = distance since last location in km, SPEED = speed since last location in km/h.

Appendix 11. Data from loggerhead 4935 tracked via satellite in 1991 - 1992. POINT NO. corresponds to number points in Figure 29. TIME in Greenwich mean time, LAT = north latitude, LONG = west longitude, TSLL = time since last location in minutes, DSLL = distance since last location in km, SPEED = speed since last location in km/h.

POINT NO.	DATE	TIME (GMT)	LAT	LONG	TSLL (m)	DSLL (km)	SPEED (km/h)

Appendix 12. Data from loggerhead 1235 tracked via satellite in 1992. POINT NO. corresponds to number points in Figure 31. TIME in Greenwich mean time, LAT = north latitude, LONG = west longitude, TSLL = time since last location in minutes, DSLL = distance since last location in km, SPEED = speed since last location in km/h.

POINT NO.	DATE	TIME (GMT)	LAT	LONG	TSLL (m)	DSLL (km)	SPEED (km/h)

Appendix 13. Data from loggerhead 4931 tracked via satellite in 1989 - 1990. POINT NO. corresponds to number points in Figure 33. TIME in Greenwich mean time, LAT = north latitude, LONG = west longitude, TSLL = time since last location in minutes, DSLL = distance since last location in km, SPEED = speed since last location in km/h.

POINT NO.	DATE	TIME (GMT)	LAT	LONG	TSLL (m)	DSLL (km)	SPEED (km/h)

Appendix 14. Data from loggerhead 1228 tracked via satellite in 1991. POINT NO. corresponds to number points in Figure 35. TIME in Greenwich mean time, LAT = north latitude, LONG = west longitude, TSLL = time since last location in minutes, DSLL = distance since last location in km, SPEED = speed since last location in km/h.

POINT NO.	DATE	TIME (GMT)	LAT	LONG	TSLL (m)	DSLL (km)	SPEED (km/h)

Appendix 15. Data from loggerhead 1230 tracked via satellite in 1991. POINT NO. corresponds to number points in Figure 36. TIME in Greenwich mean time, LAT = north latitude, LONG = west longitude, TSLL = time since last location in minutes, DSLL = distance since last location in km, SPEED = speed since last location in km/h.

POINT NO.	DATE	TIME (GMT)	LAT	LONG	TSLL (m)	DSLL (km)	SPEED (km/h)

## VITA

## JOHN A. KEINATH

Born in New London, Connecticut, 6 October 1959. Graduated from Suffield High School in 1977. Earned B.S. in Zoology in 1981, B.A. in Chemistry in 1984, and M.S. in Zoology in 1986, all from the University of Rhode Island. Entered the doctoral program in the College of William and Mary, School of Marine Science in 1986.
