## Abstract

*This project presents a design of high gain cascaded low noise amplifier (LNA), which operates at 5.8 GHz frequency for WiMAX application. The LNA designed used T-matching network consisting of lump reactive elements and microstrip at the input and the output matching load uses quarter wavelength techniques. A cascaded LNA is developed in this project contribute a high gain of 36.8 dB with overall noise figure of 1.3 dB. The overall measured bandwidth measures is 1.240 GHz with S parameters  $S_{11}$ ,  $S_{12}$  and  $S_{22}$  measured are -11.4dB, -39.1dB and -12.3dB respectively. The input sensitivity of the LNA is -80dBm which compliant with the IEEE 802.16 WiMAX application. The LNA used FET transistor FHX 76 LP from Eudina Inc.*

**Keywords:** Cascaded Low Noise Amplifier, Radio Frequency, Microstrip, T-Matching Network

## I. INTRODUCTION

The first stage of a receiver is typically a low noise amplifier (LNA), whose main function is to provide enough gain to overcome the noise of subsequent stages. Many researchers have been done in CMOS LNA area from 900 MHz to 9 GHz [1-4]. In the literature there were many LNA work designed in GaAs and bipolar technology [5-8]. In this paper a low voltage, low power and wideband Pseudomorphic High Electron Mobility Transistor (PHEMT) LNA at 5.8 GHz is designed and simulated using Ansoft Designer and ADS 2000A. As a design tool sensitivity analysis gives a measure of

sensitivity for a LNA circuit performance due to change the active element to be PHEMT and assisting the designer in choosing adequate circuit elements tolerances [1]. Such sensitivity analysis of LNA is very beneficial for making appropriate design trade-off. Four LNA designed Using PHEMT with two operation condition. The first two LNA is designed with the same parameters published in [1]. The second two LNA is optimized to achieve a minimum noise figure with maximum gain available.

The progress of wireless communication services has increased the need for LNA designed which has higher capability in providing higher gains, better input sensitivity and minimize noise level. It is desirable to combine two or more standards in one mobile unit for overall capacity enlargement, higher flexibility and roaming capability as well as backward compatibility. Moreover multi standard RF receiver will allow access to different system providing various services. These are the cause of the investigation to increase the bandwidth of the systems for multi-band multi-mode operation.

In WiMAX system, LNA designed for receiver system are breaking the bonds of wired connections in separated buildings to be connected in the area that the wired bridge is impossible to be deployed and installed. WiMAX wireless technology can be more economical and efficient than installing wired networks. With

the current technology of Orthogonal Frequency Division Multiplexing (OFDM) adopted in IEEE 802.16 WiMAX standard, the system can provide high data rate up to 70 Mbps [2]. The RF receiver in WiMAX system plays a paramount role in converting baseband signal from the RF signal so that the system can be communicating wirelessly. Therefore, the performance of the WiMAX system also relies on the RF front end receiver system such as LNA where it must be well designed to minimize the noise level (or distortions) in the system.[3] .

The approach taken in designing the amplifiers involves a series of chronological steps. No design is complete without some desired goals. The design specifications for the low noise amplifier were shown in Table 1:

Table 1 Design specifications for LNA

	LNA
Gain dB	> 35
Frequency	5.8 GHz
NF dB	< 3
Matching Technique	Microstrip and lump reactive element
VSWR	1.5
Bandwidth MHz	>1000 (5.8 GHz Centre)
Input sensitivity	- 80 dBm (WiMAX)

Referring to Table 1 the gain targeted for the LNA is more than 35 dB. This gain is necessary to amplify weak signals and separated from the noise. The amplifier will maintain noise figure less than 3 dB and provide bandwidth of 1000 MHz. The input sensitivity for the LNA is set at -80dBm compliant with the standard WiMAX application.

**II. THEORETICAL DISCRPTION**

Basically, for the design of an amplifier, the input and output matching network are designed to achieve the required stability, small signal gain, and bandwidth [4]. Super high frequency amplifier is a typical active circuit used to amplify the amplitude of RF signal. Basic concept and consideration in design of super high frequency amplifier is presented below. For the LNA designed, the formulae and

equation were referred to [1]. Figure 1 shows a typical single-stage amplifier including input/output matching networks.

Figure 1 Typical amplifier designed

The basic concept of high frequency amplifier design is to match input/output of a transistor at high frequencies using S parameters [S] frequency characteristics at a specific DC-bias point with source impedance and load impedance. I/O matching circuit is essential to reduce unwanted reflection of signal and to improve efficiency of transmission from source to load. The targeted specification amplifier is shown in Table 1.

**Power Gain**

Several power gains were defined in order to understand operation of super high frequency amplifier, as shown in Figure 2, power gains of 2 port circuit network with power impedance or load impedance at power amplifier represented with scattering coefficient are classified into Operating Power Gain, Transducer Power Gain and Available Power Gain.[4],[5]

Figure 2 I/O circuit of 2-port network

### Operating Power Gain

Operating power gain is the ratio of power ( $P_L$ ) delivered to the load ( $Z_L$ ) to power ( $P_{in}$ ) supplied to 2 port network. Power delivered to the load is the difference between the power reflected at the output port and the input power, and power supplied to 2-port network is the difference between the input power at the input port and the reflected power. Therefore, Operating Power Gain is represented by

$$G_p = \frac{\text{Power delivered to the load}}{\text{power supplied to the amplifier}} = \frac{P_L}{P_{in}} = \frac{1}{1-|\Gamma_{in}|^2} |S_{21}|^2 \frac{1-|\Gamma_L|^2}{|1-S_{22}\Gamma_L|^2} \quad (1)$$

Where,  $T_{in}$  indicates reflection coefficient of load at the input port of 2-port network and  $T_s$  is reflection coefficient of power supplied to the input port.

### Transducer Power Gain

Transducer Power Gain is the ratio of  $P_{avs}$ , maximum power available from source to  $P_L$  power delivered to the load. As maximum power is obtained when input impedance of circuit network is equal to conjugate complex number of power impedance, if  $T_{in} = T_s^*$  transducer power gain is represented by

$$G_p = \frac{\text{Power delivered to the load}}{\text{power supplied to the amplifier}} = \frac{P_L}{P_{in}} = \frac{|S_{21}|^2 (1-|\Gamma_s|^2)(1-|\Gamma_L|^2)}{|(1-S_{11}\Gamma_s)(1-S_{22}\Gamma_L) - (S_{12}S_{21}\Gamma_s\Gamma_L)|^2} \quad (2)$$

Where,  $T_L$  indicates load reflection coefficient.

### Available Power Gain

Available Power Gain,  $G_A$  is the ratio of  $P_{avs}$ , power available from the source, to  $P_{avn}$ , power available from 2-port network, that is,  $G_A = \frac{P_{avn}}{P_{avs}}$ . Power gain is  $P_{avn}$  when  $T_{in} = T_s^*$ . Therefore Available Power Gain is given by:

$$= \frac{P_{avn}}{P_{avs}} = \frac{1-|\Gamma_s|^2}{|1-S_{11}\Gamma_s|^2} |S_{21}|^2 \frac{1}{|1-S_{22}\Gamma_L|^2} \quad (3)$$

That is, the above formula indicates power gain when input and output are matched.

### Noise Figure

Signals and noises applied to the input port of amplifier were amplified by the gain of the amplifier and noise of amplifier itself is added to the output. Therefore, SNR (Signal to Noise Ratio) of the output port is smaller than that of the input port. The ratio of SNR of input port to that of output port is referred to as noise figure and is larger than 1 dB. Typically, noise figure of 2-port transistor has a minimum value at the specified admittance given by formula:

$$F = F_{min} + \frac{R_N}{G_s} |Y_s - Y_{opt}|^2 \quad (4)$$

For low noise transistors, manufactures usually provide  $F_{min}, R_N, Y_{opt}$  by frequencies.  $N$  defined by formula for desired noise figure:

$$N = \frac{|\Gamma_s - \Gamma_{opt}|^2}{1-|\Gamma_s|^2} = \frac{F - F_{min}}{4R_N / Z_0} |1 + \Gamma_{opt}|^2 \quad (5)$$

### Condition for Matching

The scattering coefficients of transistor were determined. The only flexibility permitted to the designer is the input/output matching circuit. The input circuit should match to the source and the output circuit should match to the load in order to deliver maximum power to the load. After stability of active device is determined, input/output matching circuits should be designed so that reflection coefficient of each port can be correlated with conjugate complex number as given below:

$$\Gamma_{IN} = \Gamma_S^* = S_{11} + \frac{S_{12}S_{21}\Gamma_L}{1 - S_{22}\Gamma_L}$$

$$(6) \Gamma_{OUT} = \Gamma_L^* = S_{22} + \frac{S_{12}S_{21}\Gamma_S}{1 - S_{11}\Gamma_S} \quad (7)$$

The noise figure of the first stage of the receiver overrules noise figure of the whole system. To get minimum noise figure using transistor, power reflection coefficient should match with  $T_{opt}$  and load reflection coefficient should match with  $T_{out}^*$

$$\Gamma_S = \Gamma_{opt} \quad (8)$$

$$\Gamma_L = \Gamma_{out}^* = \left( S_{22} + \frac{S_{12}S_{21}\Gamma_S}{1 - S_{11}\Gamma_S} \right) \quad (9)$$

### Design LNA

From equation (1) to (9), the related power gain and noise figure for single stage LNA are calculated. By using ADS 2005A, the noise figure circle was outside the unit circle and the VSWR recorded was 2.179. From simulation, it was recorded that the amplifier gain S21 was 17.23 dB. The input insertion loss S11 was -6.28dB and the output insertion loss S22 was -7.60dB. The reflected loss S12 was -20.18 dB and the noise figure was 1.16 dB. These values were within the design specification and were accepted.

The overall performance of the low noise amplifier is determined by calculating the transducer gain GT, noise figure F and the input and output standing wave ratios, VSWR<sub>IN</sub> and VSWR<sub>OUT</sub>. The optimum,  $T_{opt}$  and  $T_L$  were obtained as  $T_{opt} = 17.354 + j 50.131$  and  $T_L = 79.913 - j7.304$ . The calculated gain for the LNA was 19.3 dB, which correspond to a noise figure of 0.301 dB. The input matching load  $T_{opt}$  is required to provide high-loaded Q factor for better sensitivity. A T-network was used to match the input impedance. The elements of T-network can be realized in the form of lump reactive elements and microstrip line impedance. Using Smith Chart matching technique, the component values are shown in Table 2. The DC

block capacitor was selected for the circuit and the value is recommended at least 10 times from the  $C_1$ . For this reason 7.5 pF capacitors are selected as bypass capacitors. With these components, the schematic circuit for single stage LNA is shown in Figure 3.

Table 2 LNA Amplifier parameters

Components	Values
L <sub>1</sub>	3.60 nH
L <sub>2</sub>	0.88 nH
L <sub>3</sub>	0.67 nH
L <sub>4</sub>	0.75 nH
C <sub>1</sub>	0.5012 pF
C <sub>B</sub>	7.5 pF

Figure 3 The schematic circuit for single stage amplifier

To achieve the targeted overall gain of 35 dB, it was decided to design a cascaded amplifier using similar stages to double the LNA gain. The simulation of cascaded amplifier will be discussed in section III.

### III. SIMULATION

The cascaded amplifier is then redrawn and simulated again using Ansoft Designer SV and the related frequency response and output gain is shown in Figure 4.

Figure 4 Cascaded LNA

Figure 5 Frequency Response versus Gain

The S parameters output is shown in Figure 5, it is observed that the gain archive  $S_{21}$  was 36.80 dB at 5.8 GHz frequency and the corresponding input insertion loss  $S_{11}$  was -9.12 dB, reflection loss  $S_{12}$  was -39.13 dB and output insertion loss  $S_{22}$  was -10.86 dB. The stability factor after matching load was shown in Figure 6 and Figure 7. Figure 6 shows the stability circle lies inside Smith Chart diagram while Figure 7 shows the obtained stability factor  $k$  was 1 and VSWR observed was 1.49. These parameters are compliant with the targeted specifications of the amplifier for unconditional stable condition  $k$  is 1 and VSWR was targeted at 1.5. The noise figure output observed is 1.37 dB for the cascaded amplifier as shown in Figure 8.

Figure 6 Stability circle refer to Smith Chart

Figure 7 Stability factor  $k$  for matched load

Figure 8 Noise Figure parameter for matched load

The simulated S parameters of the amplifier is tabulated in Table 4

Table 4 S Parameter Output and Targeted Parameters of Cascaded LNA

S Parameters	LNA	Simulated LNA
Input reflection $S_{11}$ dB	-10	-9.12
Return Loss $S_{12}$ dB	-10	-39.13
Forward Transfer $S_{21}$ dB	35	36.80
Output Reflection loss $S_{22}$ dB	-10	-10.86
Noise Figure NF dB *	<3	1.37
Bandwidth MHz	>1000	> 1000

Figure 9 LNA Layout

This designed circuit is sent for fabrication and the LNA layout is shown in Figure 9.

#### IV. MEASUREMENT

Referring to the measurement setup shown in Figure 10, the S parameter of the amplifier; whereas  $S_{11}$ ,  $S_{12}$ ,  $S_{21}$  and  $S_{22}$  were measured using the network analyzer. The gain of the amplifier was measured using the setup Figure 11. The noise figure values and 3 dB bandwidth were obtained from setup Figure 12. Before all measurement was recorded, a standard procedure of calibration was followed to ensure that the measurement tools were calibrated

#### V. RESULT

The result for LNA RF front-end module is presented in Table 5.

Table 5 S Parameter result for LNA

S Parameters	Targeted	Measured
Input Reflection $S_{11}$ dB	<-10 dB	-11.4
Return Loss $S_{12}$ dB	<-10 dB	-39.1
Forward transfer $S_{21}$ dB	>35 dB	36.8
Output Reflection $S_{22}$ dB	<-10 dB	-12.3
NF dB *	<3 dB	1.3
BW MHz	>1000	1240

Measured using noise figure analyzer in Telecom R&D.

From the tabulated values, the  $S_{11}$  parameter measured was 11.4 dB. This is -1.4 dB less than targeted which is better and acceptable.  $S_{22}$  measured was -12.3 dB which is less than targeted and acceptable. The return loss required  $S_{12}$  obtained was less than -39 dB. The related measured gain  $S_{21}$  for the LNA amplifier was 36.8 dB measured using the setup Figure 11. The noise figure values obtained from setup Figure 12 was 1.37 dB which complied with the targeted value of less 3 dB. The use of T lump reactive element and microstrip line matching technique at the input of the LNA contributes the best performance for the amplifier. This matching technique was used to provide high-loaded Q factor for better sensitivity and thus minimized the noise figure [6]. The elements of T-network were realized in the form of lump reactive elements and microstrip line impedance. The 3 dB bandwidth for the amplifier is measured using setup Figure 11. The 3dB bandwidth obtained is 1.24 GHz compliant with

targeted result of more than 1 GHz. The measured parameters for the LNA were also compliant with the formulae (1) to (9) using MathCAD analysis.

## VI. CONCLUSION

A low noise amplifier has been simulated and developed successfully with IEEE standard 802.16 WiMAX. It is observed that the simulated and experiment results have not much different. It observed that the gain of the simulated analysis is 34.22 dB and the experimental value is 36.8 dB. It is important to take note when designing the amplifier to match the amplifier circuits. The 5.8GHz LNA has been developed successfully and the circuit cab contributed to the front end receiver at the described frequency. For better performance in gain of the amplifier, it can be achieved by increasing the number of stages to improve the gain and noise figure of the design. Higher gain would expand the coverage or communication distance.

## ACKNOWLEDGMENT

The authors would like to thank UTeM for financing this research project under short-term research grant.
