ABSTRACT

The kombucha beverage is usually prepared from black tea, with sucrose, inoculated with previously fermented liquid broth and/or tea fungus pellicle, and incubated. Alternative sources have been used for kombucha beverages. Guava leaves have been used for long time as traditional medicine. It is found in many commercially available botanical supplements in form of decoction, milled and used as comprises. They are rich in polyphenolic compounds. Several changes are produced during fermentation of the beverages. The main objective of the present work is to characterize fermentation process of guava leaves infusions by kombucha and studying possible chemical changes in their polyphenolic profile. Infusions from guava leaves were prepared and fermented by the kombucha consortium. The pH, titrable acidity, polyphenolic compounds, sugar consumption, organic acid along the fermentation was made by UPLC-ESI-MS. Kombucha from *Camellia sinensis* (CS) was made as a control. Higher rate of sucrose consumption was observed for Kombucha made with CS, also, higher production of organic acids (acetic and succinic acid) was observed too. Both behaviors were related to the content of glucose. The flavan-3-ols were diminishing along the fermentation time, with the exception of epigallocatechin in *Camellia sinensis*, Flavan-3-ol content in Guava leaves was low. Higher content of dicaffeoyl quinnic acid was observed for both systems in special for CS, falling after a maximum peak; minor constituents of hydroxycinnamic acids were stable along the fermentation for both systems.

Keywords: Fermentation, Guava leaves, Kombucha, Polyphenols

INTRODUCTION

Guava (*Psidium guajava*) is a fruit that grows in tropical countries. The variety of fruit dictates its shape (i.e. round, oval, or pear-shaped), diameter (approximately 1–4 in), and color (i.e. pink, white, yellow, salmon, or deep red color) [1]. *Psidium guajava* L. (guava) leaves have been used for a long time as traditional medicine in form of decoction, milled and used as comprises, etc., currently they are still employed [2]. Guava leaves after drying is suitable as a botanical supplement. Several biological activity studies showed that guava leaves have important beneficial healthy effects as anti-inflammatory, hypoglycemic, antibacterial, antidiarrheal and antioxidant properties [3-5] indicated that in India, guava leaves were used to treat skin wounds and alleviate toothaches.

The leaves contain antimicrobial components effective against *Staphylococcus aureus* that may ward off

infection, and its tannin content may promote healing. Indigenous people from Southeast Asian countries consumed the fruit to reduce or prevent hypertension and to fight influenza infection. In Malaysia, guava leaves are used in an astringent solution to treat diarrhea and stomach ache. Researchers have also reported the use of guava leaves to expel the placenta during child birth [5]. Other health conditions related to guava use were reviewed by [6] who suggested that different plant constituents, usually the leaves, may exhibit antidiabetic, antimicrobial, antidiarrheal, and anti-cough properties.

Similarly, some *in vivo* studies have proved the anti-inflammatory action of extracts, essential oils, or steam distilled components of guava leaf [7, 8]. About studies on its phytochemical profile, several authors report presence of flavonoids, in special, quercetin [9, 10] in guava leaves. In contrast, the guava leaves fermentation process showed

a lack of knowledge. In a previous study, *P. linteus* mycelium was grown with guava leaf as a substrate, and was later fermented with *Lactobacillus plantarum* and *Saccharomyces cerevisiae* for developing fermented guava leaf extracts [2]. However, they do not described changes produced during the fermentation process, particularly on the chemical composition.

The kombucha drink is mainly prepared from black tea (1–2%), sucrose (5–10%) and with fermented liquid broth (10–20%) and/or tea fungus pellicle (2.5–5.0%), and incubated at 25–37 °C for 7–12 d [11].

There are previous reports about health improvement, disease treatments etc [12, 13]. In earlier reports, *Thymus vulgaris* L., *Lippiacitriodora*, *Rosmarinus officinalis*, *Foeniculum vulgare* and *Mentha piperita* [14] and *Quercus resinosa* [15] were used as substrates to produce kombucha tea.

From our best knowledge, there is only one report about the use of guava leaves and kombucha consortium [16], they tested antioxidant activity of kombucha analogues from guava leaves by DPPH method, finding an increase after 14 d of fermentation. However, the behavior of polyphenolic profile and sugar and organic acids in the kombucha analogues from guava leaves was unknown. The main objective of the present work is to characterize fermentation process of guava leaves infusions by kombucha and studying possible chemical changes in the present polyphenol compounds.

MATERIALS AND METHODS

Psidium guajava leaves were collected from Michoacán state, Mexico, during the spring of 2014. Leaves were dried at room temperature, milled and stored until their use.

Infusions

Decoctions were obtained by putting 2% (w/v) of milled dry guava leaves into water at 80 °C by 10 min [17]. Afterwards, obtained infusion was paper filtered (whatman, # 1).

Fermentation conditions

The starting kombucha consortium was maintained in sweetened (sucrose 10% w/v) black tea at 25 °C. Freshly cultured kombucha was used for further subcultures or fresher fermentation batches. Fermentation conditions were time 11 d, with 10% (w/v) of sucrose, inoculum (2.5% w/v, Kombucha consortium) and incubation temperature of 22 °C. Total volume of fermented guava leaves was 0.5 L.

Chemical Analysis

Flavonoid analysis was performed following the standard method [18].

Sugar analysis

Carbohydrates analysis was made by the use of Acquity UPLC (Waters Corp. Milford, MA, USA) coupled to mass tandem Xevo TQ-S triple quadrupole (Waters Corp.). Column used was Acquity BEH amida 100 mm x 2.1 mm, 1.7 µm (Waters Corp.) at 35 °C. Elution profile was acetonitrile: water with 0.1% of ammonium hydroxide (80:20) (A) and acetonitrile: water with 0.1% of ammonium hydroxide (30:70) (B): gradient of 5–60% B in 5 min, 60% B by 1 min, after that 60–5% B by 0.5 min, and finally standby for 5 min. Flow rate was 0.25 ml/min. MRM data were registered from 0 to 12 min. Evaluation

was made in negative mode of ionization. ESI conditions were capillary voltage 2.85 kV, desolvation temperature 500 °C, source temperature 150 °C, gas flow of desolvation and cone 794 L/h y 151 L/h, collision gas 0.14 ml/min (gas used was argon grade). Pure samples of saccharose, glucose and fructose were used as standards. Control and data analysis were made by use of software MassLinx (Waters Corp.).

Organic acids

Organic acids evaluation was performed according to [19]. Briefly, 20 µL of sample were poured into eppendorf tube, followed by 10 µL of 3-nitrophenylhydrazine (3NPH•HCl) 40 mmol and 10 µL of 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC•HCl) 37.5 mmol with 1.5 % of pyridine. The blend was incubated at 40 °C (30 min), then frozen in an ice bath (1 min), and added with 960 µL of acetonitrile: water (10:90), before filtration.

Chromatographic analysis was done in an Acquity UPLC (Waters Corp. Milford, MA, USA) coupled to a mass tandem system (Xevo TQ-S triple quadrupole, Waters Corp.), using a column Acquity HSS C18 100 mm x 2.1 mm, 1.7µm (Waters Corp.) at 40 °C. The elution program, included two solvents; acidified water with formic acid (99.99:0.01 v/v) (A) and acetonitrile: formic acid (99.99:0.01 v/v) (B), following the next elution profile: 0–2 min 85% of A and 15% of B, 2–11 min 45% of A and 55% of B, 11–12 min 100% of B and 12–15 min 85% of A and 15% of B. Using acetic acid as standard. Data analysis was made by the use of MassLinx software (Waters Corp.).

Yeast analysis

Yeasts were isolated using Potato-dextrose (PDA) agar incubated at 28 °C for 24h. Isolated yeasts were used to obtain genomic DNA by the method of [20]. It was amplified the gene 5.8S rARN, adding 50 ng of DNA to the mix of PCR until final volume of 50 µl: 50 mmol ITS1 (5' TCCGTAGGTGAACCTGCGG-3'), 50 mmol ITS4 (5' -TCCTCCGCTTATTGATATGC-3') (Invitrogen), 0.25 mmol of mix of dNTP, 1X Buffer Taq with (NH₄)₂SO₄ (750 mmol Tris-HCl pH 8,8, 200 mmol (NH₄)₂SO₄, 0.1% Tween 20), 2.5 mmol MgCl₂, and 1U of Taq Polimerase (Fermentas, USA). The amplified product was analyzed by restriction analysis using enzymes HindI and HaeI. Digestion products were analyzed by electrophoresis agarose gel (1.5%), stained with ethidium bromide and visualized by UV transilluminator and camera with UV filter. Band sizes were analyzed using molecular weight standard Invitrogen 100pb. The size was evaluated in pair of bases and the stripes obtained were compared with identified yeast.

Data analysis

Hydroxycinnamic acid, succinic acid and glucose data (4-O-caffeoylquinnic acids) were analyzed by Spearman correlation analysis. Multiple linear regression analysis was used for glucose and succinic acids. One-way anova and Tukey test (p<0.05) was used for data analysis.

RESULTS AND DISCUSSION

Carbohydrates

The obtained results for sugars (sucrose, fructose and glucose) are shown on fig. 1 a,b. Sucrose consumption behavior in *Camellia sinensis* kombucha (CS) (fig. 1a) was different to the previously observed by [21]. They did not observe oscillating behavior of sucrose along the

fermentation time, as can be seen on the results of the present experiment. The differences could be related in function of different strain used for fermentation, because [21] used a *Saccharomyces* strain, in contrast, in the present work, it was used a kombucha consortium. Main microorganism present in the consortium is *Acetobacter xylinum*. This microorganism has been reported with strong sucrose synthesis activity in presence of glucose, fructose, inorganic phosphate and disaccharide glucosyltransferase [22].

It is interesting that the oscillating behavior was present after three days for *Camellia sinensis* fermented infusions but was not for *Psidium guajava* fermented infusions (fig. 1 b). Also, it is important to note, that the rate of sucrose consumption was faster in *Camellia sinensis* in comparison to *Psidium guajava* (at day 3, CS 10 g/l, PG 38 g/l of residual sucrose).

Organic acids

Succinic acid (SA) plus acetic acid (AA) production reached a maximum amount after 9 d in guava leaves kombucha (GK) fermentation. On the other hand, the maximum amount of SA+AA in kombucha from *Camellia sinensis* (6.8 g/l), was observed at 5th day of fermentation (fig. 2 a,b). After that, *Camellia* kombucha has shown a reduction in the amount of SA+AA thru the end of fermentation; An opposite behavior was observed by guava, that remained almost stable until day 5 of fermentation, followed by an increase in concentration of organic acids at day 9 of

fermentation, and a decrease by the end of fermentation time (11 d). At this point, no differences were observed on SA+AA content between Guava leaves and *Camellia* kombucha. The presence of organic acids as succinic acid and acetic acid is a function of strain and substrate [23]; these authors claim that a slow growth of *Acetobacter* diminishes the presence of organic acids. However, in the present work, at the end of fermentation time no differences were observed about succinic acid+acetic acid. SA+AA can act as fermentation end-products for a selection of microorganism, in special bacteria, however, several strains such as *Saccharomyces cerevisiae* have been reported as organic acids producers, at lower yield than bacteria in sake production [24].

Also, results about presence of yeast at the time of fermentation (guava kombucha) are shown in table I. At day 3 of fermentation, *Saccharomyces cerevisiae* was observed in guava kombucha, which has been reported as producer of organic acids. After that (i.e. day 7) *Shizosaccharomyces* and *Pichia angophorae* were present in guava kombucha, and under acidic conditions these yeasts can produce succinic acid [25]. Thus, it is possible that organic acids present at the beginning of fermentation (until day 3) were produced by *Saccharomyces cerevisiae* in CS kombucha. However, in the Guava kombucha, *Pichia angophorae* (present at day 7 and 9) is a yeast that produces important amount of ethanol but in presence of oxygen, may produce high amount of organic acids [26].

Phenolic compounds

Results about flavan-3-ols behavior along the fermentation are shown in fig. 3a, b. At the beginning of the fermentation, epicatechin was the most abundant flavan-3-ol present in *Camellia sinensis* kombucha (fig. 1 a) as expected. However, its concentration was diminishing after day 1 until about 60% of the initial

amount of epicatechin. After that, the amount of epicatechin was stable until the end of fermentation process (day 11). Similar behavior was observed for galocatechin and catechin measured in the present experiment, i.e. a strong reduction at the first day of fermentation; except for galocatechin gallate and epicatechin gallate, they showed an increase at the first day of fermentation (CSK).

Fig. 3: Concentration of flavonoids, left side (a and c) (*Camellia sinensis*) and right side (b and d) (guava leaves)

The stability of flavan-3-ols has been reported by several authors. pH-driven degradation of EGCG and EGC is thought to proceed by oxidative mechanisms involving the donation of H· to quench oxygen radicals, thus, catechins holding catechol B-ring structures (EC and ECG) are more stable [27]. An interesting explanation on the behavior of flavan-3-ol in fermented beverages was done by [28]. They demonstrated that monomers of several flavan-3-ols can form colloidal aggregates in special gallocatechin gallate and the formation of self-agglomerates may be a function of the ethanol concentration, i.e. at low concentration of ethanol (2% v/v), there is an increase of surface tension, driving to the formation of agglomerates, but at higher levels of ethanol, tension surface diminishes, stopping the aggregate formation. About this fact, is possible that some aggregates of flavan-3-ols were obtained, and in function of this behavior, a lower content in the experimental samples were detected.

On the other hand, the behavior of flavan-3-ols tannins was not observed for guava fermented kombucha. This different behavior could be related with the notable differences in the amount of flavan-3-ols in both beverages, CS is very rich, while guava leaves is poor in flavan-3-ols.

Results about hydroxycinnamic acids are shown in fig. 4 a,b. Important differences were observed between guava leaves and *Camellia sinensis*. About behavior of kombucha from CS (fig. 4a), there is great content of dicaffeoyl quinnic derivate at the beginning of fermentation, inclusive at day 3 there is an increase (up to 38 µg/ml), after that, there is a reduction until similar levels to another hydroxycinnamic acids. In comparison to GL fermented (fig. 4b), it was observed the presence of dicaffeoyl quinnic acid at lower amounts, but it was observed a light increase of DQ compound at day 5 of fermentation. Subsequently, it was observed a decrease to levels similar to other hydroxycinnamic acids present in

the fermented infusion. It was interesting that a correlation analysis showed a high relationship between 4-O-caffeoyl quinnic acid and organic acids ($r= 0.91$) for kombucha from *Camellia sinensis*. Also, it should be mentioned that succinic acid was related with the glucose content, thus, the changes in content of 4-O-caffeoyl quinnic acid could be related with the metabolism of yeast, in special *Saccharomyces cerevisiae*. On the other hand, the behavior of caffeoyl quinnic acid was also related to the presence of succinic acid ($r=0.87$). However, the initial amount of hydroxycinnamic acids is lower than *Camellia sinensis*, therefore, the level of derivatives of caffeic acid are lower in *Psidium guajava* leaves.

Several reports about hydroxycinnamic acids of fermented beverages has been published, in special related with wine fabrication; however in general, papers report on diminishing amounts of hydroxycinnamic acids associated with enzyme activity (i.e. hydrolases and decarboxylases associated to yeast and lactic bacteria) [29; 30;31] and an increase of caffeic acid, however in the present work, caffeic and coumaric acids were stable along the fermentation time in both fermented beverages (CS and GL). However, [32] reported an increase of 5-O-caffeoylquinnic acid in coffee brews related with the coffee cultivar, also, [33] reported an increase of different compounds resulted from several reactions between 5-O-caffeoylquinnic acid and hot water, these reactions are dependent on the pH; these differences were observed at the time of infusion, not subjected to the fermentation process.

Several fermentation processes have been related with the increase of some phenolic compounds, [34] fermented green tea with *Aspergillus oryzae* and found an increase of several derivatives of quinnic acid. More research is needed on the metabolic changes of hydroxycinnamic acids under fermentation by the kombucha consortium and their relationship with yeast, in special *Saccharomyces cerevisiae*.

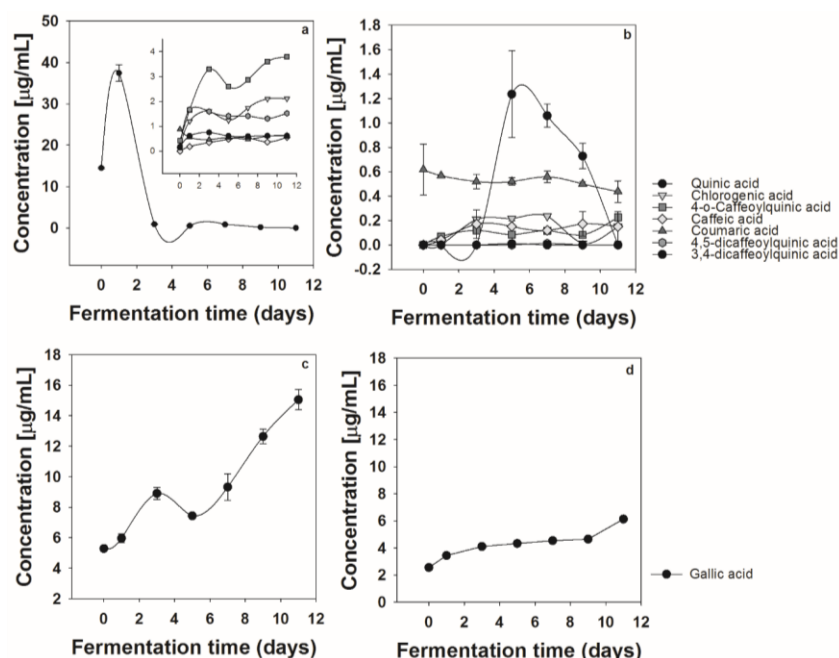

Fig. 4: Concentration of hydroxycinnamic acids and gallic acid along fermentation of left side (a and c) (*Camellia sinensis*), right side (guava leaves) (b and d)

CONCLUSION

The rate of sucrose consumption was higher for kombucha made with *Camellia sinensis* in comparison to fermented guava leaves. This fact affected the kinetic behavior of carbohydrates (fructose and glucose), and therefore the organic acids production was affected consequently by the kinetics of carbohydrates production and consumption. Finally, the production of organic acids affects the pH of the system, and this factor along others modifies the stability of the polyphenol compounds present.
