## Introduction

Investigating reports of missing persons is a longstanding challenge for the police in the UK, for two main reasons. The first is the volume of missing person incidents. In 2015/16, for example, more than 130,000 children and adults were reported missing in England and Wales; the equivalent of 662 reports per day<sup>1</sup>. Second is the diversity of missing person reports. In the UK, the police define a missing person as ‘anyone whose whereabouts cannot be established where the circumstances are out of character or the context suggests the person may be the subject of crime or at risk of harm to themselves or another’ (ACPO, 2013, p. 5). In practice, the term ‘missing persons’ refers to a heterogeneous group of people whose vulnerability may be exacerbated by factors associated with their age, neglect, exploitation and abuse, mental illness or suicide risk. It covers, for example, adults who go missing for reasons of financial hardship, teenagers running away from residential care, children who are abducted, individuals missing in the wake of a disaster and persons who are simply waylaid or disoriented. Variation in the motivation behind and circumstances of missing incidents can make it challenging to ascertain a proportionate police response (Fyfe et al. 2015) – all the more so if the available information is limited. Thus, although the vast majority of missing persons are located safely and within 24 hours (see Holmes, 2017), the police must respond with the knowledge that a small number of missing person cases involve an immediate threat to life (Newiss, 1999).

The police costs associated with missing persons are substantial (Shalev Greene and Pakes, 2013). The UK College of Policing (COP, 2015) estimate that the police in England and Wales devote around 3.3 million ‘investigation hours’ per year on missing persons. Recent estimates

1  
2  
3 place the annual police cost between £394 million and £509 million (Babuta and Sidebottom,  
4  
5 2018). Furthermore, the costs associated with missing persons go beyond the economic. To  
6  
7 be reported missing is to be missed. Henderson et al. (2000) suggest that for every person  
8  
9 missing, a further 12 individuals are affected. Qualitative studies demonstrate the significant  
10  
11 emotional and physical impact of a loved one going missing (Holmes, 2008). As Wayland  
12  
13 observes, 'families respond in similar ways to those exposed to a sudden trauma: shock,  
14  
15 distress, confusion, ambivalence and a considerable sense of being overwhelmed' (2007, p.  
16  
17 11).

18  
19  
20  
21  
22  
23  
24  
25 Our focus here is on children and young people who go missing. Throughout the paper we  
26  
27 use the term children to refer to those aged under 18, in accordance with the United Nations'  
28  
29 Convention on the Rights of the Child. Police data for England and Wales indicate that around  
30  
31 60% of all missing person incidents involve children (NCA, 2016). Similar patterns are  
32  
33 observed in Australia (Bricknell and Renshaw, 2016), Canada (Government of Canada, 2017)  
34  
35 and Scotland (Police Scotland, 2018). Moreover, the police place a high priority on the  
36  
37 investigation of missing children in part because of emerging evidence that going missing is  
38  
39 both a potential indicator of underlying vulnerabilities (Hayden and Shalev Greene, 2018) and  
40  
41 a risk factor for abuse (Sharp-Jeffs, 2016; Simon, Setter and Holmes, 2016), health-related  
42  
43 harm (Whitbeck et al. 2007) and youth offending (Heerde et al. 2014). It forms part of the  
44  
45 police 'duty of care', enshrined in the Human Rights Act 1998, to 'safeguard the rights of  
46  
47 individuals who may be at risk' (ACPO, 2010, p. 15).

48  
49  
50  
51  
52  
53  
54  
55  
56  
57 Some children go missing more frequently than others. Presently, however, the prevalence  
58  
59 and patterns of repeat disappearances of children have received limited research attention  
60

1  
2  
3 (exceptions include Shalev-Greene, 2011 and Babuta and Sidebottom, 2018). The current  
4  
5 study seeks to address this gap and contribute to the limited evidence-base concerning  
6  
7 (repeatedly) missing children. The analyses that follow draw on prior research, theory and  
8  
9 practice concerned with the patterns and prevention of repeat victimisation (see Farrell,  
10  
11 1995; Pease, 1998; Farrell and Pease, 2017), with particular focus on work which  
12  
13 demonstrates that crime is unevenly distributed across victims (Farrell, 1995; Pease, 1998)  
14  
15 and that the risk of being a repeat victim is elevated in the immediate period following  
16  
17 victimisation and decays over time (see Chenery et al. 1997; Polvi et al. 1990; Sagovsky and  
18  
19 Johnson, 2007; Townsley et al. 2000). Going missing is clearly neither a crime nor a form of  
20  
21 victimisation. Rather, in this paper we take a similar analytical approach to that which has  
22  
23 examined repeat victimisation, and use it to explore three hitherto understudied research  
24  
25 questions in the missing persons literature. First, how prevalent are repeat missing incidents  
26  
27 involving children (defined here as two or more police recorded missing episodes in a one  
28  
29 year period)? Second, what factors are associated with a child repeatedly going missing? And  
30  
31 third, what is the time course of repeat disappearances by children, measured here as the  
32  
33 time elapsed between a child's first and second missing episode? This paper is, to the best of  
34  
35 our knowledge, the first to examine the time-to-repeat for missing children.

47 The remainder of this paper is divided into four sections. The first section reviews the  
48  
49 literature on children who repeatedly go missing. The second section describes our data and  
50  
51 methods. The third presents our results, organised according to the three research questions  
52  
53 outlined above. The final section outlines the limitations of this study and considers its  
54  
55 implications for research and practice.

### On children who repeatedly go missing

Estimates vary on the extent to which children go missing repeatedly. This variation is partly attributed to the quality of available data and differences in how a repeat missing incident is defined. In relation to the former, a 2013 report argued that 'there is little or no reliable data on missing children ... [and] data on incidence reported by local authorities and that reported by the police are very significantly different' (OFSTED, 2013, p. 5). In relation to the latter, a recent assessment concluded that police services in England and Wales measure 'repeat missing' in different ways, with the most common definition being three or more disappearances in a 90 day period (HMIC, 2016). Mindful of inconsistencies in data and definition, previous studies suggest that between 29% (Rees and Lee, 2005) and 64% (Babuta and Sidebottom, 2018) of missing incidents involving children are repeats. This is typically higher than is observed for adults. For example, based on UK police data, 52% of all recorded missing incidents involving children were repeats compared with just 18% of those involving adults (NCA, 2016). Likewise, an analysis of nearly 6,000 missing incidents from the Thames Valley Police (UK) jurisdiction, found that children were significantly more likely to be reported missing twice or more than adults were over the six month study period (Vo, 2015). Indeed, of the 25 most frequently missing persons, 24 were children (Vo, 2015). Similar patterns are observed for non-police data. For example, the proportion of cases referred to the UK's Missing Persons Helpline where an individual had gone missing three times or more was substantially higher for those aged 24 years and under (32%, n=593) than those aged 25 years or older (19%, n=1,005) (Biehal et al. 2003).

1  
2  
3 A recent study by Babuta and Sidebottom (2018) sought to quantify the extent of repeat  
4 disappearances by children. Using data from one mainly rural UK police service for the period  
5  
6  
7  
8 January 2011 to May 2013, they found that the distribution of disappearances across young  
9  
10  
11 persons was heavily skewed, more so than would be expected on the basis of chance. While  
12  
13 the majority of young people in their sample were reported missing once (n = 392, 58%), 15%  
14  
15 were reported missing five times or more and together accounted for 53% of all incidents (n  
16  
17 = 1,001). Furthermore, children who went missing 10 times or more made up just 5% (n = 35)  
18  
19 of the sample but accounted for 30% of all missing incidents involving children (n = 573).  
20  
21  
22  
23  
24

25 A small number of studies have investigated the characteristics, experiences and trajectories  
26  
27 of children reported missing once compared with those reported missing twice or more. For  
28  
29 example, Baker et al. (2003) collected longitudinal data on two cohorts of youths (repeat  
30  
31 runaways and one-time runaways) accessing shelter services over a two-year period in one  
32  
33 US city. They found that repeat runaways were more likely to be female and to report having  
34  
35 experienced problems at school, higher levels of family conflict and higher levels of parental  
36  
37 discipline. Using data from Victoria (Australia), Stevenson and Thomas (2018) report findings  
38  
39 of a ten-year follow-up study of 215 randomly selected individuals aged 25 and under who  
40  
41 were reported missing for the first time in 2005. Just over a third of participants (n = 74,  
42  
43 34.4%) went missing repeatedly. Those that did were more likely than individuals reported  
44  
45 missing once to exhibit mental-health related vulnerabilities and to have higher offending  
46  
47 rates (see also Shalev-Greene, 2011).  
48  
49  
50  
51  
52  
53  
54

55 Research has also examined police attitudes towards children who frequently go missing.  
56  
57 Drawing on interview data from nine UK police forces, Newiss (1999, p.7) observes how, 'the  
58  
59  
60

1  
2  
3 temptation for the police to view the report of a missing person as simply an administrative  
4  
5 exercise would appear to be significantly increased when responding to repeat runaways'.  
6  
7  
8 Indeed, a recent inspection of UK police services concluded that children who persistently  
9  
10 went missing and who did not want to engage with the police tended to be viewed as a 'time  
11  
12 waster rather than a vulnerable child in need of help' (HMIC, 2016, p. 10). Consistent with  
13  
14 this statement, Harris and Shalev Greene (2016) concluded that the customary return to  
15  
16 home interviews and police 'Safe & Well Check'<sup>ii</sup> are carried out with less rigour for repeat  
17  
18 runaways than for those reported missing for the first time. They quoted one police officer as  
19  
20 saying that, "after a child has gone missing three times, a return interview is a fairly pointless  
21  
22 exercise' (Harris and Shalev Greene, 2016, p. 260).  
23  
24  
25  
26  
27  
28

29 In addition to studies focused specifically on missing children, other research has considered  
30  
31 going missing within the context of various forms of abuse and exploitation. While the  
32  
33 proportion of missing incidents linked to serious victimisation may be low (figures are not  
34  
35 known at present), there is evidence suggesting a high rate of going missing among exploited  
36  
37 children. For example, a study of over 9,000 children accessing Barnardo's support services  
38  
39 for child sexual exploitation (CSE) in the UK found that over half were referred due to concerns  
40  
41 around missing episodes (Cockbain et al. 2015). Numerous other studies and reports have  
42  
43 emphasised a link between child sexual exploitation and going missing (e.g. CEOP, 2011; Jago  
44  
45 et al., 2011; OCCE, 2012; Scott & Skidmore, 2006; Sharp, 2012; Smeaton, 2013). As alluded to  
46  
47 above, going missing is now widely regarded both as a risk factor for and an indicator of CSE  
48  
49 (Sharp, 2012). Rather than necessarily 'running away' permanently, sexually exploited  
50  
51 children may go missing for short periods on a regular basis (CEOP, 2011; OCCE, 2012). Recent  
52  
53 years have also seen growing concern in the UK about so-called 'county lines' related criminal  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 exploitation - in which children and other vulnerable people are used in the distribution,  
4 storage and sale of class-A drugs (see, e.g., Coomber & Moyle, 2017; National Crime Agency,  
5 2017a). Although the research literature on county lines is presently underdeveloped, going  
6 missing has been identified as both a potential indicator and a risk factor for 'county lines'  
7 related criminal exploitation (see, e.g., Crown Prosecution Service, 2017; National Crime  
8 Agency, 2017; The Children's Society et al., 2018). Finally, a study found that both trafficked  
9 children (28%, n=167) and unaccompanied minors (13%, n=593) went missing at high rates  
10 from local authority care in the UK in 2014-2015 (Simon, Setter and Holmes, 2016), raising  
11 concerns that these vulnerable children may be disappearing into exploitative situations (see  
12 also Beddoe, 2007; Child Exploitation and Online Protection Centre, 2010).

## 29 **The current study**

### 32 *Data*

33  
34  
35  
36  
37 One medium-sized, predominantly urban UK police service provided anonymised data on all  
38 missing person reports for the calendar year of 2015. Each entry included a unique identifier,  
39 the individuals' age, gender and ethnicity, the date and time they were last seen, their  
40 reported whereabouts whilst missing (e.g. stayed with friend, slept rough, not known), how  
41 they returned (e.g. found by the police/family, returned of their own accord) and whether  
42 they were in care at the time of disappearance. Also included were responses to nineteen  
43 (yes/no) questions concerning 'risk factors' associated with the missing person (Eales, 2017)<sup>iii</sup>.  
44  
45 These questions are completed by the attending police officer(s) handling the missing person  
46 investigation. Questions covered the missing person's physical and mental capacity,  
47 perceived suicide risk, experience of family conflict and the circumstances of the  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 disappearance (e.g. involvement in an altercation or harassment prior to going missing). From  
4  
5 the information provided, we computed four additional variables: (1) the length of time a  
6  
7 person was recorded as missing, (2) whether they had previously been reported missing  
8  
9 within the 12 month study period (i.e. our definition of a repeat incident), (3) the total number  
10  
11 of missing episodes per individual across the 12 month study period and (4) the length of time  
12  
13 between missing episodes for those individuals reported missing more than once.  
14  
15  
16

17  
18  
19  
20 We excluded a small number of cases prior to analysis. These related mainly to duplicate cases  
21  
22 and recording errors (e.g. when a person was recorded as being found on a date that  
23  
24 preceded the date they were logged as missing). After removal, our final dataset contained  
25  
26 4,746 police recorded missing person incidents involving 2,516 individuals. In nearly three  
27  
28 quarters of cases, the missing person was aged under 18. Put differently, although children  
29  
30 constituted 53% of all individuals in our data ( $n = 1,331$ ), they accounted for 71% of all missing  
31  
32 person incidents ( $n = 3,352$ ). The analyses that follow focus only on children.  
33  
34  
35  
36  
37  
38  
39

40 Three features of our data warrant mention at this point. The first relates to children who go  
41  
42 missing from care. In our data we were unable to differentiate between the different types  
43  
44 of care arrangements available (i.e. local authority, voluntary sector, placements with wider  
45  
46 family members, etc (see Hayden, 2017). The second relates to our assessment of repeat  
47  
48 disappearances, and the so-called time-window effect (see Farrell, Sousa and Lamm-Wiesel,  
49  
50 2001). Simply put, we do not have information on whether children in our sample went  
51  
52 missing before and/or after the one year period covered in this study. This likely undercounts  
53  
54 the extent of repeat missing incidents involving children. Finally, it is important to note that  
55  
56 the data used here do not include cases classified as 'absent', referring to persons whose  
57  
58  
59  
60

1  
2  
3 whereabouts are unknown but who are considered to be at no apparent risk to themselves  
4  
5 or others (ACPO, 2013). The category of absent was introduced to UK policing in 2013, in part  
6  
7 to help manage the high demand associated with investigating missing person reports (see  
8  
9 Bayliss and Quinton, 2013). Whether an incident is classified as 'absent' or 'missing' is  
10  
11 determined by the police call handler based on the information provided. Incidents classified  
12  
13 as 'absent' do not require an immediate police response; incidents classified as 'missing' do,  
14  
15 with the speed and intensity of response determined by the assessed level of risk: low,  
16  
17 medium or high (see Eales, 2017). Instead, those cases marked as 'absent' are regularly  
18  
19 reviewed and re-assessed for further risk. Force guidance states that no person under the age  
20  
21 of 16 should remain classified as absent for longer than 15 hours. It is possible that some of  
22  
23 the missing person cases within our dataset started out as 'absent' and were later upgraded  
24  
25 to missing, though we do not have that information.  
26

## Results

### *Descriptive statistics*

Table 1 (column 2) presents the characteristics of our entire sample of missing children. The mean age at time of first disappearance was 14 (SD = 2.6; range = 0 - 17). The number of missing males is seen to be similar to that of missing females. Moreover, the majority of missing children were white (91%), reflecting the demographic profile of the police force area (where around 90% of the total population self-identify as white). Over a quarter of missing children in our sample were recorded as having a history of family conflict (26.4%), although details about the nature and type of such conflict were not available in the data used here. Moreover, consistent with previous research (Hayden, 2017), we find that a considerable proportion of missing children in our sample (43.7%) were reported as being in care. To put this figure into context, according to British government statistics, there were just over 69,000 children in local authority care in England in 2015. That equates to a national rate of approximately 60 children in care per 10,000 children (although this rate varied across regions from 20 per 10,000 to 158 per 10,000). The same rate using our data on missing children is 4,732 per 10,000 children<sup>iv</sup>.

Turning to missing incidents, Table 1 shows that the majority of children were located within 24 hours of being reported missing (85.4%). In only 5% of cases was the child missing for more than one week. In roughly half of all incidents, the missing child returned of their own accord (47.0%), while in just over a third (35.4%) of incidents they were located by the police. A small number of cases (n = 52, 1.6%) resulted in the missing child being discovered as part of an

1  
2  
3 arrest. This might be a survival strategy on the part of the missing child (i.e. arrested for  
4 shoplifting) or instances where they are victims of criminal exploitation, as is the case with  
5  
6 the abovementioned county lines activity. Finally, a small but concerning minority of children  
7  
8 were found in hospital (n = 8, 0.2%) or harboured/abducted (n = 2, 0.1%). The former typically  
9  
10 relates to acts of self-harm whilst missing resulting in hospital admission.

### 23 ***On the extent of repeat child disappearances*** 24 25 26 27

28 Table 2 shows the extent of repeat disappearances by children. It can be interpreted in several  
29  
30 ways. First, it shows that 75% of missing incidents involving children were repeats, that is,  
31  
32 missing episodes by children who had already been reported missing in 2015. Second, it  
33  
34 shows that the distribution of disappearances is highly skewed among our sample of missing  
35  
36 children. Most children (n = 834; 62.7%) were recorded as missing once in 2015. However,  
37  
38 those children reported missing ten times or more (n = 59) made up under 5% of our sample  
39  
40 of missing children but accounted for almost 30% of all missing incidents involving children  
41  
42 (28.4%)<sup>v</sup>.

50 <INSERT TABLE 2 ABOUT HERE>  
51  
52  
53  
54

55 Following Babuta and Sidebottom (2018), we assume that it is not by chance that some  
56  
57 children go missing more often than others. Drawing on previous research on repeat  
58  
59 victimisation (see for e.g. Sagovsky and Johnson, 2007), this was examined by assessing  
60

1  
2  
3 whether the observed number of children reported missing one to ten or more times was  
4 sufficiently different to a Poisson distribution. Column four of Table 2 shows that the number  
5 of children who went missing ten times or more was much greater than would be expected  
6 by chance. A chi-square test confirmed that the difference between the observed and  
7 expected frequency of missing episodes per child was statistically significant,  $\chi^2 (9) = 12072$ ,  
8  $p < .001$ ), lending support to the notion that children who have been reported missing once  
9 exhibit a greater likelihood of being reported missing again<sup>vi</sup>.

### ***On the characteristics of children who repeatedly go missing***

20  
21  
22  
23  
24  
25  
26  
27 Having established the extent of repeat missing incidents involving children, we then explored  
28 the characteristics of children who, over the one year study period, were reported missing  
29 once, two to nine times or ten times or more. Percentages across the three groups are shown  
30 in Table 1 (columns 3 to 5). Chi-square tests revealed significant associations between these  
31 groups and the variables 'being in care',  $\chi^2 (2, n = 1,331) = 94.02, p < .0001$ ) and 'drug or  
32 alcohol dependency',  $\chi^2 (2, n = 1,331) = 11.09, p < .005$ ). The proportion of children in care  
33 was around 2.5 times higher among those reported missing ten times or more (83%)  
34 compared to children reported missing once (34%). The proportion of children with recorded  
35 drug or alcohol dependencies was, although still low, three times higher among those  
36 reported missing ten times or more (12%) than those reported missing once (4%). Differences  
37 between the remaining variables were not statistically significant.

49  
50  
51  
52  
53  
54  
55  
56  
57 Table 3 shows these relationships in a slightly different way. Statistics are presented as odds  
58 ratios with one-time missing children acting as the reference group. It can be seen that  
59  
60

1  
2  
3 children missing ten times or more were over three times more likely to exhibit drug or  
4 alcohol dependencies, over four times as likely to be teenagers and nine times more likely to  
5 be in care compared to children who went missing once. The same pattern held when  
6 comparing one-time missing children with those who went missing two to nine times, but the  
7 magnitude of the effect in each case was reduced. The analysis was repeated to compare  
8 children who went missing two to nine-times and those missing on ten or more occasions  
9 (analyses not shown). Only one variable was found to be statistically significant: being in care  
10 (OR = 3.82, CI = 1.89 – 7.75,  $p < .05$ ).

### 30 ***The time course of repeat missing incidents involving children***

31  
32  
33  
34  
35 The results above suggest that going missing in the past may be a reliable predictor of going  
36 missing in the future. A limitation of our analyses thus far is that it covers the entire calendar  
37 year of 2015. No indication is hence provided as to *when* the risk of a repeat disappearance  
38 is greatest, and for how long risk may be elevated. To explore this question, we again draw  
39 on the repeat victimisation literature, where extensive research across a range of crime types  
40 suggests that following an initial victimisation, the risk of being revictimised is heightened and  
41 decays quickly over time (Chenery et al. 1997; Polvi et al. 1990; Sagovsky and Johnson, 2007;  
42 Townsley et al. 2000). As indicated previously, to date, the temporal patterns of missing  
43 incidents involving children has received limited research attention. Prior research has tended  
44 to look at the duration of missing episodes as opposed to the time elapsed *between* repeat  
45 disappearances. Both kinds of temporal research have implications for practice. Whilst  
46  
47  
48  
49  
50  
51

54  
55  
56  
57  
58  
59  
60

1  
2  
3 research evidence on the duration of missing episodes is important for investigation  
4 purposes, we contend that research on the time-to-repeat can usefully inform police and  
5 partner efforts to prevent subsequent (repeat) disappearances. To this aim, our final analysis  
6 examines the time course of repeat disappearances.  
7  
8  
9  
10  
11  
12  
13  
14

15 Before proceeding, it is important to address two limitations which have been discussed in  
16 relation to the time course of repeat victimisation but which are also germane to repeat  
17 disappearances by children. Both concern issues of aggregation. The first is the tendency to  
18 measure the time course of repeat victimisation by pooling together all revictimisations  
19 experienced by the population of interest (be it people or properties). Doing so means that,  
20 say, individuals that experience three or more victimisations over a given time period will  
21 necessarily contribute two or more observations to the analysis. It follows that the aggregated  
22 time course of revictimisation using such data may be skewed to reflect the time course of  
23 those individuals who were victimised most frequently. To overcome this, Sagovsky and  
24 Johnson (2007) recommend analysing only the time to first revictimisation, with each victim  
25 therefore contributing only one victimisation to the data being analysed. This study similarly  
26 only analyses the time to first repeat disappearance (i.e. the time elapsed between a child's  
27 first and second police recorded missing episode).  
28  
29  
30  
31  
32  
33

35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49

50 The second limitation relates to heterogeneity in risk. In the case of burglary, for example, it  
51 is well-known that owing to the design of households or the behaviour of occupants, some  
52 properties exhibit a higher risk of burglary than others (see Tseloni, 2006). It follows that  
53 across any time period, all things being equal, those households with features known to  
54 confer a greater risk of victimisation would be expected to be revictimised faster than low-  
55  
56  
57  
58  
59  
60

1  
2  
3 risk households. As above, Sagovsky and Johnson (2007) argue that the aggregated  
4  
5 distribution might therefore reflect the time course associated with the revictimisation of  
6  
7 *high risk* properties as opposed to the population more generally. To overcome this, they  
8  
9 suggest that the time course of repeat victimisation be analysed separately for populations  
10  
11 where evidence indicates differential levels of risk. In their study, for example, they assessed  
12  
13 the time course for households revictimised once and those revictimised twice or more. Here,  
14  
15 informed by prior research and the findings described above, we analyse the time-to-first  
16  
17 repeat disappearance separately for children in care verses those not in care.  
18  
19  
20  
21  
22  
23  
24

25 Figure 1 presents the time course of first repeat disappearances by children. It indicates that  
26  
27 the risk of going missing a second time decays swiftly over the two months following an initial  
28  
29 missing episode. In both groups, roughly half of all first repeats occurred within four weeks  
30  
31 of an initial disappearance (in care = 59.2%, not in care = 53.4%).<sup>vii</sup> The count of repeat  
32  
33 disappearances per week following an initial missing incident was significantly correlated  
34  
35 across the two groups ( $r = 0.90$ ,  $n = 52$ ,  $p < .001$ ), indicating that the temporal signature of  
36  
37 time to first disappearance was similar whether a child was in care or not.  
38

## 50 Discussion

51  
52  
53

54 Responding to reports of missing children is an everyday occurrence for the police in the UK.  
55  
56 It is a leading source of police demand. Protecting missing children is not only a priority for  
57  
58 the police but also a public health concern, in light of emerging evidence that missing children  
59  
60

1  
2  
3 may be at heightened risk of abuse, exploitation and harm. Despite this, relatively little is  
4  
5 known about the prevalence and temporal patterns of repeat child disappearances, as well  
6  
7 as the characteristics of those involved. This study, informed by research and theory on repeat  
8  
9 victimisation, set out to examine (1) the extent of repeat disappearances by children, (2) the  
10  
11 characteristics of children who go missing more frequently than others, and (3) the time  
12  
13 course of repeat disappearances.  
14  
15  
16  
17  
18  
19

20 The present analysis found a high volume of repetition. Repeat missing episodes constituted  
21  
22 75% of all police recorded missing incidents involving children over the one year study period.  
23  
24 This is markedly higher than is typically found for repeat victimisation – normally in the order  
25  
26 of 40% (Farrell, Tseloni and Pease, 2005) – and represents the sizable proportion of missing  
27  
28 incidents that might, in theory, be reduced if repeat disappearances by children were  
29  
30 prevented. Our results also indicated that missing incidents were highly concentrated across  
31  
32 our sample of missing children. While the majority of children (n = 834; 62.7%) were recorded  
33  
34 as missing once over the 12 month study period, 59 children (4.4%) were recorded as being  
35  
36 missing ten times or more and accounted for 28.4% (n=952) of all police recorded missing  
37  
38 child incidents. From a safeguarding perspective, there are obvious grounds to believe that  
39  
40 these chronically missing children may be at greater risk of harm (broadly defined). Moreover,  
41  
42 from an economic perspective, their recurrent disappearances exact considerable  
43  
44 investigation costs. Using the average cost per missing episode proposed by Shalev Greene  
45  
46 and Pakes (2013 = £2,415.80), this group of 59 children accounted for an estimated police  
47  
48 expenditure of £2.29 million over the one year study period<sup>viii</sup>.  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 It is noteworthy that the level of concentration observed in this study closely resembles that  
4 reported by Babuta and Sidebottom (2018), where 5.2% of children who went missing ten  
5 times or more accounted for 30.4% of all child disappearances. Although two localised studies  
6 is too limited a basis to assume generalisability, the similarities between the results may be  
7 suggestive of a wider pattern deserving of further research. In the interests of inviting  
8 falsification, we hypothesise that in any sample of missing children, a small proportion of  
9 repeatedly missing children will account for a sizable proportion of all missing child incidents.  
10 If generalisable, these concentration patterns may hold important opportunities for  
11 intervention. There is now extensive evidence on the benefits of allocating preventive  
12 resources to those victims and places where crime is shown to concentrate (see for e.g. Grove,  
13 Farrell, Farrington and Johnson, 2012). The findings of this study suggest that the same might  
14 apply to missing children, namely that preventive gains (social, health and economic in  
15 nature) might be maximised by focussing efforts on the small number of children who go  
16 missing repeatedly. Of course, advocating targeted prevention of this nature should not  
17 detract from taking *all* incidents of children going missing seriously and responding to their  
18 unique circumstances. Moreover, knowledge about where resources might sensibly be  
19 targeted says nothing about the sorts of interventions that might be put in place, and whether  
20 differing levels of repetition requires a different type and intensity of response (akin to the  
21 'graded' response sometimes implemented to reduce repeat victimisation, see Anderson et  
22 al. 1995). In this respect, regrettably, there are very few interventions that have been shown  
23 to effectively reduce repeat missing episodes involving children (for a recent review of the  
24 evidence on police response to missing persons, see Giles, 2017).

1  
2  
3 On comparing children who were recorded missing once, two to nine times and ten times or  
4 more across various characteristics, two findings are considered noteworthy. The first  
5  
6 concerns the relationship between being in care and going missing repeatedly. Previous  
7  
8 research converges on the finding that children in care are overrepresented in missing  
9  
10 persons data (Hayden and Goodship, 2013; Hayden and Shalev Greene, 2018; Hayden, 2017;  
11  
12 Rees, 2011). This finding comes with two qualifiers: (1) children going missing from care may  
13  
14 have also gone missing before their care placement, thereby suggesting that “care” is not  
15  
16 causally related to going missing and (2) the high frequency of disappearances by children in  
17  
18 care may reflect reporting procedures whereby carers are obliged to contact the police when  
19  
20 the whereabouts of a child within their care is unknown (sometimes referred to as ‘quick  
21  
22 calling’; see Newiss, 1999; Simon et al. 2016). These qualifiers notwithstanding, in this study  
23  
24 we also find that the proportion of children in care was significantly higher among those  
25  
26 reported missing ten times or more (83%) than for children recorded as missing on two to  
27  
28 nine occasions (56%) or only once (34%).  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39

40 The second noteworthy finding relates to drug or alcohol dependency. Children in this study  
41  
42 who went missing ten times or more exhibited significantly higher levels of recorded drug or  
43  
44 alcohol dependencies (12%) than children who went missing once only (4%). Regrettably, our  
45  
46 data do not allow us to determine if and how drug and alcohol dependencies are causally  
47  
48 related to a child (repeatedly) going missing. Moreover, possible inconsistencies in what is and  
49  
50 isn’t reported to the police may affect the reliability of these findings. However, if such  
51  
52 problems are characteristic of children who persistently go missing, it suggests that efforts to  
53  
54 reduce repeat child disappearances might usefully incorporate drug and/or alcohol abuse  
55  
56 programmes. Likewise, early intervention programmes oriented towards safeguarding  
57  
58  
59  
60

1  
2  
3 vulnerable children might include drug and alcohol dependencies as a possible risk factor for  
4  
5 going missing. In the literature on CSE, a common theme is that children can be manipulated  
6  
7 into sexual abuse using drugs/alcohol and/or turn to them to cope with the associated trauma  
8  
9 (see, e.g. Cockbain, 2018; OCCE, 2012). Consequently, the higher prevalence of substance  
10  
11 abuse among repeatedly missing children gives additional cause for concern about these  
12  
13 individuals' welfare. Of course, the suggestion of potential links to exploitation is only one of  
14  
15 several possible explanations for the patterns observed and should not be overstated.  
16  
17  
18  
19  
20  
21  
22

23 The final part of our analysis examined the time-to-first repeat. It is interesting that the  
24  
25 observed time course is similar to that routinely found for repeat victimisation, whereby the  
26  
27 risk of repeat victimisation is elevated following an initial victimisation and decays over time.  
28  
29 In the context of this study, over half of all first-repeats were found to occur within four weeks  
30  
31 of an initial disappearance. This pattern held for children that were in care and those that  
32  
33 were not. As the first analysis of this kind in relation to missing children, the  
34  
35 representativeness of these results is uncertain. If generalisable, however, this pattern may  
36  
37 hold both theoretical and preventive implications. From a theoretical perspective, it is useful  
38  
39 to consider why repeat missing episodes exhibit such temporal patterns. For repeat criminal  
40  
41 victimisation, the frequently observed time course is explained in terms of event dependence  
42  
43 (the boost account) and risk heterogeneity (the flag account), and interactions between the  
44  
45 two (see Farrell and Pease, 2017). Something similar might also apply here: some aspect of a  
46  
47 prior missing episode might increase the likelihood of a child going missing again (boost  
48  
49 account), likewise some factor(s) at the child's home might remain unchanged thereby  
50  
51 propelling them to go missing again. From a prevention perspective, the time course pattern  
52  
53 observed here suggests that efforts to reduce recurrent disappearances by children may need  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 to be put in place shortly after (within four weeks) a child has returned home. The same is  
4 true of Return to Home Interviews, if the intention is to elicit information that might inform  
5 a police and/or partner response. To this end, useful insights can again be gleaned from the  
6 repeat victimisation literature, which contains multiple case studies on the processes for and  
7 challenges of responding quickly in a bid to reduce the demonstrable time-elevated risk of  
8 repeats (see for e.g. Chenery et al. 2002; Fielding and Jones, 2012; Johnson et al. 2017).  
9  
10  
11  
12  
13  
14  
15  
16

17  
18  
19  
20 Finally, the limitations of this study are acknowledged and suggestions of some might be  
21 addressed in future research are provided. First, there is the familiar problem of  
22 underreporting. Not all missing incidents are reported to the police (Rees and Lee, 2005).  
23 Consequently, the figures reported here may underestimate the true scale of (repeat) child  
24 disappearances. Anecdotally, there are reports that some parents and guardians may give up  
25 reporting children as missing if they perceive the police response to be ineffective. Second,  
26 the accuracy of information provided in response to the risk factor questions could not be  
27 verified (for e.g. the presence of drug or alcohol dependencies). Again, it is possible that there  
28 is a degree of underreporting in relation to such questions. A third limitation, mentioned  
29 previously, is our inability with the data available to differentiate between or within different  
30 types of child care arrangements. In relation to the latter, absence of geographic information  
31 meant we were unable to analyse the distribution of missing incidents across comparable  
32 care settings (i.e. local authority care homes), as is commonly practiced in the crime analyses  
33 literature (see the work of Eck et al. 2007 on so-called 'risky facilities'). This is a promising  
34 area for future research. Related to this, we did not have information on children whose  
35 repeat disappearances may have contributed to them being placed in a care setting outside  
36 of the police jurisdiction for which we have data, as sometimes occurs because of  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 safeguarding concerns (DfE, 2014; Eaton, 2019). Such practices would mean that the extent  
4  
5 of repeat disappearances would be understated.  
6  
7  
8  
9

10 Fourth, the dataset used here was not designed for research purposes. Numerous factors that  
11  
12 would have been of research interest, relating to both the individual (i.e. being bullied,  
13  
14 truanting or youth offending) and the environment from which they went missing (i.e.  
15  
16 number of staff in care home) were hence not recorded. Similarly, we did not have  
17  
18 information on the destination that children went missing to. For operational purposes, it  
19  
20 would be useful to determine if repeatedly missing children always went to the same location.  
21  
22 This could be explored in future research. Finally, throughout this analysis, independence of  
23  
24 observations has been assumed. More specifically, we assumed that all children in our sample  
25  
26 are independent. In reality, it is plausible that some children go missing in part because of  
27  
28 their exposure to and interactions with other children who have gone missing (Babuta and  
29  
30 Sidebottom, 2018). This relationship is challenging to test quantitatively using police data as  
31  
32 often little information is available at scale on the links between individuals. Using individual  
33  
34 case files can offer insights and has led to identification (albeit on a small scale) of how young  
35  
36 people's peer relations can spread and sustain CSE, for example (Cockbain, 2018). Elsewhere,  
37  
38 large-scale arrest data on co-offending has been used to examine how homicide victimisation  
39  
40 concentrates among linked individuals within high-risk communities (Papachristos and  
41  
42 Wildeman, 2014). Social network analysis is an area where future research might usefully be  
43  
44 directed to examine the strength and role of peer effects in children who go missing  
45  
46 repeatedly.  
47

## ENDNOTES

---

<sup>i</sup> According to the National Crime Agency, there were 242,317 police recorded missing person incidents in England and Wales in 2015/16. By way of comparison, over the same time period the police recorded 193,773 domestic burglary offences and 45,483 robbery of personal property offences (ONS, 2016).

<sup>ii</sup> Return to home interviews are designed to help understand why a child has gone missing, identify harm and help them feel safe. They are conducted by an independent, trained professional, whereas Safe and Well checks are conducted by the police, to locate vulnerable people at risk of harm in order to safeguard them.

<sup>iii</sup> These questions are derived from the College of Policing's Decision-Making Guide (2009) available online at: <http://library.college.police.uk/docs/APPREF/Decision-making-guide-2009.doc>

<sup>iv</sup> 582/1331\*10000.

<sup>v</sup> The most prolific individual was recorded as going missing forty one times in 2015.

<sup>vi</sup> We performed the same analysis for boys and girls separately and observed similar results (available from the authors on request).

<sup>vii</sup> It is important to note that initial disappearance, as defined herein, need not denote *first* disappearance. Some children may have been reported missing at some point in time that predates this study period. Initial, for the purposes of this study, refers to the first disappearance reported during the calendar year of 2015.

<sup>viii</sup> This is likely to be a conservative estimate, for two reasons. First, the cost estimate computed by Shalev Greene and Pakes (2013) relates to a medium-risk medium-term missing persons case. Of the 952 incidents associated with our chronically missing group (children who went missing 10 times or more in the one year study period), fifty (5%) were categorised as high risk. These investigations likely cost considerably more than £2,415.80. Second, this estimate does not include the costs imposed on partner agencies affected by missing person incidents. For example, local authorities who undertake return to home interviews.

## Tables

Table 1. Descriptive statistics

Characteristics	Full sample	Missing once	Missing two to nine times	Missing ten times or more
<i>Individuals</i>	(n = 1,331)	(n = 834)	(n = 438)	(n = 59)
Age (mean)	14.1	13.8	14.5	14.5
Sex (% male)	51.9	52.6	50.6	52.5
Ethnicity (% white)	91.3	90.8	92.0	93.2
In care (%)	43.7	34.4	56.2	83.1
History of family conflict (%)	26.4	26.9	25.6	27.1
Health concerns (%)*	15.6	17.0	13.7	10.2
Drug/alcohol dependency (%)	5.0	3.7	6.6	11.9
<i>Incidents</i>	(n = 3,352)	(n = 834)	(n = 1566)	(n = 952)
Returned <24 hrs (%)	85.4	90.9	85.4	80.8
Returned >24 but <48 hrs (%)	8.9	5.9	9.6	10.5
Returned > 48hrs but <1 week (%)	5.0	2.5	4.5	7.8
Returned of own accord (%)	47.0	44.5	47.6	48.3
Found by police (%)**	35.4	35.7	36.3	33.7

NOTE: nationality was not available in our data.

\* Both physical and mental

\*\*Remaining entries on how the missing child was returned (in descending order) are 'found by family/carer' (11.4%), 'not known/other' (4.3%), 'arrested' (1.6%), 'found in hospital' (0.2%) and 'found harboured and/or abducted' (0.1%)

**Table 2:** Observed and expected distribution of police recorded disappearances involving children

No. of disappearances	Observed no. (%) of children	Observed no. (%) of incidents	Expected no. of children*
1	834 (62.7)	834 (24.9)	294
2	173 (13.0)	346 (10.3)	370
3	97 (7.3)	291 (8.7)	311
4	64 (4.8)	256 (7.6)	196
5	38 (2.9)	190 (5.7)	99
6	21 (1.6)	126 (3.8)	41
7	17 (1.3)	119 (3.6)	15
8	14 (1.0)	112 (3.3)	5
9	14 (1.1)	126 (3.8)	1
10 or more	59 (4.4)	952 (28.4)	<1
Total	1,331 (100)	3,352 (100)	

\*calculated using Poisson distribution

**Table 3:** Comparison of the characteristics of one-time missing children and those missing on two to nine occasions and on ten or more occasions

Variables	Missing two to nine times ( <i>n</i> = 438)	Missing ten times or more ( <i>n</i> = 59)
	OR (95% CI)	OR (95% CI)
Age (teenage)#	2.55 (1.76 – 3.71)*	4.54 (1.40 – 14.69)**
Sex (% male)	1.09 (0.86 – 1.37)	1.00 (0.59 – 1.70)
Ethnicity (% white)	1.17 (0.77 – 1.78)	1.40 (0.49 – 3.96)
In care at time of disappearance (%)	2.44 (1.93 – 3.09)*	9.34 (4.66 – 18.71)*
History of family conflict (%)	1.07 (0.82 – 1.39)	0.99 (0.54 – 1.79)
Physical/mental health concerns (%)	1.29 (0.93 – 1.79)	1.81 (0.76 – 4.30)
Drug or alcohol dependency (%)	1.84 (1.09 – 3.09)**	3.49 (1.47 – 8.30)**

NOTE: children missing once act as reference group

# Age is operationalised here as a binary variable (0 = 0-12 years of age, 1 = 13-17 years of age)

\*\* Significant to a  $p < .01$  level.

\* Significant to a  $p < .05$  level.
