EXECUTIVE SUMMARY

The present government's concern is aimed towards poverty alleviation, productive employment generation, income redistribution and sustained economic growth. Given these development goals, issues concerning employment, wages and productivity which have gained prominence through the years should be dealt with. Rising levels of unemployment and underemployment along with declining productivity and real wages continue to plague the economy. Likewise, the balance of payments problems and the increasing indebtedness further aggravate the worsening economic condition. These major problems began to attract much attention for there arose dissatisfaction among the populace with the upsurge in the incidence of poverty and the occurrence of other related problems.

With the task of finding solutions to these problems, the government implemented policies and initiated a structural reform program. The purpose of the present study is twofold. First, the nature of the abovementioned problems is studied by looking at the labor market conditions. Specifically, an analysis of the trends in employment, wages and productivity, and a comprehensive historical account of how policies and policy changes affected them directly and indirectly, are presented. Moreover, the impacts of policies adopted by the government in the 1980s on employment, wages and productivity are assessed qualitatively. Policy recommendations are drawn based on the findings of the study.

Secondly, the employment impact of the various structural adjustment measures adopted in the 1980s is re-examined within a general equilibrium framework. Specifically, the study provides estimates of the employment and wage effects of the structural adjustment program based on simulation experiments using the PIDS-NEDA (1987 version) macroeconometric models and Habito's (1986) computable general equilibrium model of the Philippine economy. Based on these, policy recommendations and new directions for future research in the area are provided.

Part I of this study discusses the recent trends in employment, unemployment, underemployment, wages and productivity. It was observed that employment has generally increased over the period 1970-87 with a few years exhibiting slight declines. It was also observed that more than 50 percent of total employment was engaged in agriculture while the share of agriculture to total employment showed an apparent tendency to decline. The structural shift has been from agriculture to services, instead of agriculture to industrial sector. Unemployment rates in the country were high especially during the 1980s. Likewise, underemployment rates were also rapidly rising. Labor productivity roughly measured by output per worker has increased from 1961 to 1980 but declined thereafter until 1986 afterwhich a slight increase was observed in 1987. Nominal agricultural and nonagricultural wages has been increasing through the years. However, real wages in both sectors declined.

A review of the past and present policies showed that the industrialization policies implemented during the post-war period generally increased output and investments but their inherent capital bias resulted in the low rate of labor absorption, The manufacturing sector failed to generate enough jobs necessary to absorb the increasing labor force. This was due to factors like the limitations in the domestic market for output of import substituting firms, and the misallocation of investible funds to high cost industries as a result of incentives and short-sighted labor legislation which raised labor costs and discouraged employment. In addition, the adoption of an outward-looking strategy like export promotion is hindered by the lack of reciprocal response in the international setting due to increasing protectionism and stagnation among developed economies.

In search for policies which can increase labor absorption, the following points were made based on the analysis. First, what is called for is a system of taxation and protection which is nonfactor price distortive. Secondly, economic growth and employment generation can be accelerated with a firmer commitment on the part of the authorities in implementing the structural reforms. And lastly, the outward-looking strategy is worth pursuing giving emphasis to light manufacturing industries which showed resiliency to the impact of the economic crisis as evidenced by its ability to maintain relatively high levels of sales and small levels of labor displacement during the crisis years.

Part II provides a quantitative assessment of the impact of structural adjustment measures on employment and wages. Using the PIDS-NEDA macroeconometric models, three counterfactual experiment related to structural adjustment policy reform were conducted to appraise their employment effect for 1980 to 1990. Firstly, simulation results showed that the tariff reform program (TRP) has a positive effect on output, employment, exports and prices. Secondly, removal of export taxes on all products except logs in 1986 has a small positive effect on output and total employment except in 1989 and 1990. The policy has favorable influence on current account balance by effecting an increase in exports. Thirdly, an evaluation of the financial liberalization program using the PIDS-NEDA model was found not to be feasible given the shortcomings of the present version of the model.

Using Habito's computable general equilibrium model, two simulations were done. First, the estimates showed that TRP increased total output and average wage implying positive effect on the labor market. The policy increased the relative price of nontradables while it decreased relatively price of importables. It also decreased average wage in agriculture and manufacturing while it increased that of nontradables. TRP was found to favor middle income groups. Second, BOI incentives decreased total output, average wage and total employment. It has a regressive impact on real income across household group. The shift to a flexible exchange rate regime has a positive effect on output and prices. Labor is reallocated into export and import substituting sector away from nontradables.

EMPLOYMENT, PRODUCTIVITY AND WAGES IN THE PHILIPPINE LABOR MARKET: AN ANALYSIS OF TRENDS AND POLICIES

Edna A. Reyes, Edwin Milan and Ma. Teresa C. Sanchez

I. INTRODUCTION

The resurgence of massive unemployment and the persistently increasing level of underemployment, occurring against a backdrop of low and declining productivity and real wages especially at the turn of the decade, have acquired prominence in the new government's list of major concerns. This is rightly so, because not only are these conditions reflective of major structural weaknesses in the economy which usually result in resource misallocation and wastages, they also constitute the important dimensions in the incidence of poverty and its consequent problems. This concern is explicitly expressed in the country's medium-term development plan for the period 1967-1992 <u>1</u>/ which declared the following as its development goals: poverty alleviation, productive employment generation, income redistribution and sustained economic growth. Given this concern, and the government's commitment to find solutions to these problems, a study, therefore, of the nature of these problems, especially in the context of more recent developments in the country, is very much called for.

The authors are Research Fellow, former Research Associate and Research Associate, respectively, of the Philippine Institute for Development Studies (PIDS).

The authors wish to acknowledge the research assistance of Glorivic Maite Salveron and the funding support provided by the United States Agency for International Development (USAID).

1/ This plan has been updated for the period 1988-1992 to allow for the incorporation of some constitutional provisions as stipulated in the 1987 Constitution as well as to address the shortfalls on some indicators in 1987. The general objectives/ goals of the plan, however, remain the same. This study will attempt to present in a coherent and more systematic way conditions in the labor market, especially in terms of employment, unemployment, underemployment, productivity and wages. Specifically it aims to:

- a) analyze the trends in employment, wages and productivity;
- b) provide a comprehensive historical account of the policies and policy changes directly and indirectly related to employment, wages and productivity;
- c) assess qualitatively the impacts of the pattern of development that is going to take shape in view of the present policies related to employment, wages and productivity; and relatedly to construct short-term, employment scenarios based on these policies; and
- d) come up with policy recommendations based on the findings.
- A. Data Sources
- 1. Employment 2/

The main source of labor statistics is the Integrated Survey of Households (ISH) being conducted by the National Statistics Office (NSO) on a quarterly basis. The ISH was previously known as the Philippine Statistical Survey of Households (PSSH) up to 1958 and Bureau of Census and Statistics Survey of Households (BCSSH) from 1959 to 1976.

During the period 1956-1969, the household surveys were conducted bi-annually mostly in the months of May and October. Starting 1971, the survey was conducted on a quarterly basis. This was interpreted as an improvement in the data's ability to capture the seasonality of labor force participation, especially in agriculture. Mijares and Ordinario (1973) argued that the October or third quarter survey is more representative than say the May survey, because the latter month coincides with the school summer vacation when many students join the labor force temporarily. Likewise, the demand for labor is likely to be higher during the month of May especially in agriculture since this period marks the start of the wet season (Oshima 1984).

^{2/} This discussion draws upon the work of Tidalgo and Esguerra (1984) and Canlas (1987).

From May 1956 to August 1976, labor force data included household population 10 years and over who were either classified as employed or unemployed based on the reference week, i.e., the calendar week, Saturday to Sunday preceding the visit of the interviewer. In the third quarter of 1976, the population coverage was adjusted to 15 years and over and the reference period was changed to past quarter. The collection of data was done in the month following the reference quarter. 3/ For the second quarter series of 1987, the reference week was again used and the questionnaire underwent some changes.

The data used in this study are from the third quarter or October surveys. This set is supplemented by data from the 1970 and 1980 Censuses of Population and Housing (CPH), the 1975 Integrated Census of Population and Economic Activities (ICPEA) and the Annual Survey of Establishments (ASE).

2. Wages

Several government agencies collect data on wages. These agencies include the National Statistics Office (NSO), the Central Bank (CB), the National Wages Council (NWC), the Bureau of Agricultural Economics (BAEcon), and the Compensation and Position Classification Board (CPCB), formerly the Office of Compensation and Position Classification (OCPC) and earlier the Wage and Position Classification Office (WAPCO).

NSO, CB, CPCB and NWC conduct surveys on nonagricultural wages while BAEcon is the sole agency monitoring agricultural wages.

CPCB conducted its surveys once every three years from 1960 to 1969; once every two years from 1969 to 1973 and 1979 onwards. 4/ The data from these surveys are being used officially in determining how much the salary level in private employment has changed relative to government employment. The information regarding the changes in private wage and salary

^{3/}Tidalgo and Esguerra (1984) noted that the change in the reference period had no systematic effect on the size of the labor force but employment figures based on the reference quarter were higher than those based on the reference week for the period 1976-1978. NSCB likewise provides comparative statistics on labor force and employment using the two reference periods from 1976-1987, and similar observations surfaced.

4/ Available data after 1979 are for the years 1981 and 1985. The latest survey was conducted by SGV, and we were informed that this data set is not comparable with the previous series and hence cannot be used to complete the series.

levels are used as basis for reviewing and updating government salary scales to evolve a truly realistic compensation scheme for government employees, and to keep their salary levels competitive with the prevailing salary levels in private employment. Firms included in the surveys are large in terms of employment size and are mostly in Metro Manila. The surveys concentrate on selected jobs common to both private and government agencies. 5/

The NSO data set is wider in scope. It provides data on average earnings and compensation for a wider variety of occupations through the Integrated Quarterly Survey of Establishments (IQSE), the Annual Survey of Establishment (ASE), the Census of Establishments (CE), the Integrated Survey of Households (ISH) and the Survey of Key Enterprises in Manufacturing (SKEM). However, data on average weekly cash earnings are not available for certain years due to its noninclusion in the survey questionnaire.

More significant series, although smaller in scope are the Central Bank's Survey of Laborers in Industrial Establishments in Manila and suburbs conducted yearly and the Wage Commission's Survey of Base Compensation, Personnel Practices and Fringe Benefits conducted quarterly. The CB series contains the average daily wage rates derived from data furnished by 102 establishments covering major industries. 6/ The Wage Commission's survey series was conducted in Metro Manila and included information on monthly compensation (overall, by employment size and for unionized and non-unionized firms), summary of personnel practices and fringe benefits, and occupational data (ranges by industry). The first survey was conducted in 1974 and a total of 43 surveys covering 27 industries were conducted until 1980 when the wage commission was abolished. Likewise, CB's surveys were stopped in 1980.

The NWC Occupational Survey started in 1985 and data collection is undertaken twice a year. The survey covers 450 firms in Metro Manila and 450 firms outside Metro Manila, all representing 35 major industries. There are 11 general occupational categories and 132 specific occupations included in the survey.

For a more detailed discussion of the CPCB surveys, see Sanchez (1986).

6/ These establishments include automobile dealers, brokerages, lumberyards, furniture manufacturers, printing and publishing, transportation and construction firms.

The BAEcon is the single source of data on agricultural wages up to the present. Data are obtained from surveys of farm labor engaged in palay, corn, coconut, sugarcane and vegetables production. $\underline{7}$ /

3. Productivity

The simple estimation of labor productivity (Q/L) requires information on output (GDP) and gross value added by major sector and industry and total employment by industry. Basic data are taken from NSO's Annual Survey of Establishments and NSCB's National Income Accounts.

II. AN OVERVIEW OF RECENT TRENDS

This section will discuss trends in employment, unemployment, underemployment, wages and productivity. While data, especially for employment and unemployment are available for as early as 1956, the discussion will concentrate on changes during the 1970s and 1980s. Several studies have already discussed the trends in the earlier periods and this section hopes to update and supplement these earlier works. 8/

A. Employment, Unemployment and Underemployment

Employment has generally increased over the period 1970-1987, despite some slight declines in 1976, 1982 and 1986 (Table 1). The highest growth rate was experienced in the first half of the 70s, having reached an average annual rate of 5.1 percent (Table 2). Employment rate was 94.6 percent on the average, a relatively stable figure for the period except for 1973 and 1974 when the rates were at the peak of 99.4 percent and 98.4 percent, respectively. This observation can very well be traced to the increasing labor force which experienced high rates of growth especially after the middle of the seventies until 1985, i.e., 4.0 percent and 4.3 percent for the periods 1975-1980 and 1980-1985, respectively (see Tables 3 & 4). This fast increase in the labor force is indicative of the relatively young and growing population (see Tables 7 to 10) and the increasing number of females joining the labor force. In fact, the latter has been observed to have grown faster than males, especially during the second half of the 70s (Table 4). This is also evidenced by the labor force ratio which has shown a generally declining trend especially after 1970. Likewise, female labor force

 $\frac{7}{}$ The total output of the first four crops comprise about 69 percent on the average of total crop production, hence only these four groups of farmers are included in the analysis. <u>8</u>/

See for example Tidalgo (1972), Tidalgo and Esguerra (1984), Lal (1979), Canlas (1987) and Reyes (1987).

participation rate (LFPR) has been observed to be generally on the uptrend since 1970, peaking during the early 80s, perhaps as a consequence of the difficult economic conditions during the period (Table 5). Generally, when real incomes of families decline, women tend to join the labor force in order to augment family income. 9/ In the case of the observed decline in female labor force for the period 1985-1987, the unusually depressed economic conditions may have adversely affected the socalled marginal workers, especially women.

The acceleration in the growth of agriculture as well as the expansion of the services sector allowed for the higher rate of absorption of the enlarging stock of the labor force in the early 1970s. For the period 1970-1987, more than 50 percent on the average of total employment was engaged in agriculture. There was an apparent tendency in agriculture's share to total employment to decline, but it was a little bit slow, i.e., from 54 percent in 1970 to 48 percent in 1987 (Table 11) compared to what newly industrializing countries like Taiwan and South Korea have experienced before. 10/ The net transfer of employment has evidently been from agriculture to the services sector. From about 28 percent in 1970, this sector's share to total employment expanded to 38 percent in 1987. The share of the industrial sector has shown a generally declining movement, with the lowest level of 13.3 percent registered in 1986. More specifically, the manufacturing sector did not provide the employment opportunities needed to absorb the new entrants to the labor force which number about 750,000 annually, as well as to those moving out of humber about 750,000 annually, as well as to those moving out the agricultural sector. From a share of about 12 percent in 1970, employment in manufacturing declined to only about 10 percent of total employment in 1987 (Table 12). The declining percent of total employment in 1987 (Table 12). The declining pattern has been consistent since 1970 and this is reflective of the capital-intensive nature of the industrialization program of the country as well as the deteriorating economic conditions which prevailed during the early 1980s. In the services sector, wholesale and retail trade and community, social and personal services sectors have shown increasing employment shares hitting 14 percent and 18 percent, respectively in 1987.

In Table 13, we observe that most of those employed are wage and salary workers. More than 40 percent of workers are in this category and about 39 percent are own-account workers as of 1987. However, a continuous decline in the share of wage and salary workers is observed between 1976 and 1983. The share of unpaid

Several studies have already studied this behavior in the Philippines (e.g., Canlas 1978, Encarnacion and Canlas 1977, and Paqueo and Angeles 1979).

<u>10</u>/

These countries' shares have been reduced to about 20 to 30 percent of total employment.

family workers increased from 16 percent to 20 percent also for the same period. Own-account workers remained close to 38 percent for the whole period. However, from 1984 to 1987, a reversal of the movement is observed with the wage and salary workers increasing again accompanied by a decreasing share of unpaid family workers. This observation may have been due to the shift of labor from farm activities to off-farm and non-farm activities especially in the rural sector. Since most of the unpaid family workers are really agricultural workers, the deteriorating economic conditions which prevailed during the period under consideration must have pushed these workers out of the farms into other non-farm rural activities. Of particular significance was the unfavorable price movements in the international market of our major natural resource or land based exports especially sugar and coconut. This explanation is partly corroborated by the observed increase of production workers from 18.4 percent in 1983 to 20.0 percent in 1987 (Table 14).

For the same period 1976-1987, close to half of total employed were agricultural, animal husbandry and forestry workers, fishermen and hunters. Likewise the shares of sales and service workers increased significantly. However, the share of professional, technical, administrative, executive and managerial workers remained relatively small evidently signifying the relative scarcity of skilled workers. This is supported by the observation that more than 55 percent of all persons employed have elementary schooling as their highest educational attainment.

Unemployment rates in the Philippines are still considered high especially during the 1980s (Table 16). They have almost always exceeded the target levels set in the various development plans of the country (see Reyes and Milan 1988). Although there seems to have been a tremendous decline in unemployment especially during the onset of Martial Law until 1973, this achievement should be viewed with some reservations. There are indications showing that this decline may really just have been "managed" figures to support the new programs introduced by the government during the period. Likewise, maintaining the rates just slightly above four percent, after 1976 compared to above seven percent on the average for the years before 1972, was possible as a result of the change in the reference period from past week to past quarter. Generally though, unemployment rate has been increasing especially at the start of the current decade. From 5.0 percent in 1980, unemployment rate has almost continuously risen to 6.7 percent. The figure for 1987, i.e., 9.1 percent is much higher on account of the change in the reference period again, from past quarter to past week.

Unemployment was highest among the young members of the labor force especially those in the 15-24 age group (Table 17). These are members of the labor force most likely to have high turnover rates and long unemployment spells (Canlas 1987). Their

Scirce: bepartuent of labor, Yearbook of Labor Statistics, various issues. WSO, Integrated Survey of Households (Unpublished).

educational attainments are low, mostly elementary grade (Table 18). Unemployment among male and female members of the labor force vary especially during the child-bearing stage of a female's life cycle. This is usually the time when married women move in and out of the labor force and usually re-entry after childbirth may prove to be difficult.

Unemployment was also high among agricultural and production workers, followed closely by sales workers (Table 19). However, from 1983 to 1986, the proportion of unemployed production workers to total unemployed outpaced that of agricultural workers, suggesting that the former group was the hardest hit by the economic crisis. Finally, most of the unemployed are in the National Capital Region capturing about 29 percent on the average of total unemployed.

Underemployment was most severe during the 80s (Table 21). <u>11</u>/ Rates have gone beyond 20 percent and were rapidly increasing until 1984. This trend was common for both males and females, although the rates were much higher for males averaging about 28 percent with the peak of 39.3 percent experienced in 1984. For females, the average level was 21 percent and the highest level reached was 31.5 percent, also in 1984. This situation clearly points to the fact that earnings have become very inadequate during this period as a result of the economic crisis. This is even highlighted by the high proportion of full-time workers who still want additional work, i.e., on the average 39 percent from 1980 to 1986. Underemployment is prevalent among agricultural and production workers with low educational attainments and belong to age groups 25-34 and 35-44 (Tables 23, 24, 25). The high incidence of underemployment among agricultural workers may be attributed to the seasonality of work in monsoon agriculture and the absence or limited non-farm job opportunities in the rural sector. Data presented in Table 26 confirm this observation with agriculture getting more than 50 percent of total underemployed from 1976 to 1986.

The existence of underemployment is basically a result of inadequate income. This is clearly shown by data on Table 26 which indicates that most of the underemployed earn less than \$5,000 per quarter and this group accounts for more than 90 percent of the total underemployed.

<u>11/</u> Underemployed are those employed who express preference for additional work. The survey of households classifies underemployment as visible or invisible depending on the length of employment. The visibly underemployed are those working less than 40 hours/week or 65 days/quarter and wanting additional work, while the invisibly underemployed are those working at least full time but still want additional job.

The regional distribution of underemployment seems to indicate that the relatively poor and agricultural regions experienced high underemployment rates (Table 28). This conforms with the earlier observation that underemployment is most prevalent in agriculture on account of the seasonality of farm work. Specifically, Regions I, V, VI, X, XI & XII experienced rates which were significantly higher than the national rate.

B. Labor Productivity, 1970-1987

Measured roughly by output per worker, labor productivity has consistently increased from 1970 to 1980, posting average annual growth rates of 3.4 percent and 2.7 percent for the past two decades, respectively (Tables 29 and 30). From 1981, labor productivity started to decline until 1986 afterwhich a slight improvement was observed in 1987. From a high level of p5,700per worker in 1976, productivity went down to p4,410 per worker in 1986, a figure close to the 1974 level of p4,430 per worker. The decline in productivity especially after 1982 manifests the decline in output as a result of the economic slowdown experienced by the country especially in the periods 1983-1984 and 1984-1985 when real GDP declined by -5.7 percent and -4.7, respectively.

The overall trend in national labor productivity can be better understood if we look closely at the sectoral trends. Agriculture, for example, has shown a generally increasing trend up to about 1980. However, it has remained relatively stable since then. Absolute levels have remained low from $\mathcal{P}1,860$ in 1971 to only $\mathcal{P}2,750$ per worker in 1987, although the rate of increase during the earlier periods was relatively high compared to the other sectors, except for the industrial sector in the period 1971-80.

The industrial sector as a whole likewise experienced increasing labor productivity during the first two decades, especially during 1971-1980 when the average annual growth rate was 6.7 percent. The highest level of \$14,450 per worker was attained in 1982, afterwhich the levels started to decline continuously until 1987. Average annual rate of decline was 6.6 percent for 1981-1985. The largest contributors to this decline were mining and quarrying and construction, whose average annual rates of decline were 13.6 percent and 16.6 percent, respectively. Mining and quarrying experienced the steepest decline in 1983 and 1984, the periods when metal prices in the world market were very low. This period was also marked by large increases in employment. Hence, from a high value of \$33,500 per worker in 1977, productivity level plunged to \$10,420 per worker in 1987. Similarly, construction has shown large productivity declines in 1983-1986. Gross value added for this sector declined tremendously during this period on account of the economic crisis which drastically slowed down economic activities

Table 38 AVERAGE GROWTH RATE OF LABOR PRODUCTIVITY

a/ Includes wholesale and retail trade, financing, insurance, real estate and business services.

in the economy starting in 1983. Construction's labor productivity was reduced to \$5,200/worker in 1987 from a high value of \$13,380/worker in 1982. The 1987 level has drastically gone down to its 1968 level. Manufacturing likewise exhibited a similar trend in labor productivity movements. Although the sector was also hard hit by the crisis, labor productivity has not declined as much as in the other two sectors. For one, the decline in output was not as much, and employment has not been growing significantly. In fact, even during the early 80s, employment in manufacturing has already experienced some declines. Finally, labor productivity in the utilities sector showed a generally increasing trend on the average, with some efratic movements especially during the 1980s. Productivity levels were high, especially during the 1980s, with the peak level of \$24,950/worker achieved in 1986.

The services sector as a whole also experienced increasing labor productivity during the first two decades under study. However, the rate of increase was generally lower than the other sectors. The productivity levels were relatively lower than the sub-sectors in the Industrial Sector, but they were higher than those in agriculture. Highest level was attained in 1982, with a value of $\not P5,700/worker$, but this continuously declined until 1986, hitting a low $\not P4,410/worker$, a level comparable with those during the late 60s and early 70s. Looking at the subsectors, wholesale and retail trade experienced a big drop in labor productivity in 1970, but this continuously rose until 1977 afterwhich it again declined. This sector's productivity levels were the highest in the service sector with the highest level of $\not P13,250/worker$ achieved in 1970. Similarly, labor productivity in the transport, storage and communication sector followed an increasing trend during the first half of the 70s. Productivity, however, tended to remain relatively stable for the next seven years, afterwhich it started to significantly decline after 1983. Other services, which includes community, social and personal services, registered the lowest productivity level, and the movement over the years followed those of the other sub-sectors.

C. <u>Wages</u>

The analysis of the trends and structure of wages in the Philippine labor market will be done separately for the agricultural and nonagricultural sectors. Data used in the analysis of agricultural wages are taken from the annual farm surveys conducted by the Bureau of Agricultural Economics. For nonagricultural wages, data from the surveys conducted by the CPCB and the National Wages Council will be utilized. <u>12</u>/ The

^{12/} The CB series was not used even if it gives annual data, since data collection was discontinued in 1980. Also, the NWC and CPCB wage data include both basic wage and cost of living allowances of workers while the CB data includes only the farmer.

two sets of wage data are not exactly comparable since different sets of occupation were included in the surveys. The latter data set nevertheless provides more recent information on wages for a similar set of broad occupational categories. 13/ The CPCB surveys cover the period from 1960 to 1981 while the NWC gives data from 1985 to 1987. An additional survey ideally meant to continue the series of wage data for CPCB was conducted in 1985. However, we were informed that the data gathered are not comparable with the previous series due to methodological differences.

1. Agricultural Wages, 1974-1987

Table 31 presents nominal and real wages in the agricultural sector by crop from 1974 to 1987. Obviously, nominal wages exhibited an increasing trend across crops during the period and the increase was prominently high during the first half of the 80% (Table 31). This was especially true for palay farmers whose nominal wages increased by about 43 percent in 1983-84 (Table 32). Similarly, corn and coconut farmers also experienced high nominal wages increases during this period. Sugar farmers had the biggest increase in 1984-1985. After 1985, the rate of increase in nominal wages for all crops started to decline. If we go back to the earlier periods, nominal wage rate increases peaked in 1975-76, afterwhich the rate of increase started to decline until 1980. The behavior of nominal wages seems to conform very well with the growth of the value of crop production given in Table 34. In particular, the high rates of increase in nominal wages towards the mid-1970s was accompanied by a relatively high rate of expansion in crop production, especially for palay and corn. Similarly, the period when peak rates were achieved, i.e., 1984 and 1985, was also marked by very high rates of growth in production. The imposition of minimum wage increases in the agricultural sector may have helped sustain the increase in nominal wages, but the sharp increases were more in consonance with increases in production.

The behavior of real wages, however, shows a different pattern. From high growth rates in the period 1974 to 1976, real wages of farm workers declined from 1976 to 1981, with the biggest declines occurring between 1978 and 1980 (Table 33-A). After 1981, real wages started to move up, except for a significant decline in 1984. This big decline is attributable to the very high inflation rate experienced during the period. In fact, inflation rate for all the regions outside NCR in 1984 was 50.5 percent. The increase in real wages in agriculture may have been brought about by the significant decline in inflation rates

<u>13/</u> Included in this study are the reported wage rates for Metro Manila only. The revised series was not available yet as of this writing.

after 1984. The increase in labor productivity especially after 1986 may have also contributed to this increase, but for the earlier periods especially for the first half of the 80s, this was not so since labor productivity from 1981-1985 declined at an annual average of 0.21 percent. The expected positive effects of the reforms introduced in the agricultural sector cannot possibly account for such increases. What is more plausible as a factor which sustained real wage increases in this sector was the fast increase in nominal wages on account of the series of minimum wage adjustments introduced during this period.

It is also instructive at this point to see how real wages vary across crops and across regions. Table 33-B gives estimates of wage dispersion across crops. A widening trend in wage differentials is evident for the period 1978-1987 except in 1986. One possible explanation for this behavior is the differential growth rates in nominal wages in the different crop groups. For example, we observe very high growth rates in nominal wages among palay farmers relative to the other crop farmers. However, in the case of real wages, the dispersion fluctuated: it narrowed from 1978 to 1979, then widened in 1980 to 1983, and finally narrowed and widened alternately from 1984 to 1987. Across regions, however, there is a generally narrowing trend in regional wage differentials (Tables 35-A to 35-C).

2. Non-agricultural Wages and Earnings, 1960-86

Using data from the OCPC surveys covering selected occupations in Metro Manila from 1960 to 1981, Tables 36 and 37 give the money and real wages of three types of workers namely, manual, clerical and professional. 14/ Obviously again, nominal wages for the three occupational groups have risen over the years. However, real wages fluctuated. For example, real wages for laborers and clerical workers declined from the 60s up to the mid-70s, but have risen since then. In the case of professionals, real wages have consistently declined except for the years 1963 and 1966. This behavior seems to reflect the increase in the supply of professionals relative to the demand. Similarly, data from the National Wages Council indicate substantial increases in the average daily money wage of workers in Metro Manila. However, real wages significantly declined from 1982 after a long period of increase from 1975. Finally, the most recent figures on wages taken from NWC in Table 41 indicates that for 1986 and 1987, real wages of laborers have generally decreased, while those for clerical and administrative workers

¹⁴ Several occupations were included in the surveys. For the purposes of this study, three broad occupational groups were selected which included the more specific occupations chosen based on their inclusion in all the surveys. Sanchez (1986) provided the classification and data for this part of the study.

The original wage and salary data are expressed in annual terms. \mathbf{b}_{i}^{\prime}

Money wages of clerical workers = average wage of the five major occupations classified as clerical by the OCPC survey (cashier, clerk, accounting machine operator, stenographer and storekeeper. 6

Money wages of professionals = average wage or salary of the four major occupations classified as professional by the OCPC survey (lawyer, accountant, engineer, and physician).

have increased. In the case of professionals, there was an increase in 1986 and a decrease in 1987. These latest figures, however, have to be considered with caution since they represent only a limited number of occupations/professions. In particular, the professional group included mainly nurses, doctors and teachers.

Using the OCPC data, occupational wage differentials were computed for the Philippines and Metro Manila (Tables 42 and 43). 15/ The figures show some fluctuations for the earlier years, but in general, the emerging trend is one of narrowing differentials particularly from 1976 to 1981.

In terms of real average earnings, all the three broad sectors of the economy experienced declines from 1976-78 and from 1983-86. There was some increase during 1980-1982, with peak levels reached in 1982. Workers in agriculture, however, received the lowest earnings with workers in both service and industry sectors receiving twice as much (Table 44). 16/ The rates of decline in real earnings were highest in the period 1983-1986, with Agriculture and Industry experiencing declines of 22.7 percent and 23.0 percent in 1983 and 1984, respectively (Table 45).

Looking at earnings by more disaggregated industry groups, we observe that real quarterly earnings in all the industries declined at least during the first four years of the 70s, (Table 46). After the mid-70s, a general tendency to increase was observed and this continued until about the early 80s except for observed and this continued until about the early 80s except for agriculture. After 1982, real wages almost uniformly declined. In terms of nominal earnings, all the sectors showed an increasing trend, especially after 1978. Very noticeable, though, was the tendency of the agricultural sector to lag behind in terms of earnings (Table 47). In fact if we look at the ratios of earnings of each industry to agriculture, we easily note that in the early 70s, there was a tendency for the earnings differentials to decline. However, this movement reversed during the 80s, and we observe widening differentials between the 80s, and we observe widening differentials between agriculture and the other industries, except for manufacturing.

In terms of occupational groups, nominal earnings have generally been on the uptrend from 1971-1986 (Table 48). Real earnings, however, declined for all occupations especially after

15/ The differentials are measured by the ratios of other occupations' wages to those of laborers.

16/ There was an unusual decline in agriculture's average earnings which consequently made earnings in the other sectors more than nine times as much. However, we feel that this was more of a data measurement problem rather than a real decline.

Table 49 AVERAGE REAL QUARTERLY EARNINGS OF EMPLOYED PERSONS BY REGION

Source: Department of Labor, Yearbook of Labor Statistics, various issues. MCSO, Integrated Survey of Households (Unpublished). 1982. There were some fluctuations in earnings for the different occupations during the period 1976-1981. Nevertheless, the figures reveal clearly the unfavorable movements of earnings for certain groups of workers. While the administrative, executive and managerial workers, as well as the professional and technical workers have maintained relatively high levels of earnings during the 80s, the services production and agricultural workers have experienced tremendous declines and were receiving very low earnings towards the end of 1986. The three groups were receiving on the average $\not = 611$, $\not = 771$ and $\not = 450$ per quarter, respectively.

Another significant observation is that the decline in earnings among agricultural workers has been very steep especially in 1980. In fact for the earlier years, this group of workers was receiving higher earnings than the service and production workers.

Based on these figures, the general trend has been that of a narrowing differential across occupations in the 1970s and a slightly increasing trend in the 80s particularly in 1985-1986.

D. Productivity and Wages

The movements of productivity and real wages and earnings in the course of the development of the Philippine economy especially during the 70s until the early 80s raise some puzzling questions. This period was marked by a generally rising labor productivity (output per worker) and declining real wage rates and earnings. This observation is intriguing considering that when productivity per worker rises, real wages are likely to rise, too. Oshima (1986) observed that this behavior exceptional, although in principle may not be impossible is although in principle may not be impossible since exceptional, the two indicators refer to somewhat different magnitudes. However, he cites the cases of growth studies for countries like Britain, France and Japan where post-war economic growth was accompanied by productivity increases. Further, the neoclassical model of growth explicitly suggests the rise in wages relative to capital return and this accelerates the substitution of capital for labor. In the Lewis model, real wages do not fall but remain constant as productivity per worker rises, and the economy expands. This occurs despite the presence of unemployment. Profits rise, but total compensation also rise since employment increases. Even among Asian countries, the Philippine case is unusual according to Oshima (1986). In Japan, Taiwan and Korea, growth was accompanied by rising real wages despite unemployment. Malaysia and Sri Lanka as well experienced constant real wages in the 60s but these began to rise in the 70s.

Oshima (1986) offers two possible explanations to such a behavior. One is the possibility that even if real daily wages are falling, total employment measured by aggregate days worked

per worker increases so that this increase can more than offset the decline in wages. However, this implies a substantial increase in days worked which was unlikely (Oshima, p. 3). The other explanation involves possible shifts in the distributive shares of the different types of incomes, i.e., from compensation to property, proprietors' and public/government incomes. This implies that compensation's share to total income declined. To be plausible, there must have been large structural changes occurring in the economy to allow for the shift. The analysis in the previous sections do not seem to support this as the structural changes which occurred during the period were not that large. Likewise, a look at the share of total wages to GNP shows that compensation's share has in fact increased during the 70s (Table 50) until 1982 afterwhich it started to decline on account of the crisis.

The analysis of the statistics in the previous sections offer some initial points to consider in explaining the divergence. First, labor supply expanded rapidly and underemployment was widespread. Both exerted a downward pressure on wages. These conditions were matched by a relatively low demand, a consequence of the overall macroeconomic policy environment during the period. Lastly, the institutional factors, specifically the minimum wage law did not really help in keeping wages at pace with productivity increases.

III. POLICY ENVIRONMENT

This part of the study shall review past and present policies implemented by the government which affected and will likely affect employment, productivity and wages in the Philippines.

Several studies have already been written on the effects of policies on employment. <u>17</u>/ Tidalgo (1972) and Tidalgo and Esquerra (1984) specifically looked at employment policies in 1956-1971 and 1970-1980, respectively. This part of the study will review policies covering three periods, namely, 1950-1971, 1972-1980 and 1981-1988. <u>18</u>/ The last period is significant since it is a period of important structural adjustment policies.

17/ There are other policy studies of equal importance but which do not specifically focus on employment effects (e.g., ILO 1974; Power and Sicat 1971; Bautista, Power and Associates 1979; Pernia, Paderanga and Hermoso and Associates 1983; and David 1983). They have nevertheless been useful in the analysis. 18/

A similar analysis can be found in Reyes and Milan (1988).

Source: Oshima (1986). Appendix Table 6.

Moreso, with the change of government in 1986 after years of authoritarian rule, questions can be raised as to whether the critical employment issues brought up in the past are properly addressed now.

The methodology will follow Tidalgo and Esguerra (1984). The policies will be classified according to fiscal and monetary policies, labor legislation and institutional reforms. Impact of policies which indirectly affect employment will be identified through its effect on the level of output, technology and relative factor prices.

A. Policies in 1950 to 1971

Concern for high economic growth rate dominated all concerns, the major thrust being industrialization during the post-war years. What actually emerged as dominant was a pattern of incentives and programs geared towards the provision of a climate conducive to investment activity. Generating employment was considered more as a dimension rather than the main focus. The economic development plans of the government did not explicitly include any employment target but rather expressed the employment generation forthcoming from an investment target as an important consequence of economic growth. Most policies were aimed towards providing incentives for import-substitution in manufacturing.

There were actually no explicit fiscal policies affecting employment aside from import controls and tariff protection until 1967. The post-war years started off with quantitative import restrictions initially intended to address severe balance of payments problems. Later, this inadvertently became the major device to protect firms producing import substitutes (Bautista et al. 1979). A comprehensive Tariff Law enacted in 1957 replaced the quantitative controls which later became the source of protection after the decontrol program of 1960-62. The Basic Industries Act of 1961 explicitly exempted from import tariff imports of equipment and machinery for firms classified as "basic industry." The first of the series of comprehensive fiscal incentive packages was enacted in 1967 under the Investment Incentives Act (IIA). This was followed by the Export Incentives to exports of "non-traditional" products.

Fiscal policies were mostly in the form of tax relief. Their expected impact on output was positive. However, this did not present itself as a viable strategy to generate employment. First, their effects were capital cheapening and thus biased towards the use of capital. Second, the capital bias favored large firms since they tend to be capital-intensive. Small- and medium-scale industries which are largely labor-intensive were, therefore, less favored. Tidalgo (1972) noted that small- and medium-scale industries employed a large percentage of the labor force. Thus it can be expected that the positive incremental effect of this fiscal package on employment was not substantial.

Government intervention in wage setting in the form of minimum wage and defining labor standards only served to further the capital bias.

The shift from quantitative controls of imports in the 50s to tariff protection of "non-essentials" in the 60s imposed high level of protection on these industries. Meanwhile, the low protection rates for capital and raw material inputs to these industries discouraged the development and adoption by the formal sector of indigenous forms of technology appropriate to the country's existing factor endowments. What resulted was the emergence of assembly-type manufacturing with low backward linkages (Tidalgo 1984). But the relatively poor performance of this sector in the late 50s and the 60s resulted in less than satisfactory effect on labor absorption (Reyes, forthcoming) which was also partly caused by the inability to expand output due to the limitations imposed by the domestic market. The products were also prices higher than that in the world market which resulted in the inability of the protected firms to export.

These fiscal incentives had similar effect on. agriculture. Fiscal incentives under the IIA favored labor-displacing mechanization in agriculture as observed by Barker and Cordova (1978) on rice farms in Central Luzon. Mechanization, however, was not widely adopted in major agricultural areas in the country, hence the negative impact on employment may not have been substantial.

The role of government infrastructure and public works programs was an important component of the overall development program because of their immediate employment effects, large backward linkages, and long-run sustainable impact. They also encourage the dispersal of economic activities from the urban to the rural areas. The Emergency Employment Administration (EEA) was created in July 1962 intended to provide temporary short-run stabilization through infrastructure, public works, and construction in the rural areas. Later in 1967 to 1970, the government financed massive rural infrastructure and electrification programs. All these programs were to have positive impacts on employment.

B. Policies in 1972 to 1980

Concerns regarding the growing unemployment and underemployment rates during the decade of the 70s signaled the need to address these problems directly. Employment targets were set in practically all the subsequent development plans of the government. Manpower training was emphasized to close the gap in the demand and supply of skilled manpower in the capital- and skill-intensive manufacturing industries.

Despite the emerging concern for the unfavorable effects of the inherent capital-bias of the existing pattern of fiscal and credit incentives and trade policies as espoused in the scholarly works of economists, the pattern of incentives under the IIA and the Tariff Structure of 1957 remained enforced. There were attempts at increasing the backward linkages of the protected sectors. For example, the Progressive Car Manufacturing Program (PCMP) of 1973 and the Progressive Motorcycle Manufacturing Program (PMMP) were supposed to work towards increasing the ločal content in production. While the inherent capital-intensity of these activities cannot be avoided, it was expected that the increase in backward linkages through subcontracting with parts producers would generate more employment. Their employment impact, however, still remains to be seen.

Labor laws on industrial relations in the 70s appeared more supportive of employers rather than the workers (Tidalgo 1984, p. 77). However, actual effects of mandated minimum wage and labor standards generally depend on the coverage of such laws, the actual enforcement, and the relative strength of workers' organizations in demanding compliance by employers. Thus its negative effect on employment was minimal.

There were few serious attempts to develop the small- and medium-scale industries (SMIs). SMIs have the characteristic of being labor-intensive and less skill-intensive since they use relatively simple techniques of production. They also tend to be regionally dispersed because their minimum efficient market size requirement is small. Policies directed at SMIs were mostly fiscal incentives, credit subsidies and technical assistance under the National Cottage Industries Development Authority (NACIDA). These policies benefitted the SMIs but they conflicted with the existing structure of tariff protection during this period. For instance, Hiemenz (1983) showed that relative to those enjoyed by large firms, their effective protection rates were very low.

While export demand can be thought of as having positive output effects, the imposition of export taxes and agricultural levies served to penalize exports and discourage production in general, thus can be regarded as having a negative effect on employment.

Building of rural infrastructure was more prominent during these years. Irrigation programs proliferated in several areas. Their favorable effects on productivity and employment are particularly significant in the reduction of rural under- and unemployment especially during the dry season.

Major structural reforms emerged in the 1970s. The first serious attempt at land reform was initiated under Presidential Decree No. 27 on rice and corn lands in 1973. Consequent decrees, however, delayed its implementation pending studies to be made in pilot projects. This kind of reform is generally redistributive in character. Its effect on employment can be inferred from the relative labor intensity of land use in smaller farm sizes compared to large ones. Khan and Lee (1981) pointed out that the relative small farm sizes in East Asia even before the land reforms took place used relatively more labor per hectare of land. More labor intensity is positively associated with farm productivity at least during periods of unemployment. The Philippine case is not any different from these observations. Quisumbing. and Adriano (1988) showed that farm population per cultivated hectare of land tends to monotonically decrease as farm size increases. Land reform, therefore, likely results in a substantial increase in employment in the rural areas. This may be so because large landholdings can be prone to the use of capital intensive technology due to economies of scale. Big landlords also have access to formal credit markets, hence may reap the benefits from credit subsidy schemes provided by the government to be used in the financing of acquisition of these technologies.

It was also during this period when there was unprecedented growth of the government corporate sector. It started as a countercyclical measure, but later on was advertently used to regulate private enterprises (Manasan 1988). The share of the public sector enterprises' employment to total employment in the economy is small yet their presence could have stifled entry of new private enterprises as well as expansion of existing ones.

C. Policies in 1981 to 1988

Major structural reforms were initiated during this period. Trade and financial liberalization and another round of foreign exchange decontrol started in 1981. The pattern of fiscal incentives were revised under Batas Pambansa (BP) No. 391 to remove the existing capital bias of the IIA.

The Tariff Reform Program (TRP), an integral part of the trade liberalization program is structured in the following The first stage is the elimination of quantitative manner. imports restrictions and a gradual reduction of tariff rates. Second, tariff rates will be adjusted to conform to a more uniform protection. The lowering of tariff rates will remove the implicit tax on exports, and simultaneously, the exchange rate adjustment of the peso would make exports more competitive in the world market. This manner of sequencing of the program would likely result in a reduction in output and labor displacement in the protected industries during the initial stages. What crucial is the time lag involved from the lowering of costs production and devaluation of currency to export expansion. is of The expected export expansion will generate more employment considering that the country has comparative advantage over labor-intensive goods. This is, however, subject to a favorable external environment and prospective bilateral trading

arrangements. The increase in labor demand from export industries will far outweigh the displacement from the capitalintensive protected sector. Power and Medalla (1987) quoting a special paper by Mabida indicated a fall in employment by an amount from $\emptyset.3$ to 1.6 percent less than the expected fall in income in the initial stages of the Tariff Reform Program. 19/

Interest rate ceilings and subsidies were common forms of monetary policy in the past. The former has been criticized for its inability to mobilize domestic savings to finance investments. 20/ The scarcity of foreign sources of funds during this period necessitated the move to liberalize the local financial market. Removal of these ceilings resulted in higher interest rates in the formal financial markets. Rising interest rates will raise the rental cost of capital and lower investment spending. Montes (1987) showed a strong negative influence of rising real interest rate on output from estimates made in a macroeconomic model. Given that high interest rates make loanable funds more expensive, some form of labor displacement can be expected from all establishments due to rising working capital costs and reduction in economic activity.

The reorientation of fiscal incentives under BP No. 391 in 1983 was a positive step towards restructuring the existing misallocation of scarce capital resources. However, these initial efforts were counteracted by the reinstatement of the previous incentive pattern in a series of presidential decrees (PDs) in 1984 mainly due to political pressures.

The new government which took over in 1986 has spelled out the following strategies in the Medium Term Development Plan for 1987-1992:

- Limiting the government's role on the achievement of socioeconomic goals which will be implemented through a decentralized decisionmaking process;
- reemphasizing the prime role of development to the private sector;
- 3. population control;
- removal of biases against labor in the choice of technology;

^{19/} Power and Medalla, however, caution the readers on the use of these figures. Firstly, the estimates were made under partial equilibrium assumptions. Thus the likely effects will be potential and may not actually be realized.

^{20/} Please see ILO 1974, and Lamberte 1983.

- 5. government nonintervention in wage setting;
- reduced reliance on foreign sources of savings to finance investments;
- 7. removing the bias against the agricultural sector stemming from the system of industrial protection;
- agrarian reform;
- focusing the development of world-competitive industries complementary to growth in agricultural output and rural incomes;
- 10. the provision of and increased access to social services in rural areas;
- 11. stress. on the development of indigenous resources in research and development;
- 12. debt management allowing for an acceptable rate of growth and eventual settlement of all debts;
- 13. implementation of a flexible exchange rate policy;
- 14. setting interest rate targets to mitigate capital outflows while ensuring attractiveness of real productive investments and elimination of interest rate subsidies on Central Bank credit facilities; and
- 15. fiscal expenditures to give top priority to programs that generate the highest employment impact particularly in rural areas as well as the provision of basic services while tax policies shall focus on equitable and efficient mobilization of domestic resources.

It can be observed that current development strategies are mostly directed to the rural areas. This is a good indication considering that if resources would be channeled to rural areas, labor absorption will be substantial considering these areas' dominant use of labor-intensive techniques. Another observation is that as in the development plans of the 70s and early 80s, it reiterates the government's concern over the inherent capitalbias of the existing patterns of fiscal and monetary policies. Also, the development plan calls for a more market-oriented economy with minimal government intervention in economic development.

One can therefore ask whether such concerns will be properly addressed in the actual policies implemented. The major policies are as follows.

First, the new Omnibus Investments Code of 1987 provided a return to the same pattern of fiscal incentives and thus will likely suffer the same employment effects as the previous Investments Incentives Act.

Second, privatization of the government corporate sector was initiated. Government financial institutions accumulated a tremendous amount of non-performing assets mostly of those corporations which it has subsidized in the past by offering liberal credit terms. Revitalization of these non-performing assets when sold to private investors can have a positive employment effect. On the other hand, reorganization of existing firms when privatized may result in employment reduction given the concern for efficiency. The likely labor displacement from privatization, however, may be minimal. Manasan (1988) showed that most of these firms are capital-intensive and hire an insignificant amount in the labor force. Also, privatization of these assets may relieve the government of providing resources to maintain these companies and reallocate the funds to more socioeconomic projects.

Third, the agricultural sector continues to experience the same set of monetary and fiscal policies. Existing construction of rural infrastructure and public works programs continue. For example, the Community Employment and Development Program (CEDP) initiated in 1986, was aimed at easing the unemployment in the rural areas through public works, construction, and infrastructure projects similar to the Emergency Employment Authority in the late 60s. CEDP was intended to run for two years up to 1987. An assessment made by the National Economic Development Authority (NEDA) showed that the program fell short of the targetted one million new jobs it hoped to generate. Further, it was observed that the projects did not really absorb the unemployed members of the rural labor force since about 40 percent of those employed in these projects were in fact already initially employed.

Fourth, from among the policies directed to the rural areas, agrarian reform and the removal of monopolies in agriculture are the most important. The latter is even an integral part in the economic platform of the present government. Government monopolies in cash crops were initially set to stabilize the otherwise volatile international crop prices. Findings, however, showed that these were intended more to extract surplus from lucrative agricultural markets. This can be shown by the relatively small number of farmer beneficiaries of the intended programs sponsored by the government monopolies (See Agricultural, Policy and Strategy Team, 1986). The implementation of the Comprehensive Agrarian Reform Program (CARP) is crucial in promoting equity and social justice and increasing agricultural productivity and incomes. It is also expected to bring about higher levels of employment in the rural sector as smaller farms tend to be more labor intensive.

Besides, this program has a much wider coverage compared to the previous land reform program. Questions as regards its ability to truly bring about equitable redistribution are, however, raised by some sectors. These questions are specifically directed at the retention limit set under the program.

Fifth, most of the government's budget after 1982 were allocated to foreign debt-service. Earlier in the 70s, the biggest share of government expenditures was allocated to utilities and infrastructure, at least until 1983. This activity has high labor absorptive effects because of its less skill intensity and high backward linkages, and has long-run benefits. After 1983, the share of debt service significantly increased reaching about 45 percent in 1987. This is a large set-back in terms of the goverment's employment-generation concerns during the crisis.

The same set of policies affecting employment seem to have contributed to the decline in productivity and wages in the past. Hooley (1984) for example noted that the structure of tariff protection has contributed to declining TFP. It created incentives to use excessive amounts of intermediate inputs with correspondingly dysfunctional impacts on TFP. Likewise. productivity growth, especially in the manufacturing sector, was found to be intimately connected with the distress of country's financial system in the past. Credit resources the have been extended mostly to industries with very poor productivity records. Lal (1979) also suggested that declining wages in the Philippines was not a result of the failure of the labor market to adjust to changes in market forces, rather it was the result of the overall macroeconomic policy environment and the exchange rate policy which prevailed during the period. This effect worked through changing relative commodity prices which affect relative factor prices. His study covered the period from 1956 to 1978. Perhaps the slight increases in real wages during the early 80s were already the initial result of the structural reforms initiated during the period.

IV. SUMMARY, CONCLUSION AND PROSPECTS

The employment impact of industrialization thrusts initiated during the post-war period created a dominant pattern of fiscal and monetary policies which have conflicting objectives in terms of achieving both economic growth and full employment. While the policies in general increased investments and output, their inherent capital bias resulted in the low rate of labor absorption. Experience, however, showed that the performance of manufacturing in terms of increasing output and generating new employment was unsatisfactory due to several factors. <u>First</u>, the limitations in the domestic market for output of importsubstituting firms did not allow them to hargess the economies of

scale of capital intensive technologies. Second, the outward looking strategy initiated in the late 60s to generate new markets for these products provided a new impetus but was limited in that there was no attempt at altering the existing pattern of fiscal incentives. The government has shown reluctance in redirecting these incentives. As such the implementation of the major reforms has not been given the right element of administrative commitment. Third, the incentives resulted in a misallocation of investable funds in that it has been directed at high cost industries rather than at low cost industries where the country has comparative advantage (Bautista et al. 1979). Thus, potential output and employment may have been substantially higher than what was actually experienced. Fourth, sweeping labor legislations were highly short-sighted and only served to raise labor costs and discourage employment. However, reliance on bargaining among labor and management can still prove unviable at present because of the low incidence of unionized labor and the lack of government institutions to provide the necessary information to help labor to bargain for their welfare. This being the case, there are efforts at the National Wages Council to come up with studies on the feasibility of other alternative measures to keep real wages from falling, at the same time minimize government interference in wage setting.

The major problem of adopting an outward-looking strategy as mentioned above is the lack of reciprocal response in the international setting. The prospect for increased exports in the country remains bleak in the face of increasing protectionism and stagnation among developed economies. However, current developments point to future favorable external factors. Similar to what the NICs experienced with Japan, rising real wages and strengthening of their currencies resulted in shifting comparative advantage out of traditional labor-intensive exports to more skilled and technology intensive activities. This opens up bright prospects for the ASEAN countries which will likely fill-up the vacancy left by the NICs in the export of traditional commodities.

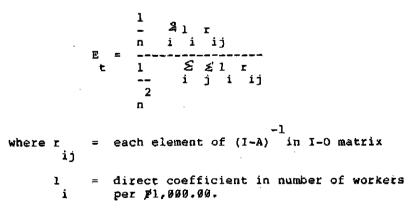

There are, however, two obstacles to realizing these objectives (Ariff and Hill 1985). One is on how to sustain the shift towards export-promotion. Existing incentives still favor capital-intensity although institutions supporting the more labor intensive SMIs are being put in place. Agriculture is not likely to totally shift from traditional methods and generate surplus until full-employment is reached. The lack of resources for research and development of indigenous technologies which are labor-using remains a problem. Second is the current political and financial crisis which is closely linked with the first obstacle. The high proportion of the budget allocated to debt service creates financial bottlenecks to vital socioeconomic development programs and institutional reforms. In the meantime, the political instability tends to affect the credibility and continuity of existing programs which may hinder further progress

in the private sector. The peace and order situation in the country has severely deteriorated and unless current efforts are successful to contain the problem, the expected growth in investments may not be realized.

Thus, in search for policies which can increase labor absorption, certain points may be made based on the analysis. First, what is called for is a system of taxation and protection which is nonfactor price distortive. The adoption of the appropriate technology which is more labor using will follow as a consequence. Secondly, economic growth and therefore employment generation can be accelerated with a firmer commitment on the part of the authorities in implementing the structural reforms. And lastly, the outward-looking strategy is worth pursuing giving emphasis to light manufacturing industries. 22/ This group has consistently shown resiliency during the economic crisis as evidenced by its ability to maintain relatively high levels of sales and small levels of labor displacement during the period 1980-1984. This policy direction would remain in accord with the overall development objective of creating productive employment as these industries are basically labor intensive and maintain a relatively high proportion of total employment (Table 51). Furthermore these industries have relatively high backward linkages (Table 53) and high total employment coefficients (Table 54). 23/ There is also bright prospect for these

These industries include the following: weaving apparel and foctwear; logs, lumber and plywood; furniture; electronics; food processing; tobacco, cigars & cigarettes; and textiles. 23/

Total employment coefficients provide the direct and indirect employment effects of a given increase in output. This is computed using the inverse matrix of the I-O table following the formula:

76

industries to prosper in the light of current developments in the country's neighbors (i.e., Korea, Taiwan, Malaysia and Singapore) which are experiencing high and increasing real wages.

All these policies when successful in increasing productive employment opportunities and consequently induce faster labor absorption, will also bring about favorable influence on productivity and wages.
