Abstract: China is the world's largest capture fisheries and aquaculture producer. Over recent decades, China's domestic marine catch composition has changed markedly, from large volumes of a few high-valued food species to multiple, small, low-valued, species, a significant proportion of which is primarily used as animal, especially fish, feed. Despite the growing volume and economic importance of the feed catches, their species composition, catch volumes and socio-environmental impacts are all poorly understood. Based on a nationwide survey of >800 fishing vessels, and the identification and measurement of >12,000 fish and invertebrate individuals, the present study provides an overview of the feed component of China's domestic marine catch, by volumes, species, and sizes, and found it to be substantial and biologically unsustainable. Half of the trawler catch (3 million metric tons, mmt), or 35% of the total catch (4.6 mmt) in China's exclusive economic zone are now comprised of low-valued 'feed grade fish'. The present study identified 218 fish species, 50 crustaceans and five cephalopods and of these, 102 fish species were food species with 80% in their juvenile size ranges. Feed grade fish were mainly used as aquaculture feed directly, or indirectly through the feed industry after reduction to fishmeal and fish oil. The unparalleled scale and poor fisheries resource condition of China's domestic marine fisheries, in parallel with severe overfishing of juveniles, creates a demand for fundamental changes to fishery management practices, including a significant reduction of fishing effort to ensure productivity and ecosystem resilience.

Keywords: biodiversity, feed grade fish, management, multispecies fisheries, trash fish, trawl

1 **1. Introduction**

2 China is the world's largest capture fisheries and aquaculture producing country,
3 accounting for 19.2% of global marine capture fisheries production and 61.5% of global
4 aquaculture production in 2016 (FAO 2018). In 2016, China's total domestic marine
5 capture fisheries production was 13.3 mmt (million metric tons), and total aquaculture
6 (marine and freshwater) production was 51.4 mmt (MOA 2017a). Capture fisheries and
7 aquaculture in China provide food and income, 13.8 million jobs, and livelihoods for
8 nearly 20 million people (MOA 2017a).

9 Despite the introduction of a range of marine fisheries management measures at
10 both national and local levels since the 1980s (Cao *et al.* 2017), fishing pressure has
11 grown over the last four decades (Figure S1). Persistently high fishing pressure,
12 together with other pervasive deleterious anthropogenic influences, such as runoff of
13 fertilizers and habitat loss and degradation, have resulted in sharp declines in fishery
14 biomass and catch per unit effort (CPUE) in China's major fishing grounds. In the
15 Bohai Sea, the CPUE declined from $>420 \text{ kg haul}^{-1} \text{ h}^{-1}$ in 1959, to $\sim 160 \text{ kg haul}^{-1} \text{ h}^{-1}$ in
16 1982, $\sim 30 \text{ kg haul}^{-1} \text{ h}^{-1}$ in 1993, and $<8 \text{ kg haul}^{-1} \text{ h}^{-1}$ in 1998-2011 (Jin *et al.* 2013; Shan
17 *et al.* 2013). In the Yellow Sea and East China Sea, the CPUE dropped from 73.54 kg
18 $\text{haul}^{-1} \text{ h}^{-1}$ to $39.19 \text{ kg haul}^{-1} \text{ h}^{-1}$ in just ten years between 1991 to 2000 (Cheng and Yu
19 2004). In the northern South China Sea, the fishery biomass declined from 2.7 mt km^{-2}
20 in the 1930s, to 1.5 mt km^{-2} in 1956, 1.1 mt km^{-2} in 1960-1973, and 0.3 mt km^{-2} in 1997-
21 1999 (Qiu 2002).

22 In concert with biomass and CPUE declines, the species composition of China's

23 domestic marine catches over the past six decades has undergone substantial changes
24 from a predominance of a few medium to relatively large-sized, high-valued, high
25 trophic level, demersal species to multiple small, low-valued, short-lived, low trophic
26 fishes (Liu and Sadovy de Mitcheson 2008; Shen and Heino 2014; Cao *et al.* 2017)
27 (Figure S2). These changes are largely attributable to the overfishing of these larger
28 species driven by ineffective management resulting in increased numbers of smaller,
29 lower trophic level species (Pauly *et al.* 1998; Lundgren *et al.* 2006; Shen and Heino
30 2014; Cao *et al.* 2017).

31 Since the 1990s fisheries production has increasingly been used to supply fishmeal
32 and animal feed, particularly aquaculture feed, shifting away from its historic use for
33 direct human consumption. This pattern is observed not only in China (Funge-Smith *et*
34 *al.* 2005; Lundgren *et al.* 2006; Cao *et al.* 2015), but also in Vietnam (Edwards *et al.*
35 2004) and several other Asian countries and areas (Funge-Smith *et al.* 2005). The
36 increasing importance of animal feed during a period when food fisheries were
37 declining enabled some fisheries to remain viable; for example in Hong Kong after
38 declines in traditional trawl fisheries occurred due to overfishing, fishers were
39 increasingly able to earn money from smaller, poorer quality fish, being sold as animal
40 feed for the burgeoning mariculture sector. This enabled the fisheries to remain
41 economically viable and allowing overfishing to continue (e.g. Hong Kong, Cheung
42 and Sadovy 2004).

43 Due to the highly diverse nature of the world's fisheries and because of different
44 terminologies and histories among countries (FAO 2011b), there is no single or

45 consistent definition or term for fisheries fishing for feed, or their product, that clearly
46 describes the specific proportion of the catch that to be used as aquaculture (or livestock)
47 feed. In the past, when fisheries were in good condition and aquaculture less developed,
48 small-sized, low-valued fish were typically discarded and variously referred to as
49 ‘discards’ or ‘bycatch’ or ‘trash fish’, reflecting the fact that they were not targeted,
50 were incidental, or were of little or no economic value, and often being unfit for human
51 consumption due to small size and/or poor condition (Alverson *et al.* 1994; Nguyen *et*
52 *al.* 2009; FAO 2011a). In the early days of fishery development, this discarding in
53 Southeast Asia was responsible for an estimated loss of some 3.4 mmt of fish catch per
54 year (Chee 1997).

55 Other terms have been variously and inconsistently used, making comparisons
56 across studies a challenge. Terms for the catch component not directly used for human
57 food initially reflected what happened to the catch to, more recently, the fisheries that
58 target fish used as feed. Catch terms range from ‘pig fish’ (Edwards *et al.* 2004; Funge-
59 Smith *et al.* 2005), ‘low value/trash fish’ (Funge-Smith *et al.* 2005; Lundgren *et al.*
60 2006), ‘feed fish’ (Huntington and Hasan 2009), to ‘mixed fish feed’ (Chau and Sadovy
61 2005). Although reduction fisheries have existed for centuries for industrial purposes
62 (Smith 1991), as the use of catches for animal feed became more important, specific
63 fisheries terminology began to be identified, such as feed fisheries (Hasan and Halwart
64 2009) and forage fisheries (Watson *et al.* 2006) which were used alongside the term
65 ‘reduction fisheries’ (Parker and Tyedmers 2011; Shepherd and Jackson 2013).

66 Some terms for this ‘feed’ component fisheries are no longer fit-for-purpose or are

67 even misleading. The best example is the still widely used term ‘trash fish’. As fisheries
68 focused on food fish declined and aquaculture increased, a growing proportion of ‘trash’
69 fish was retained and came to have economic value in the aquaculture (or other
70 livestock) sector (Alverson *et al.* 1994; Funge-Smith *et al.* 2005; Zeller *et al.* 2018).
71 Moreover, what may be bycatch in one fishery or in one season, may be valuable food
72 fish in another or would become food fish if animals were retained in better condition
73 or were taken at larger body sizes.

74 Along with the development of aquatic food processing technologies and
75 improvements in the handling of fish, there was also a rapid expansion of markets for
76 other human food products such as surimi, fish balls, sauces or pastes. Species used to
77 be by-catch but suited for processing into surimi are increasingly targeted or diverted
78 from the fishmeal supply chain and used as raw material (Siriraksophon *et al.* 2009;
79 Funge-Smith *et al.* 2012; Anon 2016).

80 While in many parts of the world the ‘feed’ component is primarily (if not solely)
81 caught from targeted forage (or reduction) fisheries (Hasan and Halwart 2009; FAO
82 2011a), the sourcing of it in China is more complicated. This is because multiple fishing
83 gears are involved which take a complex mix of species that are both targeted and non-
84 targeted and can be used as direct feed for aquatic animals and, indirectly, to produce
85 fishmeal, or for direct human consumption, according to their condition, species and
86 size. In the present study, we use the term ‘*feed grade fish*’ to describe those fish (and
87 invertebrates) that are targeted or retained to be used as fish or livestock feed.

88 Over the past two decades, fishing for feed grade fish in China has become

89 increasingly important, due to overfishing of food fish associated with poor fisheries
90 management, and, growth in demand for feed grade fish, especially with the
91 development of aquaculture (Naylor *et al.* 2000; Funge-Smith *et al.* 2005; Huntington
92 and Hasan 2009; Cao *et al.* 2015). Into the new millennium, China's aquaculture has
93 been greatly intensified with much more formulated feed and direct feeding of feed
94 grade fish required (Edwards 2008a,b; Chiu *et al.* 2013), with a trend to 'farming up'
95 the food web with increasingly more high value species, especially carnivore species,
96 being farmed (Naylor *et al.* 2000; Miao and Liao 2007; Zhou 2007), further contributing
97 to the increasing demand for feed grade fish.

98 The feed component is today a significant aspect of China's domestic marine
99 fisheries. Estimates based on FAO data over a decade ago show that the feed component
100 represented more than one-third of China's marine catch (Han and Xu 2004; Funge-
101 Smith *et al.* 2005; FAO 2007) and was mainly constituted by unidentified 'nei' (not
102 elsewhere included) species and forage species (Han and Xu 2004; Cao *et al.* 2015).
103 Sporadic surveys also suggest that 26-90% of the fisheries catch by weight or number
104 in China's EEZ are feed grade fish, especially from non-targeted trawls and stow nets,
105 in some cases higher than the situation found in other Southeast Asian countries (Table
106 S1) but similar to countries where targeted reduction fisheries are operating.

107 However, the feed component of China's domestic marine fisheries has not been
108 documented systemically at the national level. Its scale, species composition, as well as
109 biological, ecosystem and management implications are poorly understood. For
110 example, 'nei' accounts for approximately 31% of China's domestic marine catch (Cao

111 *et al.* 2015), but its composition is largely unknown. This situation makes it difficult to
112 assess the impact of the source fisheries and seriously constrains the development of
113 effective management.

114 Meanwhile, there are growing concerns that the demonstrable declines in large-
115 scale, and unmanaged, fisheries bring substantial risks to the marine ecosystem,
116 threaten biodiversity and endanger long-term marine ecosystem resilience. One critical
117 risk is that further overfishing of a wide range of species and sizes in China EEZ will
118 seriously reduce the future productivity of marine fisheries (Cao *et al.* 2015, 2017).

119 The objectives of the present study were to reveal the complicated nature of the
120 feed component of China's domestic marine catch, related fisheries, volumes, species
121 composition, destination/use of catches, and its impacts and implications without
122 management. A better understanding of the current situation of China's domestic
123 marine fisheries, especially the little-understood component used as feed can provide a
124 solid basis for supporting future policy reforms in China's marine fisheries sector.

125 **2. Methodology**

126 The present study adopted an integrated, interdisciplinary methodology by
127 combining both top-down and bottom-up approaches to develop a holistic
128 understanding of the feed component of China's domestic marine catch. We started
129 from systematic literature reviews then proceeded to a nationwide field survey of
130 fishing vessels/gears and analysis of feed grade fish samples, collected in eight major
131 fishing provinces (Tables S2 and S3; Figure S3).

132 Field survey and feed grade fish sampling were focused on the most important

133 fishing months from August to December in 2016, which is right after the national
134 fishing moratorium and prior to the winter when fishing activities were largely closed
135 in the north. In 2016, the total capture fisheries production (both marine and freshwater)
136 in the second half of the year was 11.69 mmt, which accounts for 66.4% of annual
137 production (Economic Daily 2016; MOA 2017a).

138 **2.1. Terms used**

139 In the present study, domestic marine fisheries catches were classified into three
140 categories: (1) *food species*; (2) *forage species*, particularly small pelagic and
141 planktivorous species; and (3) all other *mixed species*, mainly used for aquaculture feed
142 (Table 1). In relation to supplying the animal feed sector, we suggest that the term ‘feed
143 grade fish’ for catch used as animal feed (either directly, or indirectly after reduction),
144 which consists of a wide range of species and sizes from small-sized individuals of food
145 species (category 1), forage species (category 2) to mixed species (category 3).
146 Specifically, ‘feed grade fish’ refers to the mixture of poorly preserved, small-sized and
147 low commercial-value fishes and invertebrates primarily used as animal feed. The term
148 ‘feed grade fish’ refers to ‘Xiao Za Yu’ in Mandarin, which literal translation is ‘small
149 and miscellaneous fish’.

150 **2.2. Fishing vessel/gear survey**

151 Fishing vessel/gear surveys were conducted in December 2016. The sampling of
152 fishing vessels for interviews followed a multi-stage sampling approach from
153 provincial level to district and port levels. Eight major marine fisheries provinces were
154 selected for the survey: Liaoning, Shandong, Jiangsu, Zhejiang, Fujian, Guangdong,

155 Guangxi, and Hainan. The total marine catch in these eight provinces represented 97.7%
156 of the national domestic marine catch in 2016 (Table S2). The most important one or
157 two districts for marine capture fisheries in each province, in terms of the number of
158 fishing vessels and landing volumes, giving a total of 22 fishing ports in 12 districts,
159 were selected for the surveys (Table S3; Figure S3).

160 Surveys covered the following areas of interest. (1) Basic information about
161 interviewees such as position, name, age, and contact information. (2) Vessel
162 information such as registration number, length, and horsepower. (3) Major fishing
163 areas and major fishing gears. (4) Total catch of food species in different taxonomic
164 groups (i.e. fishes, cephalopods, crustaceans and others). (5) Total catch of feed grade
165 fish (i.e. the fish is marketed as such). (6) Catches of major species among food species.
166 (7) Major species of feed grade fish. (8) Destination and price of feed grade fish. Survey
167 questions were designed to cover the whole fishing season in the second half of 2016
168 (August to December).

169 Fishing vessel surveys at port level were primarily conducted according to fishing
170 gear type. Fishing gears were classified according to The International Standard
171 Statistical Classification of Fishing Gear (FAO 2016) and standards in publications
172 (Wang and Yu 2012; Hainan Aquaculture Institute 2013; Sun 2014). Survey sample
173 sizes for each fishing gear category were at least 30, except for trawler. The trawler was
174 the focus of the present study because trawlers produce half of China's marine catch by
175 weight in the EEZ (Figure S4) and account for a high proportion of feed grade fishes
176 (Table S1). Survey sample sizes for trawler in each selected province were at least 30.

177 The term ‘trawler’ covers vessels that may target feed grade fish (especially midwater
178 trawlers) and those that catch feed grade fish incidentally (generally bottom trawlers).
179 Fishing vessels were randomly selected in each port, with interviewees being mainly
180 fishing vessel owners, captains, or senior fishers.

181 **2.3. Fish sampling, identification, and measurement**

182 From August to December 2016, feed grade fish samples of up to 1 kg in weight
183 were collected 2-3 times per month in each of eight provinces directly from fishing
184 vessels. Species were identified, and individuals were counted and measured for body
185 weight and length. Identified species from collected samples were classified as *food*
186 *species*, *forage species*, or *mixed species* based on the opinions of four experts from
187 different research institutes. Classifications also referenced major aquatic trading
188 websites, and marine capture species lists in the FAO FishstatJ database (FAO 2017),
189 China Fishery Statistical Yearbook (MOA 2017a), the list of commercially important
190 aquatic animals and plants under special national protection for resources (MOA 2017b),
191 the standard of catchable size of important fisheries species part 1 (economic marine
192 species (MOA 2017c)), and marine capture species information in FishBase (Froese
193 and Pauly 2017). The IUCN Red List Status of Threatened Species
194 (www.iucnredlist.org) was referred to for conservation status of identified species.
195 Stock assessments from fisheries in China or the wider SE Asia region were collected
196 from FAO evaluations and related publications.

197 **2.4. Data analysis**

198 A multiple linear regression model was used to investigate factors contributing to

199 different proportions of feed grade fish in catches using SPSS 22 statistics software
200 (IBM 2013). All fishing vessels surveyed were classified into one of three length
201 categories (<12 m, 12-24 m, >=24 m) according to the China Fisheries Yearbook (MOA
202 2017a). The proportion of feed grade fish in catches was calculated based on survey
203 results for all major fishing gears surveyed across all eight provinces. Using marine
204 fisheries production by province and fishing gear type as a weighting factor for
205 proportion of feed grade fish, the overall proportion of feed grade fish for the whole
206 country was calculated. Independent-samples Kruskal-Wallis test was used for
207 significance test using SPSS 22 statistic software (IBM 2013). The Chinese Yuan (CNY)
208 was converted to US dollars (USD) using the annual average exchange rate in 2016 as
209 1 USD=6.66 CNY (<https://www.investing.com/>).

210 Maturity stage was inferred from knowledge of recorded or estimated size (body
211 length) at first maturity (L_m). L_m was collected from FishBase (Froese and Pauly 2017).
212 When the recorded L_m for a species was missing, the estimated L_m in the FishBase
213 Species Ecology Matrix was used; estimated L_m was calculated from the recorded
214 asymptotic length of a species and an empirical relationship between length at first
215 maturity and asymptotic length (Froese and Binohlan 2000; Froese and Pauly 2017).

216 Several potential sources of variation and uncertainty in the present study
217 (Appendix S1) could affect the calculations of total feed grade fish volume as well as
218 feed grade fish sampling. To estimate the aggregate impact of data uncertainty on feed
219 grade fish production in China, a Monte Carlo analysis was conducted in Oracle Crystal
220 Ball (Release 11.1.2.3.500). The Monte Carlo method is extensively used in fisheries

221 research to estimate uncertainty by repeated random sampling based on predefined
222 parameters of probability distributions (Pauly *et al.* 2014). The type of probability
223 distributions and uncertainty parameters for the model were calculated by the Batch Fit
224 module in Oracle Crystal Ball and based on survey data of the present study. The
225 uncertainty parameters represented variations in the proportion of feed grade fish from
226 different fishing gear category. We calculated uncertainty based on a distribution of
227 100,000 runs resulting from the Monte Carlo sampling method.

228 A sensitivity analysis was conducted to explore the juvenile percentages associated
229 with variation of length at sexual maturity (Appendix S1). Instead of using the
230 estimated Lms, body length at 50% of the maximum body length (L50) reported in the
231 FishBase (Froese and Pauly 2017) was used as a comparable criterion for the size of
232 sexual maturation.

233 **3. Results**

234 **3.1. Proportion of feed grade fish in catch**

235 A total of 886 interviews was conducted from domestic vessels in 22 major fishing
236 ports in eight major fishing provinces in December 2016 (Tables S3 and S4). The
237 multiple linear regression model shows fishing gear and sampling location (province)
238 to be the major factors associated with different proportions of feed grade fish
239 (including fishes and invertebrates) in catches ($p < 0.05$; Table S5). The average engine
240 power of fishing vessels, according to respondents willing and able to answer this
241 question, was 410.5 ± 343.3 kW ($n=582$) and the average vessel length is 31.3 ± 10.0 m
242 ($n=851$) (Figure S5). Although large fishing vessels produced significantly more catch

243 per vessel than small fishing vessels (Table S6), vessel size (length) has little effect on
244 the proportion of feed grade fish in catches (Table S7).

245 Trawls, stow nets, gillnets and entangling nets, and surrounding nets and seine nets
246 were identified as the main fishing gears taking feed grade fish. Trawls accounted for
247 the highest proportion of feed grade fish catch overall by weight (Figure 1), with nearly
248 half ($48.9 \pm 26.5\%$, $n=538$) of trawler catches being feed grade fish. This is not surprising
249 as midwater trawls primarily target forage fishes, mainly anchovies in the Bohai and
250 Yellow Seas, producing $71.5 \pm 31.2\%$ ($n=76$) of feed grade fish as a proportion of their
251 total catch by weight. This was significantly ($p < 0.05$) higher than the proportion taken
252 from bottom trawlers ($43.6 \pm 21.3\%$, $n=336$) (Table 2) and probably reflects the fact that
253 midwater trawls are used to target small pelagic species that are commonly used for
254 animal feeds.

255 Three-fifths (58.5%) of trawlers, 46.6% of stow net vessels, 23.5% of gillnet and
256 entangling net vessels, and 7.1% surrounding nets and seine nets vessels by number,
257 were predominantly producing feed grade fish, which accounting for at least 50% of
258 their total catch by weight (Figure 2). Trawlers in Liaoning, Shandong, Guangxi, and
259 Hainan reported significantly higher proportions of feed grade fish in their catches than
260 other provinces ($p < 0.05$) (Table 3).

261 **3.2. Feed grade fish production**

262 The overall proportions of feed grade fish, according to 886 interviews, weighted
263 by production by gear and province (Tables 4 and 5) show that 34.7% of China's marine
264 catch, or 4.6 mmt marine fisheries production, was feed grade fish. The Monte Carlo

265 analysis also shows that about 4.6 mmt (95% confidence interval: 2.1–7.0 mmt) of total
266 production was feed grade fish (Figure S6, Table S8).

267 The proportion of feed grade fish produced by all trawlers combined, weighted by
268 production by province, was 48.7%, which is equivalent to 3.0 mmt of feed grade fish
269 production from China's EEZ (Table 5). This is followed by stow nets 0.7 mmt, gillnets
270 and entangling nets 0.6 mmt and surrounding nets and seine nets 0.2 mmt (Table 5).
271 Shandong, Guangxi, and Zhejiang had the highest proportions of feed grade fish (Figure
272 3) in their catches, reflecting the reliance of these provinces on trawlers (Figure S7).
273 The top capture fisheries provinces are also major feed grade fish producing provinces,
274 especially Zhejiang and Shandong (Figure 4; Table S2).

275 **3.3. Use and prices of feed grade fish**

276 A total 88.2% of interviewees (n=781) reported that their feed grade fish catch was
277 mainly used in the aquaculture and feed industries, either as direct feed (e.g. using
278 unprocessed whole fish or fish parts directly in aquaculture cages/ponds) or indirectly
279 to produce fishmeal and fish oil which is then used as raw material for aquaculture and
280 livestock feed (Figure 5). Some mink and fox farms in Shandong and Liaoning, and,
281 occasionally, chicken and pig farms in fish-producing areas, also use feed grade fish
282 but the scale of this use is not known. A low proportion (4.9%) of the interviewees
283 (n=43) reported discarding feed grade fish because of poor condition, while 6.7% (n=59)
284 reported their catch was mainly used for human consumption after processing into
285 minced products such as fish balls, dried or salted product, or sauces and pastes. The
286 consumption of feed grade fish (4.6 mmt) was estimated according to survey data

287 (Figure 6).

288 Prices of feed grade fish purchased from fishing vessels or at fishing ports varied
289 from USD 0.1 to 0.8 per kg and averaged USD 0.2 ± 0.1 per kg ($n=684$) depending on
290 province, freshness/quality, species composition, the type of utilization intended, and
291 the demand for feed grade fish by the aquaculture sector (Figure S8). Small size and
292 poor condition of feed grade fish led to particularly low prices, making them affordable
293 for purchase and use whole by aquaculture producers or for manufacturing of fishmeal.

294 A nationwide feed grade fish value chain has developed, and a stable market and
295 price structure for feed grade fish now exists. Feed grade fish transactions take place
296 both within the capture fisheries sector and across a trade chain that links feed grade
297 fish capture to transportation networks by sea or by land and involving cold storage,
298 with aquaculture farms and fishmeal factories as major end-users. The trade network
299 runs across the country; for example, feed grade fish caught in Zhejiang could supply
300 aquaculture farms in Fujian, and fishmeal factories in Shandong.

301 **3.4. Species composition**

302 A total of 80 samples of feed grade fish, with a total weight of 64.4 kg, after
303 removing unidentifiable fish and invertebrate body parts and garbage, were collected
304 from 22 fishing ports surveyed throughout eight major marine fisheries provinces. A
305 total of 12,206 individuals were measured, the majority being fish, with 10,796 (88.5%)
306 individuals, followed by 1,263 (10.4%) crustaceans, and 147 (1.2%) cephalopods.

307 Species identification focused on fishes; 98.0% of fish individuals were identified
308 to species level. A total of 218 fish species were identified (three to genus level only),

309 including three Chondrichthyans (two orders and two families) and 215
310 Actinopterygians (19 orders and 84 families) (Figure 7; Figure S9, Tables S9-S11).
311 The most numerous fish families were Engraulidae (3,668 individuals from 10 species),
312 Gobiidae (1,852 individuals from 14 species), Clupeidae (752 individuals from 8
313 species), Synodontidae (734 individuals from 5 species), Bregmacerotidae (632
314 individuals from 1 species), and Sciaenidae (488 individuals from 17 species). In
315 addition, 50 crustaceans (2 orders and 20 families) and five cephalopods were identified
316 (Tables S12 and S13). Many crustaceans and cephalopods were small-sized and/or body
317 damaged; therefore, body size/weight measurements were not made.

318 **3.5. Food fish species and proportion of catches composed of juveniles**

319 Of 218 identified fish species, 102 (46.8%) were food species, 19 (8.7%) were
320 forage fish and 97 (44.5%) mixed fish. Of the 10,580 fish individuals identified to
321 species, 3,112 (29.4%) were food fish, 4,392 (41.5%) forage fish, and 3,076 (29.1%)
322 mixed fish. A total of 9,377 (88.6%) individuals had measurable body length. Three-
323 quarters (7,225 individuals, 77.05 %) of these fish individuals were estimated to be in
324 the juvenile phase in terms of the criterion of Lm's (Tables S9-S11). The majority
325 (88.9%) of food fish were likely to be in their juvenile stage while 71.8% and 73.1% of
326 forage fish and mixed fish were juveniles respectively (Figure 8).

327 The percentages of juveniles were lower (food fish 79.7%, forage fish 60.9%,
328 mixed fish 37.3% and overall 59.9%) when the criterion for size of maturity was set for
329 the criterion of L50 (Figure S10). The reduced percentage of juveniles is mainly
330 because the estimated Lm tends to be longer in small fish than in large fish (Froese and

331 Binohlan 2000; Tsikliras and Stergiou 2014; Froese and Pauly 2017). Most of the fish
332 species identified in this study are small-sized species (Tables S9-S11), and their
333 estimated Lm's are more likely longer than the sizes of 50% of the maximum body
334 length.

335 **3.6. Stock assessment and conservation status**

336 Of 218 fish species identified, stock assessments published in reports, books or
337 papers from 2005 to 2015 were found for 32 species and taxonomic groups (to genus
338 level), of which 28 (87.5%) were over-exploited, and 4 (12.5%) were fully exploited or
339 starting to decline at the time of reporting, all were Actinopterygians (Tables S14 and
340 S15).

341 In terms of conservation status, 143 fish species have not been evaluated (NE)
342 against the IUCN Red List Criteria. Among the 72 species evaluated, one was
343 endangered (EN, *Evyinnis cardinalis*), one vulnerable (VU, *Nemipterus virgatus*), 59
344 least concern (LC), and 11 data deficient (DD) (Tables S9-S11).

345 Eight species of fish, one crustacean, and one cephalopod have been important for
346 China's national stock enhancement projects (Table S16). Of these ten species, most
347 individuals taken in samples of the current study were still in their juvenile stage.
348 National stock enhancement projects, therefore, are likely being compromised by
349 uncontrolled fisheries that catch feed grade fish as these projects rely on the dispersal
350 of juvenile fish into the wild.

351 **4. Discussion**

352 **4.1. Fishing for feed in China is substantial and biologically unsustainable**

353 Although the reported production from China's fishing grounds remained stable
354 over multiple years, an increasing and significant proportion of domestic marine catch
355 comprises poorer quality fish, less marketable as direct human food than previously,
356 and now primarily used as animal feed. The loss of historically major food fisheries,
357 declining fisheries biomass and CPUE, changing species composition, declining fish
358 size, and shifting end use of marine catch, primarily driven by severe overfishing and
359 excessive capture of juveniles, are trends that have largely been obscured by this stable
360 reported production.

361 At the global level, around one-quarter, or 20 mmt, of fisheries landings were used
362 for purposes other than direct human consumption (FAO 2018). The present study
363 found that about 35% (4.6 mmt) of China's marine catch is now sold at low prices as
364 feed grade fish, 40% higher than the global average. Considering China's feed grade
365 fish production alone would rank it fourth among World's leading marine fisheries
366 countries (Figure 9).

367 Thirty percent (29.4%) of feed grade fish catch was identified as food fish species,
368 with most of these (79.7%) in their juvenile size range. If allowed to reach marketable
369 size, these fish could potentially have gone directly to human food use and gained
370 higher prices, which in turn would maximize yield or, at least, optimize individual value
371 per recruit (Beverton and Holt 1993; Froese *et al.* 2016; Cashion *et al.* 2017) (also see
372 Table S17). Forage fish are also overfished in China, with 71.8% of the individuals

373 sampled being juveniles. This is in contrast to many of the World's major reduction
374 fisheries that specifically target forage fish which are effectively managed using a
375 variety of catch control tools, such as quotas and effort limits (Tveteras *et al.* 2011;
376 Pikitch *et al.* 2012).

377 Protecting juveniles is a core component of fisheries management and sustainable
378 resource use (Garcia *et al.* 2003; Crowder *et al.* 2008; Pinsky *et al.* 2011; Froese *et al.*
379 2016). There are examples of fisheries collapses of multiple different individual species
380 stocks associated with depletion of adult individuals and an increasingly high
381 proportion of juveniles in catches. For example, the large yellow croaker was heavily
382 exploited to the point of severe depletion in the 1980s with an increasingly heavy take
383 of juveniles (Liu and Sadovy de Mitcheson 2008) (Figure S11). Trends of increasingly
384 higher proportions of juveniles in catches were also observed with many other major
385 food species such as Largehead hairtail (*Trichiurus lepturus*), Yellow croaker
386 (*Larimichthys polyactis*), Silver pomfret (*Pampus argenteus*) and Japanese Spanish
387 mackerel (*Scomberomorus niphonius*) (Figure S12).

388 The outcomes of decades of overfishing and excess fishing capacity in China's
389 domestic marine fisheries resulted in depletions of some 'traditionally taken' species
390 by the 1970s and 1980s. By the 1980s and 1990s, some forage species and recently
391 exploited food species such as the scaly hairfin anchovy (*Setipinna taty*) and the filefish
392 (*Thamnaconus modestus*) had also become over-exploited (Figure S2). The mean
393 trophic level of China's marine catch has declined from 3.7 to 3.46 during the past half-
394 century (Cao *et al.* 2017), which is linked to the expanding proportion of low-trophic-

395 level forage species in catches, eroding biodiversity and degrading marine ecosystem
396 structure, functioning and resilience (Smith *et al.* 2011). Unmanaged over the long term,
397 there is a real risk that the fishery resources underpinning the feed component of
398 China's marine catch will also inevitably collapse (Beverton 1990; Costello 2017)
399 (Figure S2).

400 **4.2. Effective management is needed for both food and feed components**

401 China has regulations, policies and measures aimed at controlling fishing capacity,
402 including a fishing license system, fishing moratorium, and minimum mesh size
403 regulation (Cao *et al.* 2017). However, these efforts have clearly been inadequate in
404 part due to ineffective compliance/enforcement of regulations but also because these
405 measures do not control fishing effort. For example, along with depleted traditional
406 fisheries resources, fishers tend to reduce their mesh size to maintain or increase their
407 catches (Yu 2003); the legal minimum stretched mesh size requirement of 25 mm
408 (which is still lower than 40 mm recommended by the APFIC Trawl Guidelines (FAO
409 2014a)) is poorly implemented. Cod-end mesh sizes net of 10 mm or less are
410 extensively used by Chinese trawlers (Liang and Pauly 2017).

411 China's fisheries resources have been over-exploited since the 1970s, well before
412 the development of intensive feed and aquaculture industries. Indeed, the aquaculture
413 industry could be considered a beneficiary of changed marine catch composition.
414 Although aquaculture development and intensification was not the direct cause of over-
415 exploited fisheries resources in China, the rapid development of the feed and
416 aquaculture industries in China fueled a high market demand for feed grade fish and

417 provided new incentives to continue fishing even as traditional fisheries were being
418 depleted. In this way, the high demand for feed exacerbated the already overfished state
419 of resources allowing fishers to continue making money even as the ecosystem became
420 further degraded.

421 With globally expanding aquaculture, fishmeal prices in the international market
422 have more than tripled over the past decade (FAO 2014b) (also see Figure S13), and
423 the price of domestically produced fishmeal has increased in tandem. The high demand
424 for fish feed from the aquaculture sector is supported by a large number of fishmeal
425 factories. Their operation, often well below full capacity (20-45% in 2016 (Wang
426 2017)), suggests increasing competition for scarce supplies. Such pressures place
427 further stress on overexploited fishery resources.

428 The fishery fuel subsidy policy was introduced in 2006 in China and became the
429 most important type of fishery subsidy in the country, accounting for 94% of overall
430 fishery subsidies (Mallory 2016). The fuel subsidy covers about one-third of the total
431 cost of marine capture fisheries (Zhu and Huang 2014). Without fuel subsidies, more
432 than 90% of fishing vessels would lose money (Guo 2015). Economic incentives, from
433 increasing demand for feed grade fish, high fuel subsidies, along with depletion of
434 traditional fishing target species, further increase the motivation for overfishing.

435 The unparalleled scale (i.e. high volume) and poor fisheries resources condition
436 (i.e. highly depleted) of China's domestic marine fisheries make them distinctive and
437 the solutions to the problems created need to be large-scale and must significantly
438 reduce current levels of fishing effort. China, like many other tropical and sub-tropical

439 Asian countries (Leadbitter 2013), has a high biodiversity of fishes. The best option for
440 managing the take of hundreds of different species, on the one hand, while addressing
441 conservation principles that reduce threats to species and maintain functional marine
442 ecosystems, may not be to seek Maximum Sustainable Yield (see for example
443 Sainsbury 1984 (Sainsbury 1984)). One alternative is to generate a ‘Pretty Good Yield’
444 (Rindorf *et al.* 2017a,b) conditions with acceptable trade-offs where marine ecosystems
445 are able to satisfy diverse societal needs ensuring most stocks and the ecosystem are
446 protected or remain biologically viable (Cheung and Sumaila 2008; FAO 2014a;
447 Costello 2017). Conservation measures, such as marine protected areas, can be used to
448 safeguard key spawning and nursery areas that enable species to replenish themselves
449 (Edgar *et al.* 2014; Hastings *et al.* 2017; Roberts *et al.* 2017).

450 By reducing excess fishing capacity, safeguarding key life history times and/or
451 places, and effectively enforcing the current minimal mesh size requirement, fishery
452 collapse could be averted, fisheries biomass, total catch and value could be increased,
453 and the catch profile could be shifted to favor a greater proportion of larger fish
454 (Jacobsen *et al.* 2013; Costello 2017; Szuwalski *et al.* 2017). This could also produce a
455 better mix of products for direct human consumption, and indirectly via fish and
456 livestock feed.

457 **5. Conclusions**

458 Significant changes in species composition in catches, the high proportion of catch
459 comprised of juveniles, and loss of or severe declines in traditionally important fisheries
460 are clear evidences of weak fisheries management and decades-long history of

461 persistent overfishing and excess fishing capacity in China's domestic marine fisheries.
462 The growing proportion of catch used to supply the aquaculture sector since the 1990s
463 has meant that pressure continues to be high across the coastal ecosystem, even as these
464 declines and shifts occur. To date, commitments to resolve fishery issues remain
465 unfulfilled and existing management measures have been ineffective.

466 Under current fishery policy, China's fisheries risk a further downwards shift due
467 to intensification of both fishing down and farming up the food web (Pauly *et al.* 1998;
468 Naylor *et al.* 2000; Tacon *et al.* 2010). Unchecked, this trajectory will continue and
469 could ultimately result in an ecosystem shift towards species that have little or no
470 human value and other challenges of ecosystem degradation, some of which may not
471 be reversible, and which may not even be able to supply feed grade fish into the future.
472 There is also a long-term threat associated with loss of marine biodiversity and loss of
473 ecosystem function and resilience.

474 Based on the outcomes of the present study, it is clear that the feed component of
475 China's marine catch should be documented and managed as part of the overall national
476 planning for sustainable fisheries resources use and marine ecosystem management. A
477 biologically sustainable balance between fishing for food and fishing for feed could be
478 achieved to produce a better mix of products by effectively managing China's
479 multispecies fisheries and reducing excessive fishing capacity, while not further
480 compromising the ecosystem and associated biodiversity. Overall, a more ecosystem-
481 level and precautionary approach is needed for fisheries management, aquaculture
482 development (such as a better selection of species cultured), including management of

483 the feed component of China's marine catch to ensure long-term sustainability.

Table 1. Characteristics of three fisheries catch categories.

Category	Food species	Forage species	Mixed species
Targeted	Yes	Yes	No
Utilization†	Human food	Mostly feed	Mostly feed
Production scale	Medium to large	Small to large	Small to large
Commercially importance	High	Medium	Low
Planktivorous	Yes/No	Mostly Yes	Mostly No
Pelagic/Demersal	Demersal/Pelagic	Mostly pelagic	Mostly demersal
Market value	Medium to high	Low to medium	Low
Primary fishing gear	All	Midwater trawl	Bottom trawl
Example species	Groupers, yellow croaker (<i>Larimichthys polyactis</i>)	Anchovies, sardines	Pinkgray goby (<i>Amblychaeturichthys hexanema</i>)

† Marketed and used as such, and dependent on size of fish, quality of handling, volume available, time of year and location.

Table 2. Proportions of feed grade fish in catches (by weight) from different fishing gears (n=886 interviews)

Vessel type	Proportion of feed grade fish (%)
Midwater trawler	71.51±31.20 (n=76) ^a
Bottom trawler	43.59±21.25 (n=336) ^b
Unspecified trawler †	49.57±29.01 (n=126) ^b
Stow nets	40.94±26.31 (n=151) ^b
Gillnets and entangling nets	27.54±25.26 (n=55) ^{cd}
Surrounding nets and seine nets	17.18±19.21 (n=87) ^d
Other ‡	7.63±6.37 (n=19) ^d
Transport ship	43.50±29.56 (n=36) ^{bc}

Note: † Unspecified trawler include both midwater trawler and bottom trawler, but not specified by the interviewees; ‡ ‘Other’ category includes hooks and lines, pots, rakes and other miscellaneous gears. Independent-samples Kruskal-Wallis test was used for significance test using SPSS 22 statistic software (IBM 2013). Means superscripted by different letters indicate significant differences (p<0.05).

Table 3. Proportions of feed grade fish in catches (by weight) from trawlers in eight provinces (n=538 interviews)

Province	Bottom trawler (%)	Midwater trawler (%)	Unspecified trawler (%)†
Liaoning	36±35 (n=15) ^b	94±8 (n=21) ^a	23±40 (n=3) ^{abc}
Shandong	35±26 (n=41) ^b	85±13 (n=27) ^{ab}	67±23 (n=15) ^a
Jiangsu	33±29 (n=15) ^b		33±33 (n=9) ^{abc}
Zhejiang	56±13 (n=51) ^a	57±16 (n=5) ^{bc}	35±32 (n=24) ^{bc}
Fujian	40±18 (n=63) ^b	26±34 (n=14) ^c	9±12 (n=10) ^c
Guangdong	31±13 (n=73) ^b		0±0 (n=3) ^{bc}
Guangxi	58±11 (n=63) ^a	51±0 (n=3) ^{bc}	60±9 (n=11) ^{ab}
Hainan	62±11 (n=15) ^a	62±27 (n=6) ^{bc}	65±14 (n=51) ^a

Note: † Unspecified trawler include both midwater trawler and bottom trawler but not specified by the interviewees. Independent-samples Kruskal-Wallis test was used for significance test using SPSS 22 statistic software (IBM 2013). Means superscripted by different letters indicate significant differences ($p < 0.05$).

Table 4. Weighting factors and weighted proportion of feed grade fish in different fishing gears

Fishing gear	Province	Proportion of feed grade fish collected from interview (Pp, %)	Marine catch in China's EEZ in 2016 (Pd, mt)[†]	Weighting factors (Wt)[‡]	Weighted proportion of feed grade fish of each fishing gear category (WPP, %)[§]
Trawls	Liaoning	66.01	397,894	0.065075	48.70
	Shandong	56.91	1,398,197	0.228673

	Guangdong	3.89	433,718	0.194851	
	Guangxi	90.00	84,030	0.037751	
Stow nets	Liaoning	21.92	95,891	0.065429	47.53
	Shandong	51.69	190,367	0.129892	
	Jiangsu	31.00	211,978	0.144638	
	Zhejiang	47.18	613,130	0.418355	
	Fujian	62.82	346,156	0.236191	
	Guangdong	58.64	8,052	0.005494	
Others ¶	All	0.00	1,360,431	-	0

Note: †: Data source: (MOA 2017a); ‡: Weighting factors (Wt_i) are calculated separately for each fishing gear category and based on production in each province (Pd_i), as $Wt_i = Pd_i / \sum_{i=1}^n Pd_i$, for each fishing gear category $\sum_{i=1}^n Wt_i = 1$; §: Weighted proportion of feed grade fish of each fishing gear category (WPP) are calculated separately for each fishing gear category and based on proportion of feed grade fish collected from interview (Pp_i) and its weighting factors (Wt_i), as $WPP = \sum_{i=1}^n Pp_i \times Wt_i$; ¶: 'Others' category includes hooks and lines, pots,

rakes and other miscellaneous gears. The proportion of feed grade fish from 'Others' category was set at 0% due to the limited sample size of it.

Table 5. Weighted means of proportion and production volume of feed grade fish in total landings in China

Fishing gear	Weighted proportion of feed grade fish (WPP, %)†	Marine catch of each fishing gear category in China's EEZ in 2016 (GPd, mmt)‡	Overall weighting factors (OWt)§	Overall weighted proportion of feed grade fish (OWPp, %)¶	Feed grade fish production (FFPd, mmt)#
Trawls	48.70	6.23	0.469	34.69	3.03
Surrounding nets and seine nets	20.34	1.10	0.083		0.22
Gillnets and entangling nets	20.20	3.04	0.229		0.61
Stow nets	47.53	1.55	0.117		0.74
Others ⊥	0.00	1.36	0.102		0.00
Total catch in China's EEZ in 2016 (mmt)					13.28
Total feed grade fish production in China in 2016 (mmt)					4.61

Note: †: The weighted proportion of feed grade fish of each fishing gear category (WPP) please see Table 4. ‡: Data source: (MOA 2017a); §: Overall weighting factors (OWt_j) are calculated based on marine catch production of each fishing gear category in China's EEZ in 2016 (GPd_j), as $OWt_j = GPd_j / \sum_{j=1}^n GPd_j$, and $\sum_{j=1}^n OWt_j = 1$; ¶: Overall weighted proportion of feed grade fish (OWPp) are calculated based on weighted proportion of feed grade fish of each fishing gear category (WPP_j) and overall weighting factors (OWt_j), as $OWPp = \sum_{j=1}^n WPP_j \times OWt_j$; #: Feed grade fish production (FFPd) are calculated based on weighted proportion of feed grade fish of each fishing gear category (WPP_j) and marine catch production of each fishing gear category in China's EEZ in 2016 (GPd_j), as $FFPd = WPP_j \times GPd_j$; ⊥: 'Others' category includes hooks and lines, pots, rakes and other miscellaneous gears. The proportion of feed grade fish from 'Others' category was set at 0% due to the limited sample size of it.

Figure legends

Figure 1. Proportions of feed grade fish in catches (by weight) from different fishing vessels classified by fishing gears and transport ship. ‘Other’ category includes hooks and lines, pots, rakes and other miscellaneous gears.

Figure 2. Proportions of feed grade fish in catches (by weight) from all types of trawlers in eight provinces (A) by proportion of feed grade fish and (B) by province (n=538).

Figure 3. Proportions of feed grade fish in marine fisheries catches in different provinces.

Figure 4. Contribution of feed grade fish production (by weight proportion) in China by major producing province.

Figure 5. Feed grade fish consumption and other use, in different provinces. Using feed grade fish as direct feed or produce fishmeal was not specified in surveys conducted in Zhejiang province.

Figure 6. Estimated production and consumption of marine catch in China’s EEZ. The proportions of forage and mixed species are based on data in Figure S2; the use of feed grade fish in Zhejiang was set at national average (Figure 5); the unit for all numbers is mmt.

Figure 7. Taxonomic coverage of feed grade fish samples. (A) Class (B) Order (C) Family

Figure 8. Number and the proportion of juveniles and adults in the samples in three categories (Food fish, Forage fish, Mixed fish). Unidentified individuals are those

individuals identified to species level, but no available measurable body length.

Figure 9. Production of top 10 World's leading marine (domestic + distant) fisheries countries and production of feed grade fish in China's marine catch in 2016. Data source: (FAO 2017); Aquatic plants excluded.
