23 **Abstract**

24 Complement activation leads to membrane-attack complex (MAC) formation which can lyse  
25 not only pathogens but also host cells. Histones can be released from the lysed or damaged  
26 cells and serve as a major type of damage-associate molecular pattern (DAMP), but their  
27 effects on the complement system are not clear. In this study, we pulled down two major  
28 proteins from human serum using histone-conjugated beads, one was C-reactive protein and  
29 the other was complement component C4 as identified by mass spectrometry. In Surface  
30 Plasmon Resonance (SPR) analysis, histone H3 and H4 showed stronger binding to C4 than  
31 other histones with Kd around 1.0 nM. The interaction did not affect C4 cleavage to C4a and  
32 C4b. Since histones bind to C4b, a component of C3 and C5 convertases, their activities were  
33 significantly inhibited in the presence of histones. Although it is not clear whether the  
34 inhibition was achieved through blocking C3 and C5 convertase assembly or just through  
35 reducing their activity, the outcome was that both classical and mannan-binding lectin (MBL)  
36 pathways were dramatically inhibited. Using a high concentration of C4 protein, histone-  
37 suppressed complement activity could not be fully restored, indicating C4 is not the only  
38 target of histones in those pathways. In contrast, the alternative pathway was almost spared  
39 but the overall complement activity activated by zymosan was inhibited by histones.  
40 Therefore, we believe that histones inhibiting complement activation is a natural feedback  
41 mechanism to prevent the excessive injury of host cells.

42

43

44

45

46 **Introduction** The Complement system forms a major part of the host response to infection  
47 and cellular injury(1, 2). This system is intricately involved in these processes and consists  
48 of a cascade of more than 50 proteins, participating in three activation pathways; namely the  
49 classical, mannose binding lectin (MBL) and alternative pathways(2). The classical pathway  
50 recognises antigen-antibody complexes contained on the surface of pathogenic factors,  
51 including gram-negative bacteria, viruses and damaged cells(3). The MBL pathway binds  
52 mannose containing pathogenic surfaces(4). Finally, the alternative pathway directly targets  
53 surface carbohydrate regions on pathogens such as viruses, bacteria and fungi(5). The  
54 terminal pathway of complement activation by different stimuli is the formation of C3 and C5  
55 convertases to lead to assembly of C5b-9 complex, the membrane- attack complex (MAC) to  
56 lyse pathogens. Many products generated during complement activation are also able to  
57 opsonize damaged cells or pathogens to facilitate phagocytosis(1, 2). In this way,  
58 complement activation enhances the ability of antibodies and phagocytic cells to clear  
59 invading pathogens and cellular debris from the circulation(6).

60

61 Complement activation not only kills pathogens but also damages host cells during an  
62 inflammatory reaction and excessive activation contributes to inflammation-driven tissue  
63 injury(7). Host cell lysis will release cell breakdown products, including DNA and histones,  
64 and those damage-associate molecular patterns (DAMPs) have been demonstrated to play  
65 important roles in disease progression and host immune responses(8-10). Histones, the most  
66 abundant and important DAMPs, can be detected in blood taken from many critical illnesses,  
67 such as severe trauma(11), severe sepsis(12, 13) and necrotising pancreatitis(14). Histones  
68 are positively charged proteins and have high affinity for negatively charged phospho-groups  
69 in DNA or cell membranes. Histone binding to cell membrane allows ions, particularly  $Ca^{2+}$   
70 influx into cells to cause harmful effects to cells contacted(11). In addition, histones are also

71 the ligands of Toll-like receptors (TLR)-2, 4 and 9 receptors to trigger immune response,  
72 including inflammasome activation and cytokine release(15-17). Histones also interact with  
73 coagulation factors in the circulation to promote thrombin generation, fibrin deposition and  
74 systemic coagulation activation(18-22). In animal models, extracellular histones have been  
75 shown to mediate multiple organ injury and even death in sepsis(13, 23). Clinically,  
76 correlation between circulating histone levels and organ injury as well as disease severity has  
77 also been demonstrated(12).

78

79 Recently, we found that extracellular histones interact with complement component 4 (C4)  
80 protein. Complement C4 coded by both C4A and C4B genes is synthesised into a single  
81 peptide (precursor) and then cleaved into  $\alpha$  (98kDa),  $\beta$  (73kDa) and  $\gamma$  (33kDa) chains(24, 25).  
82 Upon complement activation, C4 is cleaved by C1S enzyme into C4a (kDa) and C4b, the  
83 latter mainly participates in classical and lectin pathways by forming C3 and C5 convertases,  
84 whilst C4a as an anaphylatoxin enhances smooth muscle contraction, histamine release and  
85 vascular permeability as well as serving as a chemotaxis and inflammatory mediator(26, 27).  
86 In many disease conditions, particular in sepsis, complement activation(28) and histone  
87 release(12) coexist. The outcome of histones binding to C4 appears important and this study  
88 is trying to understand the pathophysiology related to the complement system and  
89 extracellular histones.

90

## 91 **Materials and Methods**

### 92 **Human plasma and serum**

93 Citrate plasma and serum were isolated from whole blood drawn from critically ill patients,  
94 according to the protocol granted by Liverpool Adult Ethical Committee (Ref: 13/NW/0089).  
95 Human normal serum was purchased from CompTech, USA.

96 **Fractionation of human serum and plasma by ultracentrifugation**

97 Citrate plasma and serum (1 ml) from patients were fractionated by ultracentrifugation at  
98 40,000 rpm (4°C) for one hour and then 6 layers of equal volume fractions (166 ul per  
99 fraction) were collected. Histones and Histone-DNA complexes were then measured in each  
100 fraction by Western blotting and ELISA (Cell death detection ELISA PLUS, Roche),  
101 respectively, as previously described.(11)

102 **Isolation of histone binding protein from plasma and mass spectrometry analysis**

103 Isolated citrated plasma was diluted with 2 × phosphate buffered saline (PBS) (v/v) and  
104 centrifuged to eliminate insoluble contents. The harvested supernatant was then pre-cleared  
105 using blank Sepharose resin and then loaded on a CNBr-activated Sepharose 4B (GE  
106 Healthcare, Little Chalfont, UK) column conjugated with calf thymus histones (Roche, West  
107 Sussex, UK). After a high stringency wash with PBS+0.5% (v/v) Tween-20 (Sigma-Aldrich,  
108 Dorset, UK) followed by PBS, histone-binding proteins were eluted and separated by gel  
109 electrophoresis. Gel slices from SDS-PAGE were washed (2 x 30 min) with 50%  
110 acetonitrile, 0.2M ammonium bicarbonate pH 8.9 and then dried in a rotary evaporator. The  
111 slices were re-swollen in RHB [2 M urea, 0.2 M ammonium bicarbonate pH 7.8] containing  
112 0.2 µg trypsin and incubated at 37°C overnight. Excess RHB was then removed and peptides  
113 were extracted from the gel slices with 60% acetonitrile, 0.1% TFA. The total peptide extract  
114 was concentrated in a rotary evaporator and then desalted using C18 ZipTips according to the  
115 manufacturer's instructions. MS analysis was performed using a MALDI-Tof instrument  
116 (Waters-Micromass) using a saturated solution of alpha-cyano-4 hydroxycinnamic acid in  
117 50% acetonitrile/0.1% trifluoroacetic acid.

118

## 119 **Detection of Histone-C4 complexes by ELISA**

120 Histone-C4 complexes were detected in normal and critically ill patient plasma using Cell  
121 death detection ELISA PLUS kit (Roche) with modification. In brief, normal plasma was pre-  
122 incubated with different concentrations of calf thymus histones for 10 minutes. Histones in  
123 plasma were first captured by biotinylated-anti-histone antibody immobilized on streptavidin-  
124 coated 96 well plates. After extensive washing, rabbit anti-human C4 antibody (Abcam)  
125 followed by anti-rabbit-HRP antibody were used to probe histone-C4 complexes. Arbitrary  
126 units (AU) were calculated based on the absorbance (450nm) to represent the relative levels  
127 of the complexes.

## 128 **Western blotting using HRP conjugated C4**

129 In order to double confirm the interaction of C4 with individual histones by different assay, 2  
130  $\mu\text{g}$  of H2A, H2B, H3 and H4, 4  $\mu\text{g}$  of H1 and 6  $\mu\text{g}$  of S100P (as control) were subjected to  
131 Western blotting with HRP-conjugated C4 protein. C4 was purchased from Fitzgerald, USA  
132 and conjugated using Lighting-Link HRP conjugation kit (Innova bioscience, Babraham,  
133 Cambridge, UK, ref. 701-0000) according to the procedure recommended by the  
134 manufacturer.

## 135 **Surface Plasmon resonance measurements**

136 The binding parameters of C4 to individual histones, including the equilibrium dissociation  
137 constant ( $K_d$ ), affinities on-rates ( $k_{on}$ ), and off-rates ( $k_{off}$ ) were measured by surface plasmon  
138 resonance analysis on a Proteon XPR36 system (Bio-Rad). Chips coated with 20 $\mu\text{g}$ .ml  
139 streptavidin (GLH, GE Healthcare), which could directly interact with histones,(29) were  
140 used for immobilizing individual histones and measuring binding affinities to C4. Running  
141 buffer (10 mM HEPES pH7.4, 150 mM NaCl (0.05% Tween 20) and regeneration buffer (0.1

142 M glycine pH2.2) were used throughout the assay. Five µg/mL of each recombinant histone  
143 (H1, H2A, H2B, H3 or H4) in running buffer was captured only on the surface of flow cells  
144 Fc (2-6) with Fc1 set as blank. For kinetics, a concentration series C4 was injected at a flow  
145 rate of 10 µl/min over both captured histone surface and reference surface (blank) at 20°C.  
146 Kds were calculated using software provided by the manufacturer.

### 147 **Complement activity assay**

148 The effect of histones on complement activity in the three pathways was measured using  
149 COMPL300 Total Complement Functional Screen kit from Wielisab (Sweden). Briefly,  
150 mixtures of the reaction were added to strips of wells for classical pathway (CP) estimation,  
151 that were precoated with IgM, strips for alternative pathway (AP) determination were coated  
152 with LPS, while Mannan binding lectin pathway (MBL) strips were coated with mannan.  
153 Normal human sera were diluted 1/101 (CP and MBL) and 1/18 (AP) assay in specific kit  
154 buffers, to ensure that only the pathway in question was activated.(30) After one hour of  
155 incubation at 37 °C then washing the strips, alkaline phosphatase-conjugated antihuman C5b-  
156 9 was added before incubation at room temperature for 30 min. Additional washing was  
157 performed, the substrate was added, and the wells were incubated for 30 min. Finally,  
158 absorbance values were read at 405 nm. In each assay, standard positive and negative control  
159 sera provided in the kit were used. The complement activity for each pathway was expressed  
160 as a percentage of the activity of the calibrating serum. C3a and C5a were measured using  
161 C3a and C5a ELISA kits (e-Bioscience). C5b-9 induced by zymosan (Comp Tech) was  
162 measured using an ELISA kit from Quidel Corporation, USA.

### 163 **Antibody and heparin blocking assay**

164 Anti-histone reagent, non-anticoagulant heparin 20µg/ml, was incubated with 20µg/ml H1,  
165 H2A, H2B, H3 or H4 proteins, or 20 µg/ml anti-histone H4 antibody incubated with H4, prior

166 to complement activation using Wieslab COMPL CP310 kit. Percentage changes were  
167 calculated by comparing to untreated (100%).

#### 168 **C4 cleavage assay**

169 C1S (50µg/ml, Comp Tech, USA) was incubated with C4 (250µg/ml) in the presence or  
170 absence of histones (100µg/ml) at 37°C for 30 mins, then 2X SDS loading buffer was added  
171 and boiled for 10 mins prior to SDS-PAGE. The gel was stained with Coomassie brilliant  
172 blue or subjected to Western blotting with anti-C4a antibody (Comp Tech). The C4a band  
173 intensities were measured using software 7.05 GeneSnap from Syngene and fold changes  
174 were calculated.

#### 175 **Cell viability assay**

176 Viability was assessed using a WST-8 cell proliferation assay kit (Enzo Life Sciences), as  
177 described previously(31). Briefly,  $5 \times 10^4$  cells were seeded into each well of a 96-well plate  
178 and grown until fully confluent (24 hours). Cells were treated with histones at 100 µg/ml with  
179 and without different concentrations of C4 (10-300 µg/ml) for 1 hour. After treatment, the  
180 medium was changed to a fresh 100 µl growth media and 10 µl of WST-8 dye was added to  
181 each well, followed by further incubation for 2 hrs. Viability was assessed by measuring the  
182 absorbance at 450 nm against a reference 650 nm using a microplate reader (Multiskan  
183 Spectrum, Thermoelectron Corporation). Viability of untreated cells was set as 100% for  
184 comparison.

#### 185 **Statistical analysis**

186 Intergroup differences were analysed using ANOVA followed by Student-Newman-Keuls test. Two  
187 group comparisons with or without treatment used Student's t test unless otherwise specified.

#### 188 **Results**

189 **Free histones exist in circulation and can form complexes with complement C4**

190 Although it is known that nucleosomes can be released after cell death or NETs  
191 formation(32-36), it is not clear whether circulating histones are still exclusively in the form  
192 of histone-DNA complexes. Using ultracentrifugation to fractionate plasma or serum with  
193 high circulating histone levels into 6 fractions, we found that histones were detectable in all 6  
194 fractions (Figure 1A upper panel). However, DNA-histone complexes (most likely  
195 nucleosomes) were in fraction 6 only (bottom fraction) (Figure 1A, lower panel). No  
196 difference was found between plasma and serum. This experiment demonstrated that DNA  
197 free-histones exist in circulation.

198 Histone-conjugated Sepharose beads were then used to pull down human plasma proteins.  
199 Following extensive washing, proteins bound to histone-beads were eluted. Multiple proteins  
200 were visualised on Coomassie blue stained gels with two major protein bands at  
201 approximately 70 kDa and 25 kDa (Figure 1B). Following liquid chromatography-mass  
202 spectrometry (LC-MS/MS) analysis, complement C4 and C-reactive protein (CRP) were  
203 identified (Figure 1C and 1D). CRP has been reported to be a major histone-binding protein  
204 that neutralises histone toxicities(37). As to complement C4, we could detect histone-C4  
205 complexes in normal plasma spiked with calf thymus histones (Figure 1E) and also in plasma  
206 from critically ill patients with high circulating histone levels (Figure 1F), confirming that  
207 histones form complexes with C4 in vivo. In this study, we further investigated the  
208 interaction of histones with C4 and its potential biological roles and significance.

209 **Individual histones bind to complement C4 with different affinity**

210 To determine the relative binding extents of individual histones to C4, equal molar  
211 concentrations of individual histones were subjected to gel overlay assay (Figure 2A upper)  
212 with Coomassie blue stained gel demonstrated equal loading (Figure 2A lower). Figure 2A

213 shows that H3 and H4 predominantly bound to C4 and to a lesser extent H1 and H2B, with  
214 H2A-C4 binding undetectable using this method. To determine the comparative binding  
215 strengths under physiological conditions, we used surface plasmon resonance (SPR, Biocore  
216 X-100) (Figure 2B-F). Table 1 shows that H3 ( $K_D = 0.76 \pm 0.12$  nM) and H4 ( $K_D = 0.91 \pm 0.07$   
217 nM) had much higher binding affinity than equal molar concentrations of H1 ( $K_D =$   
218  $7.26 \pm 0.80$  nM) and H2B ( $K_D = 9.45 \pm 1.43$  nM), with weak binding to H2A ( $K_D = 12.67 \pm 0.59$   
219 nM).

### 220 **Histones dramatically inhibit classical and lectin but not alternative pathways**

221 To investigate functional consequence, we used a Complement functional screen kit to  
222 measure the effects of histones on the activation of classical, MBL and alternative pathways.  
223 Pre-incubation of different concentrations of calf thymus histones with human serum  
224 significantly reduced the production of MAC by activated classical and MBL pathways.  
225 Significant reduction could be detected at 10  $\mu\text{g/ml}$  histones, and only trace amount of MAC  
226 could be formed in the presence of 50  $\mu\text{g/ml}$  histones (Figure 3A). In contrast, histones  
227 showed much less effect on the alternative pathway and 50  $\mu\text{g/ml}$  histones only reduced  
228 MAC about 20%. To evaluate the overall effect of histones on complement activation in  
229 human serum, zymosan was used to activate complement in the presence or absence of  
230 histones. We found that histones at 50  $\mu\text{g/ml}$  could significant inhibit the production of MAC  
231 induced by zymosan (Figure 3B). We also assessed the role of individual histones in the  
232 classical (C, D), and MBL (E, F) pathway activation and found that 20  $\mu\text{g/ml}$  individual  
233 histones started to significantly reduce activation of both classical and MBL pathways, with  
234 H4 and H2B showing the most significant effects.

### 235 **Anti-histone reagents can rescue complement activation**

236 To demonstrate the specificity of histones on complement activation, anti-histone H4 and  
237 non-anticoagulant heparin that have been shown to specifically inhibit histone toxicity both *in*  
238 *vitro* and *in vivo*(11, 38), were used. Heparin could reverse the inhibition of both classical and  
239 MBL pathways by all individual histones (Figure 4A, B), whilst anti-histone H4 could  
240 significantly rescue the H4-inhibited complement activation of both pathways (Figure 4C, D).  
241 Those data demonstrated that the effect of histones on complement inactivation was specific  
242 to histones.

#### 243 **Histones do not affect C4 cleavage but significantly reduce C3 and C5 convertase** 244 **activity**

245 To clarify the molecular mechanism of histone-inhibited complement activation through  
246 interaction with C4, the effect of histones on the cleavage of C4 to C4b and C4a by C1s, a  
247 process of C4 activation, was investigated. We found that histones showed no effect on the  
248 production of C4a (Figure 6 A-B), indicating histone binding does not affect the ability of  
249 C1s to cleave C4 protein. Further investigation showed that histones bind to C4b but not C4a  
250 (Figure 6C). However, in the presence of histones, the production of C3a and C5a were  
251 significantly reduced in the classical and MBL pathways but not the alternative pathway  
252 (Figure 6E-F), suggesting that histone-bound C4b is not as efficient as C4b alone in forming  
253 active C3 and C5 convertases. The overall C3a, C5a and C5b-9 production induced by  
254 zymosan (Figure 6E-F) was significantly reduced by histones due to the suppression of both  
255 classical and MBL pathways.

#### 256 **Excess C4 protein only partially rescues histone-inhibited complement activation but** 257 **significantly reduces cytotoxicity of histones**

258 Using C4 protein up to 300 µg/ml, only 1/3 of the maximal complement activity of classical  
259 and MBL pathways could be recovered in the presence of calf thymus histones up to 20

260  $\mu\text{g/ml}$  (Figure 5A, B). However, the zymosan-induced complement activation could be  
261 recovered by 300  $\mu\text{g/ml}$  C4 from 25% to 70% of total activity in the presence of 20  $\mu\text{g/ml}$   
262 histone H4 protein (Figure 5C). This observation suggests that histones may also target other  
263 components of the complement system rather than C4 alone. On the other hand, C4 protein  
264 could significantly reduce the cytotoxicity of histones to cultured endothelial cells (Figure  
265 5D).

## 266 **Discussion**

267 Complement activation generates membrane attack complexes (MAC) to lyse cells and leads  
268 to cell death and content release, including histones. The inhibitory effects of histones on  
269 complement activation could form a physiological feedback loop to prevent over production  
270 of MAC and excessive tissue damage. This finding is novel and with evidence that histone-  
271 C4 complexes exist in the circulation of critically ill patients, adds relevance to filling the  
272 unknown gap on communication between targeted cells and complement (Figure 7).

273 Complement C4 is activated by C1s cleavage to produce C4a and C4b. The C4b is the  
274 essential component of both C3 and C5 convertase, a common step of both classical and  
275 MBL pathways (Figure 7). Histones strongly bind to C4 but do not affect C4 activation  
276 because there is no difference in C4a production in the presence or absence of histones.  
277 Histones binds to C4b but not C4a, therefore their major effect is to reduce the activity of C3  
278 and C5 convertase, as indicated by reduction of C3a and C5a, the products of C3 and C5  
279 activation. One mechanism could be the interruption of the convertase formation and the  
280 other could just affect the catalytic activity even though the complexes are formed. Since the  
281 life time of C3 and C5 convertases in solution are very short, it is difficult to distinguish the  
282 two potential mechanisms. In contrast, histones have minimal effect on alternative pathways,  
283 in which C4b is not required. However, the overall effect is the significant reduction of C3

284 and C5 activation as well as the MAC formation. This finding suggests that C4 is a major  
285 target of the complement system. However, excess of C4 could not fully restore the  
286 complement activation in the presence of histones. This finding suggests that histones may  
287 have more targets on those pathways, such as C1 or C2 (Figure 7). This needs further  
288 investigation.

289 It is known that circulating C4 is about 0.4 mg/ml, but no histones could be detected in blood  
290 from healthy donors(39). In critical illness, for example sepsis, histones could surge up to  
291 100-200 mg/ml(12) but C4 was reported to decrease due to consumption(39). Therefore the  
292 high levels of histones are sufficient to inhibit both classical and MBL pathways. Although  
293 high levels of C4 could efficiently detoxify histones in vitro, the low levels of C4 in sepsis  
294 may not be sufficient to neutralise high levels of histones. In non-critical illness, such as  
295 chronic inflammatory diseases with complement activation, the circulating histones could be  
296 very low but the local concentration of histones released from lysed cells may be high and  
297 sufficient to suppress further complement activation and prevent excessive injury of host  
298 tissues. However, further laboratory experiments and clinical investigation are required to  
299 clarify those points.

300 **Grant support:** This work was supported by the Medical Research Council (G0501641);  
301 British Heart Foundation (PG/14/19/30751 and PG/16/65/32313) and National Institute of  
302 Health Research (II-FS-0110-14061, NIHR-BRF-2011-026). Yasir Qaddoori was sponsored  
303 by The Higher Committee for Education Development in Iraq HCED.

304 **Abbreviations:** AP: alternative pathway; CP: classical pathway; CRP: C-reactive protein;  
305 DAMPs: damage-associate molecular patterns; MAC: membrane- attack complex; MBL:  
306 Mannan binding lectin; LPS: lipopolysaccharides; NETs: neutrophil extracellular traps; SPR:  
307 surface plasmon resonance; TLR: Toll-like receptors.

308 **Author contributions:** YQ, STA and YA performed experiments, analysed the data and  
309 performed statistical analysis. PM and YQ did SPR assay. STA, GW and CHT wrote, edited  
310 and reviewed the manuscript and figures. GW, SEC and CHT supervised the work.

311 **Conflict-of-interest disclosure:** the authors declared no conflict of interest exists.

## 422 **Figure legends**

### 423 **Figure 1. Identification of Complement component 4 as a histone binding protein. (A)**

424 Critically ill patient plasma was separated into 6 fractions (1 = upper fraction; 6 = lower

425 fraction) based on density using ultracentrifugation. Circulating histones (top panel) were

426 measured by Western blot and histone-DNA complexes (bottom panel) quantified by ELISA

427 (n=4). **(B)** Using histone-conjugated Sepharose, a few proteins were pulled down. Among

428 them, there were 2 major bands on Coomassie blue stained gel, one was complement C4 and

429 the other was CRP, as identified by mass spectrometry. **(C) and (D)** The typical spectra of

430 the two major proteins are presented. **(E)** Histone-C4 complexes were detected by ELISA

431 following the addition of different concentrations of histones to normal plasma. **(F)** Histone-

432 C4 complexes are elevated in critically ill patient plasma compared to normal (n=3).

### 433 **Figure 2. Complement C4 binds to individual histones. (A)** Two $\mu$ g individual histones

434 and 6  $\mu$ g S100P as a control were subjected to SDS-PAGE. One gel was transferred onto

435 PVDF membrane and probed with HRP-conjugated C4 protein (upper panel). The other gel

436 was stained with Coomassie brilliant blue (lower panel). **(B-F)** SPR analysis. Individual  
437 histones were first immobilized on streptavidin surfaces. Different concentrations of C4 were  
438 applied onto each surface and typical binding curves are presented.

439 **Figure 3. Histones inhibit complement activation.** **(A)** Classical, MBL and alternative  
440 complement pathways were activated by IgM, mannan and LPS respectively in the absence  
441 or presence of different concentrations of calf thymus histones (0-50  $\mu\text{g/ml}$ ). MAC was  
442 detected by anti-human C5b-9 antibodies. The complement activity of control wells without  
443 histones was set up as 100%. The Means $\pm$ SD of relative activities were presented. **(B)** Shows  
444 the Means $\pm$ SD of relative activities activated by zymosan (activating different pathways) in  
445 the presence of different concentration of calf thymus histones (0-50  $\mu\text{g/ml}$ ). The Means $\pm$ SD  
446 of relative activities of Classical **(C)** and MBL **(D)** pathways in the presence of 20 $\mu\text{g/ml}$   
447 individual histones. The Means $\pm$ SD of relative activities of Classical **(E)** and MBL **(F)**  
448 pathways in the presence of different concentration of individual histones (0-50  $\mu\text{g/ml}$ ).  
449 Means $\pm$ SD were calculated from at least 3 independent experiments. **ANOVA test**, \* $p < 0.05$   
450 compared to untreated.

451 **Figure 4. Anti-histone treatment rescues complement activation.** **(A)** and **(B)** non-  
452 anticoagulant heparin (20  $\mu\text{g/ml}$ ) was used to rescue complement activities of classical **(A)**  
453 and MBL pathways inhibited by individual histones (20  $\mu\text{g/ml}$ ). **(C)** and **(D)** Anti-histone H4  
454 antibody (12  $\mu\text{g/ml}$ ) was used to rescue complement activities of Classical **(C)** and MBL **(D)**  
455 inhibited by H4 (20  $\mu\text{g/ml}$ ). The Means $\pm$ SD of relative activities from at least 3 independent  
456 experiments were presented. **ANOVA test**, \* $P < 0.05$  when compared to untreated. # $P < 0.05$   
457 when compared to that treated with histone alone.

458 **Figure 5. Histones show no effect on C4 cleavage but significantly reduce C3 and C5**  
459 **convertase activities.** **(A)** In vitro cleavage of C4 by C1S in the presence or absence of

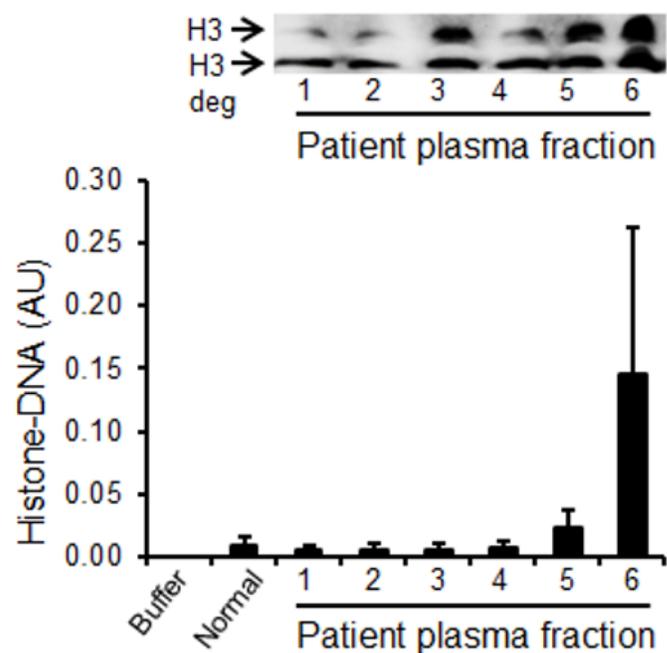

460 histones. C4 (250  $\mu\text{g/ml}$ ) was incubated with C1S (50  $\mu\text{g/ml}$ , active enzyme to cleave C4 into  
461 C4a and C4b)  $\pm$  calf thymus histones (100  $\mu\text{g/ml}$ ) at 37°C for 30 mins and subjected to 8-18%  
462 gradient SDS-PAGE along with calf thymus histones, C4a, C4b, C4 and C1s proteins. A  
463 typical Coomassie brilliant blue stained gel is presented. **(B)** A typical Western blot with anti-  
464 C4a antibody is presented (Upper panel). Fold changes were calculated by setting up C4a  
465 intensity without histones as 1.0. The relative fold changes of that with calf thymus histones  
466 from 3 independent experiments are presented (Lower panel). **Student's t test, P=0.2.** **(C)**  
467 Two  $\mu\text{g}$  C4, C4b, C4a and S100P (as a control) were subjected to blotting with HRP-  
468 conjugated calf thymus histones. A typical blot is presented. **(D-F)** Complement in serum  
469 was activated by IgM (Classical pathway, CP), Mannan (MBL), LPS (Alternative pathway,  
470 AP) or zymosan in the absence or presence of calf thymus histones treated (50  $\mu\text{g/ml}$ ) for 1hr  
471 at 37°C. Then the C3a **(D)**, C5a **(E)** or MAC levels **(F)** were detected by ELISA. Means $\pm$ SD  
472 from at least 3 independent experiments are presented. **ANOVA test, \*P<0.05** when  
473 compared to that without histones.

474 **Figure 6. Effect of C4 protein on histones.** **(A-B)** C4 protein affects histone-inhibited  
475 complement activity. Adding C4 protein (0-300  $\mu\text{g/ml}$ ) rescued 20  $\mu\text{g/ml}$  histone H4-  
476 inhibited activation of Classical pathway **(A)**, MBL pathway **(B)**. **(C)** zymosan activated  
477 complement activity in the absence or presence of histone H4 20  $\mu\text{g/ml}$  and C4 protein 300  
478  $\mu\text{g/ml}$  (histone H4: C4 molar ratio= 1:1). **(D)** Human endothelial cell line, EA.hy926, was  
479 treated with 100  $\mu\text{g/ml}$  calf thymus histones in the presence 0-300  $\mu\text{g}$  C4 proteins for one  
480 hour. The percentage of cell viability was detected using WST8 cell viability kit. Means $\pm$ SD  
481 from 3 independent experiments are presented. **ANOVA test, \*P<0.05** when compared to  
482 histone alone.
