## Abstract

**Purpose of Review** This article reviews the most recent publications on community-acquired pneumonia (CAP) in the HIV-infected population on antiretroviral therapy (ART), focusing on epidemiology, prognostic factors, etiology, and antimicrobial therapy. The data discussed here were mainly obtained from a non-systematic review using Medline and references from relevant articles.

**Recent Findings** CAP remains a major cause of morbidity and mortality among HIV-infected patients and incurs high health costs despite the introduction of ART.

**Summary** HIV-infected patients are generally known to be more susceptible to bacterial pneumonia. *Streptococcus pneumoniae* is the most frequently reported pathogen in HIV-infected patients on ART, who present a higher rate of bacteremia than non-HIV-infected patients. Several studies have also examined microbial etiology and prognostic factors of CAP in HIV-infected patients on ART. Despite the high rate of bacterial pneumonia in these patients, mortality rates are not higher than in patients without HIV infection.

**Keywords** Community-acquired pneumonia · Treatment · HIV infection

## Introduction

According to the World Health Organization (WHO), at the end of 2016, there were approximately 36.7 million people living with human immunodeficiency virus (HIV): 25.6 million in Africa, 3.5 million in Southeast Asia, 3.3 million in the Americas, 2.4 million in Europe, 1.5 million in the Western Pacific, and 360,000 in the Eastern Mediterranean. By mid-

2017, approximately 20.9 million people living with HIV were receiving active antiretroviral therapy (ART), including seven out of every 10 pregnant women living with HIV [1]. In 2016, 1.8 million people became newly infected with HIV [2]. The introduction of active ART has changed the epidemiology of HIV infection and acquired immune deficiency syndrome (AIDS) worldwide [3, 4]. However, community-acquired pneumonia (CAP) remains a frequent cause of morbidity and mortality among HIV-infected patients on ART, and incurs high health costs [4–6]. Some associated factors that contribute to the high incidence of CAP in HIV-infected patients on ART are active or passive smoking, alcohol abuse, and intravenous drug use [7\*\*].

Although ART reduces viral replication and systemic inflammation and improves immune response, the risk of pneumonia remains high in these patients in part because they present altered immunity and their immune activation persists even when they receive therapy [6]. The incidence of CAP in HIV-infected patients on ART is reported to be between 2.5 and 8 cases per 1000 patients per year [8]. The risk of CAP in HIV-infected patients on ART and the probability of mixed infections or pneumonia caused by intracellular pathogens is inversely associated with the CD4 cell count [6, 7\*\*, 9].

This article is part of the Topical Collection on *Respiratory Infections*

55 Mortality in HIV-infected patients on ART with CAP ranges  
 56 from 6 to 9% [9, 10]; in patients with severe CAP, however,  
 57 it may be above 30% [11, 12]. *Streptococcus pneumoniae*  
 58 (pneumococcus) is the main pathogen involved in CAP in both  
 59 HIV-infected patients on ART and the general population  
 60 [9, 13, 14]. HIV is a known risk factor for invasive pneumo-  
 61 coccal disease (IPD); even when receiving ART, HIV-infected  
 62 patients on ART had a 20-fold increased risk of IPD [7, 15, 16].

64 Vaccination (pneumococcal conjugate [PCV13] and poly-  
 65 saccharide vaccines [PPV23]) represents one of the most im-  
 66 portant preventive strategies for CAP in HIV-infected patients  
 67 on ART [17]. Implementation of programs to help patients  
 68 comply with ART and early diagnosis of suspected HIV-  
 69 infected patients are key measures for improving CAP  
 70 management.

71 **Global Epidemiology of CAP in HIV-Infected**  
 72 **Adult Patients**

73 The introduction of ART changed the global epidemiology of  
 74 pulmonary infection in the HIV-infected population [18] by  
 75 reducing the incidence of opportunistic pulmonary infections.  
 76 In high-income countries, such as Europe and the USA, bac-  
 77 terial pneumonia (especially pneumococcal pneumonia) is the  
 78 predominant lung disease in the HIV-infected population on  
 79 ART [4, 9].

80 A Brazilian study of CAP in HIV-infected adult patients  
 81 receiving ART for at least 60 days reported an incidence of  
 82 pneumonia of 3.07 cases per 100 persons-years. Viral load and  
 83 CD4 cell counts were identified as predictive factors for pneu-  
 84 monia. Uncontrolled HIV infection (detectable viral load)  
 85 doubled the risk for pneumonia, while time-updated increases  
 86 in CD4 cell counts represented a protective factor [19].  
 87 Analyzing more than 10,000 patients in 34 countries, the  
 88 EuroSIDA cohort study reported an incidence of 0.53 cases  
 89 per 100 persons-year and identified low CD4 cell count (200–  
 90 349 cells/ $\mu$ l), current smoking, and higher viral load as risk  
 91 factors for pneumonia [20]. Similarly, Mussini et al. [21] re-  
 92 ported an incidence of 0.56 cases of pneumonia per 100  
 93 persons-year and found the probabilities of first episode of  
 94 bacterial pneumonia at 3, 5, 10, and 14 years after ART initi-  
 95 ation to be 2%, 2.9%, 4.3%, and 5.7% respectively. The fac-  
 96 tors associated with the first episode of bacterial pneumonia  
 97 were low nadir CD4<sup>+</sup>, low current CD4, high CD8<sup>+</sup>, low he-  
 98 moglobin, unfavorable virological outcome, older age, male  
 99 gender, non-Italian nationality, smoking, and longer time to  
 100 ART initiation.

101 In a 10-year study of survival of HIV-infected patients ad-  
 102 mitted to the ICU in the UK between 1999 and 2009 [22], it  
 103 was observed that respiratory disease remains the main cause  
 104 of ICU admission. The proportion of patients on ART prior to

ICU admission increased from 37% in the early period (1999–  
 2005) to 60% in the late period (2006–2009). In patients new-  
 ly diagnosed with HIV, the rates of survival to ICU and hos-  
 pital discharge were 69% and 57% respectively. In patients  
 with known HIV diagnosis, survival to ICU and hospital dis-  
 charge was 80% and 74% respectively.

Another UK study [23] of the implementation of automated  
 HIV testing for pneumonia patients admitted to the ICU re-  
 ported that prior to this measure, the HIV testing rate in pa-  
 tients with pneumonia within 2 weeks of admission was 29%.  
 After the implementation of automated HIV testing to all ad-  
 mitted patients, 80% of ICU patients with pneumonia were  
 tested for HIV infection within 48 h and 73% with 24 h.  
 Adopting universal testing for HIV in patients with pneumo-  
 nia admitted to ICU is mandatory in order to reduce morbidity  
 and mortality.

121 **Microbial Etiology of CAP in HIV-Infected**  
 122 **Patients**

123 Despite advances in microbiological tests, microbial diagnosis  
 124 is achieved in only 40–50% of CAP cases [9, 13]. The bac-  
 125 terial etiology of pneumonia is similar in HIV-infected pa-  
 126 tients on ART and in the uninfected population [24, 25].  
 127 Factors that have an impact on microbial etiology in CAP  
 128 are the characteristics of the population, the geographical area  
 129 (developed or developing countries), and the methodology  
 130 applied to microbial diagnosis [6, 26].

131 A recent prospective observational study of 331 adult CAP  
 132 cases in HIV-infected patients from Spain [13] described the  
 133 microbial etiology in this population. The most frequently  
 134 detected microorganisms were *S. pneumoniae* (30%),  
 135 *P. jirovecii* (13%), mixed etiology (11%), respiratory viruses  
 136 (5%), *Haemophilus influenzae* (2%), *Staphylococcus aureus*  
 137 (2%), and *Legionella pneumophila* (1%). *S. pneumoniae* was  
 138 the most frequent microorganism in the group with a CD4+  
 139 cell count of  $\geq 200$  cell/mm<sup>3</sup> and *P. jirovecii* in the group of  
 140 patients with a CD4+ cell count of  $< 200$  cells/mm<sup>3</sup> and in  
 141 patients with HIV-RNA  $\geq 200$  copies/mL. The authors also  
 142 reported that  $\leq 5$  days of symptoms (OR 2.6, 95% CI 1.5–  
 143 4.4), C-reactive protein level  $\geq 22$  mg/dL (OR 4.3, 95% CI  
 144 2.3–8.2), and hepatitis C-virus co-infection (OR 2.3, 95% CI  
 145 1.4–3.9) were predictors of bacterial CAP, whereas a WBC  
 146 count  $\leq 4000 \times 10^9$  cells/L (OR 3.7, 95% CI 1.2–11.5), LDH  
 147  $\geq 598$  U/L (OR 12.9, 95% CI 4.2–39.7), and multilobar infil-  
 148 tration (OR 5.8, 95% CI 1.9–19.5) were predictors of  
 149 *P. jirovecii*. In that study, HIV infection had been diagnosed  
 150 prior to hospital admission in 83% of patients, and 51% of  
 151 patients were on ART; the other 17% were diagnosed with  
 152 HIV infection during the pneumonia episode (Fig. 1).

153 Pneumococcal pneumonia in HIV-infected patients fre-  
 154 quently presents with bacteremia and invasive pneumonia

**Fig. 1** Microbial etiology in HIV-infected patients with CAP

155 [7<sup>11</sup>, 9]. In an earlier Spanish study of the microbial etiology of  
 156 CAP in HIV-infected patients, 15% of the study population  
 157 presented bacteremia, and pneumococcus was the main patho-  
 158 gen involved [13<sup>11</sup>]. In a study of 129 HIV-infected adult  
 159 patients with CAP, the factors that predicted bacteremia were  
 160 positive urinary antigen detection and the absence of ART  
 161 [27].

162 *Pseudomonas aeruginosa* is also a cause of pneumonia in  
 163 HIV-infected patients and is reported in fewer than 6% of CAP  
 164 cases [13<sup>11</sup>, 28]. Risk factors associated with *P. aeruginosa*  
 165 CAP in HIV-infected patients are previous antibiotic therapy,  
 166 neutropenia, and a low CD4 count [29].

167 *Legionella pneumophila* accounts for approximately 9% of  
 168 all adult HIV-associated pneumonias [10]. Other intracellular  
 169 pathogens causing CAP in HIV-infected patients include  
 170 *Mycoplasma pneumoniae*, *Chlamydomphila pneumoniae*, and  
 171 *Coxiella burnetii* [30]. A recent published case-control study  
 172 that compared the clinical presentation and outcomes (length  
 173 of hospital stay, ICU admission, and 30-day mortality) of  
 174 *L. pneumophila* pneumonia in HIV-infected patients (32  
 175 cases) and non-HIV-infected patients (96 controls) reported  
 176 that clinical presentation and outcomes in HIV-infected pa-  
 177 tients with *Legionella* pneumonia did not differ from patients  
 178 without HIV infection. The authors suggest that *Legionella*  
 179 infection affected with more frequently patients with correct  
 180 immunological status [31].

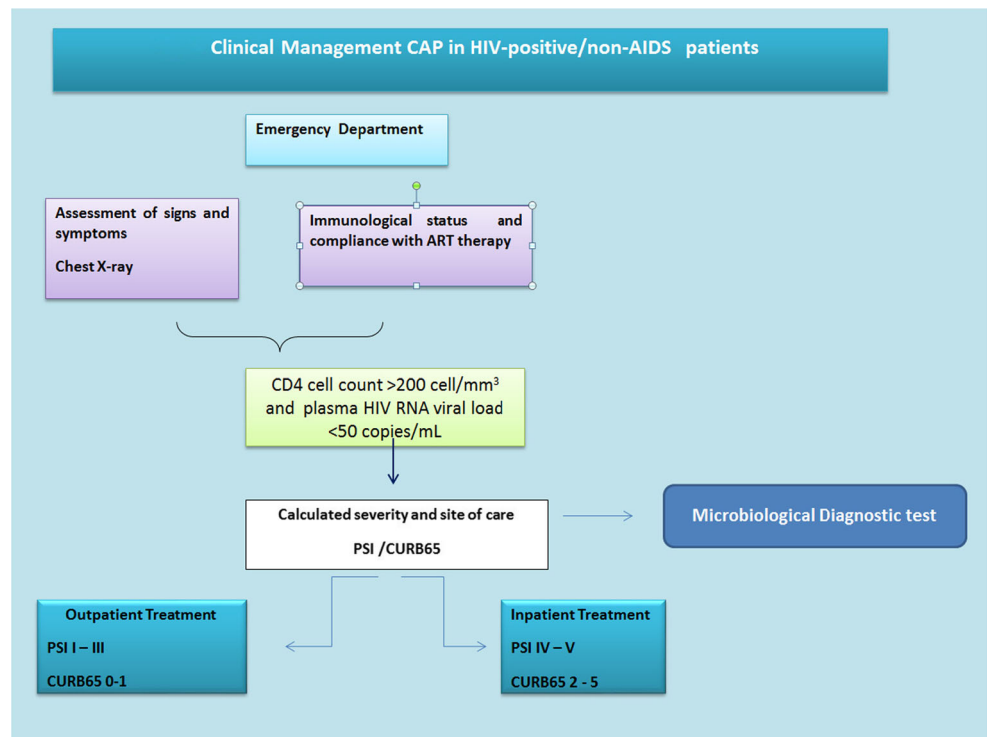

181 **Severity of CAP and Site of Care**

182 To determine the site of care, microbiological testing and the  
 183 choice of empiric antibiotic therapy, it is important to assess

the pneumonia severity (Fig. 2). Severity scores for  
 predicting short-term mortality have been developed in order  
 to allow more objective decisions regarding hospitalization  
 to be taken in the general population [32, 33]. The most  
 frequent scores are the Pneumonia Severity Index (PSI), rec-  
 ommended by the IDSA/ATS guidelines, and the CURB-65  
 criteria recommended by the BTS guidelines. However, few  
 studies have validated these severity scores in the HIV-  
 infected population [10, 34]. In 2008, evaluating the PSI  
 score in HIV-infected patients with CAP, Curran et al. [10]  
 reported that it accurately predicted high-risk pneumonia and  
 mortality. The authors suggested that the combination of  
 CD4 cell count value and PSI risk class would help to iden-  
 tify patients requiring hospitalization. More recently, a study  
 investigating the use of CURB65 in HIV-infected patients  
 reported that a higher CURB65 score and a CD4 count lower  
 than 200 cells/mL were both associated with worse out-  
 comes [34]. The authors concluded that the CURB65 score  
 plus CD4 cell count could be used in HIV-infected patients  
 with CAP.

An interesting study assessing the predictive value of ana-  
 lytical markers of full blood count that can be assessed in the  
 emergency department in 160 HIV-infected patients with CAP  
 (49% of them on ART) reported that higher red blood cell  
 distribution width (RDW) (OR = 1.2, 95% CI 1.1–1.4, *p* =  
 0.013) and a lower number of lymphocytes (OR 2.2, 95%  
 CI 1.1–2.2, *p* = 0.035) were independent predictors of admis-  
 sion to ICU in the multivariate analysis. The small number of  
 cases analyzed was a limitation, but the combination of sever-  
 ity scores and laboratory data such as RDW and lymphocytes  
 may be a good predictor for prognosis in HIV-infected pa-  
 tients with CAP [35].

**Fig. 2** Clinical management CAP in HIV-positive/non AIDS patients

**216 Microbial Diagnosis of CAP**

217 Microbiological diagnosis of CAP continues to be based on  
 218 respiratory samples or blood culture. The most important ap-  
 219 plication of these methods is in the determination of antibiotic  
 220 susceptibility patterns that allow the selection of appropriate  
 221 antimicrobial therapy, which is an important factor for reduc-  
 222 ing mortality [36].

223 In general, international guidelines recommend standard  
 224 microbiological investigation [37, 38]. In the case of patients  
 225 with low to mild pneumonia, microbiological diagnosis is  
 226 optional. Extensive microbiological diagnosis is recommend-  
 227 ed in cases of severe pneumonia or in cases that do not re-  
 228 spond to empiric antibiotic therapy. However, if clinically in-  
 229 dicated, an extensive microbiological diagnosis should be per-  
 230 formed (Fig. 3).

Microbiological test	Outpatient	Inpatient low severity	Inpatient non ICU moderate severity	Inpatients ICU high severity
Sputum culture	None routinely	X	X	X
Pneumococcal urinary antigen test		None routinely	X	X
<i>Legionella</i> urinary antigen test			X	X
Blood culture			X	X
Invasive respiratory tract sample culture				X
Others				X
<b>Specific guidelines recommendations:</b>				
*Outpatients with failure of antibiotic therapy: sputum culture, urinary antigen test for <i>Legionella pneumoniae</i> and <i>Streptococcus pneumoniae</i> .				
*Positive urinary antigen test for <i>pneumococcus</i> or <i>Legionella</i> : sputum and blood culture for positive urinary antigen test for pneumococcus and sputum culture for positive urinary antigen test for <i>Legionella</i> .				
*Severe obstructive lung disease: sputum culture				
*Severe obstructive lung disease: sputum culture Cavitary infiltrates: sputum culture ( bacterias, fungal and mycobacterias) and blood culture.				
*Active alcoholism: sputum and blood culture, urinary antigen test for pneumococcus and <i>Legionella</i> .				
* Severe CAP admitted to intensive care unit (ICU): sputum and blood culture, urinary antigen test for pneumococcus and <i>Legionella</i> , tracheal aspirate or bronchoalveolar lavage culture.				
* Epidemiological factor or specific risk factors suggesting pathogen: urinary antigen test for <i>Legionella</i> (Legionnaires disease), influenza test during influenza season				

**Fig. 3** International guideline recommendation for microbiological diagnostic test in CAP

**Figure 4. Empiric therapy for CAP in HIV-infected Patients on ART**

**Fig. 4** Empiric therapy for CAP in HIV-infected patients on ART

231 Blood cultures, sputum staining, sputum culture, and urinary  
 232 primary antigen testing for *Legionella* and pneumococcus should  
 233 be carried out in patients with severe CAP. Since influenza  
 234 viruses present in seasonal epidemics, rapid antigen or direct  
 235 fluorescent antibody testing is recommended to guide decisions  
 236 regarding antiviral therapy and may help to reduce the  
 237 use of antibacterial agents.

238 In recent years, the development and implementation of  
 239 molecular diagnostic tests for pneumonia have been major  
 240 advances in the microbiological diagnosis of respiratory pathogens.  
 241 These technologies achieve rapid results (within 1–2 h) and may  
 242 be useful in the decision management of patients, especially with  
 243 regard to the early initiation of appropriate antimicrobial therapy,  
 244 a factor associated with mortality. The rapid identification of  
 245 antibiotic resistant pathogens is also central to timely isolation  
 246 of patients. However, the main limitations of these technologies  
 247 are their reduced ability to differentiate between colonization and  
 248 infection and their cost-effectiveness [39].

250 **Microbiome**

251 A new challenge for microbiologists and clinicians has arisen  
 252 with the study of the pulmonary microbiome, which has changed  
 253 our current concept of pneumonia [40]. It is

254 now known that the lungs are a dynamic microbiological  
 255 ecosystem, and the new data show us that pneumonia involves  
 256 a dysbiosis or alteration of the lung microbiome [39, 41].

257  
 258 An interesting study addressed by Iwai et al. [42\*\*] compared  
 259 oral and airway microbiota in patients with and without HIV-  
 260 infection. The authors reported that HIV-infected patients with  
 261 pneumonia have an increased abundance of phylogenetically  
 262 distinct taxa, which included Firmicutes and Prevotellaceae  
 263 compared with the presence of Proteobacteria-enriched  
 264 communities in non-HIV-infected patients with pneumonia.  
 265 A second interest study published by the same authors compared  
 266 the lung microbiome between HIV-infected patients from  
 267 Ugandan with pneumonia to pneumonia patients from San  
 268 Francisco. The authors reported that the microbiome  
 269 composition of lower airway of HIV-infected patients with  
 270 pneumonia in Uganda was significantly different from those  
 271 in San Francisco. The author suggested that these differences  
 272 may be due to the clinical status, age, and/or pneumonia  
 273 type across the geographically distinct cohorts. The profile  
 274 of microbiome in Uganda patients was enriched by  
 275 Proteobacteria, being *Pseudomonas aeruginosa* the pathogen  
 276 more frequently detected. On the other hand, lung microbiome  
 277 in patients from San Francisco was enriched for Firmicutes  
 278 and Actinobacteria [43].

**Q3** t1.1 **Table 1** International guidelines for the management and treatment for community-acquired pneumonia

t1.2 Pneumonia severity	Low severity	Moderate severity	High severity

References: [35, 36, 39, 40]

279 The new investigations about the lung microbiome in HIV-  
 280 infected patients have provided novel insights and new knowl-  
 281 edge about the mechanisms of microbial pathogenesis in  
 282 pneumonia in this population.

283 **Initial Empiric Therapy**

284 When a HIV-infected patient with CAP is admitted to the  
 285 emergency department, clinicians should check the immuno-  
 Q2 286 logical status (CD4+ cell/count) and compliance with ART. If  
 287 patients are on ART and have a CD4 lymphocyte count of >  
 288 200 cells/mm<sup>3</sup>, the empiric antibiotic therapy for CAP is sim-  
 289 ilar to that administered in the general population [13\*\*] and  
 290 complies with the international guidelines recommendations  
 291 for CAP [37, 38, 44, 45]. All patients will be visited within  
 292 30 days after hospital discharge and followed up on an outpa-  
 293 tient basis (Fig. 4).

294 Initial empiric therapy for CAP should be guided by the site  
 295 of care, age, previous use of antibiotics within the previous

90 days, the presence of comorbidities (risk of resistant path- 296  
 ogens), and drug intolerance. 297

Empiric antiviral therapy for influenza may be necessary 298  
 when the clinical and epidemiological criteria are met. Several 299  
 studies reported that 1 to 6% of patients hospitalized with 300  
 H1N1 were HIV-infected [46, 47]. In an American study, 301  
 HIV patients with influenza experienced similar rates of ICU 302  
 admission (29% vs. 34%) and mortality (13% vs. 13%) to 303  
 those of non-HIV patients [46]. Ormsby et al. [48] suggested 304  
 that the 2009 H1N1 infection was more severe in HIV- 305  
 infected patients with late and advanced HIV disease than in 306  
 well-controlled patients on ART. 307

Two groups of antiviral drugs are currently available 308  
 for influenza: M2-protein-inhibitors (amantadine and 309  
 rimantadine) and neuraminidase inhibitors (zanamivir and 310  
 oseltamivir). These antivirals should be administered with- 311  
 in 48 h of symptom onset. In cases of severe pneumonia, 312  
 medication is recommended even 48 h after symptom 313  
 onset. 314

Empiric antibiotic therapies recommended by international 315  
 guidelines are summarized in Table 1 [37, 40, 41\*, 44]. 316

317 Drug interactions between ART and CAP antibiotic therapy  
 318 represent an important issue for clinicians. However, pen-  
 319 icillins, betalactam inhibitors, and levofloxacin do not interact  
 320 with ART. For its part, moxifloxacin has a low interaction with  
 321 atazanavir and lopinavir which are protease inhibitors. As  
 322 moxifloxacin has been shown to prolong the QT interval,  
 323 clinicians should exercise caution with its use, especially in  
 324 the case of patients with pre-existing risk factors (bradycardia,  
 325 long congenital QT, electrolyte imbalances). Caution is also  
 326 required in these patients regarding the use of azithromycin  
 327 since it may cause abnormal changes in the electrical activity  
 328 of the heart, and since the interactions between atazanavir,  
 329 lopinavir and saquinavir (protease inhibitors), and rilpivirine/  
 330 FTC/TAF (NNRTIS) are low.

331 Clarithromycin presents more drug interaction with all  
 332 classes of antiretrovirals (protease inhibitors, NNRTIS, entry  
 333 and integrase inhibitors, and nucleoside/tide analogues) be-  
 334 cause it can lead to a prolonged QT interval. In patients with  
 335 long QT syndrome, cardiac disease, or in patients taking other  
 336 QT-prolonging medications, this can increase the risk of life-  
 337 threatening arrhythmias [49]. So the use of azithromycin is  
 338 preferred. For more information on drug-drug interaction,  
 339 consult

340 <https://www.hiv-druginteractions.org/checker>

341 **Conclusions**

342 Despite the advent of ART, pneumonia remains a major cause  
 343 of disease in the HIV-infected population. Pulmonary infec-  
 344 tions are also the main cause of ICU admission. *Streptococcus*  
 345 *pneumoniae* (pneumococcus) remains the most frequently de-  
 346 tected cause of CAP in HIV-positive/non-AIDS on ART. The  
 347 clinical presentation and management of CAP are similar in  
 348 HIV-infected patients on ART and in uninfected patients, and  
 349 outcomes in HIV virologically suppressed patients on ART  
 350 with > 350 CD4+ T cell counts/mm<sup>3</sup> are similar to those in the  
 351 general population. The general recommendation is that these  
 352 patients do not need special treatment, admission, or sites of  
 353 care. Treatment of HIV-positive/non-AIDS patients with CAP  
 354 is also similar to that in the general population and should  
 355 follow international guidelines.
