March 3, 2007

Abstract

We present the first cryptographically sound security proof of the well-known Otway-Rees protocol. More precisely, we show that the protocol is secure against arbitrary active attacks including concurrent protocol runs if it is implemented using provably secure cryptographic primitives. We prove secrecy of the exchanged keys with respect to the accepted cryptographic definition of real-or-random secrecy, i.e., indistinguishability of exchanged keys and random ones, given the view of a general cryptographic attacker. Although we achieve security under cryptographic definitions, our proof is performed in a deterministic setting corresponding to a slightly extended Dolev-Yao model; in particular, it does not have to deal with probabilistic aspects of cryptography and is hence in the scope of current proof tools. The reason is that we exploit a recently proposed ideal cryptographic library, which has a provably secure cryptographic implementation, as well as recent results on linking symbolic and cryptographic key secrecy. Besides establishing the cryptographic security of the Otway-Rees protocol, our result also exemplifies the potential of this cryptographic library and the recent secrecy preservation theorem for symbolic yet cryptographically sound proofs of security.

1 Introduction

Many practically relevant cryptographic protocols like SSL/TLS, S/MIME, IPSec, or SET use cryptographic primitives like signature schemes or encryption in a black-box way, while adding many non-cryptographic features. Vulnerabilities have accompanied the design of such protocols ever since early authentication protocols like Needham-Schroeder [54, 36], over carefully designed de-facto standards like SSL and PKCS [60, 33], up to current widely deployed products like Microsoft Passport [38]. However, proving the security of such protocols has been a very unsatisfactory task for a long time.

One way to conduct such proofs is the cryptographic approach, whose security definitions are based on complexity theory, e.g., [40, 39, 41, 30]. The security of a cryptographic protocol is proved by reduction, i.e., by showing that breaking the protocol implies breaking one of the underlying cryptographic primitives with respect to its cryptographic definition. This approach captures a very comprehensive adversary model and allows for mathematically rigorous and precise proofs. However, because of probabilism and complexity-theoretic restrictions, these proofs have to be done by hand so far, which yields proofs with faults and imperfections. Moreover, such proofs rapidly become too complex for larger protocols.

The alternative is the formal-methods approach, which is concerned with the automation of proofs using model checkers and theorem provers. As these tools currently cannot deal with cryptographic details like error probabilities and computational restrictions, abstractions of cryptography are used. They are almost

*Preliminary versions appeared in [4] and [6].

always based on the so-called Dolev-Yao model [37]. This model simplifies proofs of larger protocols considerably and gave rise to a large body of literature on analyzing the security of protocols using various techniques for formal verification, e.g., [51, 49, 45, 34, 57, 1].

Among the protocols typically analyzed in the Dolev-Yao model, the Otway-Rees protocol [55], which aims at establishing a shared key between two users by means of a trusted third party, stands out as one of the most prominent protocols. It has been extensively studied in the past, e.g., in [56, 44, 57], and various new approaches and formal proof tools for the analysis of security protocols were validated by showing that they can prove the protocol in the Dolev-Yao model (respectively that they can find the well-known type-flaw attack if the underlying model does not provide sufficient typing itself; the model that our proof is based upon excludes this attack). However, all existing proofs of security of the Otway-Rees protocol are restricted to the Dolev-Yao model, i.e., no theorem exists which allows for carrying over the results of an existing proof to the cryptographic approach with its much more comprehensive adversary. Thus, despite the tremendous amount of research dedicated to the Otway-Rees protocol, it is still an open question whether an actual implementation based on provably secure cryptographic primitives is secure under cryptographic security definitions. We close this gap by providing the first security proof of the Otway-Rees protocol in the cryptographic approach. We show that the protocol is secure against arbitrary active attacks if the Dolev-Yao-based abstraction of symmetric encryption is implemented using a symmetric encryption scheme that is secure against chosen-ciphertext attacks and that additionally ensures integrity of ciphertexts. More precisely, we prove real-or-random secrecy of the exchanged keys, i.e., we show that no cryptographic attacker is able to distinguish fresh, random keys and keys that are actually exchanged between two honest participants unless the underlying cryptography can be broken. This is the accepted cryptographic definition of key secrecy. Moreover, we show consistency of the protocol in that parties that have successfully established a shared key have a consistent view of who the peers of the sessions are.¹ Chosen-ciphertext security and integrity of ciphertexts are the standard security definition of authenticated symmetric encryption schemes [32, 31], and efficient symmetric encryptions schemes provably secure in this sense exist under reasonable assumptions [31, 59].

Obviously, establishing a proof in the cryptographic approach presupposes dealing with the mentioned cryptographic details, hence one naturally assumes that our proof heavily relies on complexity theory and is far out of scope of current proof tools. However, our proof is not performed from scratch in the cryptographic setting, but based on a recently proposed cryptographic library [22, 24, 16], which provides cryptographically faithful, deterministic abstractions of cryptographic primitives, i.e., the abstractions can be securely implemented using actual cryptography. Moreover, the library allows for nesting the abstractions in an arbitrary way, quite similar to the original Dolev-Yao model. While this was shown for public-key encryption and digital signatures in [22] and subsequently extended with message authentication codes in [24], the most recent extension of the library further incorporated symmetric encryption [16] which constitutes the most commonly used cryptographic primitive in the typical proofs with Dolev-Yao models, and also serves as the central primitive for expressing and analyzing the Otway-Rees protocol. However, as shown in [16], there are intrinsic difficulties in providing a sound abstraction from symmetric encryption in the strong sense of security used in [22]. Very roughly, a sound Dolev-Yao-style abstraction of symmetric encryption can only be established if a so-called *commitment problem* does not occur, which means that whenever a key that is not known to the adversary is used for encryption by an honest user then this key will never be revealed to the adversary. We will elaborate on the origin of this problem in more detail in the paper. While [16] discusses several solutions to this problem, the one actually taken is to leave it to the surrounding protocol to guarantee that the commitment problem does not occur, i.e., if a protocol that uses symmetric encryption should be faithfully analyzed, it additionally has to be shown that the protocol guarantees that keys are no

¹A violation of this consistency property has been pointed out in [44] which arises due to a different modeling of the trusted third party. We will discuss this in the following.

longer sent in a form that might make them known to the adversary once an honest participant has started using them. Our proof shows that this is a manageable task that can easily be incorporated in the overall security proof without imposing a major additional burden on the prover.

Once we have shown that the Otway-Rees protocol does not raise the commitment problem, we prove the security of the Otway-Rees protocol based on the deterministic abstraction. In combination with a recent result on linking symbolic and cryptographic key secrecy [18], this allows us to perform a symbolic proof of secrecy for the Otway-Rees protocol and to derive the desired cryptographic key secrecy from that. Similarly, we establish the consistency property based on the abstraction and exploit a general integrity preservation theorem [10] to derive the consistency property for the cryptographic setting. As the proof is deterministic and rigorous, it should be easily expressible in formal proof tools, in particular theorem provers. Even done by hand, our proof is much less prone to error than a reduction proof conducted from scratch in the cryptographic approach. We also want to point out that our result not only provides the up-to-now missing cryptographic security proof of the Otway-Rees protocol, but also exemplifies the usefulness of the cryptographic library [22], their extensions [24, 16], and the corresponding general theorems for linking symbolic and cryptographic properties based on this library [10, 21, 14, 15, 18, 5] for the cryptographically sound verification of cryptographic protocols.

Further Related Work. Cryptographic underpinnings of a Dolev-Yao model were first addressed by Abadi and Rogaway in [3]. However, they only handled passive adversaries and symmetric encryption. The protocol language and security properties handled were extended in [2, 46], but still only for passive adversaries. This excludes most of the typical ways of attacking protocols, e.g., man-in-the-middle attacks and attacks by reusing a message part in a different place or a concurrent protocol run. A full cryptographic justification for a Dolev-Yao model, i.e., for arbitrary active attacks and within arbitrary surrounding interactive protocols, was first given recently in [25, 22] with extensions in [24, 16]. Based on the specific Dolev-Yao model whose soundness was proven in [22], the well-known Needham-Schroeder-Lowe protocol was proved in [13], a variant of the 3KP payment protocol was proved in [8], and the Yahalom protocol was proven in [19]. Besides the proof that we present in this paper, the proof in [13, 8, 19] are the only Dolev-Yao-style, computationally sound proofs that we are aware of. However, they are considerably simpler than the one we present in this work since it only addresses integrity properties whereas our proof additionally establishes confidentiality properties; moreover, the Needham-Schroeder-Lowe protocol and the 3KP protocol do not use symmetric encryption, hence the commitment problem does not occur there which greatly simplifies the proof. Another cryptographically sound proof of the Needham-Schroeder-Lowe protocol was concurrently developed by Warinschi [61]. The proof is conducted from scratch in the cryptographic approach which takes it out of the scope of formal proof tools.

Laud [47] has recently presented a cryptographic underpinning for a Dolev-Yao model of symmetric encryption under active attacks. His work enjoys a direct connection with a formal proof tool, but it is specific to certain confidentiality properties, restricts the surrounding protocols to straight-line programs in a specific language, and does not address a connection to the remaining primitives of the Dolev-Yao model. Herzog et al. [42] and Micciancio and Warinschi [50] have recently also given a cryptographic underpinning under active attacks. Their results are narrower than that in [22] since they are specific for public-key encryption, but consider slightly simpler real implementations; moreover, the former relies on a stronger assumption whereas the latter severely restricts the classes of protocols and protocol properties that can be analyzed using this primitive. Section 6 of [50] further points out several possible extensions of their work which all already exist in the earlier work of [22]. Canetti and Herzog [35] have recently linked ideal functionalities for mutual authentication and key exchange protocols to corresponding representations in a formal language. They apply their techniques to the Needham-Schroeder-Lowe protocol by considering the exchanged nonces as secret keys. Their work is restricted to the mentioned functionalities and in contrast to the cryptographic

library [22] hence does not address soundness of Dolev-Yao models in their usual generality. The considered language does not allow loops and offers public-key encryption as the only cryptographic operation. Moreover, their approach to define a mapping between ideal and real traces following the ideas of [50] only captures trace-based properties (i.e., integrity properties); reasoning about secrecy properties additionally requires ad-hoc and functionality-specific arguments. Since computational soundness has become a highly active line of research, we exemplarily list further recent results in this area without going into further details [11, 23, 27, 20, 9, 17, 7, 29, 12].

Efforts are also under way to formulate syntactic calculi for dealing with probabilism and polynomial-time considerations, in particular [52, 48, 53, 43] and, as a second step, to encode them into proof tools. This approach can not yet handle protocols with any degree of automation. It is complementary to the approach of proving simple deterministic abstractions of cryptography and working with those wherever cryptography is only used in a blackbox way.

Outline. Section 2 introduces the notation used in the paper and briefly reviews the aforementioned cryptographic library. Section 3 shows how to model the Otway-Rees protocol based on this library as well as how initially shared keys can be represented in the underlying model. Section 4 contains the symbolic and cryptographic security properties of the Otway-Rees protocol. The symbolic property is proven in Section 5, and Section 6 shows how to derive the cryptographic property for the cryptographic implementation of the protocol. Section 7 concludes.

2 Preliminaries

In this section, we give an overview of the ideal cryptographic library of [22, 24, 16] and briefly sketch its provably secure implementation. We start by introducing the notation used in this paper.

2.1 Notation

Let \downarrow denote an error element available as an addition to the domains and ranges of all functions and algorithms. The list operation is denoted as $l := (x_1, \dots, x_j)$, and the arguments are unambiguously retrievable as $l[i]$, with $l[i] = \downarrow$ if $i > j$. A database D is a set of functions, called entries, each over a finite domain called attributes. For an entry $x \in D$, the value at an attribute att is written $x.att$. For a predicate $pred$ involving attributes, $D[pred]$ means the subset of entries whose attributes fulfill $pred$. If $D[pred]$ contains only one element, we use the same notation for this element.

2.2 Overview of the Ideal and Real Cryptographic Library

The ideal (abstract) cryptographic library of [22, 24, 16] offers its users abstract cryptographic operations, such as commands to encrypt or decrypt a message, to make or test a signature, and to generate a nonce. All these commands have a simple, deterministic semantics. To allow a reactive scenario, this semantics is based on state, e.g., of who already knows which terms; the state is represented as a database. Each entry has a type (e.g., “ciphertext”), and pointers to its arguments (e.g., a key and a message). Further, each entry contains handles for those participants who already know it. A send operation makes an entry known to other participants, i.e., it adds handles to the entry. The ideal cryptographic library does not allow cheating. For instance, if it receives a command to encrypt a message m with a certain key, it simply makes an abstract database entry for the ciphertext. Another user can only ask for decryption of this ciphertext if he has obtained handles to both the ciphertext and the secret key.

To allow for the proof of cryptographic faithfulness, the library is based on a detailed model of asynchronous reactive systems introduced in [58, 28] and represented as a deterministic machine $\text{TH}_{\mathcal{H}}$, called *trusted host*. The parameter $\mathcal{H} \subseteq \{1 \dots n\}$ denotes the honest participants, where n is a parameter of the library denoting the overall number of participants. Depending on the considered set \mathcal{H} , the trusted host

offers slightly extended capabilities for the adversary. However, for current purposes, the trusted host can be seen as a slightly modified Dolev-Yao model together with a network and intruder model, similar to “the CSP Dolev-Yao model” or “the inductive-approach Dolev-Yao model”.

The real cryptographic library offers its users the same commands as the ideal one, i.e., honest users operate on cryptographic objects via handles. The objects are now real cryptographic keys, ciphertexts, etc., handled by real distributed machines. Sending a term on an insecure channel releases the actual bitstring to the adversary, who can do with it what he likes. The adversary can also insert arbitrary bitstrings on non-authentic channels. The implementation of the commands is based on arbitrary secure encryption and signature systems according to standard cryptographic definitions, with certain additions like type tagging and additional randomizations.

The security proof of [22] states that the real library is *at least as secure* as the ideal library. This is captured using the notion of *reactive simulatability* [58, 28], which states that whatever an adversary can achieve in the real implementation, another adversary can achieve given the ideal library, or otherwise the underlying cryptography can be broken. This is the strongest possible cryptographic relationship between a real and an ideal system. In particular it covers arbitrary active attacks. Moreover, a composition theorem exists in the underlying model [58, 26], which states that one can securely replace the ideal library in larger systems with the real library, i.e., without destroying the already established simulatability relation.

2.3 Detailed Description of the State of the Cryptographic Library

We conclude this section with the rigorous definition of the state of the ideal cryptographic library. A rigorous definition of the commands of the ideal library used for modeling the Otway-Rees protocol as well as local adversary commands that model the slightly extended adversary capabilities can be found in [22, 16].

The machine $\text{TH}_{\mathcal{H}}$ has ports $\text{in}_u?$ and $\text{out}_u!$ for inputs from and outputs to each user $u \in \mathcal{H}$ and for $u = \mathbf{a}$, denoting the adversary. The notation follows the CSP convention, e.g., the cryptographic library obtains messages at $\text{in}_u?$ that have been output at $\text{in}_u!$. Besides the number n of users, the ideal cryptographic library is parameterized by a tuple L of length functions which are used to calculate the “length” of an abstract entry, corresponding to the length of the corresponding bitstring in the real implementation. Moreover, L contains bounds on the message lengths and the number of accepted inputs at each port. These bounds can be arbitrarily large, but have to be polynomially bounded in the security parameter.

Using the notation of [22], the ideal cryptographic library is a *system* $Sys_{n,L}^{\text{cry},\text{id}}$ that consists of several *structures* $(\{\text{TH}_{\mathcal{H}}\}, S_{\mathcal{H}})$, one for each value of the parameter \mathcal{H} . Each structure consists of a set of machines, here only containing the single machine $\text{TH}_{\mathcal{H}}$, and a set $S_{\mathcal{H}} := \{\text{in}_u?, \text{out}_u! \mid u \in \mathcal{H}\}$ denoting those ports of $\text{TH}_{\mathcal{H}}$ that the honest users connect to. Formally, we obtain $Sys_{n,L}^{\text{cry},\text{id}} := \{(\{\text{TH}_{\mathcal{H}}\}, S_{\mathcal{H}}) \mid \mathcal{H} \subseteq \{1, \dots, n\}\}$. In the following, we omit the parameters n and L for simplicity.²

The main data structure of $\text{TH}_{\mathcal{H}}$ is a database D . The entries of D are abstract representations of the data produced during a system run, together with the information on who knows these data. Each entry in D is of the form (recall the notation in Section 2.1)

$$(ind, type, arg, hnd_{u_1}, \dots, hnd_{u_m}, hnd_{\mathbf{a}}, len)$$

where $\mathcal{H} = \{u_1, \dots, u_m\}$. For each entry $x \in D$:

- $x.ind \in \mathcal{INDS}$, called index, consecutively numbers all entries in D . The set \mathcal{INDS} is isomorphic to \mathbb{N} and is used to distinguish index arguments from others. The index is used as a primary key attribute of the database, i.e., we write $D[i]$ for the selection $D[ind = i]$.

²Formally, these parameters are thus also parameters of the ideal Otway-Rees system $Sys^{\text{OR},\text{id}}$ that we introduce in Section 3.2.

- $x.type \in typeset$ identifies the *type* of x .
- $x.arg = (a_1, a_2, \dots, a_j)$ is a possibly empty list of arguments. Many values a_i are indices of other entries in D and thus in \mathcal{INDS} . We sometimes distinguish them by a superscript “ind”.
- $x.hnd_u \in \mathcal{HANDS} \cup \{\downarrow\}$ for $u \in \mathcal{H} \cup \{a\}$ are handles by which a user or adversary u knows this entry. $x.hnd_u = \downarrow$ means that u does not know this entry. The set \mathcal{HANDS} is yet another set isomorphic to \mathbb{N} . We always use a superscript “hnd” for handles.
- $x.len \in \mathbb{N}_0$ denotes the “length” of the entry; it is computed by applying the functions from L .

Initially, D is empty. $\text{TH}_{\mathcal{H}}$ has a counter $size \in \mathcal{INDS}$ for the current size of D . For the handle attributes, it has counters $curhnd_u$ (current handle) initialized with 0.

3 The Otway-Rees Protocol

The Otway-Rees protocol [55] is a four-step protocol for establishing a shared secret encryption key between two users. The protocol relies on a distinguished trusted third party \top , i.e., $\top \notin \{1, \dots, n\}$, and it is assumed that every user u initially shares a secret key K_{ut} with \top . Expressed in the typical protocol notation, the Otway-Rees protocol works as follows.³

1. $u \rightarrow v$: $M, (N_u, M, u, v)_{K_{ut}}$
2. $v \rightarrow \top$: $M, (N_u, M, u, v)_{K_{ut}}, (N_v, M, u, v)_{K_{vt}}$
3. $\top \rightarrow v$: $M, (N_u, K_{uv})_{K_{ut}}, (N_v, K_{uv})_{K_{vt}}$
4. $v \rightarrow u$: $M, (N_u, K_{uv})_{K_{ut}}$.

3.1 Capturing Distributed Keys in the Abstract Library

In order to capture that keys shared between users and the trusted third party have already been generated and distributed, we assume that suitable entries for the keys already exist in the database. We denote the handle of u to the secret key shared with v , where either $u \in \{1, \dots, n\}$ and $v = \top$ or vice versa, as $skse_{u,v}^{\text{hnd}}$. More formally, we start with an initially empty database D , and for each user $u \in \mathcal{H}$ two entries of the following form are added (the first one being a public-key identifier for the actual secret key as described below in more detail):

$$\begin{aligned}
(ind &:= pkse_u, type := \text{pkse}, arg := (), len := 0); \\
(ind &:= skse_u, type := \text{skse}, arg := (ind - 1), \\
hnd_u &:= skse_{u,\top}^{\text{hnd}}, hnd_{\top} := skse_{\top,u}^{\text{hnd}}, len := \text{skse_len}^*(k)).
\end{aligned}$$

Here $pkse_u$ and $skse_u$ are two consecutive natural numbers; treating public-key identifiers as being of length 0 is a technicality in the proof of [16], and $\text{skse_len}^*(k)$ denotes the abstract length of the secret key. These lengths will not matter in the following.

The first entry has to be incorporated in order to reflect special capabilities that the adversary may have with respect to symmetric encryption schemes in the real world. For instance it must be possible for an adversary against the ideal library to check whether encryptions have been created with the same secret key since the definition of symmetric encryption schemes does not exclude this and it can hence

³For simplicity, we omit the explicit inclusion of u and v in the unencrypted part of the first and second message since the cryptographic library already provides the identity of the (claimed) sender of a message, which is sufficient for our purpose.

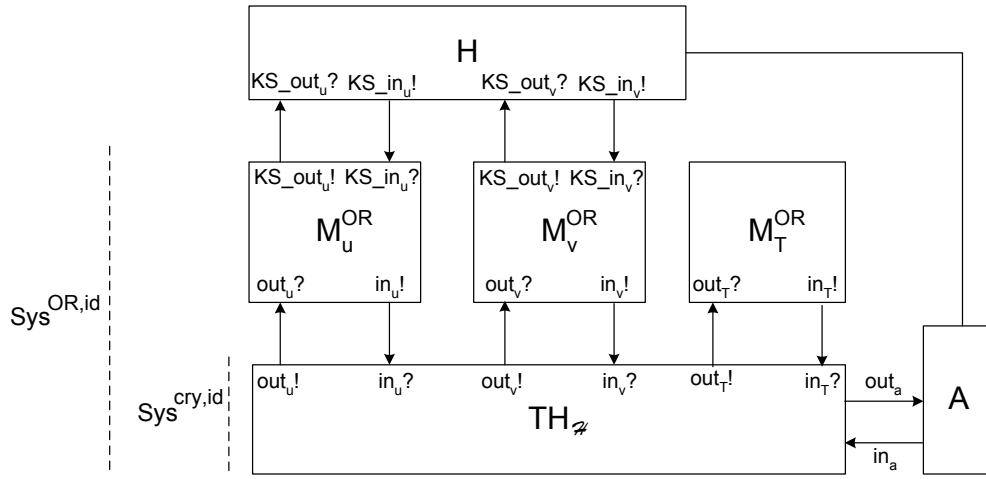

Figure 1: Overview of the Otway-Rees Ideal System.

happen in the real system. For public-key encryption, this was achieved in [22] by tagging ciphertexts with the corresponding public key so that the public keys can be compared. For symmetric encryption, this is not possible as no public key exists, hence this problem is solved by tagging abstract ciphertexts with an otherwise meaningless “public key” solely used as an identifier for the secret key. Note that the argument of a secret key points to its key identifier. In the following, public-key identifiers will not matter any further.

We omit the details of how these entries for user u are added by a command `gen_symerc_key`, followed by a command `send_s` for sending the secret key over a secure channel.

3.2 The Otway-Rees Protocol Using the Abstract Library

We now model the Otway-Rees protocol in the framework of [58] and using the ideal cryptographic library.

For each user $u \in \{1, \dots, n\}$ we define a machine M_u^{OR} , called a *protocol machine*, which executes the protocol sketched above for participant identity u . It is connected to its user via ports $\text{KS_out}_u!$, $\text{KS_in}_u?$ (“KS” for “Key Sharing”) and to the cryptographic library via ports $\text{in}_u!$, $\text{out}_u?$. We further model the trusted third party as a machine M_T^{OR} . It does not connect to any users and is connected to the cryptographic library via ports $\text{in}_T!$, $\text{out}_T?$. The combination of the protocol machines M_u^{OR} , the trusted third party M_T^{OR} , and the trusted host $\text{TH}_{\mathcal{H}}$ is the *ideal Otway-Rees system* $\text{Sys}^{\text{OR},\text{id}}$. It is shown in Figure 1; H and A model the arbitrary joint honest users and the adversary, respectively.

Using the notation of [22], we have $\text{Sys}^{\text{OR},\text{id}} := \{(\hat{M}_{\mathcal{H}}, S_{\mathcal{H}}) \mid \mathcal{H} \subseteq \{1, \dots, n\}\}$, cf. the definition of the ideal cryptographic library in Section 2.3, where $\hat{M}_{\mathcal{H}} := \{\text{TH}_{\mathcal{H}}\} \cup \{M_u^{\text{OR}} \mid u \in \mathcal{H} \cup \{T\}\}$ and $S_{\mathcal{H}} := \{\text{KS_in}_u?, \text{KS_out}_u! \mid u \in \mathcal{H}\}$, i.e., for a given set \mathcal{H} of honest users, only the protocol machines M_u^{OR} with $u \in \mathcal{H}$ are actually present in a protocol run. The others are subsumed in the adversary.

The state of the protocol machine M_u^{OR} consists of the bitstring u and a set Nonce_u of pairs of the form $(n^{\text{hnd}}, m^{\text{hnd}}, v, j)$, where $n^{\text{hnd}}, m^{\text{hnd}}$ are handles, $v \in \{1, \dots, n\}$, and $j \in \{1, 2, 3, 4\}$. Intuitively, a pair $(n^{\text{hnd}}, m^{\text{hnd}}, v, j)$ states that M_u^{OR} generated the handle n^{hnd} in the j -th step of the protocol in a session run with v and session identifier m^{hnd} . The set Nonce_u is initially empty. The trusted third party M_T^{OR} maintains an initially empty set SID_T to store already processed session IDs.

We now define how the protocol machine M_u^{OR} evaluates inputs. They either come from user u at port $\text{KS_in}_u?$ or from $\text{TH}_{\mathcal{H}}$ at port $\text{out}_u?$. The behavior of M_u^{OR} in both cases is described in Algorithm 1 and 3 respectively, which we will describe below. The trusted third party M_T^{OR} only receives inputs from the cryptographic library, and its behavior is described in Algorithm 2. We refer to Step i of Algorithm j as Step $j.i$. All three algorithms should immediately abort if a command to the cryptographic library does not

Algorithm 1 Evaluation of Inputs from the User (Protocol Start)

Input: $(\text{new_prot}, \text{Otway_Rees}, v)$ at $\text{KS_in}_u?$ with $v \in \{1, \dots, n\} \setminus \{u\}$.

- 1: $n_u^{\text{hnd}} \leftarrow \text{gen_nonce}()$.
 - 2: $ID^{\text{hnd}} \leftarrow \text{gen_nonce}()$.
 - 3: $\text{Nonce}_u := \text{Nonce}_u \cup \{(n_u^{\text{hnd}}, ID^{\text{hnd}}, v, 1)\}$.
 - 4: $u^{\text{hnd}} \leftarrow \text{store}(u)$.
 - 5: $v^{\text{hnd}} \leftarrow \text{store}(v)$.
 - 6: $l_1^{\text{hnd}} \leftarrow \text{list}(n_u^{\text{hnd}}, ID^{\text{hnd}}, u^{\text{hnd}}, v^{\text{hnd}})$.
 - 7: $c_1^{\text{hnd}} \leftarrow \text{sym_encrypt}(skse_{u,T}^{\text{hnd}}, l_1^{\text{hnd}})$.
 - 8: $m_1^{\text{hnd}} \leftarrow \text{list}(ID^{\text{hnd}}, c_1^{\text{hnd}})$.
 - 9: $\text{send_i}(v, m_1^{\text{hnd}})$.
-

yield the desired result, e.g., if a decryption requests fails. For readability we omit these abort checks in the algorithm descriptions; instead we impose the following convention on all three algorithms.

Convention 1 For all $w \in \{1, \dots, n\} \cup \{T\}$ the following holds. If M_w^{OR} enters a command at port $\text{in}_w!$ and receives \downarrow at port $\text{out}_w?$ as the immediate answer of the cryptographic library, then M_w^{OR} aborts the execution of the current algorithm, except if the command was of the form `list_proj` or `send_i`.

Protocol start. The user of the protocol machine M_u^{OR} can start a new protocol with user $v \in \{1, \dots, n\} \setminus \{u\}$ by inputting $(\text{new_prot}, \text{Otway_Rees}, v)$ at port $\text{KS_in}_u?$. Our security proof holds for all adversaries and all honest users, i.e., especially those that start protocols with the adversary (respectively a malicious user) in parallel with protocols with honest users. Upon such an input, M_u^{OR} builds up the term corresponding to the first protocol message using the ideal cryptographic library according to Algorithm 1. The command `gen_nonce` generates the ideal nonce as well as the session identifier. M_u^{OR} stores the resulting handles n_u^{hnd} and m^{hnd} in Nonce_u for future comparison together with the identity of v and an indicator that these handles were generated in the first step of the protocol. The command `store` inputs arbitrary application data into the cryptographic library, here the user identities u and v . The command `list` forms a list and `sym_encrypt` is symmetric encryption. The final command `send_i` means that M_u^{OR} sends the resulting term to v over an insecure channel. The effect is that the adversary obtains a handle to the term and can decide what to do with it (such as forwarding it to M_v^{OR}).

Evaluation of network inputs for protocol machines. The behavior of the protocol machine M_u^{OR} upon receiving an input from the cryptographic library at port $\text{out}_u?$ (corresponding to a message that arrives over the network) is defined similarly in Algorithm 3. By construction of $\text{TH}_{\mathcal{H}}$, such an input is always of the form $(v, u, i, m^{\text{hnd}})$ where m^{hnd} is a handle to a list. To increase readability, and to clarify the connection between the algorithmic description and the usual protocol notation, we augment the algorithm with explanatory comments at its right-hand side to depict which handle corresponds to which Dolev-Yao term. We further use the naming convention that ingoing and outgoing messages are labeled m , where outgoing messages have an additional subscript corresponding to the protocol step. Encryptions are labeled c , the encrypted lists are labeled l , both with suitable sub- and superscripts.

M_u^{OR} first determines the session identifier and aborts if it is not of type `nonce`. M_u^{OR} then checks if the obtained message could correspond to the first, third, or fourth step of the protocol. (Recall that the second step is only performed by T .) This is implemented by looking up the session identifier in the set Nonce_u . After that, M_u^{OR} checks if the obtained message is indeed a suitably constructed message for the particular step and the particular session ID by exploiting the contents of Nonce_u . If so, M_u^{OR} constructs a

Algorithm 2 Behavior of the Trusted Third Party

Input: $(v, \top, i, m^{\text{hnd}})$ at $\text{out}_{\top}?$ with $v \in \{1, \dots, n\}$.

1: $ID^{\text{hnd}} \leftarrow \text{list_proj}(m^{\text{hnd}}, 1)$. $\{ID^{\text{hnd}} \approx M\}$
2: $\text{type}_1 \leftarrow \text{get_type}(ID^{\text{hnd}})$.

message according to the protocol description, sends it to the intended recipient, updates the set Nonce_u , and possibly signals to its user that a key has been successfully shared with another user.

Behavior of the trusted third party. The behavior of M_{\top}^{OR} upon receiving an input $(v, \top, i, m^{\text{hnd}})$ from the cryptographic library at port $\text{out}_{\top}?$ is defined similarly in Algorithm 2. We omit an informal description.

3.3 On Polynomial Runtime

In order to use existing composition results of the underlying model, the protocol machines M_w^{OR} and M_{\top}^{OR} must be polynomial-time. Similar to the cryptographic library, we define that each of these machines maintains explicit polynomial bounds on the message lengths and the number of inputs accepted at each port.

4 The Security Property

In the following, we formalize the security property of the ideal and real Otway-Rees protocols. The property consists of a *key secrecy property* and a *consistency property*. We first formalize the ideal key secrecy property which is an instantiation of a general key secrecy definition for arbitrary protocols based on the

ideal cryptographic library. It was introduced in [18] and is symbolic, based on the typical notion that a term is not an element of the adversary’s knowledge set. In the given Dolev-Yao-style library, the adversary’s knowledge set is the set of all terms to which the adversary has a handle. After that we introduce the notion of cryptographic, real-or-random key secrecy based on the real cryptographic library. Finally, we express the consistency property, and we distinguish perfect and computational fulfillment of the property.

4.1 Definition of the Key Secrecy Property

The first step towards defining symbolic key secrecy is to consider one state of the ideal Dolev-Yao-style library and to define that a handle points to a symmetric key, that the key is symbolically unknown to the adversary, and that it has not been used for encryption. These are the symbolic conditions under which we can hope to prove that the corresponding real key is indistinguishable from a fresh random key for the adversary. Note that the operations that the Otway-Rees protocol performs on new keys are allowed in this sense. For Condition (3) in the definition, note that the arguments of a ciphertext term are (l, pk) where l is the plaintext index and pk the index of the public tag of the secret key, with $pk = sk - 1$ for the secret key index.

Definition 4.1 (*Symbolically Secret Encryption Keys [18]*) Let $\{T\} \subseteq \mathcal{H} \subseteq \{1, \dots, n, T\}$, a database state D of $\text{TH}_{\mathcal{H}}$, and a pair $(u, l^{\text{hnd}}) \in \mathcal{H} \times \mathcal{HND\mathcal{S}}$ of a user and a handle be given. Let $i := D[hnd_u = l^{\text{hnd}}].ind$ be the corresponding database index. The term under (u, l^{hnd}) (1) is a symmetric encryption key iff $D[i].type = \text{skse}$, (2) is symbolically unknown (to the adversary) iff $D[i].hnd_a = \downarrow$, (3) has not been used for encryption, or short is unused, iff for all indices $j \in \mathbb{N}$ we have $D[j].type = \text{symenc} \Rightarrow D[j].arg[2] \neq i - 1$, and (4) is a symbolically secret key iff it has the three previous properties. \diamond

A secret-key belief function is a general way to designate the keys whose secrecy should be proved. The underlying theory from [18] is based on such functions. We instantiate them for the Otway-Rees protocol and thus essentially for all individual key exchange protocols. A secret key belief function maps the user view to a set of triples (u, l^{hnd}, t) of a user, a handle, and a type, pointing to the supposedly secret keys. For the Otway-Rees protocol, we define secret-key belief functions `seckey_initiator_OR` for the initiator and `seckey_responder_OR` for the responder that designate the exchanged keys.

Definition 4.2 (*Secret-key Belief Functions for the Otway-Rees Protocol*) A secret-key belief function for a set \mathcal{H} is a function `seckey` that maps each view $view$ of the user to an element of $(\mathcal{H} \times \mathcal{HND\mathcal{S}} \times \{\text{skse}\})^*$.

The secret-key belief functions `seckey_initiator_OR` and `seckey_responder_OR` of the Otway-Rees protocol map each element $(ok_initiator, \text{Otway_Rees}, v, ID^{\text{hnd}}, skse^{\text{hnd}})$ respectively $(ok_responder, \text{Otway_Rees}, v, ID^{\text{hnd}}, skse^{\text{hnd}})$ of $view$ arriving at port `KE_outu`? in the users view to $(u, skse^{\text{hnd}}, \text{skse})$ if $u \in \mathcal{H}$, and to ϵ otherwise. Elements of $view$ that are not of this form are also mapped to ϵ . \diamond

We now define symbolic key secrecy for such a function. In addition to the conditions for individual keys, we require that all elements point to different terms, so that we can expect the corresponding list of cryptographic keys to be entirely random.

Definition 4.3 (*Symbolic Key Secrecy Generally and for the Otway-Rees Protocol*) Let a user H suitable for a structure $(\{\text{TH}_{\mathcal{H}}\}, S_{\mathcal{H}})$ of the cryptographic library $Sys^{\text{cry}, \text{id}}$ and a secret-key belief function `seckey` for \mathcal{H} be given. The ideal cryptographic library with this user keeps the keys in `seckey` strictly symbolically secret iff for all configurations $conf = (\{\text{TH}_{\mathcal{H}}\}, S_{\mathcal{H}}, H, A)$ of this structure, every $v \in view_{conf}(H)$, and every element $(u_i, l_i^{\text{hnd}}, t_i)$ of the set `seckey(v)`, the term under (u_i, l_i^{hnd}) is a symbolically secret key of type t_i , and $D[hnd_{u_i} = l_i^{\text{hnd}}].ind \neq D[hnd_{u_j} = l_j^{\text{hnd}}].ind$ for all $i \neq j$.

The ideal Otway-Rees protocol *keeps the exchanged keys of honest users strictly symbolically secret* iff the ideal cryptographic library keeps the keys in `seckey_initiator_OR` and `seckey_responder_OR` strictly symbolically secret with all users H^* that are the combination of the machines M_u^{OR} for $u \in \mathcal{H}$ and a user H of those machines. \diamond

General cryptographic key secrecy requires that no polynomial-time adversary can distinguish the keys designated by the function `seckey` from fresh keys. The cryptographic key secrecy of the Otway-Rees protocol is the instantiation for `seckey_initiator_OR` and `seckey_responder_OR` and the configurations of the Otway-Rees protocol.

Definition 4.4 (*Cryptographic (Real-or-random) Key Secrecy Generally and for the Otway-Rees Protocol*) Let a polynomial-time configuration $conf = (\hat{M}_{\mathcal{H}}, S_{\mathcal{H}}, H, A)$ of the real cryptographic library $Sys_{SE}^{\text{cry,real}}$ and a secret-key belief function `seckey` for \mathcal{H} be given. Let gen_{SE} denote the key generation algorithm. This configuration *keeps the keys in `seckey` cryptographically secret* iff for all probabilistic-polynomial time algorithms Dis (the distinguisher), we have

$$|\Pr[Dis(1^k, va, keys_{real}) = 1] - \Pr[Dis(1^k, va, keys_{fresh}) = 1]| \in NEGL$$

where $NEGL$ denotes the negligible function of the security parameter k and the used random variables are defined as follows: For $r \in run_{conf}$, let $va := view_{conf}(A)(r)$ be the view of the adversary, let $(u_i, l_i^{\text{hnd}}, t_i)_{i=1, \dots, n} := seckey(view_{conf}(H)(r))$ be the user-handle-type triples of presumably secret keys, and let the keys be $keys_{real} := (sk_i)_{i=1, \dots, n}$ with

$$sk_i := D_{u_i}[hnd_{u_i} = l_i^{\text{hnd}}].word \text{ if } D_{u_i}[hnd_{u_i} = l_i^{\text{hnd}}].type = t_i, \text{ else } \epsilon;$$

and $keys_{fresh} := (sk'_i)_{i=1, \dots, n}$ with $sk'_i \leftarrow gen_A(1^k)$ if $t_i = ska$, else $sk'_i \leftarrow \epsilon$.

A polynomial-time configuration $(\hat{M}_{\mathcal{H}} \cup \{M_u^{\text{OR}} \mid u \in \mathcal{H}\}, S_{\mathcal{H}}, H, A)$ of the real Otway-Rees protocol $Sys^{\text{OR,real}}$ *keeps the exchanged keys of honest users cryptographically secret* iff the configuration $(\hat{M}_{\mathcal{H}}, S_{\mathcal{H}}, \{H\} \cup \{M_u^{\text{OR}} \mid u \in \mathcal{H}\}, A)$ keeps the keys in `seckey_initiator_OR` and `seckey_responder_OR` cryptographically secret. \diamond

4.2 Definition of the Consistency Property

The consistency property states that if two honest users establish a session key then both need to have a consistent view of who the peers to the session are, i.e., if an honest user u establishes a key with v , and v establishes the same key with another user w , then u has to equal w . Moreover, we incorporate the correctness of the protocol into the consistency property, i.e., if the aforementioned outputs occur and $u = w$ holds, then both parties have obtained the same key.⁴ In the following definitions, we write $t : D$ to denote the contents of database D at time t , and $t : p?m$ and $t : p!m$ to denote that message m occurs at input port respectively output port p at time t .

The *consistency property* Req^{Cons} is formally captured as follows: Assume that outputs $(ok_initiator, Otway_Rees, v, ID_u^{\text{hnd}}, skse_u^{\text{hnd}})$ and $(ok_responder, Otway_Rees, w, ID_v^{\text{hnd}}, skse_v^{\text{hnd}})$ occur at $KS_out_u!$ respectively at $KS_out_v!$ at arbitrary times t_1 and t_2 for honest users u and v such that the session identifiers are the same, i.e., $t_1 : D[hnd_u = ID_u^{\text{hnd}}] = t_2 : D[hnd_v = ID_v^{\text{hnd}}]$. Then the handles $skse_u^{\text{hnd}}$ and $skse_v^{\text{hnd}}$ point to the same entry in the database, i.e., $t_1 : D[hnd_u = skse_u^{\text{hnd}}] = t_2 : D[hnd_v = skse_v^{\text{hnd}}]$ if and only if $u = w$. The formal definition of Req^{Cons} is given in Figure 2.

⁴A violation of this correctness aspect has been pointed out in [44] which arises since in their modeling the trusted third party creates multiple keys if it is repeatedly triggered with the same message. We explicitly excluded this in our definition of the trusted third party by storing the session IDs processed so far, cf. Step 7 and 10 in Algorithm 2.

$\forall u, v \in \mathcal{H}, \forall t_1, t_2 \in \mathbb{N}:$	# For all honest users u and v :
$t_1 : \text{KS_out}_u!(\text{ok_initiator}, \text{Otway_Rees}, v, ID_u^{\text{hnd}}, \text{skse}_u^{\text{hnd}}) \wedge$	# if u shares a key with v
$t_2 : \text{KS_out}_v!(\text{ok_responder}, \text{Otway_Rees}, w, ID_v^{\text{hnd}}, \text{skse}_v^{\text{hnd}}) \wedge$	# and v shares a key with w
$t_1 : D[\text{hnd}_u = ID_u^{\text{hnd}}] = t_2 : D[\text{hnd}_v = ID_v^{\text{hnd}}]$	# and the sessions are equal
$\Rightarrow (u = w \Leftrightarrow$	# then u is equal to w iff
$t_1 : D[\text{hnd}_u = \text{skse}_u^{\text{hnd}}] = t_2 : D[\text{hnd}_v = \text{skse}_v^{\text{hnd}}])$	# both keys are equal.

Figure 2: The Consistency Property Req^{Cons} .

Note that the consistency property Req^{Cons} specifically relies on the state of $\text{TH}_{\mathcal{H}}$, hence it cannot be used as is to capture the security of the real Otway-Rees system, where $\text{TH}_{\mathcal{H}}$ is replaced with the secure implementation of the cryptographic library. The corresponding consistency property $Req_{\text{real}}^{\text{Cons}}$ for the real Otway-Rees system can be defined by requiring that both handles point to the same bitstring, i.e., by replacing $t_1 : D[\text{hnd}_u = \text{skse}_u^{\text{hnd}}] = t_2 : D[\text{hnd}_v = \text{skse}_v^{\text{hnd}}]$ with $t_1 : D_u[\text{hnd}_u = \text{skse}_u^{\text{hnd}}].\text{word} = t_2 : D_v[\text{hnd}_v = \text{skse}_v^{\text{hnd}}].\text{word}$ for the databases D_u and D_v of the real library.

The notion of a system Sys fulfilling such a property Req essentially comes in two flavors [10]. *Perfect fulfillment*, $Sys \models^{\text{perf}} Req$, means that the property holds with probability one (over the probability spaces of runs, a well-defined notion from the underlying model [58]) for all honest users and for all adversaries. *Computational fulfillment*, $Sys \models^{\text{poly}} Req$, means that the property only holds for polynomially bounded users and adversaries, and only with negligible error probability. Perfect fulfillment implies computational fulfillment.

The following theorem captures the security of the Otway-Rees protocol.

Theorem 4.1 (*Security of the Otway-Rees Protocol*) Let $Sys^{\text{OR,id}}$ and $Sys^{\text{OR,real}}$ be the ideal and real Otway-Rees system, respectively, as defined in Section 3.2. Then we have:

- *Secrecy*: $Sys^{\text{OR,id}}$ keeps the exchanged keys of honest users strictly symbolically secret, and all polynomial-time configurations of $Sys^{\text{OR,real}}$ keep the exchanged keys of honest users cryptographically secret.
- *Consistency*: $Sys^{\text{OR,id}}$ perfectly fulfills the consistency property Req^{Cons} , and $Sys^{\text{OR,real}}$ computationally fulfills the consistency property $Req_{\text{real}}^{\text{Cons}}$, i.e., $Sys^{\text{OR,id}} \models^{\text{perf}} Req^{\text{Cons}} \wedge Sys^{\text{OR,real}} \models^{\text{poly}} Req_{\text{real}}^{\text{Cons}}$.

□

5 Proof in the Ideal Setting

This section contains the proof of the ideal part of Theorem 4.1, i.e., the proof of the Otway-Rees protocol using the ideal, deterministic cryptographic library. The proof idea is the following: If an honest user u successfully terminates a session run with another honest user v , then we first show that the established key has been created before by the trusted third party. After that, we exploit that the trusted third party as well as all honest users may only send this key within an encryption generated with a key shared between u and T respectively v and T , and we conclude that the adversary hence never gets a handle to the key. The main challenge was to find suitable invariants on the state of the ideal Otway-Rees system. This is somewhat similar to formal proofs using the Dolev-Yao model, and the similarity supports our hope that the

new, sound cryptographic library can be used in the place of the Dolev-Yao models in automated tools. The proof of the invariants is postponed to Appendix A.

5.1 Invariants

The first invariants, *correct nonce owner* and *unique nonce use*, are easily proved and essentially state that handles x^{hnd} where $(x^{\text{hnd}}, \cdot, \cdot, \cdot)$ is contained in a set Nonce_u indeed point to entries of type nonce, and that no nonce is in two such sets. The next two invariants, *nonce secrecy* and *nonce-list secrecy*, deal with the secrecy of certain terms. They are mainly needed to prove the invariant *correct list generation*, which establishes who created certain terms. The last invariant, *key secrecy*, states that the adversary never learns keys created by the trusted third party for use between honest users.

- *Correct Nonce Owner.* For all $u \in \mathcal{H}$, and for all $(x^{\text{hnd}}, \cdot, \cdot, \cdot) \in \text{Nonce}_u$, it holds $D[\text{hnd}_u = x^{\text{hnd}}] \neq \downarrow$ and $D[\text{hnd}_u = x^{\text{hnd}}].\text{type} = \text{nonce}$.
- *Unique Nonce Use.* For all $u, v \in \mathcal{H}$, all $w, w' \in \{1, \dots, n\}$, and all $j \leq \text{size}$: If $(D[j].\text{hnd}_u, \cdot, w, \cdot) \in \text{Nonce}_u$ and $(D[j].\text{hnd}_v, \cdot, w', \cdot) \in \text{Nonce}_v$, then $(u, w) = (v, w')$.

Nonce secrecy states that the nonces exchanged between honest users u and v remain secret from all other users and from the adversary. For the formalization, note that the handles x^{hnd} to these nonces are contained as elements $(x^{\text{hnd}}, \cdot, v, \cdot)$ in the set Nonce_u . The claim is that the other users and the adversary have no handles to such a nonce in the database D of $\text{TH}_{\mathcal{H}}$:

- *Nonce Secrecy.* For all $u, v \in \mathcal{H}$ and for all $j \leq \text{size}$: If $(D[j].\text{hnd}_u, \cdot, v, \cdot) \in \text{Nonce}_u$ then $D[j].\text{hnd}_w \neq \downarrow$ implies $w \in \{u, v, \top\}$. In particular, this means $D[j].\text{hnd}_a = \downarrow$.

Similarly, the invariant *nonce-list secrecy* states that a list containing such a handle can only be known to u , v , and \top . Further, it states that the identity fields in such lists are correct. Moreover, if such a list is an argument of another entry, then this entry is an encryption created with the secret key that either u or v share with \top . (Formally this means that this entry is tagged with the corresponding public-key identifier as an abstract argument, cf. Section 3.1.)

- *Nonce-List Secrecy.* For all $u, v \in \mathcal{H}$ and for all $j \leq \text{size}$ with $D[j].\text{type} = \text{list}$: Let $x_i^{\text{ind}} := D[j].\text{arg}[i]$ for $i = 1, 2, 3, 4$. If $(D[x_1^{\text{ind}}].\text{hnd}_u, \cdot, v, l) \in \text{Nonce}_u$ then
 - $D[j].\text{hnd}_w \neq \downarrow$ implies $w \in \{u, v, \top\}$ for $l \in \{1, 2, 3, 4\}$.
 - If $l \in \{1, 4\}$ and $D[x_3^{\text{ind}}].\text{type} = \text{data}$, then $D[x_3^{\text{ind}}].\text{arg} = (u)$ and $D[x_4^{\text{ind}}].\text{arg} = (v)$.
 - If $l \in \{2, 3\}$ and $D[x_3^{\text{ind}}].\text{type} = \text{data}$, then $D[x_3^{\text{ind}}].\text{arg} = (v)$ and $D[x_4^{\text{ind}}].\text{arg} = (u)$.
 - for $l \in \{1, 2, 3, 4\}$ and for all $k \leq \text{size}$ it holds $j \in D[k].\text{arg}$ only if $D[k].\text{type} = \text{symenc}$ and $D[k].\text{arg}[1] \in \{\text{pkse}_u, \text{pkse}_v\}$.

The invariant *correct list owner* states that certain protocol messages can only be constructed by the “intended” users respectively by the trusted third party.

- *Correct List Owner.* For all $u, v \in \mathcal{H}$ and for all $j \leq \text{size}$ with $D[j].\text{type} = \text{list}$: Let $x_i^{\text{ind}} := D[j].\text{arg}[i]$ for $i = 1, 2$ and $x_{1,u}^{\text{hnd}} := D[x_1^{\text{ind}}].\text{hnd}_u$.
 - If $(x_{1,u}^{\text{hnd}}, \cdot, v, l) \in \text{Nonce}_u$ and $D[x_2^{\text{ind}}].\text{type} \neq \text{skse}$, then $D[j]$ was created by M_u^{OR} in Step 1.6 if $l = 1$ and in Step 3.12 if $l = 2$.

- b) If $(x_{1,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, l) \in \text{Nonce}_u$ and $D[x_2^{\text{ind}}].\text{type} = \text{skse}$, then $D[j]$ was created by M_{\top}^{OR} in Step 2.22 if $l = 3$ and in Step 2.20 if $l = 4$. Moreover, we have $D[\text{hnd}_u = ID_u^{\text{hnd}}] = D[\text{hnd}_{\top} = ID_{\top}^{\text{hnd}}]$, where ID_{\top}^{hnd} denotes the handle that \top obtained in Step 2.1 in the same execution.

Finally, the invariant *key secrecy* states that a secret key entry that has been generated by the trusted third party to be shared between honest users u and v can only be known to u , v , and \top . In particular, the adversary will never get a handle to it. This invariant is key for proving the secrecy and the consistency property of the Otway-Rees protocol.

- *Key Secrecy.* For all $u, v \in \mathcal{H}$ and for all $j \leq \text{size}$ with $D[j].\text{type} = \text{skse}$:
If $D[j]$ was created by M_{\top}^{OR} in Step 2.19 and, with the notation of Algorithm 2, we have that $y_3 = u$ and $y_4 = v$ in the current execution of M_{\top}^{OR} , then $D[j].\text{hnd}_w \neq \downarrow$ implies $w \in \{u, v, \top\}$.

Formally, the invariance of the above statements is captured in the following lemma.

Lemma 5.1 *The statements correct nonce owner, unique nonce use, nonce secrecy, nonce-list secrecy, correct list owner, and key secrecy are invariants of $\text{Sys}^{\text{OR}, \text{id}}$, i.e., they hold at all times in all runs of $\{M_u^{\text{OR}} \mid u \in \mathcal{H} \cup \{\top\}\} \cup \{\text{TH}_{\mathcal{H}}, \text{H}, \text{A}\}$ for all $\mathcal{H} \subseteq \{1, \dots, n\}$, all users H and all adversaries A . \square*

The proof is postponed to Appendix A.

5.2 Proof of the Ideal Part of Theorem 4.1

For the proof of the ideal part of Theorem 4.1, the following property of $\text{TH}_{\mathcal{H}}$ proven in [22] will be useful.

Lemma 5.2 The ideal cryptographic library $\text{Sys}^{\text{cry}, \text{id}}$ has the following property: The only modifications to existing entries x in D are assignments to previously undefined attributes $x.\text{hnd}_u$ (except for counter updates in entries for signature keys, which we do not have to consider here), and appending new elements to the list of arguments of symmetric encryptions. \square

Proof. (Theorem 4.1) Assume that M_u^{OR} outputs $(\text{ok}_x, \text{Otway_Rees}, v, ID_u^{\text{hnd}}, \text{skse}_u^{\text{hnd}})$ at $\text{KS_out}_u!$ for $x \in \{\text{initiator}, \text{responder}\}$, $u \in \mathcal{H}$ and $v \in \{1, \dots, n\}$ at time t_3 , and set $\text{skse}^{\text{ind}} := D[\text{hnd}_u = \text{skse}_u^{\text{hnd}}].\text{ind}$. By definition of Algorithms 1 and 3, this output can only happen in Step 3.28 respectively 3.38, and only after there was an input $(v, u, i, m_u^{3\text{hnd}})$ respectively $(v, u, i, m_u^{4\text{hnd}})$ at $\text{out}_u?$ at a time $t_2 < t_3$. Here and in the sequel we use the notation of Algorithm 1- 3, but we distinguish the variables from its different executions by an additional superscript indicating the number of the (claimed) received protocol message, here ³ and ⁴, and give handles an additional subscript for their owner, here u .

Case 1: Output in Step 3.28. Assume that M_u^{OR} outputs $(\text{ok_responder}, \text{Otway_Rees}, v, ID_u^{\text{hnd}}, \text{skse}_u^{3\text{hnd}})$ at $\text{KS_out}_u!$ for $u \in \mathcal{H}$ and $v \in \{1, \dots, n\}$ in Step 3.28 at time t_3 . Hence, the execution of Algorithm 3 for this input must have given $l_u^{(3), 3\text{hnd}} \neq \downarrow$ in Step 3.19, since the algorithm would otherwise abort by Convention 1 without creating an output.

Let $l^{(3), 3\text{ind}} := D[\text{hnd}_u = l_u^{(3), 3\text{hnd}}].\text{ind}$. The algorithm further implies $D[l^{(3), 3\text{ind}}].\text{type} = \text{list}$. Let $y_i^{3\text{ind}} := D[l^{(3), 3\text{ind}}].\text{arg}[i]$ for $i = 1, 2$ at the time of Step 3.20. By definition of list_proj and since the condition of Step 3.22 is false, we have

$$y_{1,u}^{3\text{hnd}} = D[y_1^{3\text{ind}}].\text{hnd}_u \text{ at time } t_3, \quad (1)$$

$$(y_{1,u}^{3\text{hnd}}, ID_u^{\text{hnd}}, v, 3) \in \text{Nonce}_u \wedge D[y_2^{3\text{ind}}].\text{type} = \text{skse} \text{ at time } t_3, \quad (2)$$

and

$$(y_{1,u}^{3\text{hnd}}, ID^{\text{hnd}}, v, 2) \in \text{Nonce}_u \wedge D[y_2^{3\text{ind}}].\text{type} = \text{skse at time } t_2. \quad (3)$$

Case 2: Output in Step 3.38. This case is similar to the first one: Assume that M_u^{OR} outputs $(\text{ok_initiator}, \text{Otway_Rees}, v, ID_u^{\text{hnd}}, \text{skse}_u^{4\text{hnd}})$ at $\text{KS_out}_u!$ for $u \in \mathcal{H}$ and $v \in \{1, \dots, n\}$ in Step 3.38 at time t_3 . The execution of Algorithm 3 for this input must have given $l_u^{(2),4\text{hnd}} \neq \downarrow$ in Step 3.31, since it would otherwise abort by Convention 1 without creating an output. Let $l^{(2),4\text{ind}} := D[\text{hnd}_u = l_u^{(2),4\text{hnd}}].\text{ind}$, where the algorithm implies $D[l^{(2),4\text{ind}}].\text{type} = \text{list}$. Let $x_i^{4\text{ind}} := D[l^{(2),4\text{ind}}].\text{arg}[i]$ for $i = 1, 2$ at the time of Step 3.32. By definition of list_proj and because of the conditions of Step 3.29 and 3.34, we have

$$x_{1,u}^{4\text{hnd}} = D[x_1^{4\text{ind}}].\text{hnd}_u \text{ at time } t_3, \quad (4)$$

$$(x_{1,u}^{4\text{hnd}}, ID_u^{\text{hnd}}, v, 4) \in \text{Nonce}_u \wedge D[x_2^{4\text{ind}}].\text{type} = \text{skse at time } t_3, \quad (5)$$

and

$$(x_{1,u}^{4\text{hnd}}, ID_u^{\text{hnd}}, v, 1) \in \text{Nonce}_u \wedge D[x_2^{4\text{ind}}].\text{type} = \text{skse at time } t_2. \quad (6)$$

■

This first part of the proof shows that M_u^{OR} has received a list corresponding to a third or fourth protocol message. Now we apply *correct list owner* to the list entry $D[l^{(3),3\text{ind}}]$ for the first case respectively to $D[l^{(2),4\text{ind}}]$ for the second case to show that this entry was created by M_{\top}^{OR} .

Proof. (cont'd) Equations (1) and (2) respectively Equations (4) and (5) are the preconditions for Part b) of *correct list owner*. Hence the entry $D[l^{(3),3\text{ind}}]$ was created by M_{\top}^{OR} in Step 2.20 respectively the entry $D[l^{(2),4\text{ind}}]$ was created by M_{\top}^{OR} in Step 2.22.

In both cases, the algorithm execution must have started with an input $(w, \top, i, m_{\top}^{2\text{hnd}})$ at $\text{out}_{\top}?$ at a time $t_1 < t_2$ with $w \in \{1, \dots, n\}$. We conclude $l_{\top}^{(3),2\text{hnd}} \neq \downarrow$ in Step 2.4 because of Convention 1, set $l^{(3),2\text{ind}} := D[\text{hnd}_{\top} = l_{\top}^{(3),2\text{hnd}}].\text{ind}$, and obtain $D[l^{(3),2\text{ind}}].\text{type} = \text{list}$. *Correct list owner* furthermore implies $D[\text{hnd}_{\top} = ID_{\top}^{2\text{hnd}}] = D[\text{hnd}_u = ID_u^{\text{hnd}}]$. Let $y_i^{2\text{ind}} := D[l^{(3),2\text{ind}}].\text{arg}[i]$ for $i = 1, 2, 3, 4$ at the time of Step 2.5.

As the condition of Step 2.7 is false immediately afterwards, we obtain $y_{i,\top}^{2\text{hnd}} \neq \downarrow$ for $i \in \{1, 2, 3, 4\}$. The definition of list_proj and Lemma 5.2 imply

$$y_{i,\top}^{2\text{hnd}} = D[y_i^{2\text{ind}}].\text{hnd}_{\top} \text{ for } i \in \{1, 2, 3, 4\} \text{ at time } t_3. \quad (7)$$

Step 2.7 further ensures $y_3^2 \in \{1, \dots, n\} \setminus \{w\}$ and $y_4^2 = w$.

As above, we conclude $l_{\top}^{(2),2\text{hnd}} \neq \downarrow$ in Step 2.12, set $l^{(2),2\text{ind}} := D[\text{hnd}_{\top} = l_{\top}^{(2),2\text{hnd}}].\text{ind}$, and obtain $D[l^{(2),2\text{ind}}].\text{type} = \text{list}$. Let $x_i^{2\text{ind}} := D[l^{(2),2\text{ind}}].\text{arg}[i]$ for $i = 1, 2, 3, 4$ at the time of Step 2.13. As the condition of Step 2.16 is false immediately afterwards, we obtain $x_{i,\top}^{2\text{hnd}} \neq \downarrow$ for $i \in \{1, 2, 3, 4\}$. The definition of list_proj and Lemma 5.2 again imply

$$x_{i,\top}^{2\text{hnd}} = D[x_i^{2\text{ind}}].\text{hnd}_{\top} \text{ for } i \in \{1, 2, 3, 4\} \text{ at time } t_3. \quad (8)$$

Step 2.16 furthermore ensures $x_3^2 = y_3^2$ and $x_4^2 = y_4^2$. By definition of the command gen_symenc_key , we obtain $\text{skse}_{\top}^{2\text{hnd}} \neq \downarrow$ in Step 2.19 and set $\text{skse}^{2\text{ind}} := D[\text{hnd}_{\top} = \text{skse}_{\top}^{2\text{hnd}}].\text{ind}$.

Now we exploit that M_{\top}^{OR} creates the entry $D[l^{(3),3^{\text{ind}}}]$ in Step 3.22 with the input $\text{list}(y_{1,\top}^{2^{\text{hd}}}, skse_{\top}^{2^{\text{hd}}})$ respectively the entry $D[l^{(2),4^{\text{ind}}}]$ in Step 2.20 with the input $\text{list}(x_{1,\top}^{2^{\text{hd}}}, skse_{\top}^{2^{\text{hd}}})$. With the definitions of list_proj , and with Equations (7) and (8), this implies $y_1^{2^{\text{ind}}} = y_1^{3^{\text{ind}}}$ and $skse^{\text{ind}} = y_2^{3^{\text{ind}}} = y_2^{2^{\text{ind}}} = skse^{2^{\text{ind}}}$ respectively $x_1^{2^{\text{ind}}} = x_1^{3^{\text{ind}}}$ and $skse^{\text{ind}} = x_2^{4^{\text{ind}}} = x_2^{2^{\text{ind}}} = skse^{2^{\text{ind}}}$. Thus Equations (1) and (3) imply

$$(y_{1,u}^{2^{\text{hd}}}, ID_u^{\text{hd}}, v, 2) \in \text{Nonce}_u \wedge D[y_2^{2^{\text{ind}}}] \cdot \text{type} = \text{skse} \text{ at time } t_2 \quad (9)$$

respectively Equations (4) and (6) imply

$$(x_{1,u}^{2^{\text{hd}}}, ID_u^{\text{hd}}, v, 1) \in \text{Nonce}_u \wedge D[x_2^{2^{\text{ind}}}] \cdot \text{type} = \text{skse} \text{ at time } t_2. \quad (10)$$

■

We are now ready to show symbolic secrecy of the exchanged keys, i.e., to derive that the terms selected by $\text{seckey_initiator_OR}$ and $\text{seckey_responder_OR}$ are symbolically unused symmetric keys that have furthermore not been used for encryption yet.

Proof. (cont'd, secrecy requirement) With the notation of the previous proof, assume additionally that $v \in \mathcal{H}$. Together with Equation 9 and Equation 10, *nonce-list secrecy* applied to the entry $D[l^{(3),3^{\text{ind}}}]$ respectively $D[l^{(2),4^{\text{ind}}}]$ now immediately implies that $\{y_3^2, y_4^2\} = \{u, v\}$ respectively $\{x_3^2, x_4^2\} = \{u, v\}$. This gives the precondition to apply *key secrecy* to the entry $D[skse^{2^{\text{ind}}}]$, which implies $D[skse^{2^{\text{ind}}}] \cdot \text{hnd}_a = \downarrow$. Because of $skse^{2^{\text{ind}}} = skse^{\text{ind}}$ we have $D[skse^{2^{\text{ind}}}] \cdot \text{hnd}_a = D[skse^{\text{ind}}] \cdot \text{hnd}_a = \downarrow$, i.e., the term under $(u, skse_u^{\text{hd}})$ is symbolically unknown. Moreover Equation 9 and Equation 10 imply $D[skse^{\text{ind}}] \cdot \text{type} = D[skse^{2^{\text{ind}}}] \cdot \text{type} = \text{skse}$, i.e., the term under $(u, skse_u^{\text{hd}})$ is a symmetric key.

It remains to show that the key is unused at time t_3 . The only way to create an entry $D[j]$ with $D[j] \cdot \text{type} = \text{symenc}$ and $D[j] \cdot \text{arg}[2] = skse^{\text{ind}} - 1$ is by inputting a command sym_encrypt at port in_w ? such that $D[skse^{\text{ind}}] \cdot \text{hnd}_w \neq \downarrow$. Since we have shown that $D[skse^{\text{ind}}] \cdot \text{hnd}_w \neq \downarrow$ only if $w \in \{u, v, \top\}$, it remains to show that neither of them enters such a command until time t_3 . By inspection of Algorithm 2, this clearly holds for \top , since this may only happen in Steps 2.21 or 2.23. In both cases, the key used is one of those that were initially distributed, i.e., $D[j] \cdot \text{arg}[2] = skse_w - 1$ for some $w \in \{1, \dots, n\}$. Since we have shown that each key selected by $\text{seckey_initiator_OR}$ or $\text{seckey_responder_OR}$ is newly generated by M_{\top}^{OR} , we in particular have $skse_w \neq skse^{\text{ind}}$. Similar reasoning can be applied to Algorithm 1 and 3 of M_u^{OR} to show that the only used keys are the ones shared between u and \top respectively between v and \top .

■

It remains to show the consistency requirement Req^{Sec} .

Proof. (cont'd, consistency requirement) Assume that M_u^{OR} outputs $(\text{ok_initiator}, \text{Otway_Rees}, v, ID_u^{\text{hd}}, skse_u^{\text{hd}})$ at $\text{KS_out}_u!$ at time t_3 and that M_v^{OR} outputs $(\text{ok_responder}, \text{Otway_Rees}, w, ID_v^{\text{hd}}, skse_v^{\text{hd}})$ at $\text{KS_out}_v!$ at time t'_3 for $u, v \in \mathcal{H}$ and $w \in \{1, \dots, n\}$, and let $t_3 : D[\text{hnd}_u = ID_u^{\text{hd}}] = t'_3 : D[\text{hnd}_v = ID_v^{\text{hd}}]$. We again use the notation of the main proof.

To show the left-to-right direction of the consistency property, assume that $u = w$. Let $skse_u^{\text{ind}} := D[\text{hnd}_u = skse_u^{\text{hd}}] \cdot \text{ind}$ and $skse_v^{\text{ind}} := D[\text{hnd}_v = skse_v^{\text{hd}}] \cdot \text{ind}$. Now the main proof immediately yields $D[\text{hnd}_u = ID_u^{\text{hd}}] = D[\text{hnd}_{\top} = ID_{\top}^{2^{\text{hd}}}] = D[\text{hnd}_v = ID_v^{\text{hd}}]$, i.e., both $D[skse_u^{\text{ind}}]$ and $D[skse_v^{\text{ind}}]$ have been created in an execution of M_{\top} with the same handle ID_{\top}^{hd} . Because of the check in Step 2.7 and because of Step 2.10 both entries must have been created in the same execution, which immediately implies $t_3 : D[\text{hnd}_u = skse_u^{\text{hd}}] = t'_3 : D[\text{hnd}_v = skse_v^{\text{hd}}]$, and we are done.

To show the right-to-left direction, assume that $t_3 : D[hnd_u = skse_u^{\text{hnd}}] = t'_3 : D[hnd_v = skse_v^{\text{hnd}}]$ holds. We have already shown that

$$D[hnd_u = skse_u^{\text{hnd}}].hnd_z \neq \downarrow \implies z \in \{u, v, T\}. \quad (11)$$

Hence only u , v , and T can get a handle to $D[hnd_v = skse_v^{\text{hnd}}]$.

We first show that if w also got a handle to $D[hnd_v = skse_v^{\text{hnd}}]$ then $u = w$ trivially holds. Because of $D[hnd_u = skse_u^{\text{hnd}}].hnd_z \neq \downarrow$ only if $z \in \{u, v, T\}$, we conclude $w \in \{u, v, T\}$. Hence it remains to show $w \notin \{v, T\}$. However, the output $(\text{ok}, \text{Otway_Rees}, w, ID_v^{\text{hnd}}, skse_v^{\text{hnd}})$ may only occur if the checks in Step 3.22 or 3.29 succeeded, which ensures that $(\cdot, \cdot, w, \cdot) \in \text{Nonce}_v$ immediately before time t'_3 . Consider the first time that an element containing w as its third component was entered into Nonce_v . This could either happen in Step 1.3 or in Step 3.9. In both cases however, we obtain $w \in \{1, \dots, n\} \setminus \{v\}$ by definition of Algorithm 1 and 3, hence we have $u = w$ as desired.

To conclude the proof, we have to consider those cases where w does not get a handle to $D[hnd_v = skse_v^{\text{hnd}}]$. We show that if an honest v outputs $(\text{ok}, \text{Otway_Rees}, w, ID_v^{\text{hnd}}, skse_v^{\text{hnd}})$, then the adversary can ensure that w gets a handle to $D[hnd_v = skse_v^{\text{hnd}}]$ (i.e., that there exists an adversary that schedules messages in a way that gives w this handle), and hence we obtain $u = w$ as in the previous case. The existence of such an adversary is intuitively clear and technically follows immediately from the main proof: We have that the entry $D[hnd_v = skse_v^{\text{hnd}}]$ was created by M_T^{OR} , and assume that M_T^{OR} outputs $\text{send_i}(w', m_3^{\text{hnd}})$ in Step 2.25 for some w' . Let $m^{3\text{ind}} := D[hnd_T = m_3^{\text{hnd}}]$. We can assume that $w' \in \mathcal{H}$ as the adversary would otherwise obtain a handle to $D[hnd_u = skse_u^{\text{hnd}}]$, which would yield a contradiction to Equation 11. As shown in the proof of the secrecy property, *nonce-list secrecy* implies $w' \in \{v, w\}$, hence either the second component or the third component of $D[m^{3\text{ind}}]$ is an encryption with the key that w shares with T . The command send_i gives the adversary a handle $m_{3,a}^{\text{hnd}}$ to $m^{3\text{ind}}$, i.e., $m_{3,a}^{\text{hnd}} := D[m^{3\text{ind}}].hnd_a$. If $w = w'$ (which means that w will be able to decrypt the third component of $D[m^{3\text{ind}}]$), the adversary forwards m_3^{hnd} to w . (Formally, it inputs $\text{adv_send_i}(w, T, m_{3,a}^{\text{hnd}})$ at in_a ?.) The machine M_w^{OR} will then obtain a handle to $D[hnd_v = skse_v^{\text{hnd}}]$ in Step 3.20, where the correctness of the previous decryption step follows as in the main proof. If $w \neq w'$, i.e., w will be able to decrypt the second component of $m^{3\text{ind}}$, the adversary first determines handles to the first two components of $m^{3\text{ind}}$ by means of the command list_proj , i.e., $ID_a^{\text{hnd}} \leftarrow \text{list_proj}(m_{3,a}^{\text{hnd}}, 1)$ and $c_{3,a}^{(2)\text{hnd}} \leftarrow \text{list_proj}(m_{3,a}^{\text{hnd}}, 2)$. It then creates a message $m^{\text{hnd}} \leftarrow \text{list}(ID_a^{\text{hnd}}, c_{3,a}^{(2)\text{hnd}})$ and sends m^{hnd} to w claiming to be v . (Formally, the input is $\text{adv_send_i}(w, v, m^{\text{hnd}})$). Similar to the previous case, the machine M_w^{OR} will then obtain a handle to $D[hnd_v = skse_v^{\text{hnd}}]$, but now in Step 3.32. ■

6 Proof of the Cryptographic Realization

If Theorem 4.1 has been proven, it remains to show that the Otway-Rees protocol based on the real cryptographic library computationally fulfills corresponding secrecy and consistency requirements. Obviously, carrying over properties from the ideal to the real system crucially relies on the fact that the real cryptographic library is at least as secure as the ideal one. As briefly sketched in the introduction, this has been established in [22, 16], but only subject to the side condition that the surrounding protocol, i.e., the Otway-Rees protocol in our case, does not raise a so-called *commitment problem*. Establishing this side condition is crucial for using symmetric encryption in abstract, cryptographically sound proofs. We explain the commitment problem in detail in the next section to illustrate the cryptographic issue underlying the commitment problem, and we exploit the invariants of Section 5 to show that the commitment problem does not occur for the Otway-Rees protocol. As our proof is the first Dolev-Yao-style, computationally sound proof of a

protocol that uses symmetric encryption, our result also shows that the commitment problem, and hence also symmetric encryption, can be conveniently dealt with in cryptographically sound proofs of security by means of the approach of [16].

For technical reasons, one further has to ensure that the surrounding protocol does not create “encryption cycles” (such as encrypting a key with itself), which had to be required even for acquiring properties weaker than simulatability, cf. [3] for further discussions. This property is only a technical subtlety and clearly holds for the Otway-Rees protocol.

6.1 Absence of the Commitment Problem for the Otway-Rees Protocol

As the name suggests, a “commitment problem” in simulatability proofs captures a situation where the simulator commits itself to a certain message and later has to change this commitment to allow for a correct simulation. In the case of symmetric encryption, the commitment problem occurs if the simulator learns in some abstract way that a ciphertext was sent and hence has to construct an indistinguishable ciphertext, knowing neither the secret key nor the plaintext used for the corresponding ciphertext in the real world. To simulate the missing key, the simulator will create a new secret key, or rely on an arbitrary, fixed key if the encryption systems guarantees indistinguishable keys, see [3]. Instead of the unknown plaintext, the simulator will encrypt an arbitrary message of the correct length, relying on the indistinguishability of ciphertexts of different messages. So far, the simulation is fine. It even stays fine if the message becomes known later because secure encryption still guarantees that it is indistinguishable that the simulator’s ciphertext contains a wrong message. However, if the secret key becomes known later, the simulator runs into trouble, because, learning abstractly about this fact, it has to produce a suitable key that decrypts its ciphertext into the correct message. It cannot cheat with the message because it has to produce the correct behavior towards the honest users. This is typically not possible.

The solution for this problem taken in [16] for the cryptographic library is to leave it to the surrounding protocol to guarantee that the commitment problem does not occur, i.e., the surrounding protocol must guarantee that keys are no longer sent in a form that might make them known to the adversary once an honest participant has started using them. To exploit the simulatability results of [16], we hence have to prove this condition for the Otway-Rees protocol. Formally, we have to show that the following property NoComm does not occur: “If there exists an input from an honest user that causes a symmetric encryption to be generated such that the corresponding key is not known to the adversary, then future inputs may only cause this key to be sent within an encryption that cannot be decrypted by the adversary”. This event can be rigorously defined in the style of the secrecy and consistency property but we omit the rigorous definition due to space constraints and refer to [16]. The event NoComm is equivalent to the event “if there exists an input from an honest user that causes a symmetric encryption to be generated such that the corresponding key is not known to the adversary, the adversary never gets a handle to this key” but NoComm has the advantage that it can easily be inferred from the abstract protocol description without presupposing knowledge about handles of the cryptographic library. For the Otway-Rees protocol the event NoComm can easily be verified by inspection of the abstract protocol description, and a detailed proof based on Algorithms 1-3 can also easily be performed by exploiting the invariants of Section 5.

Lemma 6.1 (*Absence of the Commitment Problem for the Otway-Rees Protocol*) *The ideal Otway-Rees system $Sys^{OR,id}$ perfectly fulfills the property NoComm, i.e., $Sys^{OR,id} \models^{perf} \text{NoComm}$. \square*

Proof. Note first that the secret key shared initially between a user and the trusted third party will never be sent by definition in case the user is honest, and it is already known to the adversary when it is first used in case of a dishonest user. The interesting cases are thus the keys generated by the trusted third party in the protocol sessions.

Let $j \leq \text{size}$, $D[j].\text{type} = \text{skse}$ such that $D[j]$ was created by M_{\top}^{OR} in Step 2.19, where, with the notation of Algorithm 2, we have $y_3 = u$ and $y_4 = v$ for $y_3, y_4 \in \{1, \dots, n\}$. If u or v were dishonest, then the adversary would get a handle for $D[j]$ after M_{\top}^{OR} finishes its execution, i.e., in particular before $D[j]$ has been used for encryption for the first time, since the adversary knows the keys shared between the dishonest users and the trusted third party. If both u and v are honest, *key secrecy* then immediately implies that $t : D[j].\text{hnd}_a = \downarrow$ for all $t \in \mathbb{N}$, which finishes the proof. ■

6.2 Proof of Real-or-random Secrecy and Computational Consistency

As the final step in the overall security proof, we show how to derive corresponding secrecy and consistency properties from the proofs in the ideal setting and the simulatability result of the underlying library. In particular, we derive cryptographic, real-or-random key secrecy as well as computational fulfillment of the consistency property.

Once we have shown that the considered keys are symbolically secret and that the commitment problem does not occur for the Otway-Rees protocol, we can exploit the following key-secrecy preservation theorem:

Theorem 6.1 (*Symbolic Key Secrecy Implies Cryptographic Key Secrecy [18]*) Let a polynomial-time honest user H of a structure $(\{\text{TH}_{\mathcal{H}}\}, S_{\mathcal{H}})$ of the ideal cryptographic library and a secret-key belief function *seckey*s for \mathcal{H} be given such that the cryptographic library with this user keeps the keys in *seckey*s strictly symbolically secret. Then every polynomial-time configuration $(\hat{M}_{\mathcal{H}}, S_{\mathcal{H}}, H, A)$ of the real cryptographic library (with the same user H) keeps the keys in *seckey*s cryptographically secret. □

It is easy to show that this theorem implies the cryptographic secrecy part of Theorem 4.1 once the ideal, symbolic part has already been shown: We have shown in Section 5 that the ideal Otway-Rees protocol keeps the keys of honest users strictly symbolically secret, i.e., the cryptographic library with user H^* denoting the combination of $\{H\} \cup \{M_u^{\text{OR}} \mid u \in \mathcal{H}\}$ keeps the keys in *seckey*s_initiator_OR and *seckey*s_responder_OR strictly symbolically secret. Hence Theorem 6.1 implies that every polynomial-time configuration $(\hat{M}_{\mathcal{H}}, S_{\mathcal{H}}, H^*, A)$ of the real cryptographic library keeps the keys in *seckey*s_initiator_OR and *seckey*s_responder_OR cryptographically secret, and thus that the every polynomial-time configurations of $Sys^{\text{OR,real}}$ keeps the exchanged keys of honest users cryptographically secret.

We only briefly sketch how to derive $Req_{\text{real}}^{\text{Cons}}$ from the the ideal counterpart since the proofs contains requires slightly more knowledge about the underlying proof of soundness of the cryptographic library [22, 16]: One first exploits that the real and ideal consistency properties closely resemble so-called *integrity properties* in the sense of [10]. Integrity properties correspond to sets of traces at the in- and output ports connecting the system to the honest users, i.e., properties that can be expressed solely via statements about events at the port set $S_{\mathcal{H}}$; in particular, integrity property hence do not rely on the state of the underlying machine. Integrity properties are preserved under simulatability, i.e., they carry over from the ideal to the real system without any additional work. Formally, the following *preservation theorem* has been established in [10].

Theorem 6.2 (*Preservation of Integrity Properties (Sketch)*) Let two systems Sys_1, Sys_2 be given such that Sys_1 is at least as secure as Sys_2 (written $Sys_1 \geq_{\text{sec}}^{\text{poly}} Sys_2$). Let Req be an integrity property for both Sys_1 and Sys_2 , and let $Sys_2 \models^{\text{poly}} Req$. Then also $Sys_1 \models^{\text{poly}} Req$. □

Note that this theorem would allow us to derive $Req_{\text{real}}^{\text{Cons}}$ from its ideal counterparts, provided that we can somehow link the statements involving the state of the ideal and real cryptographic library, i.e., the statements $t_1 : D[\text{hnd}_u = \text{skse}_u^{\text{hnd}}] = t_2 : D[\text{hnd}_v = \text{skse}_v^{\text{hnd}}$ and $t_1 : D_u[\text{hnd}_u = \text{skse}_u^{\text{hnd}}].\text{word} = t_2 : D_v[\text{hnd}_v = \text{skse}_v^{\text{hnd}}].\text{word}$. If one looks at the underlying proof of soundness of the cryptographic library, there exists a so-called combined system that links state parts of the real library to state parts of the

ideal library. In particular, we obtain that if the real Otway-Rees protocol is run with an arbitrary adversary and if we have $t_1 : D[hnd_u = skse_u^{hnd}] = t_2 : D[hnd_v = skse_v^{hnd}]$ then there always exist an adversary against the ideal Otway-Rees protocol such that $t_1 : D_u[hnd_u = skse_u^{hnd}].word = t_2 : D_v[hnd_u = skse_u^{hnd}].word$. Together with the aforementioned integrity preservation theorem, this shows that the real Otway-Rees protocol computationally fulfills Req_{real}^{Cons} and hence finishes the proof of Theorem 4.1.

7 Conclusion

We have proven the Otway-Rees protocol in the real cryptographic setting via a deterministic, provably secure abstraction of a real cryptographic library. Together with composition and preservation theorems from the underlying model, this library allowed us to perform the actual proof effort in a deterministic setting corresponding to a slightly extended Dolev-Yao model. In particular, we prove real-or-random secrecy of the exchanged keys, i.e., no polynomial-time adversary attacking the protocol is able to distinguish fresh, random keys and keys that are actually exchanged in the protocol. Besides establishing the cryptographic security of the Otway-Rees protocol, our result also serves as an exemplification of the potential of the cryptographic library and the recent secrecy preservation theorem for symbolic, automated, and cryptographically sound proofs of security protocols.

A Proof of the Invariants

A.1 Correct Nonce Owner and Unique Nonce Use

We start with the proof of *correct nonce owner*.

Proof. (Correct nonce owner) Let $(x^{\text{hnd}}, \cdot, v, j) \in \text{Nonce}_u$ for $u \in \mathcal{H}$, $v \in \{1, \dots, n\}$, and $j \in \{1, 2, 3, 4\}$. By construction, this entry has been added to Nonce_u by M_u^{OR} in Step 1.3, Step 3.9, Step 1.25, or Step 1.37. In the last two cases, the entry $(x^{\text{hnd}}, \cdot, v, j - 1)$ respectively $(x^{\text{hnd}}, \cdot, v, j - 3)$ was already contained in Nonce_u (for the same handle x^{hnd} and the same identity v) hence it is sufficient to consider the first two cases. In both cases x^{hnd} has been generated by the command `gen_nonce()` at some time t , input at port $\text{in}_u?$ of $\text{TH}_{\mathcal{H}}$. Convention 1 implies $x^{\text{hnd}} \neq \downarrow$, as M_u^{OR} would abort otherwise and not add the entry to the set Nonce_u . The definition of `gen_nonce` then implies $D[\text{hnd}_u = x^{\text{hnd}}] \neq \downarrow$ and $D[\text{hnd}_u = x^{\text{hnd}}].\text{type} = \text{nonce}$ at time t . Because of Lemma 5.2 this also holds at all later times $t' > t$, which finishes the proof. ■

The following proof of *unique nonce use* is quite similar.

Proof. (Unique Nonce Use) Assume for contradiction that both $x_1 := (D[j].\text{hnd}_u, \cdot, w, \cdot) \in \text{Nonce}_u$ and $x_2 := (D[j].\text{hnd}_v, \cdot, w', l) \in \text{Nonce}_v$ at some time t . Without loss of generality, let t be the first such time and let $x_2 \notin \text{Nonce}_v$ at time $t - 1$. By construction, x_2 is thus added to Nonce_v at time t by Step 1.3, Step 3.9, Step 1.25, or Step 1.37. In the last two cases, the entry $(x^{\text{hnd}}, \cdot, w', l - 1)$ respectively $(x^{\text{hnd}}, \cdot, w', l - 3)$ was already contained in Nonce_u (for the same handle x^{hnd} and the same identity w') hence it is sufficient to consider the first two cases. In both cases, $D[j].\text{hnd}_v$ has been generated by the command `gen_nonce()` at time $t - 1$. The definition of `gen_nonce` implies that $D[j]$ is a new entry and $D[j].\text{hnd}_v$ its only handle at time $t - 1$, and thus also at time t . With *correct nonce owner* this implies $u = v$. Further, $x_2 = (D[j].\text{hnd}_v, \cdot, w', l)$ is the only entry that is put into Nonce_v at times $t - 1$ and t . Thus also $w = w'$. This is a contradiction. ■

A.2 Correct List Owner

In the following subsections, we prove *correct list owner*, *nonce secrecy*, *key secrecy*, and *nonce-list secrecy* by induction. Hence assume that all three invariants hold at a particular time t in a run of the system, and we have to show that they still hold at time $t + 1$.

Proof. (Correct list owner) Let $u, v \in \mathcal{H}$, $j \leq \text{size}$ with $D[j].\text{type} = \text{list}$. Let $x_i^{\text{ind}} := D[j].\text{arg}[i]$ for $i = 1, 2$ and $x_{1,u}^{\text{hnd}} := D[x_1^{\text{ind}}].\text{hnd}_u$, and assume that $(x_{1,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, l) \in \text{Nonce}_u$ at time $t + 1$.

The only possibilities to violate the invariant *correct list owner* are that (1) the entry $D[j]$ is created at time $t + 1$ or that (2) the handle $D[j].\text{hnd}_u$ is created at time $t + 1$ for an entry $D[j]$ that already exists at time t or that (3) the entry $(x_{1,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, l)$ is added to Nonce_u at time $t + 1$. In all other cases the invariant holds by the induction hypothesis and Lemma 5.2.

We start with the third case. Assume that $(x_{1,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, l)$ is added to Nonce_u at time $t + 1$. By construction, this only happens in a transition of M_u^{OR} in Step 1.3, 3.9, 3.25, and 3.37. However, in the first two subcases, the entry $D[x_1^{\text{ind}}]$ has been generated by the command `gen_nonce` input at $\text{in}_u?$ immediately before, hence x_1^{ind} cannot be contained as an argument of an entry $D[j]$ at time t . Formally, this corresponds

to the fact that D is *well-formed* [22]. Since a transition of M_u^{OR} does not modify entries in $\text{TH}_{\mathcal{H}}$, this also holds at time $t+1$. For the latter two cases, note that Step 3.22 and Step 3.29 ensure that $(x_{1,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, 2) \in \text{Nonce}_u$ respectively $(x_{1,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, 1) \in \text{Nonce}_u$ already at time t . Hence the claim follows by induction hypothesis and from the previous two subcases.

For proving the remaining two cases, assume that $D[j].\text{hnd}_u$ is created at time $t+1$ for an already existing entry $D[j]$ or that $D[j]$ is generated at time $t+1$. Because both can only happen in a transition of $\text{TH}_{\mathcal{H}}$, this implies $(x_{1,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, l) \in \text{Nonce}_u$ already at time t , since transitions of $\text{TH}_{\mathcal{H}}$ cannot modify the set Nonce_u . Because of $u, v \in \mathcal{H}$, *nonce secrecy* implies $D[x_i^{\text{ind}}].\text{hnd}_w \neq \downarrow$ only if $w \in \{u, v, \top\}$. Lists can only be constructed by the basic command list, which requires handles to all its elements. More precisely, if $w \in \mathcal{H} \cup \{\mathbf{a}, \top\}$ creates an entry $D[j']$ with $D[j'].type = \text{list}$ and $(x'_1, \dots, x'_k) := D[j].arg$ at time $t+1$ then $D[x'_i].\text{hnd}_w \neq \downarrow$ for $i = 1, \dots, k$ already at time t . Applied to the entry $D[j]$, this implies that either u, v , or \top have created the entry $D[j]$.

We now only have to show that the entry $D[j]$ has been created by u in the claimed steps. This can easily be seen by inspection of Algorithms 1, 2, and 3. We only show it in detail for the first part of the invariant; it can be proven similarly for the second part where the claim about the session identifier immediately follows from the proof.

Let $(x_{1,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, l) \in \text{Nonce}_u$ for $l \in \{1, 2\}$ and $D[x_2^{\text{ind}}].type = \text{nonce}$. By inspection of Algorithms 1, 2, and 3 and because $D[j].type = \text{list}$, we see that the entry $D[j]$ must have been created by either M_u^{OR} or M_v^{OR} in Step 1.6 if $l = 1$ or in Step 3.12. (The remaining list generation commands always have $D[x_2^{\text{ind}}].type \in \{\text{skse}, \text{symenc}\}$ by construction.) This already implies that the entry $D[j]$ has not been generated by \top . Now assume for contradiction that the entry $D[j]$ has been generated by M_v^{OR} . This implies that also the entry $D[x_1^{\text{ind}}]$ has been newly generated by the command `gen_nonce` input at $in_v?$. However, only M_u^{OR} can add elements to the set Nonce_u (it is the local state of M_u^{OR}), but if an entry $(x_{1,u}^{\text{hnd}}, \cdot, \cdot, \cdot)$ is added to the set Nonce_u by M_u^{OR} , then $x_{1,u}^{\text{hnd}}$ has been newly generated by the command `gen_nonce` input by M_u^{OR} by construction. This implies $(x_{1,u}^{\text{hnd}}, \cdot, \cdot, \cdot) \notin \text{Nonce}_u$ at all times, which yields a contradiction to $x_{1,u}^{\text{hnd}} \in \text{Nonce}_u$ at time $t+1$. Hence $D[j]$ has been created by user u . ■

A.3 Nonce Secrecy

Proof. (*Nonce secrecy*) Let $u, v \in \mathcal{H}$, $j \leq \text{size}$ with $x := (D[j].\text{hnd}_u, ID_u^{\text{hnd}}, v, l) \in \text{Nonce}_u$, and $w \in (\mathcal{H} \cup \{\mathbf{a}\}) \setminus \{u, v\}$ be given. Because of *correct nonce owner*, we know that $D[j].type = \text{nonce}$. The invariant could only be affected if (1) x is put into the set Nonce_u at time $t+1$ or (2) if a handle for w is added to the entry $D[j]$ at time $t+1$.

For proving the first case, note that the set Nonce_u is only extended by an entry x by M_u^{OR} in Steps 1.3 and 3.9 (again the modifications of Nonce_u in Steps 3.25 and 3.37 do not have to be considered since an entry $(D[j].\text{hnd}_u, ID_u^{\text{hnd}}, v, l-1)$ respectively $(D[j].\text{hnd}_u, ID_u^{\text{hnd}}, v, l-3)$ already existed in Nonce_u before, which is ensured by the checks in Steps 3.22, 3.29, and 3.34). In both cases, $D[j].\text{hnd}_u$ has been generated by $\text{TH}_{\mathcal{H}}$ at time t since the command `gen_nonce` was input at $in_u?$ at time t . The definition of `gen_nonce` immediately implies that $D[j].\text{hnd}_w = \downarrow$ at time t if $w \neq u$. Moreover, this also holds at time $t+1$ since a transition of M_u^{OR} does not modify handles in $\text{TH}_{\mathcal{H}}$, which finishes the claim for this case.

For proving the second case, we only have to consider those commands that add handles for w to entries of type `nonce`. These are only the commands `list_proj` or `adv_parse` input at $in_w?$, where `adv_parse` has to be applied to an entry of type `list`, since only entries of type `list` can have arguments which are indices to nonce entries. More precisely, if one of the commands violated the invariant there would exist an entry $D[i]$ at time t such that $D[i].type = \text{list}$, $D[i].\text{hnd}_w \neq \downarrow$ and $j \in (x_1^{\text{ind}}, \dots, x_m^{\text{ind}}) := D[i].arg$. However, both commands do not modify the set Nonce_u , hence we have $x \in \text{Nonce}_u$ already at time t . Now *nonce secrecy* yields $D[j].\text{hnd}_w = \downarrow$ at time t and hence also at all times $< t$ because of Lemma 5.2. This implies that

the entry $D[i]$ must have been created by either u or v , since generating a list presupposes handles for all elements (cf. the previous proof). Assume without loss of generality that $D[i]$ has been generated by u . By inspection of Algorithms 1 and 3, this immediately implies $j = x_1^{\text{ind}}$, since such handles only occur as first element in a list generation by u . Because of $j = D[i].\text{arg}[1]$ and $(D[j].\text{hnd}_u, \cdot, v, \cdot) \in \text{Nonce}_u$ at time t , *nonce-list secrecy* for the entry $D[i]$ implies that $D[i].\text{hnd}_w = \downarrow$ at time t . This yields a contradiction. ■

A.4 Key Secrecy

Proof. (Key Secrecy) Let $j \leq \text{size}$, $D[j].\text{type} = \text{skse}$ such that $D[j]$ was created by M_{\top}^{OR} in Step 2.19, where, with the notation of algorithm 2, we have $y_3 = u$ and $y_4 = v$ for honest u, v . Now the message output in Step 2.25 maintains the entry $D[j]$ within an encryption with $\text{skse}_{\top, u}^{\text{hnd}}$ and one with $\text{skse}_{\top, v}^{\text{hnd}}$. By assumption, these keys are shared between u and \top respectively v and \top , and they are never sent. The definition of the command `sym_decrypt` implies that only u and \top respectively v and \top can get a handle to the entry $D[j]$ out of these encryptions. Such a decryption could only happen in Steps 3.19 and 3.31 yielding handles $l^{(3)\text{hnd}}$ respectively $l^{(2)\text{hnd}}$. Let $y_1 := D[\text{hnd}_u = l^{(3)\text{hnd}}].\text{arg}[1]$, $y_1^{\text{hnd}} := D[y_1].\text{hnd}_u$, and $x_1 := D[\text{hnd}_u = l^{(2)\text{hnd}}].\text{arg}[2]$, $x_1^{\text{hnd}} := D[x_1].\text{hnd}_u$. In both cases, the checks in Step 3.22 respectively in Step 3.29 and 3.34 imply $(y_1^{\text{hnd}}, ID^{\text{hnd}}, w, 2) \in \text{Nonce}_u$ respectively $(x_1^{\text{hnd}}, ID^{\text{hnd}}, w, 1) \in \text{Nonce}_u$ as otherwise M_u^{OR} would abort the current transition without updating its state and without producing any output. Now *nonce-list secrecy* immediately implies that $D[\text{hnd}_u = l^{(2)\text{hnd}}].\text{hnd}_a = D[\text{hnd}_u = l^{(3)\text{hnd}}].\text{hnd}_a = \downarrow$. Since u, v , and \top only send the entry $D[j]$ as an argument of $D[\text{hnd}_u = l^{(2)\text{hnd}}]$ or $D[\text{hnd}_u = l^{(3)\text{hnd}}]$, we obtain $D[j].\text{hnd}_a = \downarrow$, which finishes the proof. ■

A.5 Nonce-List Secrecy

Proof. (Nonce-list secrecy) Let $u, v \in \mathcal{H}$, $j \leq \text{size}$ with $D[j].\text{type} = \text{list}$. Let $x_i^{\text{ind}} := D[j].\text{arg}[i]$ and $x_{i,u}^{\text{hnd}} := D[x_i^{\text{ind}}].\text{hnd}_u$ for $i = 1, 2, 3, 4$, and $w \in (\mathcal{H} \cup \{\mathbf{a}\}) \setminus \{u, v\}$. Let $x_{1,u}^{\text{hnd}} \in \text{Nonce}_{u,v}$.

We first show that the invariant cannot be violated by adding an element $(x_{i,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, l)$ to Nonce_u at time $t + 1$. This can only happen in a transition of M_u^{OR} in Step 1.3, 3.9, 3.25, or 3.37. As shown in the proof of *correct list owner*, in the first two cases, we have $l \in \{1, 2\}$ and that the entry $D[x_i^{\text{ind}}]$ has been generated by $\text{TH}_{\mathcal{H}}$ immediately before and hence that $x_i^{\text{ind}} \notin D[j].\text{arg}$ for all entries $D[j]$ that already exist at time $t + 1$. This also holds for all entries at time $t + 1$, since the transition of M_u^{OR} does not modify entries of $\text{TH}_{\mathcal{H}}$. This yields a contradiction to $x_i^{\text{ind}} = D[j].\text{arg}[i]$. In the last two cases, Step 3.22 and Step 3.29 ensure that $(x_{1,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, 2) \in \text{Nonce}_u$ respectively $(x_{1,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, 1) \in \text{Nonce}_u$ already at time t . In all cases, we hence know that $(x_{i,u}^{\text{hnd}}, ID_u^{\text{hnd}}, v, l) \in \text{Nonce}_u$ for $l \in \{1, 2\}$ already holds at time t .

Part a) of the invariant can only be affected if a handle for w is added to an entry $D[j]$ that already exists at time t . (Creation of $D[j]$ at time t with a handle for w is impossible as above because that presupposes handles to all arguments, in contradiction to *nonce secrecy*.) The only commands that add new handles for w to existing entries of type list are `list_proj`, `sym_decrypt`, `adv_parse`, `send_i`, and `adv_send_i` applied to an entry $D[k]$ with $j \in D[k].\text{arg}$. *Nonce-list secrecy* for the entry $D[j]$ at time t then yields $D[k].\text{type} = \text{enc}$. Thus the commands `list_proj`, `send_i`, and `adv_send_i` do not have to be considered any further. Moreover, *nonce-list secrecy* also yields $D[k].\text{arg}[1] \in \{\text{pkse}_u, \text{pkse}_v\}$. The secret keys shared between u and \top respectively v and \top are not known to $w \notin \{u, v, \top\}$, formally $D[\text{hnd}_u = \text{skse}_u^{\text{hnd}}].\text{hnd}_w = D[\text{hnd}_v = \text{skse}_v^{\text{hnd}}].\text{hnd}_w = \downarrow$. Hence the command `sym_decrypt` does not violate the invariant. Finally, the command `adv_parse` applied to an entry of type `symenc` with unknown secret key also does not give a handle to the cleartext list, i.e., to $D[k].\text{arg}[2]$, but only outputs its length.

Part b) and c) of the invariant can only be affected if the list entry $D[j]$ is created at time $t + 1$. (By well-formedness, the argument entry $D[x_3^{\text{ind}}]$ cannot be created after $D[j]$.) As in Part a), it can only be created by a party $w \in \{u, v, \top\}$ because other parties have no handle to the nonce argument. Inspection of Algorithms 1, 2, and 3 shows that this can only happen in Steps 1.6 and 3.12, because for all other commands list we have $D[x_3^{\text{ind}}].\text{type} \neq \text{data}$ which would violate the precondition.

- If the creation is in Step 1.6, the preceding Step 1.3 implies $(D[x_1^{\text{ind}}].\text{hnd}_w, ID^{\text{hnd}}, w', 1) \in \text{Nonce}_w$ for some w' and some ID^{hnd} and Step 1.4 implies $D[x_3^{\text{ind}}].\text{type} = \text{data}$. Thus the precondition $(D[x_1^{\text{ind}}].\text{hnd}_u, ID^{\text{hnd}}, v, 1) \in \text{Nonce}_u$ and *unique nonce use* then imply $u = w$. Thus Steps 1.4, 1.5, and 1.6 yield $D[x_3^{\text{ind}}].\text{arg} = (u)$ and $D[x_4^{\text{ind}}].\text{arg} = (v)$.
- If the creation is in Step 3.12, the proof is analogous: The preceding Step 3.9 implies $(D[x_1^{\text{ind}}].\text{hnd}_w, ID^{\text{hnd}}, w', 2) \in \text{Nonce}_w$ for some w' and some ID^{hnd} and Step 3.11 implies $D[x_3^{\text{ind}}].\text{type} = \text{data}$. Then the precondition, Step 3.9, and *unique nonce use* imply $u = w$. Finally, Steps 3.10, 3.11, and 3.12 yield $D[x_3^{\text{ind}}].\text{arg} = (v)$ and $D[x_4^{\text{ind}}].\text{arg} = (u)$.

Part d) of the invariant can only be violated if a new entry $D[k]$ is created at time $t + 1$ with $j \in D[k].\text{arg}$ (by Lemma 5.2 and well-formedness). As $D[j]$ already exists at time t , *nonce-list secrecy* for $D[j]$ implies $D[j].\text{hnd}_w = \downarrow$ for $w \notin \{u, v, \top\}$ at time t . We can easily see by inspection of the commands that the new entry $D[k]$ must have been created by one of the commands `list` and `sym_encrypt`, since entries newly created by other commands cannot have arguments that are indices of entries of type `list`. Since all these commands entered at a port $in_z?$ presuppose $D[j].\text{hnd}_z \neq \downarrow$, the entry $D[k]$ is created by $w \in \{u, v, \top\}$ at time $t + 1$. However, the only steps that can create an entry $D[k]$ with $j \in D[k].\text{arg}$ (with the properties demanded for the entry $D[j]$) are Steps 1.7, 3.13, 2.21, and 2.23. In all these cases, we have $D[k].\text{type} = \text{symenc}$. Further, we have $D[k].\text{arg}[1] = \text{pkse}_{w'}$ where w' denotes w 's current believed partner. We have to show that $w' \in \{u, v\}$.

- Case 1: $D[k]$ is created in Step 1.7. Then our precondition $(D[x_1^{\text{ind}}].\text{hnd}_u, ID_u^{\text{hnd}}, v, l) \in \text{Nonce}_u$ and $(D[x_1^{\text{ind}}].\text{hnd}_w, ID_u^{\text{hnd}}, w', l') \in \text{Nonce}_w$ for some ID_u^{hnd}, l' and *unique nonce use* imply $w' = v$.
- Case 2: $D[k]$ is created in Step 3.13. This execution of Algorithm 3 must give $l_2^{(3)\text{hnd}} \neq \downarrow$ in Step 3.12, since it would otherwise abort by Convention 1. Let $l_2^{(3)\text{ind}} := D[\text{hnd}_w = l_2^{(3)\text{hnd}}].\text{ind}$. The algorithm further implies $D[l_2^{(3)\text{ind}}].\text{type} = \text{list}$. Let $x_i^{0\text{ind}} := D[l_2^{(3)\text{ind}}].\text{arg}[i]$ for $i = 1, 2, 3, 4$ at the time of Step 3.12, and let $x_{i,w}^{0\text{hnd}}$ be the corresponding handles obtained in Step 3.1, 3.8, 3.11, and 3.10. As the algorithm does not abort in Steps 3.3 and 3.6, we have $D[x_3^{0\text{ind}}].\text{type} = \text{data}$ and $D[x_3^{0\text{ind}}].\text{arg} = (w')$. Together with the precondition $(D[x_1^{0\text{ind}}].\text{hnd}_u, \cdot, v, l) \in \text{Nonce}_u$, the entry $D[l_2^{(3)\text{ind}}]$ therefore fulfills the conditions of *nonce-list secrecy*. This implies $D[x_2^{0\text{ind}}].\text{arg} \in \{u, v\}$, and thus $w' \in \{u, v\}$.
- Case 3: $D[k]$ is created in Step 2.21 or Step 2.23. As in Case 3, this execution of Algorithm 2 must give $l^{(3)\text{hnd}} \neq \downarrow$ in Step 2.4 and $l^{(2)\text{hnd}} \neq \downarrow$ in Step 2.12. We set $l^{(3)\text{ind}} := D[\text{hnd}_w = l^{(3)\text{hnd}}].\text{ind}$ and $l^{(2)\text{ind}} := D[\text{hnd}_w = l^{(2)\text{hnd}}].\text{ind}$, and we have $D[l^{(3)\text{ind}}].\text{type} = D[l^{(2)\text{ind}}].\text{type} = \text{list}$. Let $y_i^{0\text{ind}} := D[l^{(3)\text{ind}}].\text{arg}[i]$ for $i = 1, 2, 3, 4$ at the time of Step 2.5, and let $y_{i,w}^{0\text{hnd}}$ be the handles obtained in Step 2.5. Let further $x_i^{0\text{ind}} := D[l^{(2)\text{ind}}].\text{arg}[i]$ for $i = 1, 2, 3, 4$ at the time of Step 2.13, and let $x_{i,w}^{0\text{hnd}}$ be the handles obtained in Step 2.13.

As the algorithm does not abort in Steps 2.7 and 2.16, we have $D[y_3^{\text{ind}}].\text{type} = D[y_4^{\text{ind}}].\text{type} = D[x_3^{\text{ind}}].\text{type} = D[x_4^{\text{ind}}].\text{type} = \text{data}$ and $D[x_4^{\text{ind}}].\text{arg} = D[y_4^{\text{ind}}].\text{arg} = (w')$. Further, the reuse of $x_{1,w}^{\text{ind}}$ in Step 2.20 implies $x_1^{\text{ind}} = x_1^{\text{ind}}$. Similarly, we obtain $y_1^{\text{ind}} = y_1^{\text{ind}}$ because of Step 2.22.

Together with the precondition $(D[x_1^{\text{ind}}].\text{hnd}_u, ID^{\text{hnd}}, v, l) \in \text{Nonce}_u$, the entry $D[l^{(3)\text{ind}}]$ respectively $D[l^{(2)\text{ind}}]$ therefore fulfills the condition of *nonce-list secrecy*. This implies $D[y_3^{\text{ind}}].\text{arg} \in \{u, v\}$ respectively $D[y_3^{\text{ind}}].\text{arg} \in \{u, v\}$, and thus $w' \in \{u, v\}$.

Hence in all cases we obtained $w' \in \{u, v\}$, i.e., the list containing the nonce was indeed encrypted with the key that one of the intended honest participants shared with the trusted third party. ■
