

A NEW FAMILY OF ISOCHRONOUS ARCS

G. Guignard and E.T.d'Amico CERN, 1211 Geneva 23, Switzerland

For the Compact Linear Collider (CLIC), the bunch time structure should be preserved in the injection and after the final compression stage up to the main linear injection about the mid-plane of the central de-ejecting magnet. At the same time because the transverse emittance growth, the growth essentially due to synchrotron radiation, should be kept as slow as possible in the project several isochronous arcs have been designed numerically to meet the requirements for a particular layout. These designs cannot be easily adapted to different configurations. The purpose of this study is to obtain analytically the main parameters of a new class of isochronous arcs which can be quickly tailored to special applications. Some of these are represented and they emphasize the small transverse emittance growth achievable even at large injection energy while keeping the arc radius in a reasonable range. Because usually the first-order isochronicity is fully cancelled higher-order contributions are less important than in other designs.

I. INTRODUCTION

In the Compact Linear Collider (CLIC) many considerations of wake-fields effects at high luminosity require that the bunch time structure should be preserved after the last bunch compression. In a long place this condition cannot be fulfilled when the beam passes through the de-ejecting system because of the difference in length between the individual bits due to the energy spread and to the different initial conditions. The system is called isochronous when it does not change the bunch time structure. It can be proved [1] that in the linear approximation such a system should be nondispersing and such that:

$$\int_{S_1}^{S_2} \frac{D(s)}{\rho(s)} ds = 0 \quad (1)$$

where $D(s)$ is the horizontal dispersion $\rho(s)$ the radius of curvature and S_1, S_2 are the positions of the beginning and end of the insertion.

The relation (1) shows that contributions to the integral come only from de-ejecting magnets and off-centre quadrupoles.

Several schemes of isochronous arcs have been developed [2][3]. They are based on lattices comprising several de-ejecting magnets where the integral (1) is minimized numerically over the whole arc. The purpose of this study was to investigate analytically isochronous modules with the minimum number of de-ejecting magnets. The juxtaposition of identical modules allows the building up of a whole family of isochronous arcs depending upon some parameters: strengths k_1, k_2 can be adjusted to meet specific design constraints, such as minimization of the emittance growth due to synchrotron radiation.

It can be proved [1] that the minimum number of de-ejecting magnets in an isochronous module is three. For simplicity, the circulation and after the final reasons of simplicity have chosen a symmetric module.

II. ISOCHRONICITY CONDITION

Let us consider an isochronous insertion with three bending magnets (see fig. 1) where we neglect for the moment the presence of the magnet elements assumed to be perfectly centred. To simplify the algebra the bending magnets will be treated as sectors of magnets of the same length but of different curvatures r_1 and r_2 , the deflection angle being respectively ϕ_1 and ϕ_2 .

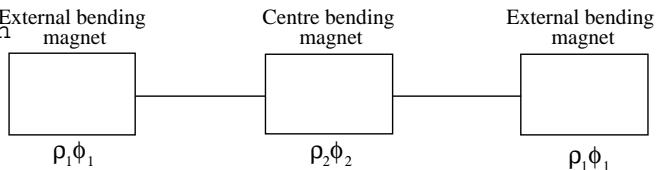

Figure 1: Isochronous insertion with three bending magnets configuration.

Assuming that the dispersion and its derivative are zero at the entrance of the first magnet, it is easy to show that the isochronicity and symmetry condition is held if the following expression for the dispersion and its derivative at the entrance of the central magnet [4]:

$$D_j = \frac{k_2}{\mu} D_j^0 \text{ctn}(\phi_2) + 1 \quad / \\ D_j^0 = i \frac{k_1}{k_2} \frac{3}{2} \text{cosec} \phi_1 \sin \phi_1 : \quad (2)$$

III. INSERTION DESIGN

To transport the beam through the insertion described in Fig. 1, we have to add quadrupoles between the bending magnets. The simplest configuration is FODO, as shown in Fig. 2 where only a half-insertion is given.

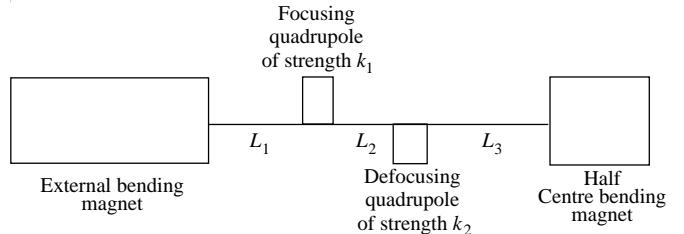

Figure 2: Layout of half isochronous insertion.

The three spaces L_1, L_2, L_3 and the two quadrupole strengths k_1, k_2 have to be chosen in order for the expressions (2) to be satisfied. After some manipulation of the transfer matrices (see Appendix A of reference [4]) the following expression for the three drift lengths functions

Table 1: Permitted ranges of k_1 ; k_2 ; ϵ L₃

| | |
|--|---|
| $k_1 \cdot \text{Minfk}_1^{(1)}; k_{\max} g$ | $q_2 < q_1 \text{ i d and } \notin L_3 > \text{Max fd i D}_j = D_j^0; i q_2 g$ $q_2 > q_1 \text{ i d and } \text{Max fd i D}_j = D_j^0; i q_2 g < \notin L_3 < \notin L_3^{(1)}$ |
| $k_1^{(1)} < k_1 \cdot \text{Minfk}_1^{(2)}; k_{\max} g$ | $P \overline{k_2} > \text{Max} \frac{\text{acosh}(\text{Max f1}; C_2' g)}{L_q}; k_2^{(1)} \text{ and}$ $\text{Max fd i D}_j = D_j^0; \notin L_3^{(2)} g < \notin L_3 < \notin L_3^{(1)}$ |
| $k_1^{(1)} < k_1 \cdot \text{Minfk}_1^{(2)}; k_1^{(3)}; k_{\max} g$ | $P \overline{k_2} < \frac{\text{acosh}(C_2')}{L_q g} \text{ and } \text{Max fd i D}_j = D_j^0; \notin L_3^{(2)} g < \notin L_3 < \notin L_3^{(1)}$ |
| $k_1^{(2)} < k_1 < \text{Minfk}_1^{(3)}; k_{\max} g$ | $P \overline{k_2} < \text{Min} k_2^{(1)}; \frac{\text{acosh}(C_2')}{L_q} \text{ and } \text{Max fd i D}_j = D_j^0; \notin L_3^{(2)} g < \notin L_3 < \notin L_3^{(1)}$ |
| $k_1^{(1)} < k_1 < k_{\max}$ | $q_2 < q_1 \text{ i d and } \notin L_3 > \text{Max fd i D}_j = D_j^0; \notin L_3^{(2)} g$ |
| where $k_1^{(1)}; k_1^{(2)}; k_1^{(3)}; k_2^{(1)}$ are the solutions of the following transcendental equations: | |
| $(l+d) \frac{q}{k_1^{(1)}} \tan(L_q \frac{q}{k_1^{(1)}}) = 1;$ | $k_1^{(2)} = \frac{q \frac{1}{k_1^{(2)}} (l+2d) + \frac{1}{\cos(L_q \frac{q}{k_1^{(2)}}) + 4d(l+d)}}{2 \sin(L_q \frac{q}{k_1^{(2)}})d(l+d)}$ |
| $(l+d) \frac{q}{k_1^{(3)}} \sin(L_q \frac{q}{k_1^{(3)}}); \cos(L_q \frac{q}{k_1^{(3)}}) = a;$ | $\frac{q}{k_2^{(1)}} \sinh(L_q \frac{q}{k_2^{(1)}}); \frac{p}{k_2^{(1)}} \cosh(L_q \frac{q}{k_2^{(1)}}); C_2' = 0$ |
| and $C_2' = k_2^{(1)}; k_{\max}; \notin L_3^{(1)}; \notin L_3^{(2)}$, are given by the expressions | |
| $C_2' = \frac{aq_1}{C_1(l+q_1+d)}; k_2^{(1)} = \frac{h + \frac{1}{c_2} \cdot \frac{1}{L_q}}{d + \frac{1}{q_1} + \frac{c_2}{ac_1}}$ | $k_{\max} = \frac{b}{4L_q^2}; \notin L_3^{(1)} = \frac{b}{d+q_2+q_1}; q_2; \notin L_3^{(2)} = \frac{q_2 C_1}{a q_1 C_2} (l+q_1+d); q_2$ |

of k_1 , k_2 and of the free parameter $L_3 = L_3(i, D_j = D_j^0)$, this is possible only when the beta function and its derivative at both ends of such a module are respectively:

$$\begin{aligned} L_1 &= a \frac{C_2 q_1}{C_1 q_2} (\frac{1}{\zeta} L_3 + q_2) ; \quad l + q_1 \\ L_2 &= q_1 i + q_2 + \frac{b}{\zeta L_3 + q_2} \\ L_3 &= D_j = D_j^0 + \zeta L_3 \end{aligned} \quad (3) \quad \text{where } m_{11} = m_{22} \text{ and } m_{21} \text{ are the elements of the} \quad (5)$$

where

$$\begin{aligned} l &= \frac{\%_1}{\%_2} \tan(\gamma_1 = 2); \quad a = i D_j^0 = \sin(\gamma_1); \\ b &= \frac{\%_2}{\%_1} \left(\frac{\%_2}{\%_1} + \frac{\%_1}{a c_1} \right); \quad q_i = \frac{C_i}{S_i k_i} p; \\ C_1 &= \cos(L_q p \frac{k_1}{k_2}); \quad S_1 = \sin(L_q p \frac{k_1}{k_2}); \\ C_2 &= \cosh(L_q p \frac{k_2}{k_1}); \quad S_2 = \sinh(L_q p \frac{k_2}{k_1}) \end{aligned} \quad (4)$$

L_q being the quadruple length Table 1 gives a subset of the range of $k_1, k_2; \in L_3$ for which the three drift lengths are larger than a given value δ , when

$$\frac{1}{q_1} \cdot \frac{1}{1+d} + \frac{1}{L_q=2+d} \dots$$

This can be shown to be the case for most of the usual hardware reconfiguration. The full set of conditions may be found in Appendix C of [4].

IV. ARC DESIGN

To build an arc we have to connect as many insertions parameters to find it we have written a simple interface as are necessary to obtain the desired section. To avoid this programs use an Excel spreadsheet which permits one large excursion of the beta function. The easiest way is to quickly obtain the main features of a 2... arc according to the advantage of the insertion symmetry and to ensure to define the choices of the number of required modules so that the values of the Twiss parameters at both ends of a module composed of an insertion described above and of a matching section are the same. It is easy to show that the ratio between the radii of curvature of the external and central bending magnets and of the gradients of the two quadrupoles and of the distance L_3 .

where $m_{11} = m_{22}$ and m_{21} are the elements of the transformation matrix for the module. It is very difficult to do without the matching section while satisfying these constraints in both planes. We have preferred to choose a matching section instead of a triplet at both ends of the insertion to obtain a module with $1 < m < 1$ in both planes. The Twiss parameters at the end of the transformation injecting in the arc should then be matched to the values given by the expression (5). In order to reduce to a minimum the contribution of magnetic errors and the sextupole effects we add the condition that the phase advance over a small number of modules should be an integer multiple... in both planes.

Aftersomemanipulationsispossibleto show that the growth of the normalized trizigalemittance Ω_x is in good approximation inversely proportional to the fourth power of the number of modules required to assemble an arc [4]. The diameter of a full-circular arc of course is proportional to the number of modules. Clearly, a compromise must be found between these two very important design parameters. To find it we have written a simple interactive program as an Excel spreadsheet which permits one to quickly obtain the main features of a 2... arc according to different choices of the number of required modules of the ratio between the radial curvature of the external and central bending magnets and of the gradients of the two quadrupoles and of the distance L_3 .

V. APPLICATIONS

In each branch of CLIC, two 360-degree arcs are needed to guide the particles in the reverse direction at 3 GeV for the dri-beam and the other at 9 GeV for the main beam. These arcs should not perturb the bunch length, which is carefully chosen for optimum performance at the final interaction region in the main line and for power transfer efficiency in the dri-line. Thus they have to be isochronous. A preliminary study of them has been carried at the first order using the tools described in the previous section. The results are summarized in Table 2 and Figs 3 and 4.

The less stringent constraint on the horizontal emittance growth for the dri-beam allows one to obtain a smaller arc radius which could be expected from the energy scaling alone. Thus large horizontal emittance growth would be acceptable but difficult to achieve due to limitations in optics matching.

On the contrary for the main beam the fraction of horizontal emittance growth ($\approx 7.4\%$) cannot be further relaxed to obtain a smaller arc radius because it would induce a significant loss of luminosity.

VI. DISCUSSION

This report shows the existence of a parametric family of isochronous arcs and analytical procedures to design them. Simple interactive programming tools have been developed to implement the procedure which speed up the search of near-optimal isochronous arcs. The first-order anisochronicity is fully eliminated and the values of the dispersion are tribute to the second-order effects as well as to limit the horizontal emittance growth. On the other hand, this makes the correction of the chromaticity with sextupoles more difficult because they cannot be placed where the dispersion is sufficiently high. This however becomes a severe problem when the arc is part of a ring through which the beam passes several times. Further investigation will be aimed at limiting these effects and studying the energy spread acceptance of such arcs. Trakings should provide results on the behaviour of this family of isochronous arcs at higher orders.

Table 2: Parameters of the 360-degree isochronous arcs

| Parameter | 3 GeV arc | 9 GeV arc |
|---------------------------------|--------------------|--------------------|
| Number of insertions | 3 | 48 |
| Length of bending magnet | 1.8 m | 1 m |
| Quadrupole length | 0.3 m | 0.5 m |
| Gradient of the focusing quad | 55 T/m | 60 T/m |
| Gradient of the defocusing quad | 55 T/m | 60 T/m |
| L_1 | 1.366 m | 2.068 m |
| L_2 | 0.227 m | 0.925 m |
| L_3 | 1.164 m | 0.310 m |
| Overall arc diameter | 15 m | 214 m |
| Horizontal phase advance | .../2 | .../2 |
| Vertical phase advance | .../3 | .../3 |
| Nominal t_x (m rad) | 5 ± 10^{-4} | 2.5 ± 10^{-6} |
| $\pm 10^{-6}$ (m rad) | 8.16 ± 10^{-6} | 1.84 ± 10^{-7} |
