# Central production of mesons: Exotic states versus Pomeron structure 

Frank E. Close ${ }^{a}$<br>and<br>Gerhard A. Schuler ${ }^{b}$<br>Theoretical Physics Division, CERN, CH-1211 Geneva 23

#### Abstract

We demonstrate that the azimuthal dependence of central meson production in hadronic collisions, when suitably binned, provides unambiguous tests of whether the Pomeron couples like a conserved vector-current to protons. We discuss the possibility of discriminating between $\mathrm{q} \overline{\mathrm{q}}$ and glueball production in such processes. Our predictions apply also to meson production in tagged two-photon events at electron-positron colliders and to vector-meson production in ep collisions at HERA.

[^0]
## 1 Introduction

The production of mesons in the central region of proton- proton collisions (pp $\rightarrow$ $\mathrm{pp} M$ ) via a gluonic Pomeron has traditionally been regarded as a potential source of glueballs [1]. However, well-established quark-antiquark ( $q \bar{q}$ ) mesons are also known to be produced and this has led to searches for a selection mechanism that could help to distinguish among such states. As a result it has been discovered [2] that the pattern of resonances produced in the central region of double tagged $\mathrm{pp} \rightarrow \mathrm{pp} M$ depends on the vector difference $\vec{k}_{\perp}=\vec{q}_{1 \perp}-\vec{q}_{2 \perp}$ of the transverse momentum recoils $\vec{q}_{i \perp}$ of the final protons (even at fixed four-momentum transfers $\left.t_{i}=-q_{i}^{2}\right)$. When this quantity $k_{\mathrm{T}}=\left|\vec{k}_{\perp}\right|$ is small $\left(\leq \mathcal{O}\left(\Lambda_{\mathrm{QCD}}\right)\right)$ all well-established $q \bar{q}$ states were observed to be suppressed [3] while the surviving resonances included enigmatic states such as $f_{0}(1500), f_{J}(1710)$ and $f_{2}(1910)$ that have variously been suggested to be glueballs or to reside on the (gluonic) Pomeron trajectory. At large $k_{\mathrm{T}}$, by contrast, $\mathrm{q} \bar{q}$ states are prominent.

However, these $k_{\mathrm{T}}$ dependences for at least $0^{-}$and $1^{+}$production have been shown to arise if the Pomeron (or perhaps a hard gluonic component that produces $M$ by gg fusion) transforms as a conserved vector current [4]. In order to help determine the extent to which the double tagged reaction $\mathrm{pp} \rightarrow \mathrm{pp} M$ depends on a vector production or the dynamical structure of the meson $M$ (of spin $J$ and parity $P$ ), we develop the earlier analysis to all $J \leq 3$.

While the $k_{\mathrm{T}}$ phenomenon has turned out to be a sharp experimental signature, we shall propose here that the azimuthal $\phi$ dependence (between the two proton scattering-planes in the pp c.m.s.) provides a rather direct probe of dynamics. In particular, observation of non-trivial $\phi$ dependences requires the presence of non-zero helicity transfer by the diffractive agent (Pomeron, gluon, ...) [5] and so the Pomeron cannot simply transform as having vacuum quantum numbers: a spin greater than zero is needed. We analyse here the simplest case, where the process is driven by the fusion of two spin- 1 currents. Imposing current conservation it immediately applies to $\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow \mathrm{e}^{+} \mathrm{e}^{-} M$ and, empirically, already exhibits features seen in $\mathrm{pp} \rightarrow \mathrm{pp} M$. We find that current non-conserving and/or scalar contributions are needed to accommodate the data.

At extreme energies where non-diffractive contributions are negligible, we show the following properties for meson production in the central region.

1. The $\phi$ dependence of $0^{-}$production provides a clear test for the presence of a significant vector component of the production Pomeron, independent of the $t$ dependence. Preliminary data on $\eta$ and $\eta^{\prime}$ production confirm this.
2. The production of $1^{+}$mesons reinforces this: The conserved vector-current (CVC) hypothesis implies (i) the cross section will tend to zero as $k_{\mathrm{T}} \rightarrow 0$, and (ii) $1^{+}$mesons are produced dominantly in the helicity-one state. Both features are prominent in the data.
3. The $0^{+}$cross section survives at small $k_{\mathrm{T}}$ for the CVC hypotheses. Moreover, for $q_{i \perp} \ll M$, we must either observe a $\cos ^{2} \phi$ distribution or a small (relative to
$0^{-}$) cross section. However, at least one $0^{+}$state (the $f_{0}(2000)$ ) appears to be suppressed at small $k_{\mathrm{T}}$. Unlike $0^{-}$or $1^{+}$production, the production of $0^{+}$will be particularly sensitive to a scalar and/or non-conserved vector component to the Pomeron. In particular the vanishing of $f_{0}(1500)$ as $\phi \rightarrow 180^{\circ}$ like $\sin ^{4}(\phi / 2)$, would be natural if longitudinal and transverse helicity amplitudes have similar strengths but opposite phase as may be possible in some simple glueball models. 4. The $2^{+}$production depends on the dynamics of the meson as well as the helicity structure of the Pomeron. In the non-relativistic q $\bar{q}$ model (a particular realization of the CVC hypothesis), we predict at small $q_{i \perp} \ll M$ a $2^{+}$cross section that is (i) basically flat in $\cos \phi$, (ii) finite for $k_{\mathrm{T}} \rightarrow 0$, and (iii) dominated by the helicity-two part. For the CVC hypothesis a suppression at small $k_{\mathrm{T}}$ is obtained only for peculiar relations between the helicity amplitudes. Hence again, data show that the CVC Pomeron is not the full story. In particular, $2^{+}$ states at 2 GeV are seen to have a different $\phi$ dependence than the established $\mathrm{q} \overline{\mathrm{q}} 2^{+}$states.

Our analysis can also be applied to ep $\rightarrow$ ep $M$ where $M$ is a vector meson. As $t \rightarrow 0$ we find that the longitudinal polarization of the meson grows initially as $Q^{2} / M^{2}$ relative to the transverse, with a characteristic $\phi$ dependence.

Readers interested in the results may proceed directly to section 3. Their detailed derivation is summarized in section 2 .

## 2 Derivation of the results

Consider the central production of a $J^{P+}$ meson $M$ in the high-energy scattering of two fermions with momenta $p_{1}$ and $p_{2}$, respectively,

$$
\begin{equation*}
f_{1}\left(p_{1}\right)+f_{2}\left(p_{2}\right) \rightarrow f_{1}^{\prime}\left(p_{1}^{\prime}\right)+f_{2}^{\prime}\left(p_{2}^{\prime}\right)+M, \tag{1}
\end{equation*}
$$

proceeding through the fusion of two conserved spin-1 vector currents $V_{1}$ and $V_{2}$ :

$$
\begin{equation*}
V_{1}\left(q_{1}, \lambda_{1}\right)+V_{2}\left(q_{2}, \lambda_{2}\right) \rightarrow M\left(J, J_{z}\right) . \tag{2}
\end{equation*}
$$

Here $\lambda_{i}= \pm 1, L$ are the current helicities $]$ in the meson rest frame with current one defining the $z$ axis. In the case of electron-positron collisions, $V_{i}$ in (2) is a photon, while for central production in proton-proton collisions, $V_{i}$ could be a Pomeron, a (colour-less) multi-gluon state, or in some models, even a single gluon (accompanied by Coulomb gluon(s) to ensure colour-conservation). For our purpose here what matters is the assumed spin-1 nature of the production field(s) and their conservation. We shall comment upon the consequences of current non-conservation at the end of the next section.

[^1]In order to investigate the helicity structure of the diffractive agent it proves useful to examine the dependence of the cross section on ${ }^{[J} \cos n \tilde{\phi}$, where $\tilde{\phi}$ is the azimuthal separation between the two proton scattering planes of (1) in the current-current c.m.s. An experimental analysis is complicated by two facts. First, what is measured is not $\tilde{\phi}$ but the azimuthal angle $\phi$ in the proton-proton rest frame. Second, experimental cuts and/or an inconvenient choice of kinematical variables might spoil the $\tilde{\phi}$ dependence predicted by theory.

This is easily understood when one recalls that the phase space for (母), $\sim$ $\left(\mathrm{d}^{3} p_{1}^{\prime} / E_{1}^{\prime}\right)\left(\mathrm{d}^{3} p_{2}^{\prime} / E_{2}^{\prime}\right)$, depends on only four non-trivial variables if the meson is either stable or has a width much smaller than its mass since one relation is provided by $W \equiv \sqrt{\left(q_{1}+q_{2}\right)^{2}}=M$ (the meson mass). These four variables are often chosen as four invariants, for example, $Q_{i}=\sqrt{-q_{i}^{2}}$ and (suitably defined) fractional current energies $x_{i}$, or as the scattered protons energies and polar angles (or transverse momenta). For whatever choice, the expression of (the fixed variable) $W$ in terms of these variables explicitly involves the angle $\tilde{\phi}$ (or $\phi$ ), which introduces additional "spurious" azimuthal dependences. Moreover, the relation between $\tilde{\phi}$ and the measurable $\phi$ is rather complicated.

However, as we shall detail below, in the kinematic regime of experimental interest, we have, to good approximation, $\tilde{\phi} \approx \phi$. Also for the WA102 experiment, we estimate the effect of the extra kinematic factors to have no significant impact on the effects discussed here.

In the approximation of single-particle (single-trajectory) exchange (one at each vertex) the cross section for (\#) factors into the product of three terms, namely two density matrices and the amplitude for (2)). Consider the (unnormalized) density matrix for the emission from particle 1. For a conserved vectorcurrent its general form is

$$
\begin{equation*}
\rho_{1}^{\mu \nu}=-\left(g^{\mu \nu}-\frac{q_{1}^{\mu} q_{1}^{\nu}}{q_{1}^{2}}\right) C_{1}\left(q_{1}^{2}\right)-\frac{\left(2 p_{1}-q_{1}\right)^{\mu}\left(2 p_{1}-q_{1}\right)^{\nu}}{q_{1}^{2}} D_{1}\left(q_{1}^{2}\right) . \tag{3}
\end{equation*}
$$

Here $C_{1}$ and $D_{1}$ are form factors associated with the non-pointlike nature of particle 1 (for a lepton, $C_{\mathrm{e}}\left(q^{2}\right)=1=D_{\mathrm{e}}\left(q^{2}\right)$, while for a proton $C_{\mathrm{p}}\left(q^{2}\right)=G_{\mathrm{M}}^{2}\left(q^{2}\right)$, $D_{\mathrm{p}}\left(q^{2}\right)=\left(4 m_{\mathrm{p}}^{2} G_{\mathrm{E}}^{2}\left(q^{2}\right)-q^{2} G_{\mathrm{M}}^{2}\left(q^{2}\right)\right) /\left(4 m_{\mathrm{p}}^{2}-q^{2}\right)$, where $G_{\mathrm{E}}$ and $G_{\mathrm{M}}$ are the proton electromagnetic form factors). A factor $1 /\left(-2 q_{1}^{2}\right)$ in $\rho_{1}$ is introduced for convenience $e^{\beta}$ since current conservation guarantees $\left(2 p_{1}-q_{1}\right)^{\mu}\left(2 p_{1}-q_{1}\right)^{\alpha} M^{\star \alpha \beta} M^{\mu \nu} \propto$ $q_{1}^{2}$.

In the following we shall be working in the current-current helicity basis. The density-matrix elements in the helicity basis are defined with the help of the polarization vectors $\epsilon_{1}^{\mu}\left(\lambda_{1}\right)$ of the (space-like) current one as [6]

$$
\begin{equation*}
\rho_{1}^{\lambda_{1}, \lambda_{1}^{\prime}}=(-1)^{\lambda_{1}+\lambda_{1}^{\prime}} \epsilon_{1}^{\mu}\left(\lambda_{1}\right) \rho_{1}^{\mu \nu} \epsilon_{1}^{\nu}\left(\lambda_{1}^{\prime}\right), \tag{4}
\end{equation*}
$$

${ }^{2} P$ and $T$ invariance forbid $\sin n \tilde{\phi}$ contributions.
${ }^{3}$ With this choice, the matrix elements of the first term are simply $\pm C_{1}$ (or zero), see (6) and (12).
where $\lambda_{1}^{(\prime)}$ label the helicity of the current one, $\lambda_{1}^{(\prime)}= \pm 1, L$. Owing to the hermiticity relations of the density matrix and the polarization vectors

$$
\begin{align*}
\rho_{1}^{\mu \nu \star} & =\rho_{1}^{\nu \mu} \\
\epsilon_{1}^{\alpha \star}( \pm 1) & =-\epsilon_{1}^{\alpha}(\mp 1), \quad \epsilon_{1}^{\alpha \star}(L)=-\epsilon_{1}^{\alpha}(L), \tag{5}
\end{align*}
$$

the helicity-density matrix is determined by four real parameters, for example, $\rho_{1}^{++},{\underset{\sim}{\rho}}_{1}^{L L},\left|\rho_{1}^{+L}\right|$, and $\left|\rho_{1}^{+-}\right|$. The phases of the latter two matrix elements are $\exp \left(i \tilde{\phi}_{1}\right)$ and $\exp \left(2 i \tilde{\phi}_{1}\right)$, respectively, where $\tilde{\phi}_{1}$ is the azimuthal angle of $p_{1}$ in the current-current c.m.s. (With the analogous definition of $\tilde{\phi}_{2}$ we have $\tilde{\phi}=\tilde{\phi}_{1}+\tilde{\phi}_{2}$.)

The expressions of $\left|\rho_{1}^{i k}\right|$ in terms of invariants and the form factors $C_{1}$ and $D_{1}$ can be derived from the formulas in [6]

$$
\begin{align*}
\rho_{1}^{++} & =C_{1}+\frac{1}{2} D_{1}\left[\frac{\left(u_{2}-\nu\right)^{2}}{X}-1+\frac{4 m_{1}^{2}}{q_{1}^{2}}\right] \\
\rho_{1}^{L L} & =-C_{1}+D_{1} \frac{\left(u_{2}-\nu\right)^{2}}{X} \\
\left|\rho_{1}^{+-}\right| & =\rho_{1}^{++}-C_{1} \\
\left|\rho_{1}^{+L}\right| & =\sqrt{\left|\rho_{1}^{+-}\right|\left(\rho_{1}^{L L}+C_{1}\right)} . \tag{6}
\end{align*}
$$

Here we have introduced $u_{2}=2 p_{1} \cdot q_{2}, \nu=q_{1} \cdot q_{2}=\left(W^{2}-q_{1}^{2}-q_{2}^{2}\right) / 2, W^{2}=$ $\left(q_{1}+q_{2}\right)^{2}$, and $X=\nu^{2}-q_{1}^{2} q_{2}^{2}$.

In this work we are interested in the dominant (and experimentally accessible) region of phase space $Q_{i} \equiv \sqrt{-q_{i}^{2}} \ll W$. Then (and only then (7) the density matrix $\rho_{1}^{\mu \nu}$ depends on only variables of current-one, namely its fractional momentum $x_{1}=p_{2} \cdot q_{1} / p_{2} \cdot p_{1}=u_{1} /\left(s-2 m_{1}^{2}\right)$ and its virtuality $Q_{1}$. Moreover, we can use

$$
\begin{align*}
Q_{i} & \simeq q_{i \perp} \\
\tilde{\phi} & =\frac{\vec{q}_{1 \perp} \cdot \vec{q}_{2 \perp}}{q_{1 \perp} q_{2 \perp}} \simeq \phi=\frac{\vec{p}_{1 \perp}^{\prime} \cdot \vec{p}_{2 \perp}^{\prime}}{p_{1 \perp}^{\prime} p_{2 \perp}^{\prime}}, \tag{7}
\end{align*}
$$

where $\vec{q}_{i \perp}\left(\vec{p}_{i \perp}^{\prime}\right)$ is the transverse momentum of current $i$ (scattered proton $i$ ) in the current-current (proton-proton) c.m. system. In addition, the dependence of $W=M$ on the azimuthal angle $\tilde{\phi}=\tilde{\phi}_{1}+\tilde{\phi}_{2}$ disappears, and we simply have $W^{2}=x_{1} x_{2} s\left(x_{2}=u_{2} /\left(s-2 m_{2}^{2}\right)\right)$. Since $m_{1}$ and $m_{2}$ are much smaller than the c.m. energy $\sqrt{s}$ we obtain

$$
\begin{align*}
2 \rho_{1}^{++} & =2 C_{1}+\left(1-\delta_{1}\right) \hat{\rho}_{1} \\
\rho_{1}^{L L} & =D_{1}-C_{1}+\hat{\rho}_{1} \\
2\left|\rho_{1}^{+-}\right| & =\left(1-\delta_{1}\right) \hat{\rho}_{1} \\
\sqrt{2}\left|\rho_{1}^{+L}\right| & =\sqrt{\left(1-\delta_{1}\right) \hat{\rho}_{1}\left(D_{1}+\hat{\rho}_{1}\right)} \tag{8}
\end{align*}
$$

where we have introduced

$$
\begin{equation*}
\hat{\rho}_{1}=\frac{4}{x_{1}^{2}}\left(1-x_{1}\right) D_{1}, \quad \delta_{1}=Q_{1 \min }^{2} / Q_{1}^{2} \tag{9}
\end{equation*}
$$

For the production (1]) of mesons at fixed-target experiments (and even more so at electron-positron colliders) the meson mass is much smaller than the c.m. energy. This implies that $x_{i} \ll 1$ and thus

$$
\begin{equation*}
\frac{2}{1-\delta_{1}} \rho_{1}^{++} \simeq \frac{2}{1-\delta_{1}}\left|\rho_{1}^{+-}\right| \simeq \sqrt{\frac{2}{1-\delta_{1}}}\left|\rho_{1}^{+L}\right| \simeq \rho_{1}^{L L} \simeq \hat{\rho}_{1} . \tag{10}
\end{equation*}
$$

Relations analogous to (6)-(10) hold also for the density matrix of current two, $\rho_{2}^{\lambda_{2}, \lambda_{2}^{\prime}}$.

Before continuing we have to make sure that (10) is not spoiled by the behaviour of the form factors, i.e. we have to make sure that $\hat{\rho}_{1} \gg C_{1}$. This is certainly true if $C_{1} \simeq D_{1}$ for all $Q_{1}^{2}$. To investigate this a bit further we assume that Pomerons (e.g. Pomeron one) couple to fermions like the current

$$
\begin{equation*}
J_{\mu}=\bar{u}\left(p_{1}^{\prime}\right)\left\{F_{1}\left(q_{1}^{2}\right) \gamma_{\mu}+\frac{\kappa}{2 m} F_{2}\left(q_{1}^{2}\right) i \sigma_{\mu \alpha} q^{\alpha}\right\} u\left(p_{1}\right) \tag{11}
\end{equation*}
$$

Then we can actually calculate the density matrix (3) defined by

$$
\begin{equation*}
\rho_{1}^{\mu \nu}=\frac{-1}{2 q_{1}^{2}} \sum_{\text {spins }} J_{\mu} J_{\nu}^{\star} \tag{12}
\end{equation*}
$$

Noting the minus sign in

$$
\left(\bar{u}\left(p_{1}^{\prime}\right) i \sigma_{\mu \alpha} q^{\alpha} u\left(p_{1}\right)\right)^{\star}=-\bar{u}\left(p_{1}\right) i \sigma_{\mu \alpha} q^{\alpha} u\left(p_{1}^{\prime}\right),
$$

we obtain the form (3) with

$$
\begin{align*}
C_{1} & =\left(F_{1}+\kappa F_{2}\right)^{2} \equiv G_{\mathrm{M}}^{2} \\
D_{1} & =F_{1}^{2}-\frac{q_{1}^{2}}{4 m^{2}}\left(\kappa F_{2}\right)^{2} \equiv \frac{4 m^{2} G_{\mathrm{E}}^{2}-q_{1}^{2} G_{\mathrm{M}}^{2}}{4 m^{2}-q_{1}^{2}} \tag{13}
\end{align*}
$$

Note that a pure $\gamma_{\mu}$ coupling gives $C_{1}=D_{1}=F_{1}^{2}$. Hence for two-photon production at $\mathrm{e}^{+} \mathrm{e}^{-}$colliders ( $F_{1}=1, F_{2}=0$ ) our assumptions are well satisfied: even at CLEO energies the typical $x_{i}$ values are small enough ( $x_{i} \sim 0.1$ ) to ensure $1 / x_{i}^{2} \gg 1$ and, in turn, $\hat{\rho}_{1} \gg C_{1}$. Moreover, the tagging setup of the scattered electrons assures that $\delta_{i} \ll 1$.

The situation may be different in fixed-target proton-proton collisions. First, at WA102 energies $(12.8<\sqrt{s} / \mathrm{GeV}<28)$ the experimentally accessible $x_{i}$ values range between about $10^{-3}$ and 0.2 guaranteeing thus $1 / x_{i}^{2} \gg 1$. The minimum $x_{i}$ values result in minimum virtualities of $Q_{i \text { min }}^{2} \approx 10^{-4} \mathrm{GeV}^{2}$. Hence if we assume
that measurements are done in a range, say $10^{-3}<Q_{i}^{2} / \mathrm{GeV}^{2}<0.5$ (statistics limits larger values) then still $\delta_{i} \ll 1$. This holds certainly for the recoil proton since it can only be detected for $Q^{2}$ larger than about $0.05 \mathrm{GeV}^{2}$. The scattered proton can, however, be measured down to very low $Q^{2}$. For completeness, we shall keep the $\left(1-\delta_{i}\right)$ terms in the following.

Central production in proton-proton collisions may differ in another aspect from the $\mathrm{e}^{+} \mathrm{e}^{-}$case: unlike the photon the Pomeron might have a dominant $\sigma_{\mu \nu^{-}}$ type coupling. The requirement for (10) to hold, namely $\hat{\rho}_{1} \gg C_{1}$, yields for zero $F_{1}$ the condition $Q_{1}^{2} \gg Q_{1 \text { min }}^{2}$. Hence as long as very low $Q^{2}$ values of the scattered proton are excluded, (10) continues to hold. There is one difference, however: if $F_{2}$ dominates then the typical $t\left(t=q^{2}=-Q^{2}\right)$ distribution $\propto \exp (-b t)$ (with $\left.b \sim 6 / \mathrm{GeV}^{2}\right)$ is modified by an extra factor $(-t)$.

Let us now continue with the current-current-meson vertex. If (2) proceeds through the fusion of two conserved vector-currents, then conservation of $P$ and $T$ as well as total helicity conservation for forward scattering, implies that the cross section for $f_{1}+f_{2} \rightarrow f_{1}^{\prime}+f_{2}^{\prime}+X$, for arbitrary final state $X$, depends on eight independent helicity structure functions, $W\left(\lambda_{1}, \lambda_{2} ; \lambda_{1}^{\prime}, \lambda_{2}^{\prime}\right)$ out of which only six can be measured with unpolarized initial-state fermions:

$$
\begin{align*}
\mathrm{d} \sigma \sim & 2 \rho_{1}^{++} \rho_{2}^{++}\{W(++,++)+W(+-,+-)\} \\
& +2 \rho_{1}^{++} \rho_{2}^{L L} W(+L,+L) \\
& +2 \rho_{1}^{L L} \rho_{2}^{++} W(L+, L+) \\
& +\rho_{1}^{L L} \rho_{2}^{L L} W(L L, L L) \\
& +2\left|\rho_{1}^{+-} \rho_{2}^{+-}\right| W(++,--) \cos 2 \tilde{\phi} \\
& -4\left|\rho_{1}^{+L} \rho_{2}^{+L}\right|\{W(++, L L)+W(L+,-L)\} \cos \tilde{\phi} . \tag{14}
\end{align*}
$$

Note that $W\left(\lambda_{1}, \lambda_{2} ; \lambda_{1}^{\prime}, \lambda_{2}^{\prime}\right) \neq 0$ only if $\lambda_{1}-\lambda_{2}=J_{z}=\lambda_{1}^{\prime}-\lambda_{2}^{\prime}$. Both the structure functions $W$ and the invariant amplitudes $A$ defined below in (15) are functions of the invariants $W, Q_{1}^{2}, Q_{2}^{2}$ only.

For the present case, (1), where $X$ is a single particle, the number of independent parameters in (14) can be reduced further. First observe that if $A\left(\lambda_{1}, \lambda_{2}\right)$ denotes the ( $V_{1} V_{2}$ c.m.s.) helicity amplitude for (2), then we have

$$
\begin{equation*}
W\left(\lambda_{1}, \lambda_{2} ; \lambda_{1}^{\prime}, \lambda_{2}^{\prime}\right)=A\left(\lambda_{1}, \lambda_{2}\right) A^{\star}\left(\lambda_{1}^{\prime}, \lambda_{2}^{\prime}\right) \delta\left(W^{2}-M^{2}\right) \tag{15}
\end{equation*}
$$

where $W^{2}=\left(q_{1}+q_{2}\right)^{2}$ and $M$ denotes the meson mass. Second, if $\eta_{i}$ denotes the naturality ${ }^{\circ}$ of current $V_{i}$ and $\eta_{M}$ that of the meson $M$, then

$$
\begin{equation*}
A\left(-\lambda_{1},-\lambda_{2}\right)=\eta A\left(\lambda_{1}, \lambda_{2}\right) \quad, \quad \eta \equiv \eta_{1} \eta_{2} \eta_{M} \tag{16}
\end{equation*}
$$

[^2]and there are five independent helicity amplitudes $A\left(\lambda_{1}, \lambda_{2}\right)$. Finally, owing to the $T$-invariance relation
\[

$$
\begin{equation*}
W\left(\lambda_{1}, \lambda_{2} ; \lambda_{1}^{\prime}, \lambda_{2}^{\prime}\right)=W\left(\lambda_{1}^{\prime}, \lambda_{2}^{\prime} ; \lambda_{1}, \lambda_{2}\right) \tag{17}
\end{equation*}
$$

\]

which implies

$$
\begin{equation*}
A\left(\lambda_{1}, \lambda_{2}\right) A^{\star}\left(\lambda_{1}^{\prime}, \lambda_{2}^{\prime}\right)=\operatorname{csgn} A\left(\lambda_{1}, \lambda_{2}\right) \operatorname{csgn} A\left(\lambda_{1}^{\prime}, \lambda_{2}^{\prime}\right)\left|A\left(\lambda_{1}^{\prime}, \lambda_{2}^{\prime}\right)\right|\left|A\left(\lambda_{1}, \lambda_{2}\right)\right| \tag{18}
\end{equation*}
$$

we are left with five real parameters. Here

$$
\operatorname{csgn} z= \begin{cases}+1 & \operatorname{Re} z>0 \text { or }(\operatorname{Re} z=0 \text { and } \operatorname{Im} z>0)  \tag{19}\\ -1 & \operatorname{Re} z<0 \text { or }(\operatorname{Re} z=0 \text { and } \operatorname{Im} z<0)\end{cases}
$$

Defining $A_{\lambda_{1} \lambda_{2}}=\left|A\left(\lambda_{1}, \lambda_{2}\right)\right|$ and

$$
\begin{align*}
& \xi_{1}=\operatorname{csgn} A(++) \operatorname{csgn} A(L L) \\
& \xi_{2}=\operatorname{csgn} A(+L) \operatorname{csgn} A(L+) \tag{20}
\end{align*}
$$

we find

$$
\begin{align*}
\mathrm{d} \sigma \sim & 2 \rho_{1}^{++} \rho_{2}^{++} A_{+--}^{2} \\
& +2 \rho_{1}^{++} \rho_{2}^{L L} A_{+L}^{2}+2 \rho_{1}^{L L} \rho_{2}^{++} A_{L+}^{2}-4 \eta\left|\rho_{1}^{+L} \rho_{2}^{+L}\right| \xi_{2} A_{+L} A_{L+} \cos \tilde{\phi} \\
& +\rho_{1}^{L L} \rho_{2}^{L L} A_{L L}^{2}-4\left|\rho_{1}^{+L} \rho_{2}^{+L}\right| \xi_{1} A_{++} A_{L L} \cos \tilde{\phi} \\
& +\left\{2 \rho_{1}^{++} \rho_{2}^{++}+2 \eta\left|\rho_{1}^{+-} \rho_{2}^{+--}\right| \cos 2 \tilde{\phi}\right\} A_{++}^{2} \tag{21}
\end{align*}
$$

For the kinematic regime of interest, $x_{i} \ll 1$ and $Q_{1} \ll M, \tilde{\phi} \approx \phi$, (7), and (10) allows us to approximate

$$
\begin{align*}
\rho_{1}^{L L} \rho_{2}^{L L} & \approx \frac{4 \rho_{1}^{++} \rho_{2}^{++}}{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)} \approx \frac{2 \rho_{1}^{++} \rho_{2}^{L L}}{1-\delta_{1}} \approx \frac{2 \rho_{1}^{L L} \rho_{2}^{++}}{1-\delta_{2}} \\
& \approx \frac{2\left|\rho_{1}^{+L} \rho_{2}^{+L}\right|}{\sqrt{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)}} \approx \frac{4\left|\rho_{1}^{+-} \rho_{2}^{+-}\right|}{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)} \tag{22}
\end{align*}
$$

If we decompose the cross section into components (subscript $i$ on $\Sigma_{i}$ ) that correspond to $\left|J_{z}\right|=2,1$, and 0 , then we obtain

$$
\begin{align*}
\mathrm{d} \sigma \sim & \Sigma_{2}+\Sigma_{1}+\Sigma_{0} \\
\Sigma_{2}= & \frac{1}{2}\left(1-\delta_{1}\right)\left(1-\delta_{2}\right) A_{+-}^{2} \\
\Sigma_{1}= & \left(1-\delta_{1}\right) A_{+L}^{2}+\left(1-\delta_{2}\right) A_{L+}^{2} \\
& -2 \eta \xi_{2} \sqrt{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)} A_{+L} A_{L+} \cos \phi \\
\Sigma_{0}= & A_{L L}^{2}-2 \xi_{1} \sqrt{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)} A_{++} A_{L L} \cos \phi \\
& +\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)(1+\eta \cos 2 \phi) \frac{1}{2} A_{++}^{2} \tag{23}
\end{align*}
$$

| $J^{P}$ | $0^{-}$ | $0^{+}$ | $1^{-}$ | $1^{+}$ | $2^{-}$ | $2^{+}$ | $3^{-}$ | $3^{+}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| $A_{+-}$ | 0 | 0 | 0 | 0 | $D$ | 1 | $D$ | 1 |
| $\kappa$ | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 |

Table 1: Model-independent features of helicity amplitudes up to $J^{P}=3^{+}$; 0 : amplitude is identical to zero; $D$ : amplitude is proportional to $D=\left(Q_{1}^{2}-\right.$ $\left.Q_{2}^{2}\right) / M^{2} ; \delta$ : amplitude is proportional to $\delta=Q_{1} Q_{2} / M^{2}$ for $Q_{i} \ll M ; 1$ : amplitude is of order one, in general. Also given are the values of $\eta$, (16), and $\kappa$, (29) (for the case $\eta_{1} \eta_{2}=+1$ ).

Introducing

$$
\begin{equation*}
r=\frac{A_{L L}}{A_{++}}, \tag{24}
\end{equation*}
$$

and making use of $(1-\eta) r=0$, we can rewrite the $J_{z}=0$ part in (23) as

$$
\begin{align*}
\Sigma_{0}=A_{++}^{2} & \left\{\delta_{\eta, 1}\left(r-\xi_{1} \sqrt{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)} \cos \phi\right)^{2}\right. \\
& \left.+\delta_{\eta,-1}\left(1-\delta_{1}\right)\left(1-\delta_{2}\right) \frac{1}{2}(1-\cos 2 \phi)\right\} \tag{25}
\end{align*}
$$

Which of the two terms in (25) contributes depends on the naturality factor $\eta$, see table 1 .

So far we have not yet made use of Bose symmetry, which states

$$
\begin{equation*}
A\left(\lambda_{1}, \lambda_{2}\right)\left(Q_{1}, Q_{2}\right)=(-1)^{J} A\left(\lambda_{2}, \lambda_{1}\right)\left(Q_{2}, Q_{1}\right) \tag{26}
\end{equation*}
$$

where $Q_{i}=\sqrt{-q_{i}^{2}}$ is the virtuality of boson $i$. It implies that (in the CVC hypothesis) the amplitudes $A_{++}$and $A_{L L}$ must be proportional to

$$
\begin{equation*}
D=\frac{Q_{1}^{2}-Q_{2}^{2}}{M^{2}} \tag{27}
\end{equation*}
$$

for odd-integer $J$. When combined with parity, (16), the amplitude $A_{+-} \propto D$ for some $J^{P}$, see table 1 .

Bose symmetry has one more consequence, namely that both amplitudes $A_{L+}$ and $A_{+L}$ in (23) can be replaced by only one of them, say $A_{+L}$. Moreover, the $\operatorname{sign}$ in (18) is then fixed in a model-independent way. We can rewrite the $\left|J_{z}\right|=1$ part of the cross section as

$$
\begin{align*}
\Sigma_{1}= & \left(1-\delta_{1}\right) A_{+L}^{2}\left(Q_{1}, Q_{2}\right)+\left(1-\delta_{2}\right) A_{+L}^{2}\left(Q_{2}, Q_{1}\right) \\
& -2(1-2 \kappa) \sqrt{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)} A_{+L}\left(Q_{1}, Q_{2}\right) A_{+L}\left(Q_{2}, Q_{1}\right) \cos \phi \tag{28}
\end{align*}
$$

where we have introduced the variable

$$
\begin{equation*}
\kappa=\frac{1-\eta(-1)^{J}}{2}, \tag{29}
\end{equation*}
$$

whose values, one or zero, are given in table 1 for states up to $J^{P}=3^{+}$.
We can exploit one more constraint, namely current conservation, which requires

$$
\begin{array}{rccc}
A_{ \pm 1, L} \propto & Q_{2} / M & \text { for } & Q_{2} \ll M \\
A_{L, \pm 1} \propto & Q_{1} / M & \text { for } & Q_{1} \ll M \\
A_{L, L} \propto & Q_{1} Q_{2} / M^{2} & \text { for } & Q_{i} \ll M . \tag{30}
\end{array}
$$

Then (7) implies that

$$
\begin{align*}
A_{+L} & \simeq a_{+L} \frac{q_{2 \perp}}{M} \\
A_{L L} & \simeq a_{L L} \delta, \quad \delta \equiv \frac{Q_{1} Q_{2}}{M^{2}} \simeq \frac{q_{1 \perp} q_{2 \perp}}{M^{2}} \\
D & \simeq \frac{q_{1 \perp}^{2}-q_{2 \perp}^{2}}{M^{2}} \tag{31}
\end{align*}
$$

where $a_{i j}$ are coefficients of order one. Hence $\Sigma_{1}$ in (28) behaves as

$$
\Sigma_{1}= \begin{cases}a_{+L}^{2} p_{\mathrm{T}}^{2} / M^{2}, & \text { for } \kappa=1  \tag{32}\\ a_{+L}^{2} k_{\mathrm{T}}^{2} / M^{2}, & \text { for } \kappa=0\end{cases}
$$

where

$$
\begin{align*}
& p_{\mathrm{T}}^{2}=\left(\sqrt{1-\delta_{2}} \vec{q}_{1 \perp}+\sqrt{1-\delta_{1}} \vec{q}_{2 \perp}\right)^{2} \\
& k_{\mathrm{T}}^{2}=\left(\sqrt{1-\delta_{2}} \vec{q}_{1 \perp}-\sqrt{1-\delta_{1}} \vec{q}_{2 \perp}\right)^{2} . \tag{33}
\end{align*}
$$

Note that $k_{\mathrm{T}} \rightarrow 0$ implies $\phi \rightarrow 0$ and $q_{2 \perp} \rightarrow q_{1 \perp}$. However, the opposite is not true: $\phi \rightarrow 0$ does not in general imply $k_{\mathrm{T}} \rightarrow 0$.

## 3 Results

The above analysis enables some immediate conclusions to be drawn according to the $J^{P C}$ of the meson.
(i) $J^{P}=0^{-}$

Only $J_{z}=0$ contributes and, with $\eta=-1$ in (25)

$$
\begin{equation*}
\frac{\mathrm{d} \sigma}{\mathrm{~d} \phi} \propto A_{++}^{2}\left(1-\delta_{1}\right)\left(1-\delta_{2}\right) \frac{1}{2}(1-\cos 2 \phi)=A_{++}^{2}\left(1-\delta_{1}\right)\left(1-\delta_{2}\right) \sin ^{2} \phi . \tag{34}
\end{equation*}
$$

This follows independent of the dynamical internal structure of the $0^{-+}$meson, and is simply a consequence of parity. Since $\phi \rightarrow 0$ as $k_{\mathrm{T}} \rightarrow 0$ we recover the result of [6], 9, 10] who noted that the production of $0^{-+}$by (conserved) vector currents would vanish as $k_{\mathrm{T}} \rightarrow 0$. Our result above provides a clear test for the vector nature of the production Pomeron (component) by the explicit prediction for the $\phi$ dependence, independent of the $t$-dependence.

Preliminary indications are that the production of $\eta$ and $\eta^{\prime}$ in $\mathrm{pp} \rightarrow \operatorname{pp} \eta\left(\eta^{\prime}\right)$ is compatible with such a $\phi$ dependence [11].
(iii) $J^{P}=1^{+}$

Since $\left|J_{z}\right| \leq 1$ the azimuthal distribution is given by the sum of (25) (with $\eta=-1$ ) and (28) (with $\kappa=0$ ). Since Bose symmetry yields $A_{++}=a_{++} D$ we find with the help of table 11 and (31) in the region of small $Q_{i}$

$$
\begin{equation*}
\frac{\mathrm{d} \sigma}{\mathrm{~d} \phi} \sim a_{+L}^{2} \frac{k_{\mathrm{T}}^{2}}{M^{2}}+a_{++}^{2}\left(1-\delta_{1}\right)\left(1-\delta_{2}\right) \sin ^{2} \phi \frac{\left(q_{1 \perp}^{2}-q_{2 \perp}^{2}\right)^{2}}{M^{4}} \tag{35}
\end{equation*}
$$

From this we can draw conclusions, which are independent of the internal structure of the $1^{++}$meson and thus hold for both $\mathrm{e}^{+} \mathrm{e}^{-}$collisions and diffractive proton-proton collisions mediated by a vector Pomeron. First, the cross section will tend to zero as $k_{\mathrm{T}} \rightarrow 0$. And second, $1^{+}$mesons are produced dominantly in the helicity-one state. Both of these phenomena are seen in the central production of $1^{++}$mesons in pp collisions which further supports the importance of the vector component of the effective Pomeron.

The tendency for large $k_{\mathrm{T}}$ to correlate with large $\phi$ may cause the apparent $\mathrm{d} \sigma / \mathrm{d} \phi$ to rise as $\phi \rightarrow 180^{\circ}$. The $\phi$ distributions should be binned in $k_{\mathrm{T}}$ to extract the full implications of (35).
(ii) $J^{P}=\mathbf{0}^{+}$

In this case the $\phi$ dependence depends on the internal structure of the meson and dynamics, specifically via the magnitude of $A_{L L} / A_{++} \equiv r$

$$
\begin{equation*}
\frac{\mathrm{d} \sigma}{\mathrm{~d} \phi}=A_{++}^{2}\left(\sqrt{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)} \xi_{1} \cos \phi-r\right)^{2} \tag{36}
\end{equation*}
$$

At small $Q_{i}, Q_{i} \ll M$ in $\mathrm{e}^{+} \mathrm{e}^{-}$collisions, we have $r \simeq c \delta \simeq c q_{1 \perp} q_{2 \perp} / M^{2}$ with $c=a_{L L} / A_{++}=O(1)$, in general.

For the particular case of two photons coupling to a non-relativistic quarkantiquark one has [12, [13] $\xi_{1}=+1$ and $c=4 / 3$ since

$$
\begin{equation*}
r=\frac{Q_{1} Q_{2} M^{2}}{\nu^{2}+\nu M^{2}-Q_{1}^{2} Q_{2}^{2}} \approx \frac{4}{3} \frac{q_{1 \perp} q_{2 \perp}}{M^{2}} \tag{37}
\end{equation*}
$$

at $q_{i \perp} \ll M$. Hence for tagged two-photon events in $\mathrm{e}^{+} \mathrm{e}^{-}$collisions we predict a cross section that survives the $k_{\mathrm{T}} \rightarrow 0$ limit and the $\phi$ distribution (36), which for $q_{i \perp} \ll M$ is a pure $\cos ^{2} \phi$ distribution.

This will also hold true for $\mathrm{q} \overline{\mathrm{q}}$ and glueball production in pp collisions if the Pomeron is a conserved vector current. So far we have taken the simplest assumption needed for a nontrivial $\phi$ distribution, namely CVC. This is immediately relevant to $\mathrm{e}^{+} \mathrm{e}^{-}$but encouragingly shows consistency with pp . The $0^{-}$is a direct test with its $\sin ^{2} \phi$ distribution which is verified for $\eta, \eta^{\prime}$ in WA102. For $1^{+}$the $k_{\mathrm{T}} \rightarrow 0$ vanishing and the helicity- 1 dominance are verified. The $0^{+}, 2^{+}$ data clearly go beyond this.

The non-trivial $\phi$ dependence required $J_{\text {Pomeron }}>0$ to be present but leaves open the question of whether there is a spin-0 component in addition to the CVC and/or whether there is a non-conserved vector current. Note that the $0^{-}$production is not sensitive to any $0^{+}$component in the Pomeron. The simplest manifestation of a scalar component or a non-conserved vector piece, is to allow $R$ to be larger than its CVC suppression $O\left(\sqrt{t_{1} t_{2}} / M^{2}\right)$. The $0^{+}, 2^{+}$ data are consistent with this. The $\mathrm{f}_{0}(1500)$ production, in particular, is well described if $R$ is negative with $|R| \sim O(1)$, in which case its $\phi$ distribution is $\sim \sin ^{4}(\phi / 2)$. This sign and magnitude are natural for the production of a gluonic system if the dynamics for $M_{L L} / M_{++}$is driven by the Clebsch-Gordon coefficients $\langle 10,10 \mid 00\rangle /\langle 11,1-1 \mid 00\rangle=-1$. We leave the discussion of the phenomenology and specific models to a later publication.
(iii) $J^{P}=2^{+}$

The azimuthal distribution is given by the sum of $\Sigma_{2}$, (23), $\Sigma_{1}$, (28) with $\kappa=0$, and $\Sigma_{0}$, (25) with $\eta=+1$. Using the small- $Q_{i}$ approximation for $\Sigma_{1}$ we have
$\mathrm{d} \sigma \sim \frac{1}{2} A_{+-}^{2}\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)+a_{+L}^{2} \frac{k_{\mathrm{T}}^{2}}{M^{2}}+\left(r-\xi_{1} \sqrt{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)} \cos \phi\right)^{2} A_{++}^{2}$.
As we can see the $\left|J_{z}\right|=1$ part is suppressed as is $A_{L L}$ (recall $r \sim \delta$ at small $\left.Q_{i}\right)$. However, in general, the other two amplitudes are of order one, i.e. $A_{+-} \sim$ $A_{++} \sim 1$.

In the non-relativistic quark model, $A_{++} \simeq\left(Q_{1}^{2}+Q_{2}^{2}\right) / M^{2}$ at small $Q_{i}$ [14, 12] and is thus very much suppressed relative to $A_{+-}$, which is $O(1)$. Hence in $\mathrm{e}^{+} \mathrm{e}^{-}$ collisions at small $q_{i \perp} \ll M$ we predict a $2^{+}$cross section that is (i) basically flat in $\cos \phi$, (ii) finite for $k_{\mathrm{T}} \rightarrow 0$, and (iii) dominated by the helicity-two part. We necessarily obtain the same behaviour, namely flat $\phi$ distribution and $k_{\mathrm{T}} \rightarrow 0$ survival, in diffractive pp collisions mediated by a conserved vector Pomeron, provided the helicity-two component is the dominant one.

If the Pomeron-q $\bar{q}$ coupling were dominantly "magnetic" (flipping the spins of the produced $q \bar{q}$ pair but leaving them in an $L_{z}=0$ state) the helicity-two amplitude $A_{+-}$would be suppressed. In this case the helicity-one amplitude would also be suppressed as $k_{\mathrm{T}} \rightarrow 0$ and the helicity-zero amplitude would dominate with a characteristic $\phi$ dependence (unless $A_{++}=0$ ). Moreover, the $2^{+}$cross section continues to survive the $k_{\mathrm{T}} \rightarrow 0$ limit since $r$ is small for CVC.

Again we conclude that, as for $0^{+}$production, a non-conserved vector piece (or
a large scalar component) is needed to accommodate for the observed small- $k_{\mathrm{T}}$ suppression of $f_{2}(1270)$ and $f_{2}^{\prime}(1520)$. In the scenario discussed above this follows if $\xi_{1} r \sim O(1)$. We point out that these predictions assume Pomeron-Pomeron or gluon-gluon fusion and hence do not apply to $\mathrm{f}_{2}$ production if the latter has a substantial contribution from $f_{2}$ exchange (i.e. from $f_{2}+$ Pomeron $\rightarrow f_{2}$. $A$ detailed comparison of $\mathrm{f}_{2} \mathrm{~s} \overline{\mathrm{~s}}(1525)$ (for which this contribution is suppressed) and $\mathrm{f}_{2} \mathrm{u} \overline{\mathrm{u}}(1270)$ (where Pomeron $-\mathrm{f}_{2}$ is possible) could help settle this.
(iii) $J^{P}=\mathbf{2}^{-}$

Here we find with the help of table 1 and (31)

$$
\begin{equation*}
\mathrm{d} \sigma \sim\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)\left\{\frac{1}{2} a_{+-}^{2} \frac{\left(q_{1 \perp}^{2}-q_{2 \perp}^{2}\right)^{2}}{M^{4}}+\sin ^{2} \phi A_{++}^{2}\right\}+a_{+L}^{2} \frac{p_{\mathrm{T}}^{2}}{M^{2}} . \tag{39}
\end{equation*}
$$

The helicity-two component vanishes as $k_{\mathrm{T}} \rightarrow 0$, as does the helicity-zero also. However, the helicity-one component ( $\propto p_{\mathrm{T}}^{2}$ ) stays non-zero, in general. In the quark model coupling to two photons, both $a_{+-}$and $a_{+L}$ are zero [14, [12], and so in this model the cross section will have the same features as that of a $0^{-+}$ meson, namely a $\phi$ distribution $\propto \sin ^{2} \phi$, a cross section that vanishes for $k_{\mathrm{T}} \rightarrow 0$, and helicity-zero dominance.

For central production in hadronic reactions mediated by a vector Pomeron we have to distinguish two cases, namely $a_{+L} \neq 0$ or $=0$. In both cases the helicity-two component is suppressed. In the first case we have a cross section that survives at small $k_{\mathrm{T}}$. Moreover, at small $k_{\mathrm{T}}$ we expect helicity-one dominance and a flat $\phi$ distribution. In the second case, i.e. for a suppressed helicity-one amplitude, we predict (i) a vanishing $2^{-}$cross section for $k_{\mathrm{T}} \rightarrow 0$ (recall, both $q_{1 \perp}-q_{2 \perp}$ and $\sin ^{2} \phi$ vanish for $k_{\mathrm{T}} \rightarrow 0$ ), and, provided $A_{++} \neq 0$, helicity-zero dominance as well as a $\sin ^{2} \phi$ distribution (since $\left(q_{1 \perp}^{2}-q_{2 \perp}^{2}\right)^{2} / M^{4}$ is smaller at low $k_{\mathrm{T}}$ than $\sin ^{2} \phi$ ).
(iv) $J^{P}=3^{+}$and $1^{-}, 3^{-}$

With the help of table 1 and (31) it is straightforward to find the $k_{\mathrm{T}}$ and $\phi$ distributions for the $3^{+}$states and possible (non-q $\bar{q}$ ) $1^{-+}$and $3^{-+}$states.

$$
\begin{align*}
\mathrm{d} \sigma\left[3^{+}\right] \sim & \frac{1}{2} A_{+-}^{2}\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)+a_{+L}^{2} \frac{k_{\mathrm{T}}^{2}}{M^{2}} \\
& +D^{2} a_{++}^{2}\left(1-\delta_{1}\right)\left(1-\delta_{2}\right) \sin ^{2} \phi \\
\mathrm{~d} \sigma\left[3^{-}\right] \sim & \frac{1}{2} D^{2} a_{+-}^{2}\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)+a_{+L}^{2} \frac{p_{\mathrm{T}}^{2}}{M^{2}} \\
& +D^{2} a_{++}^{2}\left(\delta \frac{a_{L L}}{a_{++}}-\xi_{1} \sqrt{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)} \cos \phi\right)^{2} \\
\mathrm{~d} \sigma\left[1^{-}\right] \sim & a_{+L}^{2} \frac{p_{\mathrm{T}}^{2}}{M^{2}}+D^{2} a_{++}^{2}\left(\delta \frac{a_{L L}}{a_{++}}-\xi_{1} \sqrt{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)} \cos \phi\right)^{2} . \tag{40}
\end{align*}
$$

Here we have used that $A_{L L}=D \delta a_{L L}$ for $1^{-}$and $3^{-}$mesons.

As a specific example ${ }^{-1}$ we illustrate the $1^{--}$which can be most immediately relevant in ep $\rightarrow$ ep $V$. Note that Bose symmetry is now not valid and so both the form of the first term in (40) is changed and the factor $D^{2}$ is absent in the second term. We find

$$
\begin{align*}
\mathrm{d} \sigma \sim & \left(\sqrt{1-\delta_{2}} \frac{a_{L+}}{M} \vec{q}_{1 \perp}-\eta \xi_{2} \sqrt{1-\delta_{1}} \frac{a_{+L}}{M} \vec{q}_{2 \perp}\right)^{2} \\
& +A_{++}^{2}\left(r-\xi_{1} \sqrt{\left(1-\delta_{1}\right)\left(1-\delta_{2}\right)} \cos \phi\right)^{2} \tag{41}
\end{align*}
$$

In the particular case of forward electroproduction, where $t_{2} \rightarrow 0$ but $q_{1 \perp}^{2}=Q^{2}$ is small, we have approximately

$$
\begin{equation*}
\mathrm{d} \sigma \sim \frac{Q^{2}}{M^{2}} a_{L+}^{2}+A_{++}^{2}(r-\cos \phi)^{2} . \tag{42}
\end{equation*}
$$

If for some reason we still have $A_{++}=D a_{++}$or if $A_{++}\left(Q_{1}, Q_{2}=0\right) \sim Q_{1}^{2}$ then

$$
\begin{equation*}
\mathrm{d} \sigma \sim a_{L+}^{2}+\frac{Q^{2}}{M^{2}}(r-\cos \phi)^{2} . \tag{43}
\end{equation*}
$$

Thus we would expect dominance of transversely-polarized vector-mesons and a longitudinally-polarized component of a characteristic $\phi$ dependence.

In this section we have given explicit formulae for the CVC case only. While this applies to $\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow \mathrm{e}^{+} \mathrm{e}^{-} M$, we have noted that some data involving the Pomeron in proton-proton collisions go beyond this hypothesis. We will discuss elsewhere the detailed phenomenology for both pp and ep-induced reactions.
