### Effects of Cultivar and Distillers Grains Supplementation on Grazing and Subsequent Finishing Performance of Stocker Steers Grazing Tall Fescue Pasture

#### Abstract

Four hundred thirty-two vearling steers grazing tall fescue pastures were used to evaluate the effects of fescue cultivar and dried distillers grains (DDG) supplementation during the grazing phase on available forage, grazing gains, subsequent finishing gains, and carcass characteristics. Fescue cultivars evaluated were high-endophyte 'Kentucky 31' and low-endophyte 'Kentucky 31,' 'HM4,' and 'MaxQ.' Steers were either fed no supplement or were supplemented with DDG at 1.0% body weight per head daily in 2009 or 0.75% of body weight per head daily in 2010, 2011, 2012, 2013, and 2014 while grazing. Steers that grazed pastures of low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' gained significantly more (P < 0.05) and produced more (P < 0.05) gain/a than those that grazed high-endophyte 'Kentucky 31' pastures. Gains of cattle that grazed low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' were similar (P > 0.05). Subsequent finishing gains were similar (P > 0.05) among fescue cultivars in 2009, 2012, 2013, and 2014; however, steers that previously grazed high-endophyte 'Kentucky 31' had greater (P > 0.05) finishing gains than those that had grazed 'HM4' or 'MaxQ' in 2010 and greater (P < 0.05) finishing gains than those that grazed low-endophyte 'Kentucky 31' or 'HM4' in 2011. Supplementation of grazing steers with DDG supported a higher stocking rate and resulted in greater (P < 0.05) grazing gain, gain/a, and overall daily gain and reduced the amount of fertilizer needed by providing approximately 60 lb/a, 50 lb/a, 50 lb/a, 30 Ib/a, 40 lb/a, and 40 lb/a of nitrogen (N) in 2009, 2010, 2011, 2012, 2013, and 2014, respectively, primarily from urine of grazing cattle.

## Effects of Cultivar and Distillers Grains Supplementation on Grazing and Subsequent Finishing Performance of Stocker Steers Grazing Tall Fescue Pasture

#### L.W. Lomas and J.L. Moyer

#### Summary

Four hundred thirty-two yearling steers grazing tall fescue pastures were used to evaluate the effects of fescue cultivar and dried distillers grains (DDG) supplementation during the grazing phase on available forage, grazing gains, subsequent finishing gains, and carcass characteristics. Fescue cultivars evaluated were high-endophyte 'Kentucky 31' and low-endophyte 'Kentucky 31,' 'HM4,' and 'MaxQ.' Steers were either fed no supplement or were supplemented with DDG at 1.0% body weight per head daily in 2009 or 0.75% of body weight per head daily in 2010, 2011, 2012, 2013, and 2014 while grazing. Steers that grazed pastures of low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' gained significantly more (P < 0.05) and produced more (P < 0.05) gain/a than those that grazed high-endophyte 'Kentucky 31' pastures. Gains of cattle that grazed low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' were similar (P > 0.05). Subsequent finishing gains were similar (P > 0.05) among fescue cultivars in 2009, 2012, 2013, and 2014; however, steers that previously grazed high-endophyte 'Kentucky 31' had greater (P > 0.05) finishing gains than those that had grazed 'HM4' or 'MaxQ' in 2010 and greater (P < 0.05) finishing gains than those that grazed low-endophyte 'Kentucky 31' or 'HM4' in 2011. Supplementation of grazing steers with DDG supported a higher stocking rate and resulted in greater (P < 0.05) grazing gain, gain/a, and overall daily gain and reduced the amount of fertilizer needed by providing approximately 60 lb/a, 50 lb/a, 50 lb/a, 30 lb/a, 40 lb/a, and 40 lb/a of nitrogen (N) in 2009, 2010, 2011, 2012, 2013, and 2014, respectively, primarily from urine of grazing cattle.

### Introduction

Tall fescue, the most widely adapted cool-season perennial grass in the United States, is grown on approximately 66 million acres. Although tall fescue is well adapted in the eastern half of the country between the temperate North and mild South, presence of a fungal endophyte results in poor performance of grazing livestock, especially during the summer. Until recently, producers with high-endophyte tall fescue pastures had two primary options for improving grazing livestock performance. One option was to destroy existing stands and replace them with endophyte-free fescue or other forages. Although it supports greater animal performance than endophyte-infected fescue, endophyte-free fescue has been shown to be less persistent under grazing pressure and

#### 2015 SEARC AGRICULTURAL RESEARCH

more susceptible to stand loss from drought stress. In locations where high-endophyte tall fescue must be grown, the other option was for producers to adopt management strategies that reduce the negative effects of the endophyte on grazing animals, such as diluting the effects of the endophyte by incorporating legumes into existing pastures or providing supplemental feed. In recent years, new tall fescue cultivars have been developed with a non-toxic endophyte that provides vigor to the fescue plant without negatively affecting performance of grazing livestock.

Growth in the ethanol industry has resulted in increased availability of distillers grains, which have been shown to be an excellent feedstuff for supplementing grazing cattle because of their high protein and phosphorus content. Distillers grains contain approximately 4% to 5% N, and cattle consuming them excrete a high percentage of this N in their urine and feces; therefore, feeding dried distillers grains (DDG) to grazing cattle will provide N to the pastures. Objectives of this study were to (1) evaluate two of these new cultivars in terms of forage availability, stand persistence, and grazing and subsequent finishing performance of stocker steers and compare them with high- and low-endophyte 'Kentucky 31' tall fescue; (2) evaluate DDG supplementation of cattle grazing these pastures; and (3) determine the contribution of DDG as a nitrogen fertilizer source.

#### **Experimental Procedures**

Seventy-two mixed black yearling steers were weighed on two consecutive days and allotted to 16 5-acre established pastures of high-endophyte 'Kentucky 31' or low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' tall fescue (four replications per cultivar) on March 26, 2009 (569 lb average weight); March 24, 2010 (550 lb); March 23, 2011 (536 lb); March 22, 2012 (550 lb); April 4, 2013 (600 lb); and April 1, 2014 (546 lb). 'HM4' and 'MaxQ' are cultivars that have a non-toxic endophyte. Four steers were assigned to two pastures of each cultivar and received no supplementation, and five steers were assigned to two pastures of each cultivar and supplemented with DDG at 1.0% in 2009 or 0.75% body weight per head daily during the grazing phase in 2010, 2011, 2012, 2013, and 2014. All pastures were fertilized with 80 lb/a N and  $P_2O_2$  and  $K_2O$  as required by soil test on February 5, 2009; February 10, 2010; and January 27, 2011; 90 lb/a N on January 25, 2012; 85 lb/a N on February 5, 2013; and 74 lb/a N on February 13, 2014. Pastures with steers that received no supplement were fertilized with 60 lb/a N on September 16, 2009; 46 lb/a N on August 30, 2010 and September 15, 2011; 30 lb/a N on August 10, 2012; and 46 lb/a N on September 19, 2013 and September 15, 2014. This was calculated to be approximately the same amount of N from DDG that was excreted on pastures by supplemented steers during the entire grazing season.

Cattle in each pasture were group-fed DDG in meal form in bunks on a daily basis, and pasture was the experimental unit. No implants or feed additives were used. Weight gain was the primary measurement. Cattle were weighed every 28 days; quantity of DDG fed was adjusted at that time. Forage availability was measured approximately every 28 days with a disk meter calibrated for tall fescue. Cattle were treated for internal and external parasites before being turned out to pasture and later vaccinated for protection from pinkeye. Steers had free access to commercial mineral blocks that contained 12% calcium, 12% phosphorus, and 12% salt. Two steers in 2009, one steer in 2012, and two steers in 2013 were removed from the study for reasons unrelated to

#### 2015 SEARC AGRICULTURAL RESEARCH

experimental treatment. Pastures were grazed continuously until October 13, 2009 (201 days); November 3, 2010 (224 days); October 19, 2011 (210 days); August 21, 2012 (152 days); October 17, 2013 (196 days); and October 14, 2014 (196 days) for all pastures except one replicate of low-endophyte 'Kentucky 31,' where grazing was terminated on September 17, 2014 (169 days), when steers were weighed on two consecutive days and grazing was terminated.

After the grazing period, cattle were moved to a finishing facility, implanted with Synovex-S (Zoetis, Madison, NJ), and fed a diet of 80% whole-shelled corn, 15% corn silage, and 5% supplement (dry matter basis). Cattle that received no supplement or were supplemented with DDG while grazing were fed a finishing diet for 119 or 99 days, for 112 or 98 days, for 116 or 102 days, and for 120 or 106 days, respectively, in 2009, 2011, 2013, and 2014; for 106 days in 2010; and for 113 days in 2012. All steers were slaughtered in a commercial facility, and carcass data were collected.

#### **Results and Discussion**

Grazing and subsequent finishing performance are pooled across supplementation treatment and presented by tall fescue cultivar in Tables 1, 2, 3, 4, 5, and 6 for 2009, 2010, 2011, 2012, 2013, and 2014, respectively, and by supplementation treatment in Tables 7, 8, 9, 10, 11, and 12 for 2009, 2010, 2011, 2012, 2013, and 2014, respectively. No significant interactions were detected (P > 0.05) between cultivar and supplementation treatment in 2009, 2010, 2011, 2012, and 2014; however, a significant cultivar × supplement treatment interaction (P < 0.05) was detected in 2013 for grazing ending weight, pasture gain, pasture daily gain, feed:gain, and ribeye area.

During all years, steers that grazed pastures of low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' gained significantly more (P < 0.05) and produced more (P < 0.05) gain/a than those that grazed high-endophyte 'Kentucky 31' pastures (Tables 1, 2, 3, 4, 5, and 6). Gains of cattle that grazed low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' were similar (P > 0.05). Daily gains of steers grazing pastures with high-endophyte 'Kentucky 31,' low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' were 1.70, 2.35, 2.25, and 2.33 lb/head, respectively, in 2009; 1.56, 1.91, 1.97, and 2.04 lb/head, respectively, in 2010; 1.47, 2.00, 1.96, and 1.95 lb/head, respectively, in 2011; 1.00, 1.93, 2.06, and 2.04 lb/head, respectively, in 2012; 1.29, 1.84, 1.89, and 1.93 lb/head, respectively, in 2013; and 1.52, 2.25, 2.23, and 2.04 lb/head, respectively, in 2014. Gain/a from pastures with high-endophyte 'Kentucky 31,' low-endophyte 'Kentucky 31,' 'HM4,' and 'MaxQ' were 318, 438, 415, and 428 lb/a, respectively, in 2009; 322, 390, 400, and 416 lb/a, respectively, in 2010; 288, 385, 377, and 378 lb/a, respectively, in 2011; 145, 271, 288, and 286 lb/a, respectively, in 2012; 237, 328, 339, and 346 lb/a, respectively, in 2013; and 274, 385, 398, and 367 lb/a, respectively, in 2014. In 2013, steers that grazed 'MaxQ' supplemented with DDG had higher (P < 0.05) grazing gain and higher (P < 0.05) (0.05) gain/a than those that grazed low-endophyte 'Kentucky 31' supplemented with DDG. Supplementation of steers that grazed high-endophyte 'Kentucky 31' with DDG resulted in grazing performance similar (P > 0.05) to those that grazed low-endophyte 'Kentucky 31,' 'HM4,' and 'MaxQ' with no supplementation.

In 2009, subsequent finishing gains and feed efficiency were similar (P > 0.05) among fescue cultivars (Table 1). Steers that previously grazed low-endophyte 'Kentucky 31,'

#### 2015 SEARC AGRICULTURAL RESEARCH

'HM4,' or 'MaxQ' maintained their weight advantage through the finishing phase and had greater (P < 0.05) final finishing weights, hot carcass weights, overall gains, and overall daily gains than those that previously grazed high-endophyte 'Kentucky 31.' Final finishing weights, hot carcass weights, overall gains, and overall daily gains were similar (P > 0.05) among steers that previously grazed low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ.' Backfat thickness and percentage of carcasses graded choice or higher were similar (P > 0.05) among fescue cultivars.

In 2010, steers that previously grazed high-endophyte 'Kentucky 31' had greater (P < 0.05) finishing gains than those that had grazed 'HM4' or 'MaxQ,' finishing gains similar (P > 0.05) to those that grazed low-endophyte 'Kentucky 31,' lower (P < 0.05) hot carcass weight than those that grazed 'MaxQ,' hot carcass weight similar (P > 0.05) to those that grazed 'MaxQ,' hot carcass weight similar (P > 0.05) to those that grazed low-endophyte 'Kentucky 31' or 'HM4,' and less (P < 0.05) fat thickness than those that grazed low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' (Table 2). Feed:gain and percentage of carcasses grading choice or higher were similar (P > 0.05) among fescue cultivars. Overall gain of steers that grazed high-endophyte 'Kentucky 31' or 'MaxQ' and similar (P > 0.05) to that of steers that grazed low-endophyte 'Kentucky 31' or 'MaxQ' and similar (P > 0.05) to that of steers that grazed low-endophyte 'Kentucky 31' or 'MaxQ' and similar (P > 0.05) to that of steers that grazed low-endophyte 'Kentucky 31' or 'MaxQ' and similar (P > 0.05) to that of steers that grazed low-endophyte 'Kentucky 31' or 'MaxQ' and similar (P > 0.05) to that of steers that grazed low-endophyte 'Kentucky 31' or 'MaxQ' and similar (P > 0.05) to that of steers that grazed 'HM4.'

In 2011, steers that previously grazed high-endophyte 'Kentucky 31' had greater (P < 0.05) finishing gains and lower (P < 0.05) feed:gain than those that had grazed low-endophyte 'Kentucky 31' or 'HM4' and lower (P < 0.05) hot carcass weight and smaller (P < 0.05) ribeye area than those that grazed 'MaxQ' (Table 3). Hot carcass weight, ribeye area, and overall gain and daily gain were similar (P < 0.05) between steers that grazed low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ.' Steers that previously grazed high-endophyte 'Kentucky 31' had lower (P < 0.05) overall gain and daily gain than steers that grazed 'HM4' or 'MaxQ.'

In 2012, subsequent finishing gains were similar (P > 0.05) among fescue cultivars (Table 4), but steers that previously grazed high-endophyte 'Kentucky 31' had lower (P < 0.05) feed intake, lower (P < 0.05) feed:gain, lower (P < 0.05) hot carcass weight, lower (P < 0.05) overall gain, and lower (P < 0.05) overall daily gain than those that had grazed low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' (Table 4).

In 2013, subsequent finishing gains were similar (P > 0.05) among fescue cultivars (Table 5), but steers that previously grazed high-endophyte 'Kentucky 31' had lower (P < 0.05) hot carcass weight, lower (P < 0.05) overall gain, and lower (P < 0.05) overall daily gain than those that had grazed low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' and smaller (P < 0.05) ribeye area than those that grazed 'MaxQ.' Supplementation treatment had no effect (P > 0.05) on feed:gain of steers that grazed 'HM4' pastures. Unsupplemented steers that grazed 'MaxQ' and low-endophyte 'Kentucky 31' pastures produced carcasses with greater (P < 0.05) ribeye area than any of the other treatment combinations.

In 2014, subsequent finishing gains were similar (P > 0.05) among fescue cultivars (Table 6), but steers that previously grazed high-endophyte 'Kentucky 31' had lower (P < 0.05) ending finishing weight, lower (P < 0.05) hot carcass weight, lower (P < 0.05) overall gain, and lower (P < 0.05) overall daily gain than those that had

grazed low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ'. Steers that had previously grazed high-endophyte 'Kentucky 31' had smaller (P < 0.05) ribeye area than those that grazed 'MaxQ' and lower (P < 0.05) marbling scores than those that grazed low-endophyte 'Kentucky 31.'

Steers supplemented with DDG gained significantly more (P < 0.05) and produced more (P < 0.05) gain/a than those that received no supplement while grazing (Tables 7, 8, 9, 10, 11, and 12). Grazing gains and gain/a of steers that received no supplement and those that were supplemented with DDG were 1.71 and 2.61 lb/head daily and 343 and 525 lb/a, respectively, in 2009; 1.62 and 2.12 lb/head daily and 363 and 475 lb/a, respectively, in 2010; 1.46 and 2.23 lb/head daily and 246 and 469 lb/a, respectively, in 2011; 1.31 and 2.20 lb/head daily and 160 and 334 lb/a, respectively, in 2012; 1.43 and 2.05 lb/head daily and 224 and 401 lb/a, respectively, in 2013; and 1.68 and 2.33 lb/ head daily and 264 and 448 lb/a, respectively, in 2014. Supplemented steers consumed an average of 7.8, 6.0, 5.9, 5.5, 6.1, and 5.9 lb of DDG/head daily during the grazing phase in 2009, 2010, 2011, 2012, 2013, and 2014, respectively. Each additional pound of gain obtained from pastures with supplemented steers required 6.5, 7.2, 5.6, 4.8, 6.7, and 6.3 lb of DDG in 2009, 2010, 2011, 2012, 2013, and 2014, respectively. Steers that were supplemented during the grazing phase had greater (P < 0.05) final finishing weights, hot carcass weights, overall gain, and overall daily gain than those that received no supplement while grazing during 2009, 2010, 2011, and 2012. However, in 2013 and 2014, steers not supplemented while grazing were fed a finishing diet 14 days longer than those that were supplemented and final finishing weights, hot carcass weights, and overall gain were similar (P > 0.05). Daily gain, feed efficiency, yield grade, marbling score, and percentage of carcasses grading choice or higher were similar (P > 0.05)between supplementation treatments in 2009; however, in 2010, 2011, 2012, 2013, and 2014, steers supplemented with DDG while grazing had lower (P < 0.05) finishing gains than those that received no supplement while grazing. In 2012, 2013, and 2014, steers that received no supplement while grazing had lower (P < 0.05) feed:gain ratios than those that received supplement.

Average available forage dry matter (DM) is presented for each fescue cultivar and supplementation treatment combination for 2009, 2010, 2011, 2012, 2013, and 2014 in Tables 13, 14, 15, 16, 17, and 18, respectively. A significant interaction occurred (P < 0.05) between cultivar and supplementation treatment during all six years. Within each variety, there was no difference (P > 0.05) in average available forage DM between pastures stocked with 0.8 steer/a that received no supplement and those stocked with 1.0 steer/a and supplemented with DDG at 1.0% body weight per head daily in 2009 (Table 13). Average available forage DM was similar (P > 0.05) between supplementation treatments and pastures, with supplemented steers stocked at a heavier rate, which indicates that pastures were responding to the N that was being returned to the soil from steers consuming DDG, cattle supplemented with DDG were consuming less forage, or both. High-endophyte 'Kentucky 31' pastures with or without DDG supplementation had greater (P < 0.05) average available forage DM than 'MaxQ' pastures without supplementation. No other differences in average available forage DM were observed.

In 2010, no difference occurred (P > 0.05) in average available forage DM within variety for high-endophyte 'Kentucky 31,' low-endophyte 'Kentucky 31,' or 'HM4' pastures stocked with 0.8 steer/a that received no supplement and those stocked with 1.0 steer/a and supplemented with DDG at 0.75% body weight per head daily (Table 14); however, 'MaxQ' pastures that were stocked at the heavier rate and grazed by steers supplemented with DDG had greater (P < 0.05) average available forage DM than those stocked at a lighter rate and grazed by steers that received no supplement. High-endophyte 'Kentucky 31' pastures had greater (P < 0.05) average available DM than low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' pastures stocked with 0.8 steer/a that received no supplement.

In 2011, no difference occurred (P > 0.05) in average available forage DM within variety for low-endophyte 'Kentucky 31' or 'HM4' pastures stocked with 0.8 steer/a that received no supplement and those stocked with 1.0 steer/a and supplemented with DDG at 0.75% body weight per head daily (Table 15), but 'MaxQ' pastures that were stocked at the heavier rate and grazed by steers supplemented with DDG had greater (P< 0.05) average available forage DM than those stocked at a lighter rate and grazed by steers that received no supplement. High-endophyte 'Kentucky 31' pastures that were stocked at the heavier rate and grazed by steers supplemented with DDG had lower (P < 0.05) average available forage DM than those stocked at a lighter rate. High-endophyte 'Kentucky 31' pastures had greater (P < 0.05) average available forage DM than those stocked at a lighter rate. High-endophyte 'Kentucky 31' pastures had greater (P < 0.05) average available DM than low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' pastures stocked with 0.8 steer/a that received no supplement.

In 2012, a cultivar × date interaction occurred, with similar peak available DM on April 18 (P > 0.05) but lower available DM for 'MaxQ' and 'HM4' (P < 0.05) at the end of the grazing phase on August 17. No difference occurred (P > 0.05) in average available forage DM within variety for low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' pastures stocked with 0.8 steer/a that received no supplement and those stocked with 1.0 steer/a and supplemented with DDG at 0.75% body weight per head daily (Table 16); how-ever, high-endophyte 'Kentucky 31' pastures that were stocked at the heavier rate and grazed by steers supplemented with DDG had lower (P < 0.05) average available forage DM than those stocked at a lighter rate in both 2011 and 2012. This result suggests that supplementation with DDG increased forage intake and utilization by cattle grazing these pastures. High-endophyte 'Kentucky 31' pastures had greater (P < 0.05) average available DM than low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' pastures within each stocking rate and supplementation level in 2012.

In 2013, a cultivar × date interaction occurred, with all cultivars having similar (P > 0.05) available DM at the beginning of the grazing season. On April 30, low-endophyte 'Kentucky 31' had less (P < 0.05) available DM than the other three cultivars. Available DM peaked on June 3 then declined as the grazing season progressed. On June 3, high-endophyte 'Kentucky 31' had more (P < 0.05) available DM than the other three cultivars, and 'MaxQ' had less (P < 0.05) available DM than 'HM4.' By July 31, high-endophyte 'Kentucky 31' had more (P < 0.05) and 'MaxQ' less (P < 0.05) available DM than the other emainable DM than the other cultivars, a relationship that persisted throughout the remain-

der of the grazing season. No difference occurred (P > 0.05) in average available forage DM within variety for low-endophyte 'Kentucky 31' pastures stocked with 0.8 steer/a that received no supplement and those stocked with 1.0 steer/a and supplemented with DDG at 0.75% body weight per head daily (Table 17); however, high-endophyte 'Kentucky 31,' 'HM4,' and 'MaxQ' pastures that were stocked at the heavier rate and grazed by steers supplemented with DDG had lower (P < 0.05) average available forage DM than those stocked at a lighter rate without supplement. This result suggests that supplementation with DDG increased forage intake and utilization by cattle grazing these pastures and/or DDG level was not high enough to substitute for the forage consumed by the additional steer. High-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' pastures within each stocking rate and supplementation level in 2013.

In 2014, high-endophyte 'Kentucky 31' had more available DM than the other cultivars throughout the season, with no difference among the other three cultivars. On April 7, the initial date, available DM was the lowest for the entire season, whereas the highest available DM did not occur until June 25. This was because of the unusually dry spring followed by abundant rain in June. A cultivar × supplementation/stocking rate interaction occurred in 2014, because average available forage DM was similar for the cultivars, except in 'MaxQ' pastures (Table 18). The unsupplemented 'MaxQ' pastures had less available DM than those where supplement was fed, despite being stocked at a lower rate.

Grazing gains and overall gains of steers that grazed low-endophyte 'Kentucky 31,' 'HM4,' or 'MaxQ' were similar (P > 0.05) and significantly greater (P < 0.05) than those of steers that grazed high-endophyte 'Kentucky 31.' Supplementation of grazing steers with DDG resulted in greater (P < 0.05) grazing gains, supported a higher stocking rate, resulted in greater (P < 0.05) gain/a, and reduced the amount of fertilizer needed by providing approximately 30 to 60 lb of N/a. Producers seeking to maximize production from fescue pastures should consider using one of the new fescue varieties with the non-toxic endophyte in combination with DDG supplementation.
