18 **ABSTRACT**

19 The distribution of brominated flame retardants (BFRs) including Σ_8 PBDEs, DBDPE, BTBPE,
20 EH-TBB, BEH-TEBP and PBEB in road dust (RD) collected in Xinxiang, China was
21 characterized. Analysis of RD samples indicated that the BFR abundance declined as traffic
22 density decreased, with total mean levels of 292, 184, 163, 104 and 70 ng g⁻¹ dust at sites from
23 traffic intersections, main roads, collector streets, bypasses and parks, respectively. A possible
24 explanation for this phenomenon is that the majority of BFRs may be emitted from the interior of
25 vehicles via their ventilation systems. Of the 13 analyzed substances, BDE-209 and BEH-TEBP
26 were the most abundant components in RD from Xinxiang. Similar amounts of Σ BDEs
27 excluding BDE-209 were found at different types of sampling sites, and thus, atmospheric
28 deposition is also a probable source of BFRs in RD which can be subject to air transportation.
29 The main PBDE sources were traced to commercial products including DE-71, Bromkal 79-8DE,
30 Saytex 201E and Bromkal 82 DE mixtures. Our results confirm that the use of deca-BDE
31 commercial mixture is a major source of PBDE contamination in RD. Risk assessment indicated
32 the concentrations of BFRs in RD in this study do not constitute a non-cancer or cancer risk to
33 humans through ingestion. Annual emission fluxes of the commonly detected BFRs via RD in
34 China were estimated to be up to 4980 kg year⁻¹.

44 1. Introduction

45 Brominated flame retardants (BFRs), mainly consisting of polybrominated diphenyl ethers
46 (PBDEs), hexabromocyclododecane (HBCD), tetrabromobisphenol A (TBBPA),
47 decabromodiphenylethane (DBDPE), 1,2-bis-(2,4,6-tribromophenoxy)ethane (BTBPE),
48 2-ethyl-1-hexyl-2,3,4,5-tetrabromobenzoate (EH-TBB), bis(2-ethyl-1-hexyl) tetrabromophthalate
49 (BEH-TEBP) and pentabromoethylbenzene (PBEB) are a large group of additives used in
50 numerous products to reduce fire risks. Meanwhile, BFRs are ubiquitous in various
51 environmental media, foods, and biota including humans (Harrad et al., 2010; Fromme et al.,
52 2016). Because of their toxicity and intensive application in urban environments, BFR
53 occurrence, fate, behavior and consequent human health risk have caused increasing concern in
54 recent years (de Boer et al., 2016; Liu et al., 2016; Yu et al., 2016).

55 Road dust (RD) is formed through sedimentary process of particulate matter which mainly
56 originates from atmospheric precipitation, urban traffic, construction and industrial activities
57 under the action of wind, water and gravity in road surface. RD is simultaneously an important
58 environmental reservoir and source of many contaminants (semi-volatile organic compounds,
59 heavy metals etc.) in urban environments, and fate of those contaminants is closely related to that
60 of RD (Offenberg et al., 2003). RD can enter urban drainage networks, aquatic environment and
61 waste incineration system, as well as undergoing atmospheric transport over a range of spatial
62 scales. Moreover, RD has been identified as constituting potentially over 10% of PM_{2.5} in urban
63 atmospheres (Yu et al., 2013). RD can pose serious risks to human health, especially for street
64 sweepers, pedestrians, street vendors and traffic policemen. Because of rapid urbanization, urban
65 RD is becoming an increasingly serious environmental problem (Zhao and Li, 2013a, b; Zhao et
66 al., 2014).

67 Evidence suggests that FRs can be released from associated materials and enter the
68 environment through multiple pathways (Cao et al., 2013; Cao et al., 2014; Schreder and La
69 Guardia, 2014; Cao et al., 2015). Although ventilation of indoor air is believed to be the
70 dominant source of PBDEs in urban ambient air (Law et al., 2014), it is plausible that vehicles
71 may constitute significant FR emission sources in light of studies reporting substantial
72 concentrations of FRs in vehicle air and dust (Harrad et al., 2006; Hazrati et al., 2010; Harrad
73 and Abdallah, 2011; Brommer and Harrad, 2015). However, to our knowledge, to date very few
74 studies have investigated FR concentrations in RD (Luo et al., 2009; Tang et al., 2016).
75 Moreover, there is a dearth of evidence about the RD significance of vehicles as a source of
76 BFRs to RD.

77 To fill those knowledge gaps, the major objectives of the present study were to (1) determine
78 the concentrations and distribution of BFRs in RD; (2) identify important factors influencing the
79 occurrence of BFRs in RD; and (3) examine the proportion of the environmental burden of BFRs
80 associated with RD, and its associated risk.

81 **2. Materials and methods**

82 *2.1. Sampling strategy and methods*

83 Individual RD samples were obtained from 4 traffic intersections, 14 sites on main roads, 11
84 sites on collector streets and 7 sites on bypasses in Xinxiang, China on sunny, windless days in
85 October, 2014. In addition, 4 RD samples were collected from paths in parks as reference “urban
86 background” sites. All sampling sites on roads or streets were located between two crossings and
87 kept away from construction activities. At each site, sampling was performed with bristle brushes
88 on an area of about 4 m² along road curbs. Between collecting each sample, the brushes were
89 cleaned with water and dried with a clean electric blower. After collection, samples were sieved

90 through a stainless steel mesh to $< 25 \mu\text{m}$, during which the mesh were cleaned in ultrasonic
91 water bath and dried with a clean electric blower between each sample. All 40 RD samples were
92 packed with aluminum foil, sealed in clean polyethylene zip bags and stored in the dark at
93 $-20 \text{ }^\circ\text{C}$ until analysis was performed.

94 2.2. Chemicals

95 BDE-77, BDE-128, ^{13}C -BTBPE, ^{13}C -BDE-209 and PCB-129 purchased from Wellington
96 Laboratories Inc. were used as internal standards (IS). All solvents used (acetone, n-hexane,
97 iso-octane (2,2,4-Trimethylpentane) and DCM (dichloromethane)) were HPLC grade.

98 2.2. Analytical methods

99 In summary, a sample aliquot ($\sim 100 \text{ mg}$ of dust or 30 mg for SRM 2585) was accurately
100 weighed and spiked with known amounts of IS. Two mL of solvent mixture n-hexane/acetone
101 (3:1, v/v) was employed for the extraction. The process consisted of consecutive steps of
102 vortexing (1 min), ultrasonication (5 min) and centrifugation (2 min, 2000 g) for one cycle
103 repeated three times. After each cycle, the supernatant was transferred to a clean tube. All tubes
104 were baked at $420 \text{ }^\circ\text{C}$ for 6 h before use. The extracts were then evaporated to $0.1\text{--}0.2 \text{ mL}$ under
105 a gentle nitrogen stream and further purified on Florisil cartridges (Florisil ENVI, 500 mg , 3 mL ,
106 Supleco, Bellefonte, PA, USA). Prior to use, all cartridges were pre-cleaned and conditioned
107 with 10 mL n-hexane. BFRs were eluted with 10 mL of n-hexane/DCM (1:1, v/v). The eluate
108 was concentrated to dryness and resolubilized in $100 \mu\text{L}$ isooctane with a known amount of
109 PCB-129 as a recovery determination standard ready for GC-NCI-MS analysis.

110 The analysis procedure is similar to a recent publication (Kuang et al., 2016). Analysis of eight
111 PBDEs (BDE-28, -47, -100, -99, -154, -153, -183 and -209) and five NBFRs (novel brominated
112 flame retardants, EH-TBB, BEH-TEBP, BTBPE, DBDPE, PBEB) was performed. Under

113 electron capture negative ionization (ECNI) mode, a Thermo Trace 1310 GC coupled with an
114 ISQ single quadrupole MS equipped with a programmable-temperature vaporizer (PTV) was
115 employed to conduct the analysis. Two μL of cleaned extract were injected on a Thermo
116 TG-SQC column (15 m \times 0.25 mm \times 0.25 mm). The injection temperature was set at 92 $^{\circ}\text{C}$, hold
117 0.04 min, ramp 700 $^{\circ}\text{C min}^{-1}$ to 295 $^{\circ}\text{C}$. The GC temperature program was initially 50 $^{\circ}\text{C}$, hold
118 0.50 min, ramp 20 $^{\circ}\text{C min}^{-1}$ to 240 $^{\circ}\text{C}$, hold 5 min, ramp 5 $^{\circ}\text{C min}^{-1}$ to 270 $^{\circ}\text{C}$ and then ramp
119 20 $^{\circ}\text{C min}^{-1}$ to 305 $^{\circ}\text{C}$, hold 16 min. Helium was used as a carrier gas with a flow rate of 1.5 mL
120 min^{-1} for the first 22.00 min, then ramp 1.0 mL min^{-2} to 2.5 mL min^{-1} , hold 13.00 min. The mass
121 spectrometer was employed in selected ion monitoring (SIM) mode with measured ions for each
122 compound listed in Table SI-1. Dwell times for each ion were 30 ms. Ion source and transfer line
123 temperatures were 300 and 320 $^{\circ}\text{C}$, respectively and the electron multiplier voltage was 1400 V.
124 Methane was used as moderating gas.

125 2.3. QA/QC

126 Average $\pm\sigma_{n-1}$ recoveries of BDE-77, BDE-128 and ^{13}C -BDE-209 were 84 \pm 22%, 122 \pm 25%
127 and 121 \pm 19%, respectively. The results of all analyses in 6 replicates of SRM 2585 (NIST,
128 Gaithersburg, MD, US) demonstrated both good repeatability and good agreement with the
129 certified values reported elsewhere (Van den Eede et al., 2012). However, compared with the
130 literature data it's clear that uncertainty also existed for the determination of BDE-209 and
131 BEH-TEBP because their concentrations in SRM 2585 detected from different researches were
132 not precisely consistent (Table SI-2).

133

134 3. Results and discussion

135 3.1 BFR concentrations and spatial distribution

136 Except for BDE-28, PBEB, BTBPE and DBDPE, all seven PBDEs, EH-TBB and BEH-TEBP
137 were commonly detected in all 40 RD samples (Table SI-3). A summary of the concentrations of
138 BFRs in RD samples from each location category is provided in Table 1. Concentrations of
139 \sum_6 PBDEs (excluding BDE-209) and EH-TBB varied from 3.2 to 15.5 ng g⁻¹ and from 0.7 to 19.1
140 ng g⁻¹, respectively. BEH-TEBP and BDE-209 concentrations ranged from 1.5 to 189 ng g⁻¹ and
141 from 5.7 to 261 ng g⁻¹. Concentrations of \sum_9 BFRs ranged from 17.0 to 458 ng g⁻¹, with a
142 geometric mean of 139 ng g⁻¹, at levels 1-3 orders of magnitude lower than in vehicle dust
143 reported elsewhere (Besis and Samara, 2012; Coelho et al., 2014). PBDE concentrations in RD
144 in this study are comparable with those in urban RD from Suzhou, Wuxi and Nantong in the
145 Yangtze River Delta, China (geometric mean concentration of \sum_8 PBDEs including BDE-209 was
146 169 ng g⁻¹) (Shi et al., 2014), but was much lower than that in urban RD from Beijing, China
147 (concentration of \sum_9 PBDEs including BDE-209 were 23700 ng g⁻¹ in a pooled sample) (Cao et
148 al., 2014), which indicates substantial variation between cities in China.

149 The mean concentrations of \sum_9 BFRs in RD from different sampling areas decreased in the
150 following sequence: traffic intersections > main roads > collector streets > bypasses > parks (Fig.
151 1), revealing the significant influence of traffic density on BFR abundance in RD. Moreover, for
152 all monitored BFRs, concentrations in RD from traffic intersections and streets exceeded
153 significantly those in parks. Because previous studies have identified high concentrations of
154 BFRs in air and dust samples inside vehicles (Besis and Samara, 2012), and demonstrated
155 vehicle exhaust to be an important PBDE emission source (Wang et al., 2010, 2011), it is
156 plausible that emissions from vehicles via ventilation or exhaust constitutes an important source
157 of BFRs in RD. Interestingly, while there were no significant differences in concentrations of
158 \sum_6 BDEs between trafficked locations and parks; concentrations of less volatile BFRs including

159 BDE-209 and BEH-TEBP at trafficked locations exceeded significantly those at parks (Fig. 1).
160 This suggests that the influence of vehicle emissions on BFRs in RD is greater for these less
161 volatile BFRs.

162 As RD is a mixture of soil, sand, and deposited particles, the mean organic content of RD in
163 this study was $9.9 \pm 2.7\%$. By comparison, organic content in indoor dust generally exceeds 50%
164 (Morawska and Salthammer, 2003; Cao et al., 2015). Thus, while dry mass concentrations of
165 BFRs were typically an order of magnitude lower than those in indoor settled dust from China
166 generally (Yu et al., 2012; Zhu et al., 2015); when normalized to organic content of RD, BFR
167 concentrations in RD were comparable to those in indoor dust (Fig. SI-1). Normalized mean
168 Σ_9 BFR concentrations were 2670, 1830, 1420, 1140 and 556 ng g^{-1} in RD from traffic
169 intersections, main roads, collector streets, bypasses and parks, respectively, which exceed BFR
170 concentrations in indoor dust from Germany (median: 74 ng g^{-1}) (Sjodin et al., 2008) and
171 Australia (median: 469 ng g^{-1}) (Toms et al., 2015).

172

173 *3.2 Component profiles and global comparison*

174 The relative contributions of individual BFRs to total BFR concentrations in RD are presented
175 in Fig. 2 and Fig. SI-2. BDE-209 accounted for $56.4 \pm 18.5\%$ (mean \pm standard deviation) of the
176 total BFR concentrations in all samples. The next most important contributors were BEH-TEBP
177 at $31.9 \pm 18.4\%$ Σ_9 BFRs, followed by BDE-183 ($3.0 \pm 4.6\%$) and BDE-99 ($2.2 \pm 1.3\%$). Other BFRs
178 were present only at low abundances.

179 Several reports exist of elevated concentrations of PBDEs in air and dust samples from
180 vehicles (Betts, 2008; Batterman et al., 2009; Abdallah and Harrad, 2010; Kalachova et al., 2012),
181 that exceed those reported in houses (Besis and Samara, 2012; Coelho et al., 2014), indicating

182 that vehicles are possible emission sources of PBDEs. In contrast, data on the presence of
183 NBFRs in vehicles are scarce and we are aware of only two such studies that have reported the
184 presence of DBDPE at much lower levels compared to PBDEs (Harrad et al., 2008; Kalachova et
185 al., 2012).

186 The spatial variation of BFRs in this study suggests that vehicle emissions constitute a
187 substantial source of BFRs in RD. The available global database on concentrations of BFRs in
188 vehicle and road dust is summarized in Fig. 3 and Fig. SI-3. While absolute concentrations
189 display international variation (UK>US>other EU countries), PBDE congener patterns are
190 similar in vehicle dust from different countries. Combined, this suggests that while the
191 commercial PBDE mixtures used in vehicles are universal, the amounts applied vary between
192 jurisdictions. Apparent dominance of BDE-209 (typically showing present proportion higher
193 than 90%) are consistent in RD from China and vehicle dust from abroad, indicating PBDE
194 application patterns might be similar in China with abroad. And only in some US vehicles,
195 penta-BDE congeners represented relatively higher proportion than other countries/regions,
196 representing higher application amount of Penta-BDE in US. Meanwhile, compared to vehicle
197 dust abroad, PBDEs in RD from China showed remarkable higher proportion of BDE-183,
198 possibly implicating Octa-BDE might be applied in China vehicle industry more widely than
199 abroad.

200 Similar to the former reported dominance of PBDEs in vehicle dust, this study verified the
201 dominance of PBDEs in RD, greater than other BFRs. Further, with BDE-209 as the dominant
202 congener, the PBDE congener profiles in this study are similar to previous results found for
203 urban RD (Cao et al., 2014; Shi et al., 2014) and road soils from e-waste (Luo et al., 2009) and
204 plastic waste (Tang et al., 2016) recycling region from China, probably due to more extensive

205 application of Deca-BDE than Penta- and Octa-BDE in China (Yu et al., 2016). Moreover, less
206 brominated BDEs are more volatile than BDE-209, which enhanced the dominance of BDE-209
207 in RD.

208 In contrast to previous reports of the presence of DBDPE in vehicle dust (Stuart et al., 2008;
209 Kalachova et al., 2012), DBDPE and BTBPE were rarely detected in RD in Xinxiang.
210 Nevertheless, this study firstly reported the contamination of EH-TBB and BEH-TEBP in RD,
211 suggesting that as vehicles containing PBDEs become obsolete, more attention should be paid to
212 the occurrence of NBFs in vehicle and road dust. It is demonstrated Deca-BDE and BEH-TEBP
213 might be the most important BFR components in vehicles. And this revealed that BFR
214 application patterns in vehicles were different from that indoors in China because DBDPE and
215 BTBPE have been detected in considerable levels in indoor dust recently (Cao et al., 2014; Yu et
216 al., 2016).

217

218 *3.3 Source appointment with diagnostic ratios*

219 As specific PBDE commercial formula shows distinctive congener pattern (La Guardia et al.,
220 2006; Li et al., 2015), a diagnostic ratio model is proposed and performed on concentration
221 distribution of the 7 PBDE congeners to analyze the possible sources of PBDEs. With similar
222 physical-chemical properties, two pairs of BDE congeners including BDE-100 and BDE-99,
223 BDE-154 and BDE-153 were employed as principle ratios to conduct source apportionment,
224 with the ratio of BDE-183 and BDE-209 as an auxiliary parameter. In this study, the geometric
225 mean ratio of BDE-100 to BDE-99 were 0.25, which is closer to that in the penta-BDE mixture
226 DE-71 (0.27) than Bromkal 70-5DE (0.17). The geometric mean ratio of BDE-154 to BDE-153
227 were 1.21, which is closer to that in the penta-BDE mixture DE-71 (0.83) than penta-BDE

228 mixture Bromkal 70-5DE (0.50) and octa-BDE mixture DE-79 (0.12). Thus it's concluded
229 Bromkal 70-5DE and DE-79 could not be the possible sources of penta- and octa-BDEs, and
230 BDE-183 can only origin from octa-BDE mixture Bromkal 79-8DE probably. The geometric
231 mean ratio of BDE-183 to BDE-209 was 0.03, which is essentially different from that in the
232 octa-BDE mixture Bromkal 79-8DE (0.25) and DE-79 (32.1), indicating BDE-209 can primarily
233 origin from Saytex 201E or Bromkal 82 DE. Consequently, comparison between the congeners
234 in RD and the PBDE pattern in commercial products suggested the commercial formulas
235 including DE-71, Bromkal 79-8DE, Saytex 201E and Bromkal 82 DE were the possible origin of
236 PBDEs in these RD samples. According to limited data, EH-TBB and BEH-TEBP were
237 produced as the replacements of Penta-BDE, possibly originating from the commercial mixture
238 Firemaster 550 (Stapleton et al., 2008; Covaci et al., 2011).

239 However, all these analysis is not deterministic because: firstly, BFRs were applied in various
240 materials where BFRs own different migration pathways; secondly, different BFR components
241 have different volatility and partition characteristics among environmental matrix, which result
242 in different environmental fates; thirdly, the different compounds may have undergone different
243 reductive debromination processes, from which their occurrence proportions may increase or
244 decrease in RD compared with the commercial products, especially for lower brominated BDEs;
245 fourthly, unknown mixtures which contain different relative compositions are likely to be
246 applied.

247

248 *3.4 Exposure and risk assessment*

249 Ingestion may be important contribution of human exposure to BFRs in settled dust. Daily
250 Intake (DI, $\text{mg kg}^{-1} \text{d}^{-1}$), hazard index (non-cancer) and cancer risk were estimated using the
251 following equations (Li et al., 2015):

$$DI = \frac{C \times IR \times ET \times EF \times ED}{BW \times AT \times 10^9}$$

$$\text{Hazard index} = \frac{DI}{RfD}$$

$$\text{Cancer risk} = DI \times CSF$$

252 where C is the concentration of Σ BFRs in RD (ng g^{-1}). IR is the intake rate of dust (Harrad et
 253 al., 2006; Hazrati et al., 2010). For children, adults, and professional street sweepers high-end IR
 254 were assumed to be 200 mg d^{-1} , 50 mg d^{-1} and 500 mg d^{-1} (10 times of normal adults),
 255 respectively. Due to a lack of data on human absorption efficiency of PBDEs in dust, a 100%
 256 absorption efficiency was used, representing an upper limit of the uptake rates. Exposure time
 257 (ET) is 3 hours ($1/8 \text{ d}$) for children and adults, 12 hours ($1/2 \text{ d}$, 9 h for work and 3 h for other
 258 activities) for professional street sweepers, exposure frequency (EF) is $365 \text{ days year}^{-1}$, exposure
 259 duration (ED) is 6 years for children and 30 years for adults, body weight (BW) is 15 kg for
 260 children and 70 kg for adults and professional street sweepers, averaging time (AT) is 2,190 days
 261 (6 years) for children and 10,950 days (30 years) for adults. The reference dose (RfD) varies with
 262 the types of congeners. Specifically, the RfD values promulgated by the USEPA are 0.002 mg
 263 $\text{kg}^{-1} \text{ d}^{-1}$ for penta-BDEs, $0.003 \text{ mg kg}^{-1} \text{ d}^{-1}$ for octa-BDEs, and $0.007 \text{ mg kg}^{-1} \text{ d}^{-1}$ for BDE-209
 264 (for EH-TBB and BEH-TEBP, no data are available) (Krol et al., 2012). Here, the most
 265 conservative RfD ($0.002 \text{ mg kg}^{-1} \text{ d}^{-1}$) was employed in the calculation of the aggregate exposure
 266 risk from Σ BFRs. Cancer slope factor (CSF) was assumed to be that of BDE-209 ($7 \times 10^{-4} \text{ mg}$
 267 day kg^{-1}) (Ni et al., 2012).

269 With the BFR data in this study, DI, hazard index and cancer risk were derived in Table 2.
 270 When the DI of BFRs ranged from 28.3 to $764 \text{ pg kg}^{-1} \text{ d}^{-1}$, from 1.4 to $38.2 \text{ pg kg}^{-1} \text{ d}^{-1}$ and from
 271 56.5 to $1530 \text{ pg kg}^{-1} \text{ d}^{-1}$ for children, adults, and professional street sweepers, the hazard index
 272 increased from 1.4×10^{-5} to 3.8×10^{-4} , from 7.1×10^{-7} to 1.9×10^{-5} and from 2.8×10^{-5} to 7.6×10^{-4} .

273 While the values for cancer risk in the range of 2.0×10^{-11} to 5.3×10^{-10} , 9.9×10^{-13} to 2.7×10^{-11} and
274 4.0×10^{-11} to 1.1×10^{-9} , indicated lower risk for both non-cancer (hazard index <1) and cancer (the
275 threshold level 10^{-6}). Conclusively, risk derived by BFR exposure through RD is negligible,
276 however, it is obvious that the exposure level and cancer risk for professional street sweepers
277 were approximately twice as high as the level found for children and one order of magnitude
278 higher than that for adults.

279

280 *3.5 Contamination load and implications for BFR fate*

281 According to the Chinese Standard for Quality and Assessment of City Road Sweeping and
282 Cleaning (CJJ/T126-2008), the deposition rate of urban road dust in China is $100 \text{ g m}^{-2} \cdot \text{d}^{-1}$ (Zhao
283 et al., 2014) of which 10% (w/w) is $<25 \text{ }\mu\text{m}$ (Zhao et al., 2010; Wang and Feng, 2011). The
284 mechanical cleaning area in Xinxiang City is about $7.33 \times 10^6 \text{ m}^2$, and thus the total amount of
285 RD with particle size $<25 \text{ }\mu\text{m}$ is approximately 73.3 tons d^{-1} . Based on the measured BFR
286 concentrations, the estimated mass of BFRs associated with RD in Xinxiang City alone ranges
287 between 0.09 to 0.4, from 0.2 to 7.0, from 0.02 to 0.5, from 0.04 to 5.1, from 0.5 to 12.3 kg
288 year⁻¹ for $\sum 6\text{BDEs}$ (excluding BDE-209), BDE-209, EH-TBB, BEH-TEBP and $\sum 9\text{BFRs}$,
289 respectively. Further, the vehicle amount of China was 162 million in 2015 and Xinxiang owned
290 0.4 million, from which it is deduced mass of BFRs associated with RD in China may be up to
291 162, 2840, 203, 2070 and 4980 kg year⁻¹ for $\sum 6\text{BDEs}$ (excluding BDE-209), BDE-209, EH-TBB,
292 BEH-TEBP and $\sum 9\text{BFRs}$, respectively. RD is thus an important sink of BFRs and also an
293 important source of BFRs to the environment. Large proportion of RD is possible to enter into
294 waste water treatment plants, to go through long range atmospheric transmission, or to be treated
295 via incineration and landfill, which will contribute to the formation of atmospheric BFRs or

296 PBDD/F (Zhang et al., 2016). Because Xinxiang is only a middle-scale city in China, it is
297 deduced that with much higher traffic density in metropolises, BFR contaminations in RD would
298 be much higher. As a result, from a national or global perspective, considering the tremendous
299 urban areas and dust load on roads, RD should be a significant source of BFRs in the
300 environment. Systematic monitoring and risk assessment programs should be instituted in future.

| | BEH-TEBP | 3.3 | 3.0 | 1.3 | 38.4% | 1.5 | 4.4 |
| | BFRs | 70.2 | 50.4 | 56.2 | 80.0% | 17.0 | 127 |

454 LOI: loss of ignition, which reflects the organic content of dust samples.

455

456 **Table 2.** Estimated DI, hazard index and cancer risk of BFRs for the three types of populations

| | | Min | Mean | Geomean | Median | Max |
|--|-----------------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|
| DI (pg kg ⁻¹ d ⁻¹) | children | 28.3 | 273 | 231 | 245 | 764 |
| | adults | 1.4 | 13.6 | 11.6 | 12.2 | 38.2 |
| | street sweepers | 56.5 | 545 | 463 | 490 | 1530 |
| Hazard index | children | 1.4×10 ⁻⁵ | 1.4×10 ⁻⁴ | 1.2×10 ⁻⁴ | 1.2×10 ⁻⁴ | 3.8×10 ⁻⁴ |
| | adults | 7.1×10 ⁻⁷ | 6.8×10 ⁻⁶ | 5.8×10 ⁻⁶ | 6.1×10 ⁻⁶ | 1.9×10 ⁻⁵ |
| | street sweepers | 2.8×10 ⁻⁵ | 2.7×10 ⁻⁴ | 2.3×10 ⁻⁴ | 2.5×10 ⁻⁴ | 7.6×10 ⁻⁴ |
| Cancer risk | children | 2.0×10 ⁻¹¹ | 1.9×10 ⁻¹⁰ | 1.6×10 ⁻¹⁰ | 1.7×10 ⁻¹⁰ | 5.3×10 ⁻¹⁰ |
| | adults | 9.9×10 ⁻¹³ | 9.5×10 ⁻¹² | 8.1×10 ⁻¹² | 8.6×10 ⁻¹² | 2.7×10 ⁻¹¹ |
| | street sweepers | 4.0×10 ⁻¹¹ | 3.8×10 ⁻¹⁰ | 3.2×10 ⁻¹⁰ | 3.4×10 ⁻¹⁰ | 1.1×10 ⁻⁹ |

488

BDE-209 and BEH-TEBP dominated in the road dust samples.

BFR abundance in road dust declined as traffic density increased.

Traffic was deduced to be an important outdoor emission source of BFRs.

BFRs associated with road dust in China were estimated up to be 4980 kg year⁻¹.
