Investigation of Carbene / Allen Reaction Pathways

Director: Edward E. Waal

A kinetic study of the singlet state cycloheptatrienylidene (1) -cycloheptatetraene (9) system was undertaken. The sodium salt of tropone tosylhydrazone was heated in the presence of n-butyl alcohol and 1,3-diphenylisobenzofuran. Two isomers of the DIBF product (14) were discovered, separated by chromatographic methods, and their structures elucidated by 2-D COSY ${ }^{1} \mathrm{H}$ NMR and computer modeling programs. The presence of bitropyl (24) was discovered in the course of this work. The formation of several DIBF products, the use of a heterogeneous mixture, and the possible presence of a third intermediate made a kinetic conclusion impossible.

## ACKNOWLEDGMENTS

I would like to thank the following people for their help, support, and mentorship during my tenure in graduate school here at UM:

Dr. Ed Waali for his patience, guidance, friendship, and entertaining stories (both chemistry-related and non-related),

Dr. Chuck Thompson for agreeing to be on my committee and for his valuable assistance with my thesis,

Dr. Todd Cochran for taking time out of his hectic schedule at the Pharmacy school to be on my committee,

Gayle Zachariasen for finding funds for me to continue my studies (not an easy task given the chemistry school's never-ending, bleak financial state), and for having some good stories to share,

Bonnie Gatewood also for some good advice, some good stories, and a lot of assistance, and

Mom for helping me through school for these many long years by emotional and financial assistance.

## INTRODUCTION

Reactive intermediates are integral parts of chemical reactions which do not proceed by single-step concerted mechanisms. By studying the kinetics of reactions, chemists may gain knowledge of reactive intermediates and mechanistic pathways.

This work studied two potential reactive intermediates, a carbene and an allene. It is the focus of this work to obtain kinetic data which might indicate whether a particular reaction occurs by way of one or both of these reactive intermediates.

### 1.1. Carbene Chemistry

1.1.1. Generation of Carbenes

Carbenes are highly reactive intermediates which contain divalent carbon atoms and two non-bonding electrons. ${ }^{1}$ Two ways of generating carbenes are via $\alpha$-elimination (Equations 1.2; Section 1.1.1.1.) and decomposition of certain $\pi$-systems (Equations 3,4,5; Section 1.1.1.2.).
1.1.1.1. $\alpha$-Elimination: net loss of HCl from the same carbon results in the production of the carbene.

A classical example of $\alpha$-elimination to generate carbenes is the treatment of chloroform with a hydroxide ion to yield dichlorocarbene (Equation 2). ${ }^{1}$

### 1.1.1.2. Decomposition of Compounds Containing Certain $\pi$-Systems.

## General Reaction:

The two most important ways of generating the carbene via a decomposition pathway are exemplified in Equations 4 and 5.
a. decomposition of diazomethanes (Equation 4)

b. photolysis of ketenes

### 1.1.2. Two Electronic States of Carbenes

Two predominant electronic states are possible for carbenes, including the singlet state carbene (Figure 1-1) in which the electrons are paired with opposite spins in the same orbital $\left(\sim s p^{2}\right)$, leaving an empty $p$ orbital, and the triplet state carbene (Figure 1-2) where the unpaired electrons (having the same spin) occupy two different orbitals. Triplet carbenes, in Figure 1-2, exhibit approximately $s p$ hybridization character. ${ }^{2}$

Figure 1-1
Singlet State Carbene

Figure 1-2
Triplet State Carbene

Normally, singlet state carbenes are less stable than their triplet counterparts. This is due to electron-electron repulsion that is relieved in the triplet. Hund's Rule dictates that the ground state of the lowest electronic configuration of an atom will be the one having the greatest multiplicity. ${ }^{3}$

### 1.1.3. Reactions of Carbenes

Two types of carbene reactions germane to the current study are the addition reaction (Section 1.1.3.1.) and the insertion reaction. ${ }^{4}$

### 1.1.3.1. The Addition Reaction of Carbenes

One of the best-studied reactions of carbene intermediates is their addition to alkenes generating cyclopropanes. The addition of singlet state carbene intermediates to alkenes occur stereospecifically (Equation 6). A singlet state carbene adding to a cis alkene will generate the cis cyclopropane. The triplet state carbene intermediates add nonstereospecifically to alkenes to generate cyclopropanes (Equation 7). This lack of
stereospecificity is determined just before intersystem crossing (ISC). Initially, the triplet state carbene adds to the double bond. Once the intermediate is formed, rotation about the single bonds of the carbons becomes possible. The orientation of the carbon atoms (in relation to one another before ISC) will determine the stereochemistry of the products. Once ISC occurs, the singlet state electrons will couple and form both cis and trans products. In the case of the singlet state carbene, no rotation about the bonds is possible because of the rigidity of the double bond. This is the reason for the singlet state's stereospecificity.

## Singlet Mechanism (Equation 6)

## Triplet Mechanism (Equation 7)

$+$

1.1.3.2. Carbene Addition Reactions via Carbenoid Intermediates

Addition reactions of carbenes to alkenes are important methods for the synthesis of many types of cyclopropanes. Singlet state carbenes are very reactive intermediates and sometimes require transition metals to make them less reactive (more selective) in practical syntheses. When carbenes are complexed to transition metals, the intermediates are called carbenoids. Select synthetic examples that utilize carbenoid intermediates are listed in Equations 8-14.
A. Cyclopropanes from Methylene Transfer

Equations $8^{5}, 9^{6}$, and $10^{7}$ all proceed via the Simmons-Smith zinc-copper couple reaction. ${ }^{8}$ In Equations 8-10, an iodomethylzinc iodide intermediate forms. The stereochemistry in Equation 9 and $\mathbf{1 0}$ results because the zinc present in the intermediate first couples with the hydroxyl group. The intermediate's methylene group then adds across the double bond cis to the hydroxyl group.
B. Catalytic Cyclopropanation by Diazo Compounds and Metal Salts (carbene formation via loss of dinitrogen).

### 1.2. Allene Chemistry

### 1.2.1. Hybridization of Simple Allenes

Allenes, also known as cumulenes, are dienes which have two olefinic groups sharing a central carbon atom. The central carbon atom is $s p$ hybridized, while the outer carbon atoms are $s p^{2}$ hybridized (Figure 1-3).

Figure 1-3. Allene Stereochemistry

Open chain allenes show the orbitals of the $s p^{2}$ carbons to be orthogonal to each other, as can be observed by viewing the positions of the hydrogen substituents in

Figure 1-3. This orthogonality is a result of the $p$ orbitals of the $s p$ hybridized carbon overlapping with each of the $p$ orbitals of the $s p^{2}$ carbons (Figure 1-4).

Figure 1-4. Allene Orbitals

### 1.2.2. Generation of Allenes

A common method of generating allenes is by dehalogenation of dihaloalkenes (Equation 15; allene elimination products and vinyl halide reduction products) ${ }^{13}$ and by dehydrohalogenation of haloalkenes (Equation 16). ${ }^{14}$ In Equation 16, 1-chlorocycloheptene reacts with the strong base to go to the allene intermediate. In the absence of other reagents, this intermediate then dimerizes to the cyclobutane product.

### 1.2.3. Stability of Cyclic Allene Systems

In a cyclic allene system, two major factors determine the stability or instability of that system: 1) size of the ring, and 2) presence of additional unsaturation and other functional groups. For example, 1,2-cyclononadiene (25) can be isolated at room temperature (Figure 1-5). The more unsaturated 1,2,4,6,8-cyclononapentaene (26) and the smaller-ringed 1,2-cyclohexadiene (27) are much less stable and not isolable under the same conditions. Inherently, cyclic allenes containing nine carbons or less are unlikely to be isolable under ordinary laboratory conditions. ${ }^{15,16}$

Figure 1-5. Select Cyclic Allene Systems

### 1.2.4. Allene Reactions

Allenes can dimerize to yield cyclobutanes. They can also undergo Diels-Alder cycloadditions with 1,3-dienes to yield cycloaddition products (Equations 17,18,19). ${ }^{17}$

### 1.3. Prelude to the Current Study

1.3.1. Stabilization of a Singlet State Carbene

A way of stabilizing a singlet state carbene, possibly making it the ground state, was hypothesized by Jones and Ennis. ${ }^{18}$ They proposed that by incorporating the empty $p$ orbital of the singlet state carbene (as in Figure 1-1) into a carbocyclic, completely
conjugated, aromatic system at least two effects might be observed in the properties of the singlet state carbene (Figure 1-6). First, the electrophilic nature of the vacant orbital might be diminished. This would result in the $\pi$ electron density from the aromatic system partially filling the vacant $p$ orbital. Second, the nucleophilicity of the non-bonded pair of electrons might be enhanced. As a result, the singlet state would decrease in energy relative to its triplet state, and the singlet state might approach ground state energy. ${ }^{19,20}$

Figure 1-6. Cycloheptatrienylidene

Jones and co-workers conducted experiments in which the sodium salt of tropone tosylhydrazone (2) was subjected to a thermolysis in diglyme, and a photolysis in tetrahydrofuran (THF) (Scheme 1). Both reactions yielded heptafulvalene (3) apparently via the cycloheptatrienylidene intermediate (1). It was unusual that the formal dimer 3 was apparently generated by $\mathbf{1}$, rather than carbene 1 reacting with the solvents present in the reaction. The significance of this will be more closely examined shortly.

### 1.3.2. Evidence Supporting the Nucleophilicity of Carbene $\mathbf{1}$

If cycloheptatrienylidene (1) was electrophilic, like ordinary carbenes, it would
react with an electron-rich double bond. Normal, singlet state carbenes (such as Figure 1-1) have been observed to react with electron-rich olefins to yield cyclopropanes. ${ }^{21}$ However, these normal singlet state carbenes do not normally react with electron-deficient olefins. When 2 was decomposed in the presence of cyclohexene, the addition product (4) was not observed (Scheme 1). In order to obtain evidence indicating the nucleophilic nature of $\mathbf{1}$, Jones then carried out a photolysis of $\mathbf{2}$ in the presence of the electron-deficient double bond in fumaronitrile and maleonitrile. This photolysis yielded cyclopropanes (5) stereospecifically. These experiments indicated that carbene intermediate $\mathbf{1}$ had nucleophilic character.

Scheme 1. Reaction of Carbenes with Alkenes

The nucleophilicity of this singlet state carbene was supported by Hammett studies performed by Christensen, Waali, and Jones in which $\mathbf{1}$ was generated in the presence of substituted styrenes $\left(\mathrm{X}-\mathrm{Ph}-\mathrm{CH}=\mathrm{CH}_{2}\right)\left(\right.$ Equation 20). ${ }^{22}$ Their results showed $\rho=+1.05$. (The positive $\rho$ value indicates the nature of the intermediate is nucleophilic.)

1

(20)

7

$$
\rho=+1.05
$$

The lack of reaction of $\mathbf{1}$ with cyclohexene, its reaction with fumaro- and maleonitrile, and the Hammett study performed on 1 were good evidence that the intermediate is indeed nucleophilic. These results were consistent with a ground state singlet carbene. ${ }^{23}$

At this point, this reaction mechanism in the decomposition of the sodium salt of tropone tosylhydrazone (2) was thought to proceed strictly through a singlet state carbene intermediate.

### 1.3.3. Allene Intermediate Proposed

Jones first reported the major product heptafulvalene (3) upon addition of $\mathbf{2}$ to
refluxing diglyme. In the suggested mechanism, the salt was thought to convert to the singlet state carbene $\mathbf{1}$ which in turn dimerized to 3. Shortly after this, Karl Untch discovered that the dehydrohalogenation of 1-, 2-, and 3-chlorocycloheptatrienes (8) with potassium $t$-butoxide also yielded $\mathbf{3}$ (Scheme 2). ${ }^{24}$ In addition, Untch's proposed allene intermediate (9) showed the same properties as the one resulting from the decomposition of the sodium salt (2). Untch's work introduced the possibility that the allene (9) might be involved. As such, can all previous chemistry ascribed to carbene intermediate 1 (Section 1.3.2.) be explained by allene intermediate 9 ?

Scheme 2. Two Possible Intermediates

### 1.3.4. Different Precursors, Same Products

Following the Untch study, it was found that reaction of carbene intermediate 1
with styrene initially yields the spirononatriene adduct 6 (Scheme 3; paths a,f). Upon heating, 6 rearranges to the more stable 10 (path j). ${ }^{25}$ The cyclobutane $\mathbf{1 0}$ is also the expected product for the $[2+2]$ cycloaddition of the allene 9 with styrene (path i). Therefore, it becomes apparent that the intermediate reacting with olefins to yield cyclopropanes may not be represented solely by the allene structure.

So the question arises: From which intermediate do the spirocyclopropane (6) and heptafulvalene (3) result? Reaction Scheme $\mathbf{3}$ summarizes the possibilities considered up to this point.

A carbene reaction followed by a rearrangement might give an allene-like product. Conversely, an allene reaction followed by a rearrangement might give a carbene-like product. Reactions of carbenes with alkenes inherently yield cyclopropanes (such as 6) in which the carbene carbon forms two separate $\sigma$-bonds with two other carbon atoms. Reactions of allenes with alkenes tend to yield [2+2] cycloaddition products, such as cyclobutane 10. Therefore, it is difficult at this point to determine which intermediate exists in the mechanism, based solely on structural analysis of the products.

Scheme 3. Summary of Possible Mechanistic Pathways

10

### 1.3.5. Possible Carbene/Allene Equilibrium

Thus far, products $\mathbf{3}$ or $\mathbf{6}$ have been seen to result from two entirely different precursors ( $\mathbf{2}$ and $\mathbf{8}$ ). Two different intermediates ( $\mathbf{1}$ and 9 ) have been proposed in the mechanism of each reaction. The results of the previous sections were inconclusive as to
which intermediate was present. Evidence was then gathered to either confirm or refute the possibility that both cycloheptatriene (1) and allene 9 were present and in equilibrium with one another.

### 1.3.5.1. Equilibrium Studies

Jones and co-workers performed an INDO molecular orbital calculations on cycloheptatrienylidene (1) and allene 9 to determine their conformations. ${ }^{26}$ Their results showed $\mathbf{1}$ to be planar (or nearly so) and 9 to have a twisted conformation (Figure 1-7). In addition, allene 9 can be seen to have two possible enantiomeric structures. This study is incorporated in the following MNDO study.

1

9a

9b

Figure 1-7. Carbene 1 and Two Isomers of 9

MNDO molecular orbital calculations performed by Waali showed the singlet state allene 9 to be more stable than the singlet state carbene (1) by $23 \mathrm{kcal} / \mathrm{mole}$ (Figure 1-8). ${ }^{27}$ His calculations also showed the triplet state carbene to be more stable than singlet allene 9. What is more important, the calculations suggested the carbene to be a transition state for racemization of $9 \mathbf{a}$ and its enantiomer $\mathbf{9 b}$.

Figure 1-8: Energy Diagram Indicating a Carbene Transition State

Calculations performed by Schaeffer and co-workers contradicted these results by showing cycloheptatrienylidene (1) to be an intermediate. ${ }^{28}$ Their calculations showed singlet state carbene $\mathbf{1}$ to be more stable than the triplet state carbene (thus suggesting a ground state singlet carbene responsible for reaction).

McMahon and Chapman performed an Electron Spin Resonance (ESR) study. 29 They observed the triplet state carbene $\mathbf{1 2}$ in the decomposition of lithium salt of tropone tosylhydrazone and found no evidence for the isomerization of it to the allene 9 or any other singlet state carbene intermediate. This indicated that triplet 12 was the ground state (Scheme 4). However, an interconversion between the singlet state carbene and the allene remained possible.

Wentrup and co-workers reproduced McMahon and Chapman's results, observing the triplet state carbene $\mathbf{1 2}$ by Electronic Spin Resonance (ESR) spectroscopy and suggesting a triplet ground state carbene. ${ }^{30}$

At this point, evidence strongly indicated $\mathbf{1}$ and 9 were not in equilibrium.

Scheme 4: Carbene/Allene Isomerization

$9 a$

### 1.3.6. Definite Allene Presence

### 1.3.6.1. Optical Activity Study

Harris and Jones reported definitive evidence that the allene intermediate must be present in the reactions. ${ }^{31}$ The structure of allene 9 had been calculated to be non-planar
and chiral, and carbene $\mathbf{1}$ was calculated to be planar and achiral. ${ }^{26}$ If these calculations were correct, only allene 9 could generate an optically active adduct. The planar carbene was incapable of generating optically active adducts. Harris and Jones created a THF solution of a mixture of 1-, 2-, and 3-bromocycloheptatrienes 16 and allowed it to react with the potassium salt of ( + )-menthol (optically active), in the presence of DIBF, in hopes of generating an excess of one of the enantiomeric adducts (Scheme 5). The isolated adducts were indeed found to be optically active, suggesting the allene intermediate was definitely present.

Scheme 5. Optical Activity Study

This was not conclusive evidence of an allene presence, however, because the presence of menthol can create a chiral environment during cycloaddition.

### 1.3.6.2. Isotope Study

In order to obtain unequivocal evidence of the presence of an allene intermediate. Harris and Jones then designed a reaction taking advantage of the primary deuterium isotope effect. Their goal this time was to generate an enantiomeric excess of the intermediate. They prepared a mixture of optically active 1-bromo-7-deuteriocycloheptatriene (deuterated 16, stereochemistry is assumed) by reducing 7,7-dibromocycloheptatriene with $\mathrm{LiAlD}_{3} \cdot(-)$-quinine (Scheme 6). Following allene formation, an excess of one enantiomer over the other should result since the elimination of HBr from $\mathbf{1 6}$ (path a) will yield one enantiomer, and the elimination of DBr would yield the other (path b ). This was indeed the case. Reaction of $\mathbf{1 6}$ with 1,3-diphenyl-isobenzofuran (DIBF) in potassium $t$ butoxide and tetrahydrofuran (THF) yielded optically active $\mathbf{1 4}$ (optical activity was determined qualitatively). Again, the carbene could be disregarded as the possible intermediate because of its planar, achiral structure.

Evidence was now strongly in favor of the allene (9) as being the sole intermediate.

Scheme 6. Isotope Study Results

14
opt. act.

### 1.3.7. Carbene Makes a Come-Back

Kirmse and Sluma reported evidence that carbene 1 may be present in these reactions after all. They observed that the photolysis of sodium salt of tropone tosylhydrazone (2) in the presence deuterated ethanol yielded the deuterated tropyl ether 18 (Scheme 7)..$^{32}$ They suggested that the carbene intermediate proceeded through the tropylium ion and trapped the deuterated alcohols to yield 18. If allene 9 was present in these reactions, vinyl ethers should have also resulted because available evidence indicated vinyl ethers resulted from the reaction of cyclic allenes with alcohols (Scheme 8). It was therefore suggested by Kirmse that "the nucleophilic of the carbene is trapped from an unfavorable equilibrium with the allene by protonation."

Scheme 7. Carbene Intermediate Yielding Tropyl Ethers

18
deuterated tropyl ethers

Scheme 8. Allene Intermediate Yielding Viny Ethers

This carbene trapping was questioned by Waali. ${ }^{33}$ He suggested that "the nature of the HOMO of $\mathbf{9}$ is consistent with the observed chemistry" (protonation to yield $\mathbf{1 4}$; Scheme 5). Waali concluded that all of the chemistry previously attributed to the singlet state of 1 should instead be explained in terms of the nonplanar allene 9 .

### 1.3.8. Summary of the Evidence

The preceding sections (Sections 1.3.1. through 1.3.7.) described how the literature oscillated in its indications as to whether a carbene intermediate or an allene intermediate were present in the decomposition of sodium salt of tropone tosylhydrazone (2) and the dehydrohalogenation of 2-chlorocycloheptatriene (8) (Scheme 1; Section 1.3.2.). First, only a carbene intermediate (cycloheptatrienylidene $\mathbf{1}$ ) was considered (Section 1.3.2.). An allene intermediate was then proposed (Section 1.3.3.). Next, evidence was gathered under the suspicion that both of these intermediates were present and in equilibrium with one another (Section 1.3.5.). "Definitive evidence" of the presence of allene intermediate $\mathbf{9}$ in these reactions was then reported (Section 1.3.6.).

Now with this last interpretation from Kirmse and Sluma (Section 1.3.7.), carbene 1 again becomes a possible intermediate in these reactions. More evidence must be obtained to better determine through which intermediate system these reactions proceed.

A kinetic study is needed in order to determine whether these reactions proceed by way of a single intermediate or by two intermediates.

### 1.4. Objectives

A kinetic study was initiated to reveal the preferred pathway for the tropone tosylhydrazone reaction - by way of one intermediate or two intermediates.

### 1.4.1. Synthesis of Expected Products

The sodium salt of tropone tosylhydrazone (2) was decomposed by thermolysis in the presence of $n$-butyl alcohol. An alcohol was used because of Kirmse and Sluma's interpretation that singlet $\mathbf{1}$ reacts with alcohols to give tropyl ethers. If cycloheptatrienylidene (1) was an intermediate in this reaction, it would trap the alcohol to yield the butyl tropyl ether product 20 (Figure 1-9). The ideal alcohol must have a relatively high boiling point since the thermolysis reaction occurs at $100^{\circ} \mathrm{C}$. It is for this reason $n$-butyl alcohol was selected for this study (other primary alcohols with high boiling points may also have been used).

The sodium salt was then decomposed in the presence of 1,3-diphenylisobenzofuran (DIBF). This reaction has a purported allene intermediate mechanism (Section 1.3.6.), and yields DIBF product 14 (Figure 1-9).

20

14

Figure 1-9. Butyl Ether Product 20 and DIBF Product 14

After ${ }^{1} H$ NMR of the products in these first two thermolysis reactions confirmed the presence of the expected products, the kinetics reactions were initiated.

### 1.4.2. Kinetics Reactions

The sodium salt of tropone tosylhydrazone (2) was decomposed in the presence of varying concentrations of both the $n$-butyl alcohol and the DIBF. ${ }^{1} \mathrm{H}$ NMR spectra of the resultant reaction mixture was elucidated and the peaks representing products $\mathbf{2 0}$ and $\mathbf{1 4}$ were identified. Integration of these peaks yielded the ratio of the butyl ether product $\mathbf{2 0}$ to the DIBF product (14) (the significance of this will be examined shortly).

### 1.4.3. Intermediate Reaction Mechanisms

These kinetics reactions proceeded by way of one or two intermediates. The proposed single intermediate and two intermediate reaction mechanisms are depicted in Scheme 9 and Scheme 10, respectively. ${ }^{34}$

Scheme 9. Proposed Single Intermediate Mechanism

Scheme 10. Proposed Two Intermediate Mechanism

$[\mathbf{2 0}] /[\mathbf{1 4}]=\left(\mathrm{k}_{-3} \mathrm{k}_{4}[\mathrm{BuOH}] / \mathrm{k}_{2} \mathrm{k}_{3}[\mathrm{DIBF}]\right)+\left(\mathrm{k}_{4}[\mathrm{BuOH}] / \mathrm{k}_{3}\right)$
(Derivation in Appendix I)

### 1.4.4. The Role of Kinetics

After setting up the two possible intermediate mechanisms of the kinetics reactions, the steady state assumption theory of kinetics was employed to determine concentration ratios of butyl ether product 20 and DIBF product 14 (Appendix I). The calculated concentration ratios of the single intermediate mechanism (Equation 22) and the two intermediate mechanism (Equation 23) are shown below their respective schemes (Schemes 9 and 10 , respectively).

The kinetics equations could now be put into "equation of a line" format $(y=m x+b)$ to create expected graphs representing the two reaction mechanisms (Figure 1-10).

## Single Intermediate Mechanism:

$$
\begin{align*}
{[\mathbf{2 0}] /[\mathbf{1 4}] } & =\left(\mathrm{k}_{1}[\mathrm{BuOH}] / \mathrm{k}_{2}\right)(1 /[\mathrm{DIBF}])  \tag{22}\\
\mathbf{y} & =\mathbf{m} \quad \mathbf{x}+\mathbf{b}
\end{align*}
$$

Two Intermediate Mechanism:

$$
\begin{array}{cccc}
{[\mathbf{2 0}] /[\mathbf{1 4}]} & = & \left(\mathrm{k}_{-3} \mathrm{k}_{4}[\mathrm{BuOH}] / \mathrm{k}_{2} \mathrm{k}_{3}\right)(1 /[\mathrm{DIBF}]) & +\left(\mathrm{k}_{4}[\mathrm{BuOH}] / \mathrm{k}_{3}\right)  \tag{23}\\
\mathbf{y} & =\mathbf{x} & \mathbf{x} & \mathbf{b}
\end{array}
$$

Figure 1-10. Kinetics Equations in Equation of a Line Format

By varying the concentrations of the $n$-butyl alcohol and the DIBF, and by measuring the concentration ratio between the products $([20] /[14])$, data points were then placed on graphs.

In the case of the single intermediate mechanism, no $y$-intercept (b) should be observed (Equation 22). The expected graph would appear as in Figure 1-11, where all lines have a $y$-intercept of zero. (Slopes are arbitrary in this graph.)

## $[\mathrm{BuOH}]{ }_{\mathrm{a}}$

$[\mathrm{BuOH}]_{b}$

## [20]/[14]

$[\mathrm{BuOH}]{ }_{c}$

0
0

1/[DIBF]

Figure 1-11. Plot of a Single Intermediate Mechanism (Scheme 9)

In the case of a two-intermediate mechanism, all $y$-intercepts should be non-zero and nonequivalent to one another. The expected graph would appear as in Figure 1-12.

Figure 1-12. Plot of a Two Intermediate Mechanism (Scheme 10)

### 1.5. Preliminary Results of Zepp

Preliminary results of a kinetic study performed by Zepp are shown in Table 1, along with the corresponding graph of his data in Figure 1-13. ${ }^{34}$ This data indicated the kinetics reaction proceeded by way of a two-intermediate mechanism. The preliminary results were obtained on an NMR spectrometer that was much less sensitive than the one available currently. Since the results of this kinetic study depended heavily upon spectral identification of the expected products, it became necessary to further the kinetic study in order to gain unequivocal evidence of the presence of a two-intermediate system using a much more sensitive, more reliable spectrometer.

Table 1. Data of Zepp (observing one DIBF product)

|  | $[\mathrm{BuOH}]$ |  |  |
| :--- | :--- | :--- | :--- |
|  |  |  |  |
| $\underline{3.01 \mathrm{M}}$ | $\underline{4.01} \mathrm{M}$ | $\underline{4.61} \mathrm{M}$ | $\underline{\mathbf{1 / [ D I B F}]}$ |
| 0.38 | 0.69 | 0.95 | 7.36 |
| 0.25 | 0.49 | 0.72 | 4.63 |
| 0.43 | 0.75 | 1.11 | 8.42 |
| 0.35 | 0.55 | 0.87 | 5.70 |
| 0.28 | 0.44 | 0.58 | 3.78 |

Figure 1-13. Preliminary Results of Zepp ${ }^{34}$

The graph of Zepp's preliminary results was consistent with that of a two-intermediate reaction mechanism. ${ }^{34}$ The current study was performed in order to support or contradict the suspicion that this reaction did indeed proceed by way of a two-intermediate mechanism.

## 2. Results and Discussion

### 2.1. Synthesis of the Sodium Salt of Tropone Tosylhydrazone (2)

The synthetic route to the sodium salt $\mathbf{2}$ used in this study is shown in Scheme 11. 18,38

Scheme 11. Synthesis of Sodium Salt of Tropone Tosylhydrazone (2)

2

Once 2 was synthesized, the next step required the synthesis of the two expected products in this kinetic study, the butyl ether product 20 and the DIBF product 14.

### 2.2. Synthesis of the $\boldsymbol{n}$-Butyl Tropyl Ether (20)

One of the expected products synthesized is the butyl ether product 20. In order to confirm the reaction mechanisms, this product was prepared using two methods.

Method 1: Generation of $\mathbf{2 0}$ from sodium salt of tropone tosylhydrazone ( $\mathbf{2} \mathbf{)}^{32}$

This sample was then purified by column chromatography and thin-layer chromatography (TLC). In order to confirm the chemical shifts obtained by Method I, $\mathbf{2 0}$ was then synthesized by another method known to yield tropyl ethers (Equation 25). The chemical shift of each proton in this product was determined by 1-D and 2-D COSY NMR (Figure 2-1).

Figure 2-1. COSY of Butyl Ether Product 20

Method 2: Generation of 20 from tropylium tetrafluoroborate (26)

The spectra of both butyl ether products, generated from different precursors, were identical (Figure 2-3).

Figure 2-2. Butyl Ether Product 20

The proton chemical shifts of $\mathbf{2 0}$ are listed in Table 2.

### 2.3. Bitropyl Formation

Analysis of the 1-D spectrum of the butyl ether product 20 produced from 2 (Equation 24) indicated the presence of a by-product. This by-product was theorized to be bitropyl. Bitropyl (24) was synthesized through an alternative, known method (Figure 2-4). ${ }^{35}$ Its spectrum was compared to that of $\mathbf{2 0}$. The chemical shifts of the by-product evident in the spectrum of $\mathbf{2 0}$ were consistent with those of $\mathbf{2 4}$ (Figure 2-5).

24
Figure 2-4. Alternative Bitropyl Synthesis

Figure 2-5. Spectra of Butyl Ether Product 20 and Bitropyl (24)

Butyl Ether Product

24

A COSY spectrum was also obtained for bitropyl (24) and is shown in Figure 2-6.
The most likely mechanism of the formation of the bitropyl is shown in Scheme 12.

Scheme 12. Bitropyl Formation

24

The singlet state carbene intersystem crosses (ISC) to the triplet state, which in turn abstracts a hydrogen atom from the $n$-butyl alcohol to form the tropyl radical. This free radical dimerizes to bitropyl (24). The chemical shifts for the protons in bitropyl are reported in Section 4.7..

### 2.4. Elucidation of the Structures of the DIBF Product (14)

### 2.4.1. Isomers Discovered

The other expected product in this study is the DIBF adduct (14). This was synthesized by thermolysis of $\mathbf{2}$ in diglyme in the presence of 1,3-diphenylisobenzofuran (DIBF).

A 1-D ${ }^{1} \mathrm{H}$ NMR spectrum was obtained for the crude product (Figure 2-7). This spectrum indicated the presence of at least three products in this reaction. The protons at $\delta 4.7$, 5.1, and 5.2 ppm did not exhibit a 1:1:1 ratio. Given the structure of $\mathbf{1 4}$, there should have been five protons in the alkene region of the spectrum exhibiting equal areas. The fact that there are additional unexpected peaks in the alkene region (not in an equivalent ratio with the expected peaks) leads to the conclusion that there was more than one product generated in this reaction.

Figure 2-7 was not consistent with the spectrum that would have been expected if only one product was present.

Figure 2-7. 1-D Spectrum of the Crude DIBF Reaction Mixture

The 2-D COSY spectrum of the crude product (Figure 2-9) was also consistent with the presence of three separate compounds in the DIBF reaction.

The DIBF products then underwent column chromatography and TLC. The compounds containing the protons at $\delta 4.7 \mathrm{ppm}$ and $\delta 5.1$ could not be separated. The third product at $\delta 5.4$ ppm was unstable and not seen after chromatography. Since the two surviving compounds were not separable by column chromatography and TLC, it was hypothesized that they were isomers of 14. As can be seen in Figure 2-8, isomers of 14 are possible (exo and endo structures, depending upon the position of $\mathrm{H}_{\mathrm{a}}$ ).

Figure 2-8. Isomers of 14 Possible

The products $\mathbf{1 4 a}$ and $\mathbf{1 4 b}$ were successfully separated by HPLC. A chromatogram of this separation is shown in Figure 2-10. Hydrogen 1-D spectra of the isomers before and after separation by HPLC are shown in Figure 2-11.

Figure 2-9. COSY Spectrum of the Crude DIBF Reaction Mixture Before

Figure 2-11. Spectra of the DIBF Isomers

A COSY spectrum of the isomers after column chromatography and TLC was obtained and is shown in Figure 2-12. A COSY spectrum of the minor isomer (14b) was obtained after HPLC and is shown in Figure 2-13.

The chemical shifts of the protons of each isomer were determined and placed in Table 3.

Table 3. Chemical Shifts of the Major and Minor Isomers
Major Isomer (14a): $(\mathrm{d}=$ doublet, d of $\mathrm{d}=$ doublet of doublets, $\mathrm{m}=$ multiplet $)$

| proton | $\underline{\delta}(\mathrm{ppm})$ | pattern |  | coupling constant $(\mathrm{Hz})$ |
| :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  |
| $\mathrm{H}_{\mathrm{a}}$ | 3.64 | d | $J_{\mathrm{ab}}=3.69$ |  |
| $\mathrm{H}_{\mathrm{b}}$ | 4.73 | d of d | $J_{\mathrm{bc}}=9.72$ |  |
| Hc | 5.85 | m | $J_{\mathrm{cd}}=9.87$ |  |
| $\mathrm{H}_{\mathrm{d}}$ | 6.23 | m |  |  |
| $\mathrm{H}_{\mathrm{e}}$ | 6.22 | m |  |  |
| $\mathrm{H}_{\mathrm{f}}$ | 6.01 | m |  |  |

Minor Isomer (14b):

| $\mathrm{H}_{\mathrm{a}}$ | 2.54 | d | $J_{\mathrm{ab}}=4.35$ |
| :--- | :--- | :--- | :--- |
| $\mathrm{H}_{\mathrm{b}}$ | 5.14 | d of d | $J_{\mathrm{bc}}=9.58$ |
| $\mathrm{H}_{\mathrm{c}}$ | 6.02 | d of d | $J_{\mathrm{cd}}=10.78$ |
| $\mathrm{H}_{\mathrm{d}}$ | 6.41 | d of d | $J_{\mathrm{de}}=10.93$ |
| $\mathrm{H}_{\mathrm{e}}$ | 6.44 | d of d | $J_{\mathrm{ef}}=11.06$ |
| $\mathrm{H}_{\mathrm{f}}$ | 6.20 | d |  |

As can be seen in Table 3, these two isomers became known as the major and minor isomer ( $\mathbf{1 4 a}$ and $\mathbf{1 4 b}$, respectively). These designations were assigned in lieu of the fact that the proton belonging to $\mathbf{1 4 a}$ ( $\delta 4.7 \mathrm{ppm}$ ) exhibited the larger peak area in the $1-\mathrm{D}$ NMR spectrum. The transient signal at $\delta 5.4 \mathrm{ppm}$ will be discussed shortly.

Figure 2-12. COSY Spectrum of DIBF Product's Isomers after Column
Chromatography and TLC

Figure 2-13. COSY Spectrum of Minor Isomer

The relative energies of $\mathbf{1 4 a}$ and $\mathbf{1 4 b}$ were estimated by force field calculations (SYBYL and Alchemy III). ${ }^{36}$ The results of the SYBYL calculations, determining the most stable configurations of the isomers, are shown in Figure 2-14.

Table 4 lists the numerical SYBYL results. These values supported the nomenclature of the isomers, which was initially based upon peak areas. The major isomer was calculated to be more stable (lower strain energy) than the minor isomer. (The difference was only $0.06 \mathrm{kcal} / \mathrm{mol}$, which was within the limits of the calculation.)

## Table 4. SYBYL Force Field Results

|  | DIBF Isomer |  |
| :--- | :--- | :--- |
|  | $\underline{\text { Minor }}$ | $\underline{\text { Major }}$ |
| Strain Energy | 26.5565 | 26.4934 |
| Gradient | 0.3862 | 0.1571 |
| Stretching | 0.4732 | 0.4399 |
| Bending | 23.8921 | 23.0887 |
| Torsion | 8.0486 | 8.8910 |
| VdW Energy | -5.9493 | -6.0324 |
| Out-of-Plane | 0.0918 | 0.1062 |

The chemical shifts of the protons in the isomers were then assigned to the structures in Figure 2-14 using the following logic. As can be seen in Table 3, the chemical shift of proton $\mathrm{H}_{\mathrm{b}}$ in $\mathbf{1 4 a}$ is further upfield in the spectrum than proton $\mathrm{H}_{b}$ in $\mathbf{1 4 b}$. This can be explained by proximal effects on this proton. The benzo group and one of the phenyl groups are shielding $\mathrm{H}_{\mathrm{b}}$ in the major isomer to a certain extent. In $\mathbf{1 4 b}, \mathrm{H}_{\mathrm{b}}$ is in the vicinity of one of the phenyl groups but should not be shielded to the extent that $\mathrm{H}_{\mathrm{b}}$ is in $\mathbf{1 4 a}$.

Figure 2-14. Calculated Stereochemistry of the Isomers

Major Isomer (14a)

Minor Isomer (14b)

The converse is true for proton $H_{a}$ in both structures. Proton $H_{a}$ in $\mathbf{1 4 b}$ should be found further upfield in the spectrum than in $\mathbf{1 4 a}$ due to shielding effects from the benzo and phenyl groups.

Further evidence that the two products were isomers was provided by high resolution mass spectroscopy (HRMS). After HPLC separation, the samples of the isomers underwent HRMS. ${ }^{37}$ Table 5 lists the results. (Complete analyses given in Appendix II).

Table 5. HRMS Results of the DIBF Product's Isomers ${ }^{37}$

|  | Mass, found | Mass, calculated |
| :--- | :--- | :--- |
| Major Isomer (14a): | 360.149651 | 360.151415 |
| Minor Isomer (14b): | 360.150482 | 360.151415 |

The masses found for each isomer were in good agreement with their calculated masses, and the empirical formulas of both were calculated to be $\mathrm{C}_{27} \mathrm{H}_{20} \mathrm{O}$. The two isolated DIBF products were therefore considered to be isomers, having structures 14a and 14b seen in Figure 2-14.

### 2.4.2. The Third DIBF Product

The third product generated in this reaction was unstable and disappeared rather rapidly in the spectra of the DIBF reaction mixtures. It exhibited an unusual splitting pattern in the 1-D spectrum at $\delta 5.4 \mathrm{ppm}$. At first glance it appeared to have one proton being split by four nonequivalent protons into a doublet of doublet of doublet of doublets ( $d$ of $d$ of $d$ of $d$ ) pattern. If this was the case, the largest coupling constant would have been 22 Hz . It would have been highly unlikely that any product generated in this synthesis would have exhibited this coupling constant. Upon closer inspection, the splitting pattern was seen to be two doublet of doublet of
doublets ( $d$ of $d$ of $d$ ). Due to its instability, this product was not isolated, and its structure was not identified

This product was only observed in the DIBF syntheses. It was not observed in the competition reactions, perhaps augmenting the likelihood of a rearrangement during reaction.

Scheme 13 shows one feasible structure of the unknown product (27) using both $\mathbf{1}$ and 9 as potential intermediates.

Scheme 13. Possible Formation and Structure of the Unknown DIBF Product

The carbene intermediate $\mathbf{1}$ or allene 9 may react with the DIBF to generate spiro compound 27 . This spiro compound could then rearrange to $\mathbf{1 4}$. The splitting pattern at $\delta 5.4 \mathrm{ppm}$ (Figure 2-7.) is consistent with the pattern expected for the highlighted protons in 27.

### 2.5. Reaction Time vs. DIBF Product Generation

In an attempt to see what effect the reaction time had on the generation of the three observed DIBF products, a series of six DIBF reactions were performed and terminated at designated time intervals. Table 6 lists the DIBF products' reaction durations and the percentage of each product's peak area in proportion to the combined peak area of all three products. Concentration effects were avoided by adding the same volume of sample ( $\sim 0.1 \mathrm{ml}$ ) from the reaction vessel to the NMR tubes containing equivalent amounts of the standard (TMS).

Table 6. Stabilization of the DIBF Products Over Increasing Reaction Time

The 14a:14b ratio is about $1.8: 1$ throughout. the relative amount of the third (unknown) product decreases with time. If the unknown product rearranges to $\mathbf{1 4 a}$ and/or $\mathbf{1 4 b}$ or
decomposes in some other way, it seriously impacts the kinetic study.

### 2.6. Competition Reactions

### 2.6.1. Preparation for the Kinetic Study

The competition reactions were then undertaken. The sodium salt of tropone tosylhydrazone was decomposed in diglyme in the presence of specific concentrations of $n$-butyl alcohol and DIBF concentrations. The 1-D ${ }^{1} \mathrm{H}$ NMR spectra were obtained. Due to slight variations in chemical shifts with NMR concentration, it was then necessary to "spike" the NMR samples containing the kinetics products. First, additional butyl ether product $\mathbf{2 0}$ was added to the kinetics NMR samples, allowing the chemical shifts of the protons belonging to 20 to be more easily identified. The same was then done for the DIBF products ( $\mathbf{1 4 a}$ and $\mathbf{1 4 b}$ ) and their corresponding proton chemical shifts.

Figure 2-15 shows spectra of a competition reaction (before HPLC) which had been spiked with first additional butyl ether product 20, then with additional DIBF products ( $\mathbf{1 4 a}$ and 14b). The peaks are labeled by the number of the product they represent. For example, the pattern at $\delta 5.66 \mathrm{ppm}$ increased in size after butyl ether product $\mathbf{2 0}$ was added to the competition reaction sample. The other patterns, not representing $\mathbf{2 0}$, decreased in size. The converse was true upon addition of more DIBF product. The peaks of the protons contained in the isomers increased upon addition of the DIBF product and the peaks of 20 decreased.

Figure 2-15. Spectra of the Competition Reaction Sample with Spiking

Spiked with butyl Ether Product

Spiked with olef product

Figure 2-16 shows the spectra of a competition reaction and three of the products prepared independently. Slight chemical shift differences appeared with concentration differences. The proton at $\delta 5.68 \mathrm{ppm}$ belonged to the butyl ether product $\mathbf{2 0}$ (as seen in Figure 2-15). In comparison to the butyl ether spectrum, it is likely this proton is $\mathrm{H}_{\mathrm{a}}$, due to the similarity in the splitting patterns. It is observed almost 2.5 ppm downfield of $\mathrm{H}_{\mathrm{a}}$ in the butyl ether spectrum, however. The protons at $\delta 5.42$ and 5.56 ppm are seen with question marks because it is unknown what is responsible for their presence. At first glance it appears the proton at $\delta 5.42 \mathrm{ppm}$ is $\mathrm{H}_{\mathrm{a}}$ in the butyl ether product. Results of the spiking (Figure 2-15) showed that this was not the case. The pattern at $\delta 6.7 \mathrm{ppm}$ was designated as arising from $\mathbf{2 0}$. This was because of its similarity to $\mathrm{H}_{\mathrm{c}}$ in the spectrum of $\mathbf{2 0}$, both in chemical shift and splitting pattern. With the exception of $\mathrm{H}_{\mathrm{c}}$ and $\mathrm{H}_{\mathrm{f}}$ in the minor isomer, the protons belonging to both isomers are more easily identified in the competition reaction. The same splitting patterns and similar chemical shifts were observed in the protons of the major isomer (14a) and the minor isomer (14b).

### 2.6.2. Competition Kinetics

Once the NMR peaks were identified, competition reactions were performed. Once the spectra of these competition reactions were obtained, the relative areas of the butyl ether product $(\mathbf{2 0} ; \delta 5.68 \mathrm{ppm})$, the minor isomer ( $\mathbf{1 4 b} ; \delta 5.14 \mathrm{ppm})$, and the major isomer ( $\mathbf{1 4 a} ; \delta 4.72 \mathrm{ppm})$ were measured by integration in each spectrum in order to obtain a ratio of the products.

Figure 2-16. Spectra of Competition Reaction with Its Component Products

The data obtained in the preliminary results were not reproducible. Due to incomplete NMR data, only one DIBF product was observed in the preliminaries. ${ }^{34}$ The present study observed at least three DIBF products, one of which was unstable. This seriously affects the kinetics. There were also other products which were not identifiable in the competition reactions (specifically those whose protons are at $\delta 5.40$ and 5.54 ppm ; Figure 2-16). The inability to account for all products generated in these competition reactions made a kinetic treatment of the data impossible.

## 3. Summary and Conclusions

This study was valuable in that it helped to assess the validity of the proposed kinetic treatment. It served a purpose in showing that the preliminary results performed by Zepp were based upon incomplete NMR data. ${ }^{34}$ The following is a list of reasons why this kinetic study failed to shed light on the mechanism of the thermolytic decomposition of the sodium salt of tropone tosylhydrazone (2):

1. The reaction system was much more complex than it was originally assumed. Several products were generated in these kinetic reactions. Several DIBF products, previously unobserved, were discovered.
2. Some of the products were unstable. One of the DIBF products disappeared rather rapidly. Thus, it was not possible to account for all of the products generated in the competition reactions. This inability to integrate all of the products nullified the kinetic treatment.
3. A heterogeneous mixture was unavoidable in this reaction. The solid precursor (2) was only slightly soluble in the reaction solution. The by-product, sodium $p$-toluenesulfinate, was also insoluble. This may have led to solid surface problems during the reaction, and may account for the lack of reproducibility of the preliminary results.
4. A third intermediate, the triplet state carbene, may have been present. Bitropyl (24) was reported in the synthesis of the butyl ether product $\mathbf{2 0}$ (Section 2.3.). This suggests that a triplet state carbene was present at some point in that reaction. The presence of a triplet state carbene in the competition reactions would mean the proposed kinetic schemes are questionable.

## 4. Experimental Section

## General Experimental

NMR spectra were recorded on a Varian Unity Plus 400 spectrometer at 399.953 MHz $\left({ }^{1} \mathrm{H}\right)$ and $100.568 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$ using deuteriochloroform $\left(\mathrm{CDCl}_{3}, 7.26 \mathrm{ppm},{ }^{1} \mathrm{H} ; 77.0 \mathrm{ppm},{ }^{13} \mathrm{C}\right)$ as an internal reference. Data are reported in the following order: chemical shifts are given ( $\delta$ ); multiplicities are indicated as $s$ (singlet), $d$ (doublet), $t$ (triplet), pent (pentet), hex (hextet), $d$ of $d$ (doublet of doublets), d of t (doublet of triplets), m (multiplet)); coupling constants, $J$, are reported in Hz . High performance liquid chromatography (HPLC) chromatograms were recorded using a Waters 501 solvent delivery pump and Waters 486 Tunable Absorbance Detector on Baseline 810 software.

Thin layer chromatography (TLC) was performed on preparative glass plates ( $8 \times 8 \mathrm{~cm}$ ) using Silica Gel 60 PF $254+366$ indicator (Merck). Visualization of developed plates was accomplished by UV light. The following reagents and solvents were distilled before use: $n$-butyl alcohol was distilled from sodium metal; THF was distilled from Na /benzophenone ketyl; diglyme was distilled from CaH ; petroleum ether and methylene chloride were distilled neat; diethyl ether was reagent grade and used as received.

All thermolysis reactions were performed under a dry nitrogen atmosphere.

### 4.1. Synthesis of Tropone (21) ${ }^{38}$

To a solution of potassium dihydrogen phosphate monohydrate $(27.75 \mathrm{~g}, 0.20 \mathrm{~mol})$ in water ( 67.8 mL ) in a 1 L 3-necked round bottom flask was added 1,4 dioxane ( $700 \mathrm{~mL}, 7.9 \mathrm{~mol}$ ), cycloheptatriene ( $98 \mathrm{~mL}, 0.94 \mathrm{~mol}$ ), and selenium (IV) oxide ( $103.88 \mathrm{~g}, 0.94 \mathrm{~mol}$ ). The mixture was refluxed under nitrogen for 15 h at $88{ }^{\circ} \mathrm{C}$. The mixture was allowed to cool to room temperature and was then vacuum filtered. The filtrate was divided into two halves (due to the large volume). The first half was placed into a 2000 mL separatory funnel containing 750 mL of water and extracted with methylene chloride $(3 \times 200 \mathrm{~mL})$. The organic layer was washed with a 3:2 mixture of saturated sodium bisulfite:diethyl ether ( $8 \times 400 \mathrm{~mL}$ ). The organic layer was then dried over anhydrous magnesium sulfate. The drying agent was separated from the tropone via vacuum filtration. The methylene chloride was removed by rotary evaporation until all of the desired crude tropone remained in that one flask. The second half of the filtrate was then put through the same procedure and added to the other half of the recovered tropone.

The 1,4 dioxane was then removed by direct mechanical vacuum distillation (pressure $=$ 9.48 torr, $45^{\circ} \mathrm{C}$ ). The tropone was then removed from the remaining inorganics (e.g. selenium) by direct mechanical vacuum ( 3 torr, $77{ }^{\circ} \mathrm{C}$ ). Data for 21: $n_{\mathrm{D}}{ }^{20}=1.6164 ;{ }^{1} \mathrm{H}$ NMR ( 400 MHz , $\left.\mathrm{CDCl}_{3}\right) ; \delta 6.92\left(\mathrm{~d}\right.$ of d, $\left.2 \mathrm{H}, \mathrm{H}_{\mathrm{c}}, \mathrm{H}_{\mathrm{d}}, J_{\mathrm{cd}}=9.09 \mathrm{~Hz}\right), 6.96\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{a}}, \mathrm{H}_{\mathrm{f}}\right), 7.05\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{b}}, \mathrm{H}_{\mathrm{e}}\right)$.

### 4.2. Synthesis of 7,7-dichlorocycloheptatriene (22) ${ }^{18}$

Thionyl chloride ( $143 \mathrm{~mL}, 1.98 \mathrm{~mol}$ ) was placed in a $300 \mathrm{~mL}, 3$-necked round bottom flask equipped with a magnetic stir bar and cooled to $0^{\circ} \mathrm{C}$ in an acetone/ice bath. Tropone 21 ( $24.9 \mathrm{~mL}, 0.26 \mathrm{~mol}$ ) was added dropwise to the thionyl chloride over a 5 min period.

The mixture was then refluxed for 5 min (reflux began at $57^{\circ} \mathrm{C}$ ) in an oil bath under nitrogen. The excess thionyl chloride was removed from the 7,7-dichlorocycloheptatriene (theoretical yield: $41.37 \mathrm{~g}, 0.26 \mathrm{~mol}$ ) by simple distillation, using a water aspirator as the source for the vacuum. Data for 22: ${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) ; \delta 5.99\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{c}}, \mathrm{H}_{\mathrm{d}}\right), 6.11\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{b}}\right.$, $\left.\mathrm{H}_{\mathrm{e}}\right), 6.44\left(\mathrm{~d}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{a}}, \mathrm{H}_{\mathrm{f}}, J=8.77\right)$.

### 4.3. Synthesis of Tropone Tosylhydrazone (23) ${ }^{18}$

7,7-Dichlorocycloheptatriene (22) was placed in a 1000 mL Erlenmeyer flask equipped with a magnetic stir bar. A solution of p-toluenesulfonylhydrazide ( $47.84 \mathrm{~g}, 0.26 \mathrm{~mol}$ ) in ethanol ( $642 \mathrm{~mL}, 11.0 \mathrm{~mol}$ ) was added to the 7,7-dichlorocycloheptatriene. The mixture was stirred for 2 h at room temperature, and the crude tropone tosylhydrazone (yellow precipitate) was removed by vacuum filtration. The crude product was placed in a 1500 mL Erlenmeyer flask containing 350 mL of methylene chloride and 649 mL of saturated sodium bicarbonate and stirred for 30 min. In three aliquots, this mixture was transferred to a 1000 mL separatory funnel and the organic layer was drained into a 500 mL Erlenmeyer flask. The aqueous layer was washed with methylene chloride ( $3 \times 50 \mathrm{~mL}$ ). After all of the crude product in solution was once again in the same flask, the methylene chloride was separated by rotary evaporator. The tropone tosylhydrazone ( $82 \%$ yield, $57.77 \mathrm{~g}, 0.21 \mathrm{~mol}$, m.p. range $=137.9-139.0^{\circ} \mathrm{C}$ ) was recrystallized with $95 \%$ ethanol. Data for 23: melting point $=140.5-141.0^{\circ} \mathrm{C}\left(\right.$ lit. $\left.=142.5-143.5{ }^{\circ} \mathrm{C}\right) ;{ }^{17}$ yield $=$ $61.8 \% ;{ }^{1}{ }^{\mathrm{H}} \mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 2.41(\mathrm{~s}, 1 \mathrm{H}), 6.30\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{a}}, \mathrm{H}_{\mathrm{f}}\right), 6.53\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{b}}, \mathrm{H}_{\mathrm{e}}\right)$, $6.59\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{c}}, \mathrm{H}_{\mathrm{d}}\right), 7.30(\mathrm{~d}, 2 \mathrm{H}, J=8.14$, arom.), 7.84 (d, $2 \mathrm{H}, J=8.30$, arom.).

### 4.4. Synthesis of Sodium Salt of Tropone Tosylhydrazone (2) ${ }^{18}$

A solution of tropone tosylhydrazone $23(40.0 \mathrm{~g}, 0.15 \mathrm{~mol})$ in THF ( $252 \mathrm{~mL}, 3.11 \mathrm{~mol}$ ) was prepared in a 500 mL , 3-necked round bottom flask equipped with a stir bar. To this was added sodium hydride ( $60 \%$ dispersion in oil, $7.05 \mathrm{~g}, 0.176 \mathrm{~mol}$ ). This mixture was stirred for 40 min under nitrogen and the sodium salt of tropone tosylhydrazone (brown solid, 51.28 g ) was vacuum filtered in a fritted funnel using the water aspirator as the vacuum source. The salt was washed with THF ( $4 \times 25 \mathrm{~mL}$ ) and the salt was transterred into a brown bottle and placed upright into a vacuum dessicator. The salt was subjected to direct mechanical vacuum (to rid it of any residual tetrahydrofuran) for 15 h . The bottle containing the sodium salt was capped, nitrogen was introduced into the dessicator, and the product was stored until used in the kinetics reactions. Data for 2: ${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 6.77(\mathrm{~m}, 1 \mathrm{H}), 6.88(\mathrm{~m}, 1 \mathrm{H}), 7.09(\mathrm{~m}, 1 \mathrm{H}), 7.32(\mathrm{~m}$, $2 \mathrm{H}), 7.63(\mathrm{~m}, 1 \mathrm{H}), 7.91$ (d, $2 \mathrm{H}, J=8.37$, arom.), 7.99 (d, $2 \mathrm{H}, J=8.54$, arom.), 8.61 (s, 1 H , arom.)

### 4.5. Synthesis of 1-Butoxy-2,4,6-Cycloheptatriene (Butyl Ether Product) (20) ${ }^{32}$

Data for 20: ${n_{\mathrm{D}}}^{20}=1.6173 ;{ }^{1} \mathrm{H} \operatorname{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 0.84\left(\mathrm{t}, 3 \mathrm{H}, \mathrm{H}_{\mathrm{h}}, J=7.50\right), 1.31$ (hex, $\left.2 \mathrm{H}, \mathrm{H}_{\mathrm{g}}, J=7.51\right), 1.50\left(\right.$ pent, $\left.2 \mathrm{H}, \mathrm{H}_{\mathrm{f}}, J=7.46\right), 3.30\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{H}_{\mathrm{d}}\right), 3.44\left(\mathrm{t}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{e}}, J=7.35\right), 5.40(\mathrm{~d}$ of d, $\left.2 \mathrm{H}, \mathrm{H}_{\mathrm{a}}, J_{\mathrm{ab}}=9.50\right), 6.05\left(\mathrm{~d}\right.$ of d, $\left.2 \mathrm{H}, \mathrm{H}_{\mathrm{b}}, J_{\mathrm{bc}}=9.63\right), 6.56\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{c}}\right)$.

Synthetic Route 1:32
The sodium salt of tropone tosylhydrazone $(0.5 \mathrm{~g}, 1.7 \mathrm{mmol})$, diglyme $(8.8 \mathrm{~mL})$, and $n$ butyl alcohol ( $7.5 \mathrm{~mL}, 0.082 \mathrm{~mol}$ ) were placed into a 50 mL , 3-necked round bottom flask and stirred for 1 h at $98.5^{\circ} \mathrm{C}$. The mixture was allowed to cool and transferred to a 250 mL
separatory funnel with 60 mL pet ether. The organic layer was washed with water ( $5 \times 20 \mathrm{~mL}$ ). The crude product was transferred to a 250 mL round bottom flask and the solvent was removed by rotary evaporation. The residual diglyme was removed by direct mechanical vacuum. The resulting crude butyl ether product 20 was purified by silica gel column chromatography ( $100 \%$ pet ether) and silica gel thin layer chromatography ( $100 \%$ diethyl ether).

Synthetic Route 2: ${ }^{35}$
Reagent grade tropylium tetrafluoroborate (Aldrich)( $0.50 \mathrm{~g}, 0.003 \mathrm{~mol}$ ) was dissolved in 20 mL anhydrous diethyl ether in a 125 mL Erlenmeyer flask equipped with a magnetic stir bar. With stirring, $n$-butyl alcohol ( $0.38 \mathrm{~mL}, 0.004 \mathrm{~mol}$ ) was added slowly over a period of 3 min . After the addition was complete, the reaction mixture was transferred to a 60 mL separatory funnel containing 20 mL of diethyl ether. The organic layer was separated and washed with saturated sodium bicarbonate ( $7 \times 140 \mathrm{~mL}$ ). The ether was removed from the crude product by rotary evaporation. The crude product was purified by silica gel, thin-layer chromatography ( $100 \%$ diethyl ether) to yield 0.035 g (7.6\%) of the butyl ether product 20.

## Synthetic Route 3:

Tropylium tetrafluoroborate ( $0.50 \mathrm{~g}, 0.003 \mathrm{~mol}$ ) was dissolved in 20 mL anhydrous diethyl ether in a 125 mL Erlenmeyer flask equipped with a magnetic stir bar. With stirring, $n$ butyl alcohol was added slowly over 3 min . Saturated sodium bicarbonate ( 10 mL ) was then added slowly to the reaction mixture with stirring in order to keep it basic (basicity was tested with red litmus paper). The diethyl ether was evaporated from the product to yield $0.31 \mathrm{~g},(68 \%)$
of the crude butyl ether product $\mathbf{2 0}$.

## Synthetic Route 4:

Tropylium tetrafluoroborate $(0.50 \mathrm{~g}, 0.003 \mathrm{~mol})$ was placed in a 50 mL Erlenmeyer flask to which $n$-butyl alcohol $(0.38 \mathrm{~mL}, 0.004 \mathrm{~mol})$ was added slowly with stirring. After the addition was complete, solid sodium bicarbonate (excess) was added to the mixture. Water ( $\sim 1 \mathrm{~mL}$ ) was added to the mixture to neutralize the mixture. Diethyl ether $(10 \mathrm{~mL})$ was added to the mixture, as well as more solid sodium bicarbonate (to keep it in excess). The solid sodium bicarbonate was separated from the organic layer by gravity filtration. The ether was separated from the product by rotary evaporator to yield $0.379 \mathrm{~g}(82.6 \%)$ of the butyl ether product $\mathbf{2 0}$.

### 4.6. Synthesis of the DIBF Product (14) ${ }^{31}$

The sodium salt of tropone tosylhydrazone $(0.10 \mathrm{~g}, 0.3 \mathrm{mmol}), 1,3$-diphenylisobenzofuran (Aldrich) (DIBF, $0.091 \mathrm{~g}, 0.3 \mathrm{mmol}$ ), and diglyme ( 3.0 mL ) were placed into a 15 mL test tube equipped with a magnetic stir bar. The mixture was stirred for 1 h at $100^{\circ} \mathrm{C}$. The organic layer was transferred to a 125 mL separatory funnel with 30 mL of diethy ether, washed with water ( $5 \times 60 \mathrm{~mL}$ ), and dried over anhydrous magnesium sulfate. The ether was removed by rotary evaporation and the crude product was purified twice by preparative silica gel thin-layer chromatography ( $100 \%$ pet ether). The isomers were separated by HPLC ( $3: 1$ acetonitrile $/ \mathrm{H}_{2} \mathrm{O}$ ) yielding a yellow crystalline solid (major isomer) and an opaque liquid (minor isomer).

Data for Major Isomer (14a): ${ }^{39}{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $3.64\left(\mathrm{~d}, 1 \mathrm{H}, \mathrm{H}_{\mathrm{a}}, J_{\mathrm{ab}}=3.69\right), 4.73(\mathrm{~d}$ of d, $\left.1 \mathrm{H}, \mathrm{H}_{\mathrm{b},}, J_{\mathrm{bc}}=9.72\right), 5.85\left(\mathrm{~d}\right.$ of d, $\left.1 \mathrm{H}, \mathrm{H}_{\mathrm{c}}, J_{\mathrm{cd}}=9.87\right), 6.01\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{H}_{\mathrm{f}}\right), 6.22\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{H}_{\mathrm{e}}\right)$, $6.23\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{H}_{\mathrm{d}}\right)$.

Data for Minor Isomer (14b): ${ }^{39}{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $2.54\left(\mathrm{~d}, \mathrm{IH}, \mathrm{H}_{\mathrm{a}}, J_{\mathrm{ab}}=4.35\right), 5.14$ $\left(\mathrm{d}\right.$ of d, $\left.1 \mathrm{H}, \mathrm{H}_{\mathrm{b}}, J_{\mathrm{bc}}=9.58\right), 6.02\left(\mathrm{~d}\right.$ of d$\left., 1 \mathrm{H}, \mathrm{H}_{\mathrm{c}}, J_{\mathrm{cd}}=11.06\right), 6.20\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{H}_{\mathrm{f}}\right), 6.41(\mathrm{~d}$ of d, 1 H , $\mathrm{H}_{\mathrm{d},} J_{\mathrm{de}}=10.93$ ), $6.44\left(\mathrm{~d}\right.$ of d, $\left.1 \mathrm{H}, \mathrm{H}_{\mathrm{e}}, J_{\mathrm{ef}}=11.06\right)$.

### 4.7. Synthesis of Bitropyl (24) ${ }^{35}$

Zinc dust $(0.200 \mathrm{~g}, 0.003 \mathrm{~mol})$, tropylium tetrafluoroborate $(0.53 \mathrm{~g}, 0.003 \mathrm{~mol})$, and water ( 6 mL ) were placed into a 15 mL centrifuge tube. The centrifuge tube was corked with a rubber stopper, and the mixture was shaken thoroughly for 4 min . The product was washed with pentane ( $4 \times 5 \mathrm{~mL}$ ). The pentane was removed by rotary evaporation leaving the yellow crystalline product. Data for 24: ${ }^{1} \mathrm{H} \operatorname{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 1.87\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{a}}\right), 5.21\left(\mathrm{~d}\right.$ of d, $4 \mathrm{H}, \mathrm{H}_{\mathrm{b}}$, $\left.J_{\mathrm{bc}}=9.02\right), 6.19\left(\mathrm{~d}\right.$ of $\left.\mathrm{t}, 4 \mathrm{H}, \mathrm{H}_{\mathrm{c}}, J_{\mathrm{cd}}=9.24\right), 6.62\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{H}_{\mathrm{d}}\right)$.
4.8. Competition Reaction (synthesis of 20 and $\mathbf{1 4})^{40}$

DIBF ( $0.429 \mathrm{~g}, 1.6 \mathrm{mmol}$ ), $n$-butyl alcohol ( $3 \mathrm{~mL}, 0.0328 \mathrm{~mol}$ ), and diglyme ( 6 mL ) were placed into a 15 mL test tube equipped with a magnetic stir bar and stoppered with a rubber septum. The mixture was heated at $100^{\circ} \mathrm{C}$ for 10 min . The sodium salt of tropone tosylhydrazone $(0.075 \mathrm{~g}, 0.3 \mathrm{mmol})$ was added immediately thereafter and this mixture was heated for an additional 50 min at $100{ }^{\circ} \mathrm{C}$. The solution was allowed to cool. The solution was
transferred to a 250 mL separatory funnel with 50 mL pet ether. The organic layer was washed with water ( $2 \times 125 \mathrm{~mL}$ ). The DIBF products and butyl ether product were separated by Grade III alumina column chromatography ( $100 \%$ pet ether). The DIBF products were purified by silica gel thin-layer chromatography (7:3 pet ether/methylene chloride) and separated by HPLC (RP-18 column, 3:1 acetonitrile/water). Data for Competition Reactions: reported in Section 4.5. (butyl ether product 20) and Section 4.6. (DIBF products $\mathbf{1 4 a}$ and $\mathbf{1 4 b}$ ).

## Appendix I

Scheme A1: Single intermediate kinetics (see Scheme 9, pg. 30)

$$
\begin{aligned}
& \mathrm{d}[\mathbf{9}] / \mathrm{dt}=-\mathrm{k}_{1}[9][\mathrm{BuOH}]-\mathrm{k}_{2}[9][\mathrm{DIBF}] \\
& \mathrm{d}[\mathbf{1 4}] / \mathrm{dt}=\mathrm{k}_{2}[\mathbf{9}][\mathrm{DIBF}] \\
& \mathrm{d}[\mathbf{2 0}] / \mathrm{dt}
\end{aligned}=\mathrm{k}_{1}[\mathbf{9}][\mathrm{BuOH}] \quad \begin{aligned}
& \mathrm{d}[\mathbf{2 0}] / \mathrm{d}[\mathbf{1 4}]=\mathrm{k}_{1}[\mathbf{9}][\mathrm{BuOH}] / \mathrm{k}_{2}[9][\mathrm{DIBF}] \\
& {[\mathbf{2 0}] /[\mathbf{1 4}]=\mathrm{k}_{1}[\mathrm{BuOH}] / \mathrm{k}_{2}[\mathrm{DIBF}] }
\end{aligned}
$$

Scheme A2: Two-intermediate kinetics (see Scheme 10, pg. 31)

$$
\begin{aligned}
& \mathrm{d}[1] / \mathrm{dt}=\mathrm{k}_{3}[1]-\mathrm{k}_{-3}[9]+\mathrm{k}_{4}[1][\mathrm{BuOH}] \\
& \mathrm{d}[\mathbf{9}] / \mathrm{dt}=-\mathrm{k}_{3}[1]+\mathrm{k}_{-3}[9]+\mathrm{k}_{2}[9][\mathrm{DIBF}] \\
& \mathrm{d}[\mathbf{1 4}] / \mathrm{dt}=\mathrm{k}_{2}[9][\mathrm{DIBF}] \\
& \mathrm{d}[\mathbf{2 0}] / \mathrm{dt}=\mathrm{k}_{4}[\mathbf{1}][\mathrm{BuOH}] \\
& {[\mathbf{2 0}] /[14]=\mathrm{k}_{4}[1][\mathrm{BuOH}] / \mathrm{k}_{2}[9][\mathrm{DIBF}]} \\
& \quad \mathrm{k}_{-3}[9]+\mathrm{k}_{2}[9][\mathrm{DIBF}]=\mathrm{k}_{3}[1] \\
& \quad[9]=\mathrm{k}_{3}[\mathbf{1}] /\left(\mathrm{k}_{-3}+\mathrm{k}_{2}[\mathrm{DIBF}]\right)
\end{aligned}
$$

$$
[\mathbf{2 0}] /[14]=\mathrm{k}_{4}[1][\mathrm{BuOH}] /\left\{\mathrm{k}_{2}[\mathrm{DIBF}]\left(\mathrm{k}_{3}[1] /\left(\mathrm{k}_{-3}+\mathrm{k}_{2}[\mathrm{DIBF}]\right)\right\}\right.
$$

$$
=\mathrm{k}_{4}[\mathrm{BuOH}] /\left\{\left(\mathrm{k}_{2} \mathrm{k}_{3}[\mathrm{DIBF}]\right) /\left(\mathrm{k}_{-3}+\mathrm{k}_{2}[\mathrm{DIBF}]\right)\right\}
$$

$$
=\mathrm{k}_{4}[\mathrm{BuOH}]+\left(\mathrm{k}_{-3}+\mathrm{k}_{2}[\mathrm{DIBF}]\right) /\left(\mathrm{k}_{2} \mathrm{k}_{3}[\mathrm{DIBF}]\right)
$$

$$
=\left\{\left(\mathrm{k}_{-3} \mathrm{k}_{4}[\mathrm{BuOH}]\right) /\left(\mathrm{k}_{2} \mathrm{k}_{3}[\mathrm{DIBF}]\right)\right\}+
$$

$$
\left\{\left(\mathrm{k}_{2} \mathrm{k}_{4}[\mathrm{BuOH}][\mathrm{DIBF}]\right) /\left(\mathrm{k}_{2} \mathrm{k}_{3}[\mathrm{DIBF}]\right)\right\}
$$

$$
[\mathbf{2 0}] /[\mathbf{1 4}]=\left\{\mathrm{k}_{-3} \mathrm{k}_{4}[\mathrm{BuOH}] / \mathrm{k}_{2} \mathrm{k}_{3}[\mathrm{DIBF}]\right\}+\left\{\mathrm{k}_{4}[\mathrm{BuOH}] / \mathrm{k}_{3}\right\}
$$

## Appendix II

HRMS results of the DIBF products $\mathbf{1 4 a}$ (major isomer) and $\mathbf{1 4 b}$ (minor isomer).

14a
Major Isomer

14b
Minor Isomer

Structures of the isomers were determined by SYBYL and Alchemy III.
Computer generated drawings are seen in Figure 2-14, page 56.
