#### Abstract

Let $D$ be a finite simple directed graph with vertex set $V(D)$ and arc set $A(D)$. A function $f: V(D) \rightarrow\{-1,1\}$ is called a signed dominating function $(S D F)$ if $f\left(N_{D}^{-}[v]\right) \geq 1$ for each vertex $\mathrm{v} \in \mathrm{V}$. The weight $w(f)$ of $f$ is defined by $\sum_{v \in V} f(v)$. The signed domination number of a digraph D is $\gamma_{s}(D)=$ $\min \{w(f): f$ is an SDF of $D\}$. Let $C_{m} \times C_{n}$ denotes the Cartesian product of directed cycles of length $m$ and n . In this paper, we determine the exact value of signed domination number of some classes of Cartesian product of directed cycles. In particular, we prove that: (a) $\gamma_{s}\left(\mathrm{C}_{3} \times \mathrm{C}_{\mathrm{n}}\right)=\mathrm{n}$ if $\mathrm{n} \equiv 0(\bmod 3)$, otherwise $\gamma_{s}\left(\mathrm{C}_{3} \times \mathrm{C}_{\mathrm{n}}\right)=\mathrm{n}+2$. (b) $\gamma_{\mathrm{s}}\left(\mathrm{C}_{4} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}$. (c) $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}$ if $\mathrm{n} \equiv 0(\bmod 10), \gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}+1$ if $\mathrm{n} \equiv 3,5,7(\bmod 10), \gamma_{s}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}+2$ if $\mathrm{n} \equiv 2,4,6,8(\bmod 10), \gamma_{s}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}+3$ if $\mathrm{n} \equiv 1,9(\bmod 10)$. (d) $\gamma_{s}\left(\mathrm{C}_{6} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}$ if $\mathrm{n} \equiv 0(\bmod 3)$, otherwise $\gamma_{\mathrm{s}}\left(\mathrm{C}_{6} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}+4$. (e) $\gamma_{\mathrm{s}}\left(\mathrm{C}_{7} \times \mathrm{C}_{\mathrm{n}}\right)=3 \mathrm{n}$.

Keywords: Directed graph, Directed cycle, Cartesian product, Signed dominating function, Signed domination number.

## 1. Introduction

Throughout this paper, let D be a finite simple directed graph with the vertex set $V(D)$ and the arc set $A(D)$ (briefly $V$ and $A$ ). If $u v$ is an arc of $D$, then we also write $u \rightarrow v$, and we say that $v$ is an outneighbor of $u$ and $u$ is an in-neighbor of $v$. For every vertex $\mathrm{v} \in \mathrm{V}$ let $\mathrm{N}_{\mathrm{D}}^{+}(\mathrm{v})$ and $\mathrm{N}_{\mathrm{D}}^{-}(\mathrm{v})$ denote the set of out-neighbors and in-neighbors of $v$, respectively. We write $d_{D}^{+}(v)=\left|N_{D}^{+}(v)\right|$ and $d_{D}^{-}(v)=\left|N_{D}^{-}(v)\right|$ for the outdegree and indegree of v in D , respectively (shortly $\mathrm{d}^{+}(\mathrm{v}), \mathrm{d}^{-}(\mathrm{v})$ ). A digraph D is r -regular if $d_{D}^{+}(v)=d_{D}^{-}(v)=r$ for any vertex $\mathrm{v} \in \mathrm{D}$. Let $\mathrm{N}_{\mathrm{D}}^{+}[\mathrm{v}]=\mathrm{N}_{\mathrm{D}}^{+}(\mathrm{v}) \cup\{\mathrm{v}\}$ and $\mathrm{N}_{\mathrm{D}}^{-}[\mathrm{v}]=\mathrm{N}_{\mathrm{D}}^{-}(\mathrm{v}) \cup\{\mathrm{v}\}$. The minimum and maximum indegree and minimum and maximum outdegree of $D$ are denoted by $\delta(\mathrm{D})=\delta$, $\Delta^{-}(\mathrm{D})=\Delta^{-}, \delta^{+}(\mathrm{D})=\delta^{+}$and $\Delta^{+}(\mathrm{D})=\Delta^{+}$, respectively. For a real-valued function $f: V(D) \rightarrow R$ the weight of $f$ is $w(f)=\sum_{v \in V} f(v)$, and for $S \subseteq V$, we define $f(S)=\sum_{v \in S} f(v)$, so $w(f)=f(V)$. Let $\mathrm{k} \geq 1$ be an integer and let $D$ be a digraph such that $\delta(\mathrm{D}) \geq \mathrm{k}-1$. A signed $k$-dominating function (SkDF) of D is a function $f: V \rightarrow\{-1,1\}$ such that $f\left(N_{D}^{-}[v]\right) \geq k$ for every vertex $\mathrm{v} \in \mathrm{V}$ (briefly $f[\mathrm{v}] \geq \mathrm{k}$ ). The signed $k$-domination number of a digraph D is $\gamma_{\mathrm{ks}}(D)=\min \{w(f): f$ is $S k D F$ of D$\}$. In particular, when $\mathrm{k}=1$, we get a definition of the signed dominating function and the signed domination number, i.e., $\gamma_{s}(\mathrm{D})=\gamma_{1 s}(D)$. A signed dominating function of weight $\gamma_{s}(\mathrm{D})$ is defined a $\gamma_{s}(\mathrm{D})$-function. Consult [7] for the notation and terminology which are not defined here.

The Cartesian product $D_{1} \times D_{2}$ of two digraphs $D_{1}$ and $D_{2}$ is the digraph with vertex set $V\left(D_{1} \times D_{2}\right)=$ $V\left(D_{1}\right) \times V\left(D_{2}\right)$ and $\left(\left(u_{1}, u_{2}\right),\left(v_{1}, v_{2}\right)\right) \in A\left(D_{1} \times D_{2}\right)$ if and only if either $u_{1}=v_{1}$ and $\left(u_{2}, v_{2}\right) \in A\left(D_{2}\right)$ or $u_{2}=v_{2}$ and $\left(u_{1}, v_{1}\right) \in A\left(D_{1}\right)$.

The vertices of a directed cycle $\mathrm{C}_{\mathrm{n}}$ are always denoted by the integers $\{1,2, \ldots, \mathrm{n}\}$, considered modulo $n$. The $i$ th row of $\mathrm{V}\left(\mathrm{C}_{\mathrm{m}} \times \mathrm{C}_{\mathrm{n}}\right)$ is $\mathrm{R}_{\mathrm{i}}=\{(\mathrm{i}, \mathrm{j}): \mathrm{j}=1,2, \ldots, \mathrm{n}\}$ and the $j$ th column $\mathrm{K}_{\mathrm{j}}=\{(\mathrm{i}, \mathrm{j}): \mathrm{i}=1,2$, $\ldots, m\}$. For any vertex $(i, j) \in V\left(C_{m} \times C_{n}\right)$, always we have the indices $i$ and $j$ are reduced modulo $m$ and $n$, respectively. If f is a signed dominating function for $\mathrm{C}_{\mathrm{m}} \times \mathrm{C}_{\mathrm{n}}$, then we denote $f\left(K_{j}\right)=\sum_{i=1}^{m} f(i, j)$ of the weight of a column $\mathrm{K}_{\mathrm{j}}$ and put $\mathrm{s}_{\mathrm{j}}=f\left(\mathrm{~K}_{\mathrm{j}}\right)$. The sequence $\left(\mathrm{s}_{1}, \mathrm{~s}_{2}, \ldots, \mathrm{~s}_{\mathrm{n}}\right)$ is called a signed dominating function sequence corresponding to $f$.

In the past few years, several types of domination problems in graphs have been studied [2-4, 6, 10], most of those belonging to the vertex domination. In 1995, Dunbar et al. [4], have introduced the concept of signed domination number of an undirected graph. Haas and Wexler in [5], established a sharp lower bound on the signed domination number of a general graph with a given minimum and maximum degree and also of some simple grid graph. Zelinka [11] initiated the study of the signed domination numbers of digraphs. He studied the signed domination number of digraphs for which the in-degrees does not exceed 1, as well as for acyclic tournaments and the circulant tournaments. Karami et al. [8] were established lower and upper bounds of the signed domination number of digraphs. Atapour et al. [1], presented some sharp lower bounds on the signed k-domination number of digraphs. Shaheen [9] calculated the signed domination numbers of Cartesian product of two paths $\mathrm{P}_{\mathrm{m}} \times \mathrm{P}_{\mathrm{n}}$ for $\mathrm{m}=2,3,4,5,6,7$ and arbitrary $n$. In this paper, we study the Cartesian product $C_{m} \times C_{n}$ of $C_{m}$ and $C_{n}$ for $m, n \geq 3$. We mainly determine the exact values of $\gamma_{s}\left(C_{3} \times C_{n}\right), \gamma_{s}\left(C_{4} \times C_{n}\right), \gamma_{s}\left(C_{5} \times C_{n}\right), \gamma_{s}\left(C_{6} \times C_{n}\right)$ and $\gamma_{s}\left(C_{7} \times C_{n}\right)$.

Let us introduce a definition. Suppose that $f$ is a signed dominating function for $\mathrm{C}_{\mathrm{m}} \times \mathrm{C}_{\mathrm{n}}$, and assume that $1 \leq \mathrm{j}, \mathrm{h} \leq \mathrm{n}$. We say that the $h$ th column in $\mathrm{C}_{\mathrm{m}} \times \mathrm{C}_{\mathrm{n}}$ is an $t$-shift of the $j$ th column if $f(\mathrm{i}, \mathrm{j})=f(\mathrm{i}+\mathrm{t}, \mathrm{h})$ for each vertex $(i, j) \in K_{j}$, where the indices $i, t, i+t$ are taken modulo $m$ and $j, h$ are taken modulo $n$.

Theorem 1.1(Zelinka [11]). Let $D$ be a directed cycle or path with $n$ vertices. Then $\gamma_{s}(D)=n$.
Lemma 1.2 (Zelinka [11]). Let D be a digraph with n vertices. Then $\gamma_{s}(\mathrm{D}) \equiv \mathrm{n}(\bmod 2)$.
Theorem 1.3 (Karami et al. [8]). Let D be a digraph of order n and let k be a nonnegative integer such that $d^{-}(v) \geq k$ for each $v \in V(D)$. Then

$$
\gamma_{\mathrm{S}}(\mathrm{D}) \geq \mathrm{n} \frac{1+\mathrm{k}+2\left\lceil\frac{\mathrm{k}}{2}\right\rceil-\Delta}{1-\mathrm{k}+\Delta}
$$

Corollary 1.4 (Karami et al. [8]). Let $D$ be a digraph of order $n$ in which $d^{+}(v)=d^{-}(v)=k$ for each $v \in V$, where $k$ is a nonnegative integer. Then $\gamma_{s}(D) \geq \frac{\mathbf{n}}{1+\mathbf{k}}$.

Theorem 1.5 (Atapour et al. [1]). Let $\mathrm{k} \geq 1$ be an integer, and let D be a digraph of order n with $\delta^{-} \geq \mathrm{k}-1$. Then

$$
\gamma_{\mathrm{kS}}(\mathrm{D}) \geq \mathrm{n} \frac{2\left\lceil\frac{\delta^{-}+\mathrm{k}+1}{2}\right\rceil-1-\Delta^{+}}{\Delta^{+}+1}
$$

## 2. Main results

In this section we calculate the signed domination number of the Cartesian product of two directed cycles $C_{m}$ and $C_{n}$ for $m=3,4,5,6,7$ and arbitrary $n$. We should note that, for simplicity of drawing the

Cartesian products of two directed cycles $\mathrm{C}_{\mathrm{m}} \times \mathrm{C}_{\mathrm{n}}$, we do not draw the arcs from vertices in last column to vertices in first column and the arcs from vertices in last row to vertices in first row.

Remark 2.1: Let $f$ be a $\gamma_{s}\left(C_{m} \times C_{n}\right)$-function. Then $f[(\mathrm{r}, \mathrm{s})] \geq 1$ for each $1 \leq \mathrm{r} \leq \mathrm{m}$ and each $1 \leq \mathrm{s} \leq \mathrm{n}$. Since $\mathrm{C}_{\mathrm{m}} \times \mathrm{C}_{\mathrm{n}}$ is 2-regular, it follows from $f((\mathrm{i}, \mathrm{j}))=-1$ that $f((\mathrm{i} \pm 1, \mathrm{j}))=f((\mathrm{i}, \mathrm{j} \pm 1))=1$ because $\left.f(\mathrm{i}, \mathrm{j})\right] \geq 1$, $f((\mathrm{i}+1, \mathrm{j}-1))=1$ because $f[(\mathrm{i}+1, \mathrm{j})] \geq 1$ and $f((\mathrm{i}-1, \mathrm{j}+1))=1$ because $f[(\mathrm{i}, \mathrm{j}+1)] \geq 1$. On the other hand, if $f((\mathrm{i} \pm 1, \mathrm{j}))=f((\mathrm{i}, \mathrm{j} \pm 1))=1, f((\mathrm{i}+1, \mathrm{j}-1))=1$ and $f((\mathrm{i}-1, \mathrm{j}+1))=1$, then we must have $f((\mathrm{i}, \mathrm{j}))=-1$ since $f$ is a minimum signed dominating function.
Remark 2.2. Since the case $f((\mathrm{i}, \mathrm{j}))=f((\mathrm{i}+1, \mathrm{j}))=-1$ is not possible, we get $\mathrm{s}_{\mathrm{j}} \geq 0$. Furthermore, $\mathrm{s}_{\mathrm{j}}$ is odd if $m$ is odd and even when $m$ is even.

Theorem 2.1. $\gamma_{s}\left(C_{3} \times C_{n}\right)= \begin{cases}n & \text { if } n \equiv 0(\bmod (3), \\ n+2 & \text { otherwise. }\end{cases}$
Proof. Corollary 1.3, implies that $\gamma_{s}\left(\mathrm{C}_{3} \times \mathrm{C}_{\mathrm{n}}\right) \geq \mathrm{n}$.
In any case we cannot put more than -1 in each column. We distinguish two cases:
Case 1. $\mathrm{n} \equiv 0(\bmod 3)$ : We define a function $f((\mathrm{i}, \mathrm{j}))=-1$ where $\mathrm{i} \equiv \mathrm{j}(\bmod 3)$ for $\mathrm{j}=1, \ldots, \mathrm{n}$ and $f((\mathrm{i}, \mathrm{j}))=1$ otherwise. This is a signed dominating function SDF for $\mathrm{C}_{3} \times \mathrm{C}_{\mathrm{n}}$. Furthermore, $s_{j}=\sum_{i=1}^{3} f((i, j))=1$ which means that $\gamma_{s}\left(C_{3} \times C_{n}\right) \leq n$. This together with (1) imply $\gamma_{s}\left(C_{3} \times C_{n}\right)=n$.
Case 2. $\mathrm{n} \equiv 1,2(\bmod 3)$ : The same function defined in the previous case with $\mathrm{j}<\mathrm{n}$, then $\mathrm{s}_{\mathrm{j}}=1$ for $\mathrm{j}=1$, $2, \ldots, \mathrm{n}-1$ and let $f((\mathrm{i}, \mathrm{n}))=1$ for $\mathrm{i}=1,2,3$. Then $f$ is SDF of $\mathrm{C}_{3} \times \mathrm{C}_{\mathrm{n}}$ with $w(f)=\mathrm{n}+2$. Without loss of generality, we can assume $f((1,1))=-1$. By Remark 2.1, we have $f((2,1))=f((3,1))=f((1,2))=f((3,2))=$ 1 and we can only put $f((2,2))=-1$. By similar arguments $f((1,3))=f((3,2))=1$ and $f((3,3))=-1$. We deduce that $f((1,1))=f((2,2))=f((3,3))=f((1,4))=f((2,5))=f((3,6))=\ldots=f((1,3 \mathrm{k}+1))=f((2,3 \mathrm{k}+2))=$ $f((3,3 \mathrm{k}+3))=\ldots=-1$.

If $\mathrm{n} \equiv 1(\bmod 3)$, then $\mathrm{K}_{\mathrm{n}}$ is 0 -shift of $\mathrm{K}_{1}$ and this implies that $f((1, \mathrm{n}))=-1$ and $f[(1,1)]=-1$, this is a contradiction. So, we have $f((1, \mathrm{n}))=1$. In the same time $f((3, \mathrm{n}-1))=-1$, then $f((3, \mathrm{n}))=1$ and $f((2, \mathrm{n}))=1$ (otherwise $f[(2,1)]=-1$ ), which implies that $\mathrm{s}_{\mathrm{n}}=3$. Hence,
$w(f) \geq \sum_{j=1}^{n-1} s_{j}+s_{n}=n-1+3=n+2$. We conclude that $\gamma_{s}\left(\mathrm{C}_{3} \times \mathrm{C}_{\mathrm{n}}\right)=\mathrm{n}+2$.
If $\mathrm{n} \equiv 2(\bmod 3)$, by similar arguments to the case $\mathrm{n} \equiv 1(\bmod 3)$, is the required (with notice that $\mathrm{K}_{\mathrm{n}}$ is 1 -shift of $K_{1}$ ).

Theorem 2.2. $\gamma_{s}\left(\mathrm{C}_{4} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}$.
Proof. We define a signed dominating function $f$ as follows:
$f((\mathrm{i}, \mathrm{j}))=-1$ where $\mathrm{i} \equiv \mathrm{j}(\bmod 4)$ for $\mathrm{j}=1, \ldots, \mathrm{n}$, and $f((\mathrm{i}, \mathrm{j}))=1$ otherwise.
$f_{\mathrm{n}-3}((3, \mathrm{n}-3))=f_{\mathrm{n}-2}((4, \mathrm{n}-2))=f_{\mathrm{n}-1}((1, \mathrm{n}-1))=f_{\mathrm{n}}((3, \mathrm{n}))=-1$, and $f((\mathrm{i}, \mathrm{j}))=1$ otherwise for $\mathrm{j}=\mathrm{n}-3, \mathrm{n}-2$, $\mathrm{n}-1, \mathrm{n}$. Obviously,
$f$ is a SDF of $\mathrm{C}_{4} \times \mathrm{C}_{\mathrm{n}}$ for $\mathrm{n} \equiv 0,3(\bmod 4)$. $\left\{\mathcal{A}\left\{f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup\left\{f_{\mathrm{n}}\right\}\right.$ is a SDF for $\mathrm{C}_{4} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 2(\bmod 4)$.
$\left\{f\left\{f\left(\mathrm{~K}_{\mathrm{n}-3}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}-2}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}-1}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup\left\{f_{\mathrm{n}-3} \cup f_{\mathrm{n}-2} \cup f_{\mathrm{n}-1} \cup f_{\mathrm{n}}\right\}\right.$ is a SDF for $\mathrm{C}_{4} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 1(\bmod 4)$.
We have $s_{j}=\sum_{i=1}^{4} f((i, j))=2$ for $\mathrm{j}=1, \ldots, \mathrm{n}$, and $w(f)=2 \mathrm{n}$. Therefore,

$$
\begin{equation*}
\gamma_{\mathrm{s}}\left(\mathrm{C}_{4} \times \mathrm{C}_{\mathrm{n}}\right) \leq 2 \mathrm{n} . \tag{2}
\end{equation*}
$$

Let $f^{\prime}$ is a SDF of $\mathrm{C}_{4} \times \mathrm{C}_{\mathrm{n}}$. By Remark 2.1, the case $f^{\prime}((\mathrm{i}, \mathrm{j}))=f^{\prime}((\mathrm{i}+1, \mathrm{j}))=-1$ is not exist. This implies that, for any column $\mathrm{K}_{\mathrm{j}}$ there are two cases:

Case 1. In $\mathrm{K}_{\mathrm{j}}$ we have $f^{\prime}((\mathrm{i}, \mathrm{j}))=f^{\prime}((\mathrm{i}+2, \mathrm{j}))=-1$, and $f^{\prime}((\mathrm{i}+1, \mathrm{j}))=f^{\prime}((\mathrm{i}+3, \mathrm{j}))=1$. Then $f^{\prime}((\mathrm{i}, \mathrm{j} \pm 1))=1$ for $\mathrm{i}=1,2,3,4$. Which leads, if $\mathrm{s}_{\mathrm{j}}^{\prime}=0$ then $\mathrm{s}_{\mathrm{j}-1}^{\prime}=\mathrm{s}_{\mathrm{j}+1}^{\prime}=4$. So, $\gamma_{\mathrm{s}}\left(\mathrm{C}_{4} \times \mathrm{C}_{\mathrm{n}}\right) \geq 2 \mathrm{n}$.
Case 2. In $\mathrm{K}_{\mathrm{j}}$ we have $f^{\prime}((\mathrm{i}, \mathrm{j}))=-1$ and $f^{\prime}((\mathrm{i}+1, \mathrm{j}))=f^{\prime}((\mathrm{i}+2, \mathrm{j}))=f^{\prime}((\mathrm{i}+3, \mathrm{j}))=1$. Then $f^{\prime}((\mathrm{i}, \mathrm{j}+1))=$ $f^{\prime}((\mathrm{i}-1, \mathrm{j}+1))=1$. By Remark 2.1, only one of $f^{\prime}((\mathrm{i}+1, \mathrm{j}+1))$ or $f^{\prime}((\mathrm{i}+2, \mathrm{j}+1))$ is equals -1 . We conclude that each column can not including more than one vertex which gets -1 and $s_{j}^{\prime} \geq 2$ for $j=1,2, \ldots, n$. Furthermore, $w\left(f^{\prime}\right)=\sum_{j=1}^{n} s^{\prime}{ }_{j} \geq 2 n$. Applying (2), together with the Cases 1 and 2, we get $\gamma_{s}\left(\mathrm{C}_{4} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}$.

## Theorem 2.3.

$$
\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)= \begin{cases}2 \mathrm{n} & \text { if } \mathrm{n} \equiv 0(\bmod 10) \\ 2 n+1 & \text { if } n \equiv 3,5,7(\bmod 10), \\ 2 n+2 & \text { if } n \equiv 2,4,6,8(\bmod 10), \\ 2 n+3 & \text { if } n \equiv 1,9(\bmod 10)\end{cases}
$$

Proof. We define a signed dominating function $f$ as follows:
$f((4 \mathrm{i}-3,2 \mathrm{j}-1))=-1$ for $1 \leq \mathrm{j} \leq\lceil\mathrm{n} / 2\rceil$ and $\mathrm{i} \equiv \mathrm{j}(\bmod 5)$,
$f((4 \mathrm{i}-2,2 \mathrm{j}))=f(4 \mathrm{i}, 2 \mathrm{j})=-1$ for $1 \leq \mathrm{j} \leq\lfloor\mathrm{n} / 2\rfloor$ and $\mathrm{i} \equiv \mathrm{j}(\bmod 5)$, and $f((\mathrm{i}, \mathrm{j}))=1$ otherwise.
By define $f$, we have $\mathrm{s}_{\mathrm{j}}=3$ for j is odd and $\mathrm{s}_{\mathrm{j}}=1$ for j is even. Also, $f$ is a SDF for $\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 0,3,5,7(\bmod 10)$. And $f$ is a SDF of the vertices of $\mathrm{K}_{2}, \ldots, \mathrm{~K}_{\mathrm{n}}$, when $\mathrm{n} \equiv 1,2,4,6,8,9(\bmod 10)$.
Now, let us a functions $f_{1}((4, \mathrm{n}))=-1$ and $f_{1}((\mathrm{i}, \mathrm{n}))=1$ for $\mathrm{i}=1,2,3,5 . f_{2}((3, \mathrm{n}))=-1$ and $f_{2}((\mathrm{i}, \mathrm{n}))=1$ for $\mathrm{i}=1,2,4,5 . f_{3}((5, \mathrm{n}))=-1$ and $f_{3}((\mathrm{i}, \mathrm{n}))=1$ for $\mathrm{i}=1,2,3,4$. And $f_{4}((\mathrm{i}, \mathrm{n}))=1$ for $\mathrm{i}=1,2,3,4,5$. We note:
$\left\{f \backslash f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup f_{1}$ is a SDF of $\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 2,8(\bmod 10)$.
$\left\{f \backslash f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup f_{2}$ is a SDF of $\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 4(\bmod 10)$.
$\left\{f \backslash f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup f_{3}$ is a SDF of $\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 6(\bmod 10)$.
$\left\{f \backslash f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup f_{4}$ is a SDF of $\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 1,9(\bmod 10)$. For an illustration $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{11}\right)$, see Figure 1. Also,

$$
\begin{align*}
& \gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right) \leq 2 \mathrm{n}, \text { if } \mathrm{n} \equiv 0(\bmod 10), \\
& \gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right) \leq 2 \mathrm{n}+1, \text { if } \mathrm{n} \equiv 3,5,7(\bmod 10), \\
& \gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right) \leq 2 \mathrm{n}+2 \text { for } \mathrm{n} \equiv 2,4,6,8(\bmod 10),  \tag{3}\\
& \gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right) \leq 2 \mathrm{n}+3 \text { for } \mathrm{n} \equiv 1,9(\bmod 10) .
\end{align*}
$$

By Remark 2.2, for any minimum signed dominating function $f$ of $\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}$ with signed dominating function sequence $\left(s_{1}, \ldots, s_{n}\right)$, we have $s_{j} \geq 1$. Furthermore $s_{j}=1,3$ or 5 for $j=1, \ldots, n$. Also, if $s_{j}=1$ then $\mathrm{s}_{\mathrm{j}-1}, \mathrm{~s}_{\mathrm{j}+1} \geq 3$. This implies that $w(f)=\sum_{j=1}^{n} s_{j} \geq 2 n$ for n is even, and $w(f)=\sum_{j=1}^{n} s_{j} \geq 2 n+1$ for n is odd. Thus with (3), gets
$\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}$ if $\mathrm{n} \equiv 0(\bmod 10)$ and $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}+1$ if $\mathrm{n} \equiv 3,5,7(\bmod 10)$.

For $\mathrm{n} \equiv 1,9(\bmod 10)$.
We will show $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right) \geq 2 \mathrm{n}+3$ when $\mathrm{n} \equiv 1,9(\bmod 10)$. We consider the case $\mathrm{n} \equiv 1(\bmod 10)$, and the case $n \equiv 9(\bmod 10)$ is similar to it.

Let us $2 \mathrm{n}+1 \leq \gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right) \leq 2 \mathrm{n}+3$. By Lemma 1.2, $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right) \equiv 5 \mathrm{n}(\bmod 2)$, this implies that $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=$ $2 \mathrm{n}+1$ or $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}+3$.

We know that $\mathrm{s}_{\mathrm{j}}=1,3$ or 5 and $\mathrm{s}_{\mathrm{j}}=\mathrm{s}_{\mathrm{j}+1}=1$ is not possible. If there is one column $\mathrm{K}_{\mathrm{j}}$ with $\mathrm{s}_{\mathrm{j}}=5$, then $w(f)=\sum_{j=1}^{n} s_{j} \geq 2 n+3$. By using (3) the case is finished.

Assume that $\mathrm{s}_{\mathrm{j}}<5$ for all j , then there are only two values of $\mathrm{s}_{\mathrm{j}}$ its 1 and 3 . Suppose that $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=$ $2 n+1$. Then there are $(n+1) / 2$ terms of $s_{j}=3$ and $(n-1) / 2$ terms of $s_{j}=1$. Which implies that, there are $\mathrm{s}_{\mathrm{j}}=\mathrm{s}_{\mathrm{j}+1}=3$. Without loss of generality, we can assume that $\mathrm{s}_{1}=\mathrm{s}_{\mathrm{n}}=3$. Then we gets the form $\mathrm{s}_{\mathrm{j}}=3$ where j is odd, and $\mathrm{s}_{\mathrm{j}}=1$ where j is even. So, let us $\mathrm{s}_{1}=3$ and $f((1,1))=-1$, then $\mathrm{s}_{2}=1$ and $f((2,2))=$ $f((4,2))=-1$. Also, $\mathrm{s}_{3}=3$ and $f((5,3))=-1, \mathrm{~s}_{4}=1$ and $f((1,4))=f((3,4))=-1$. We deduce that each column $\mathrm{K}_{\mathrm{j}}$ is 4 -shift of $\mathrm{K}_{\mathrm{j}-2}$. Furthermore, $\mathrm{K}_{\mathrm{n}}$ is 0 -shift of $\mathrm{K}_{1}\{4(\mathrm{n}-1) / 2=2 \mathrm{n}-2 \equiv 0(\bmod 5)\}$, i.e. $f((1, \mathrm{n}))$ $=-1$, and this is a contradiction. Therefore $\gamma_{s}\left(C_{5} \times C_{n}\right)>2 n+1$ and $\gamma_{s}\left(C_{5} \times C_{n}\right)=2 n+3$.

\{Here, we must note that, for simplicity of drawing the Cartesian products of two directed cycles $\mathrm{C}_{\mathrm{m}} \times \mathrm{C}_{\mathrm{n}}$, we do not draw the arcs from vertices in last column to vertices in first column and the arcs from vertices in last row to vertices in first row. Also for each figure of $\mathrm{C}_{\mathrm{m}} \times \mathrm{C}_{\mathrm{n}}$, we replace it by a corresponding matrix by signs - and + which descriptions -1 and +1 on figure of $f\left(\mathrm{C}_{\mathrm{m}} \times \mathrm{C}_{\mathrm{n}}\right)$, respectively $\}$.

For $n \equiv 2,4,6,8(\bmod 10)$.
We will show $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right) \geq 2 \mathrm{n}+2$ when $\mathrm{n} \equiv 2,4,6,8(\bmod 10)$. We study the case $\mathrm{n} \equiv 8(\bmod 10)$, the remained cases are similar to it.
Let $\mathrm{n} \equiv 8(\bmod 10)$. By Lemma 1.2, $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right) \equiv 5 \mathrm{n}(\bmod 2)$, so $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}$ or $\gamma_{\mathrm{s}}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}+2$. Assume that $\gamma_{s}\left(\mathrm{C}_{5} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}$. Then by the same argument similar to the case $\mathrm{n} \equiv 1(\bmod 10)$, we get $\mathrm{s}_{\mathrm{n}}=1$. Furthermore, $\mathrm{K}_{\mathrm{n}}$ is $\left(4(\mathrm{n}-2) / 2=4(10 \mathrm{k}+8-2) / 2=4(5 \mathrm{k}+3)=2\right.$-shift of $\mathrm{K}_{2}$. This mining that $f((1, \mathrm{n}))=$ $f((4, n))=-1$, and this is a contradiction. Therefore $\gamma_{s}\left(C_{5} \times C_{n}\right)>2 n$, and by $(3)$ is $\gamma_{s}\left(C_{5} \times C_{n}\right)=2 n+2$.

## Theorem 2. 4.

$$
\gamma_{s}\left(C_{6} \times C_{n}\right)= \begin{cases}2 n & \text { if } n \equiv 0(\bmod 3) \\ 2 n+4 & \text { if } n \equiv 1,2(\bmod 3)\end{cases}
$$

Proof. We define a signed dominating function f as follows:
$f((\mathrm{i}, \mathrm{j}))=-1$ and $f((\mathrm{i}+3, \mathrm{j}))=-1$ for $1 \leq \mathrm{j} \leq \mathrm{n}$ and $\mathrm{i} \equiv \mathrm{j}(\bmod 6)$, and $f((\mathrm{i}, \mathrm{j}))=1$ otherwise.
Also, $\left.f_{1}(\mathrm{i}, \mathrm{n})\right)=1$ for $\mathrm{i}=1, \ldots, 6$.

By define $f$, we have $\mathrm{s}_{\mathrm{j}}=2$ for all $1 \leq \mathrm{j} \leq \mathrm{n}$. Notice that $f$ is a SDF for $\mathrm{C}_{6} \times \mathrm{C}_{\mathrm{n}}$ where $\mathrm{n} \equiv 0(\bmod 3)$, and $\gamma_{\mathrm{s}}\left(\mathrm{C}_{6} \times \mathrm{C}_{\mathrm{n}}\right) \leq 2 \mathrm{n}$. Also, $f$ is a SDF of the vertices of $\mathrm{K}_{2}, \ldots, \mathrm{~K}_{\mathrm{n}}$ when $\mathrm{n} \equiv 1,2(\bmod 3)$. So, $\left\{f \backslash f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup f_{1}$ is a SDF for $\mathrm{C}_{6} \times \mathrm{C}_{\mathrm{n}}$ where $\mathrm{n} \equiv 1,2(\bmod 3)$, and $\gamma_{\mathrm{s}}\left(\mathrm{C}_{6} \times \mathrm{C}_{\mathrm{n}}\right) \leq 2 \mathrm{n}+4$. For an illustration $\gamma_{\mathrm{s}}\left(\mathrm{C}_{6} \times \mathrm{C}_{8}\right)$, see Figure 2 .
By Remark 2.2, we have $s_{j}=0,2,4$ or 6 . If $s_{j}=0$, then $s_{j-1}=s_{j+1}=6$. Also, when $s_{j}=2$ is $s_{j-1}, s_{j+1} \geq 2$. We deduce that $\gamma_{s}\left(C_{6} \times C_{n}\right)=\sum_{j=1}^{n} s_{j} \geq 2 n$. Hence, $\gamma_{s}\left(C_{6} \times C_{n}\right)=2 n$ for $n \equiv 0(\bmod 3)$.

|  | $\mathrm{K}_{1}$ | $\mathrm{K}_{2}$ | $\mathrm{K}_{3}$ | $\mathrm{K}_{4}$ | $\mathrm{K}_{5}$ | $\mathrm{K}_{6}$ | $\mathrm{K}_{7}$ | $\mathrm{K}_{8}$ |

| $\mathrm{R}_{2}+$ | + | - | + | + | - | + | + | + |
| $\mathrm{R}_{3}+$ | + | + | - | + | + | - | + | + |
| $\mathrm{R}_{4}-$ | - | + | + | - | + | + | - | + |
| $\mathrm{R}_{5}+$ | + | - | + | + | - | + | + | + |
| $\mathrm{R}_{6}+$ |  | + | - | + | + | - | + | + |
| $\mathrm{s}_{\mathrm{j}}$ : | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 6 |

For $\mathrm{n} \equiv 1,2(\bmod 3)$. We will show that $\gamma_{\mathrm{s}}\left(\mathrm{C}_{6} \times \mathrm{C}_{\mathrm{n}}\right) \geq 2 \mathrm{n}+4$.
If $s_{j}=0$ for some $j$, then $\sum_{j-1}^{j+1} s_{j}=12$. Since $\sum_{j} s_{j} \geq 2 j$ for $j \geq 2$, then $\gamma_{s}\left(C_{6} \times C_{n}\right) \geq 2 n+4$. Assume that $s_{j} \geq 2$ for all $j$. If there is one $s_{j}=6$ or two of $s_{j}$ are equal 4 , then gets the required. Now, assume that $s_{j}=2$ for all j accept once which is equal 4 , i.e. $\sum_{\mathrm{j}=1}^{\mathrm{n}} \mathrm{s}_{\mathrm{j}}=2 \mathrm{n}+2$. We prove the following claim:

Claim 2.1. If $\mathrm{s}_{\mathrm{j}}=\ldots=\mathrm{s}_{\mathrm{j}+\mathrm{k}}=2$ (for $\mathrm{k} \geq 1$ ), then we have one possible of $f$ is:
$f((\mathrm{i}, \mathrm{j}))=f((\mathrm{i}+3, \mathrm{j}))=-1 \Leftrightarrow f((\mathrm{i}+1, \mathrm{j}+1))=f((\mathrm{i}+4, \mathrm{j}+1))=-1$. Furthermore, each column $\mathrm{K}_{\mathrm{j}}$ is 1-shift of $\mathrm{K}_{\mathrm{j}-1}$.

Proof of Claim 2.1. Since $s_{j}=\ldots=s_{j+k}=2$ (for $k \geq 1$ ), we have each column include two vertices are assigned value -1 . By Remark 2.2 , we can assume that $f(\mathrm{i}, \mathrm{j}))=f((\mathrm{i}+2, \mathrm{j}))=-1$, this implies that $f((\mathrm{i}-1, \mathrm{j}+1))=f((\mathrm{i}, \mathrm{j}+1))=f((\mathrm{i}+1, \mathrm{j}+1))=f((\mathrm{i}+2, \mathrm{j}+1))=1$. Furthermore, at most one of the remaining vertices of $K_{j+1}$ is assigned value -1 . Which conclude that $\mathrm{s}_{\mathrm{j}+1} \geq 4$, and is a contradiction. The cases $f((\mathrm{i}, \mathrm{j}))=f((\mathrm{i}+4, \mathrm{j}))=-1$ and $f((\mathrm{i}, \mathrm{j}))=f((\mathrm{i}+5, \mathrm{j}))=-1$ are similar by symmetry to the cases $f((\mathrm{i}, \mathrm{j}))=$ $f((\mathrm{i}+2, \mathrm{j}))=-1$ and $f((\mathrm{i}, \mathrm{j}))=f((\mathrm{i}+1, \mathrm{j}))=-1$, respectively. Thus, we left with one case which $f((\mathrm{i}, \mathrm{j}))=$ $f((\mathrm{i}+3, \mathrm{j}))=-1 \Leftrightarrow f((\mathrm{i}+1, \mathrm{j}+1))=f((\mathrm{i}+4, \mathrm{j}+1))=-1$. Also, $\mathrm{K}_{\mathrm{j}}$ is 1-shift of $\mathrm{K}_{\mathrm{j}-1}$. The proof of Claim 2.1 is complete.
By Claim 2.1, and without loss of generality, we can assume $s_{1}=\ldots=s_{n-1}=2$ and $s_{n}=4$. Then $K_{n-1}$ is (n n )-shift of $\mathrm{K}_{1}$. Let $f((1,1))=f((4,1))=-1$, we distinguish two cases:

If $\mathrm{n} \equiv 1(\bmod 3)$, then $f((3, \mathrm{n}-1))=f((6, \mathrm{n}-1))=-1$. This implies that $f((2, \mathrm{n}))=f((3, \mathrm{n}))=f((5, \mathrm{n}))=$ $f((6, \mathrm{n}))=1$. Since $\mathrm{s}_{\mathrm{n}}=4$, we must have one of $f((1, \mathrm{n})), f((4, \mathrm{n}))$ is equal -1 . This is a contradiction, because $f((1,1))=f((4,1))=-1$.

If $\mathrm{n} \equiv 2(\bmod 3)$, then $f((1, \mathrm{n}-1))=f((4, \mathrm{n}-1))=-1$. By the same argument to above case, we get a contradiction, because $f((1,1))=f((4,1))=-1$.

From previous arguments, we conclude $\gamma_{s}\left(C_{6} \times C_{n}\right)>2 n+2$. By Lemma 1.2, $\gamma_{s}\left(C_{6} \times C_{n}\right) \equiv 6 n(\bmod 2)$. So, $\gamma_{\mathrm{s}}\left(\mathrm{C}_{6} \times \mathrm{C}_{\mathrm{n}}\right)=2 \mathrm{n}+4$ when $\mathrm{n} \equiv 1,2(\bmod 3)$.

Theorem 2. 5. $\gamma_{\mathrm{s}}\left(\mathrm{C}_{7} \times \mathrm{C}_{\mathrm{n}}\right)=3 \mathrm{n}$, where $\mathrm{n} \geq 7$.

Proof. We define a signed dominating function $f$ as follows:
$f((\mathrm{i}, \mathrm{j}))=f((\mathrm{i}+3, \mathrm{j}))=-1$ for $1 \leq \mathrm{j} \leq \mathrm{n}$ and $\mathrm{i} \equiv \mathrm{j}(\bmod 7)$, and $f((\mathrm{i}, \mathrm{j}))=1$ otherwise. Also, we define
$f_{\mathrm{n}-4}((4, \mathrm{n}-4))=f_{\mathrm{n}-4}((7, \mathrm{n}-4))=-1, f_{\mathrm{n}-3}((2, \mathrm{n}-3))=f_{\mathrm{n}-3}((5, \mathrm{n}-3))=-1, f_{\mathrm{n}-2}((3, \mathrm{n}-2))=f_{\mathrm{n}-2}((7, \mathrm{n}-2))=-1$,
$f_{\mathrm{n}-1}((1, \mathrm{n}-1))=f_{\mathrm{n}-1}((5, \mathrm{n}-1))=-1, f_{\mathrm{n}}((3, \mathrm{n}))=f_{\mathrm{n}}((6, \mathrm{n}))=-1$ and $f_{\mathrm{j}}((\mathrm{i}, \mathrm{j}))=1$ otherwise for $\mathrm{j}=\mathrm{n}-4, \mathrm{n}-3$, $\mathrm{n}-2, \mathrm{n}-1$, n .

By define $f$ and $f_{\mathrm{n}-4}, f_{\mathrm{n}-3}, f_{\mathrm{n}-2}, f_{\mathrm{n}-1}$ and $f_{\mathrm{n}}$ we have $\mathrm{s}_{\mathrm{j}}=3$ for all $1 \leq \mathrm{j} \leq \mathrm{n}$. Notice that:
$f$ is a SDF for $\mathrm{C}_{7} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 0,3(\bmod 7)$.
$\left\{f\left\{f\left(\mathrm{~K}_{\mathrm{n}-3}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}-2}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}-1}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup\left\{f_{\mathrm{n}-3} \cup f_{\mathrm{n}-2} \cup f_{\mathrm{n}-1} \cup f_{\mathrm{n}}\right\}\right.$ is a SDF for $\mathrm{C}_{7} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 1(\bmod 7)$. For an illustration $\gamma_{s}\left(\mathrm{C}_{7} \times \mathrm{C}_{8}\right)$, see Figure 3.
$\left\{f\left\{f\left(\mathrm{~K}_{\mathrm{n}-1}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup\left\{f_{\mathrm{n}-1} \cup f_{\mathrm{n}}\right\}\right.$ is a SDF for $\mathrm{C}_{7} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 2(\bmod 7)$.
$\left\{f\left\{f\left(\mathrm{~K}_{\mathrm{n}-4}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}-3}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}-2}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}-1}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup\left\{f_{\mathrm{n}-4} \cup f_{\mathrm{n}-3} \cup f_{\mathrm{n}-2} \cup f_{\mathrm{n}-1} \cup f_{\mathrm{n}}\right\} \quad\right.$ is $\quad$ a $\quad \mathrm{SDF} \quad$ for $\quad \mathrm{C}_{7} \times \mathrm{C}_{\mathrm{n}} \quad$ when $\mathrm{n} \equiv 4(\bmod 7)$.
$\left\{f\left\{f\left(\mathrm{~K}_{\mathrm{n}-2}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}-1}\right) \cup f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup\left\{f_{\mathrm{n}-2} \cup f_{\mathrm{n}-1} \cup f_{\mathrm{n}}\right\}\right.$ is a SDF for $\mathrm{C}_{7} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 5(\bmod 7)$.
$\left\{f\left\{f\left(\mathrm{~K}_{\mathrm{n}}\right)\right\} \cup\left\{f_{\mathrm{n}}\right\}\right.$ is a SDF for $\mathrm{C}_{7} \times \mathrm{C}_{\mathrm{n}}$ when $\mathrm{n} \equiv 6(\bmod 7)$.
In all the cases we have $\gamma_{s}\left(\mathrm{C}_{7} \times \mathrm{C}_{\mathrm{n}}\right) \leq 3 \mathrm{n}$.
By Remark 2.2, we have $\mathrm{s}_{\mathrm{j}}=1,3,5$ or 7 . Also, if $\mathrm{s}_{\mathrm{j}}=1$, then $\mathrm{s}_{\mathrm{j}-1}, \mathrm{~s}_{\mathrm{j}+1} \geq 5$ and when $\mathrm{s}_{\mathrm{j}}=3$, is $\mathrm{s}_{\mathrm{j}-1}, \mathrm{~s}_{\mathrm{j}+1} \geq 3$. This implies that $\gamma_{s}\left(C_{7} \times C_{n}\right)=\sum_{j=1}^{n} s_{j} \geq 3 n$. So, we get $\gamma_{s}\left(C_{7} \times C_{n}\right)=3 n$.

## 3. Conclusions

In this paper, we determined the exact value of the signed domination number of $C_{m} \times C_{n}$ for $m=3$, $\ldots, 7$ and arbitrary n . By using same technique methods, our hope eventually lead to determination $\gamma_{s}\left(C_{m} \times C_{n}\right)$ for $m \geq 8$.

Based on the above (Remark 2.1 and Theorems 2.1, ... 2.5), also by the technique which used in this paper, we arrive to the following conjecture:

## Conjecture 3. 1.

$$
\gamma_{\mathrm{s}}\left(\mathrm{C}_{\mathrm{m}} \times \mathrm{C}_{\mathrm{n}}\right)=\left\lceil\frac{\mathrm{m}}{3}\right\rceil \mathrm{n} \text { when } \mathrm{m}, \mathrm{n} \equiv 0(\bmod 3), \mathrm{n} \equiv 0(\bmod 2 \mathrm{~m}) \text { or } \mathrm{n} \equiv 1(\bmod 3) .
$$
