# Crystalline Field Effect on bonding Parameters of VO2+ Ion 

Ram Kripal ${ }^{1}$, Sanjay Misra ${ }^{2}$ and Awadhesh Kumar Yadav ${ }^{3}$<br>${ }^{1,2,3}$ Department of Physics, University of Allahabad, Allahabad, 211 002, India<br>E-mail: ${ }^{1}$ ram_kripal2001@rediffmail.com; ${ }^{2}$ ssopam@gmail.com, ${ }^{3}$ aky.physics@ gmail.com.

#### Abstract

The interpretation of g factor of the $\mathrm{VO}^{2+}$ ion doped in defferent single crystals is made using the Stevens model where the symmetry of the crystalline field is tetragonal. The bonding parameters $\mathrm{K}_{\|}$and $\mathrm{K}_{\perp}$, choosing the different parametric angle $\beta$, are determined. The value of $K \perp$ should be less than 0.048 in order to have a better fit to the experimental $g$ values.

Keywords: Electron paramagnetic resonance; parametric angle; Bonding parameters.

## Introduction

Electron paramagnetic resonance (EPR) provides a great deal of information about the magnetic properties of paramagnetic ion in different host lattices. This method also provides a detailed description of the ground state wave function of paramagnetic ions and enables one to understand the nature of the electric field symmetry produced by the ligands around the metal ion. $\mathrm{VO}^{2+}$ ion has only one electron, i.e., it has $3 \mathrm{~d}^{1}$ configuration which allows paramagnetic resonance to be observed at ambient temperature. The $\mathrm{VO}^{2+}$ ion is the most stable cation among a few molecular paramagnetic transition metal ions which is used extensively as an impurity probe for electron paramagnetic resonance studies. The paramagnetic $\mathrm{VO}^{2+}$ ion in different host lattices is studied and reported [1-10].

On the basis of the theoretical analysis of the behavior of $3 \mathrm{~d}^{1}$ single electron in $\mathrm{VO}^{2+}$ ion doped single crystals, the ground state wave function and nature of bonding are estimated with the help of EPR data. In the present investigation, the experimental $g$ values are explained by the Stevens model of covalent bonding in the presence of tetragonal crystalline field. It is seen that a better fit of the experimental g factor is obtained by taking one of the bonding parameters less than 0.048 .

## 1. Theoretical Aspect

When $\mathrm{VO}^{2+}$ ion is doped in a crystal lattice, it experiences crystal field of octahedral symmetry having tetragonal distortion due to ligands around the metal ion. For this the Hamiltonian can be written as [11],

$$
\begin{equation*}
\mathcal{H}=B_{4}\left(O_{4}^{0}+5 O_{4}^{4}\right)+B_{2}^{0} O_{2}^{0}+B_{4}^{2} O_{4}^{0} \tag{1}
\end{equation*}
$$

where $B_{4}$ is the magnitude of the octahedral field and other terms are the tetragonal distortions of second and fourth degree. We can take into account the tetragonal field in a potential in the form[12],

$$
\begin{equation*}
V=A_{2}^{0} r^{2} Y_{2}^{0}+A_{4}^{0} r^{4} Y_{4}^{0}+A_{4}^{4} r^{4}\left(Y_{4}^{4}+\bar{Y}_{4}^{4}\right) \tag{2}
\end{equation*}
$$

where the first and second term incorporate the tetragonal component.
The lower states and their energies are:

Doublet:

$$
\frac{1}{\sqrt{2}}(|+1\rangle+|-1\rangle)
$$

Singlet:

$$
\frac{1}{\sqrt{2}}(|+2\rangle+|-2\rangle)
$$

Energy:

$$
\begin{align*}
& -\sqrt{\frac{1}{14}} a-\sqrt{\frac{8}{63}} c \\
& \sqrt{\frac{2}{7}} a+\sqrt{\frac{1}{126}} c-\sqrt{\frac{5}{9}} d \tag{3}
\end{align*}
$$

where $\quad a=-\sqrt{\frac{5}{14 \pi}} r^{-2} A_{2}^{0}$

$$
\begin{aligned}
& \mathrm{c}=3 / \sqrt{14 \pi} r^{-4} A_{4}^{0} \\
& \mathrm{~d}=3 / \sqrt{14 \pi} r^{-4} A_{4}^{4}
\end{aligned}
$$

Stevens [12] has shown that states $|-1\rangle$ and $|+1\rangle$ etc. do not exhibit a purely d-nature due to pi- bonding between d-electron and the surrounding p-electron of oxygen atoms. We have two lower states due to a combined effect of the tetragonal field (with negative $\Delta$ ) and the spin - orbit interaction

$$
\begin{align*}
& |+1\rangle=\cos \beta|-1\rangle|-1 / 2\rangle-\sin \beta|0\rangle|+1 / 2\rangle \\
& |-1\rangle=\cos \beta|+1\rangle|+1 / 2\rangle+\sin \beta|0\rangle|-1 / 2\rangle \tag{4}
\end{align*}
$$

where

$$
\tan 2 \beta=\frac{\sqrt{2}}{(1 / 2) \lambda_{1}+\Delta} \lambda_{1}
$$

$\lambda_{1}$ is reduced spin orbit interaction. The expressions for $g$ - factors are given below as

$$
\begin{align*}
& g_{\|}=2\left|\sin ^{2} \beta-(1+K) \cos ^{2} \beta\right|  \tag{5}\\
& g_{\perp}=2\left|\sqrt{2} K \sin \beta \cos \beta+\sin ^{2} \beta\right|
\end{align*}
$$

where K is defined as

$$
\mathrm{K}=\langle+1| \mathrm{L}_{2}|+1\rangle
$$

and it is assumed that covalent bonding is isotropic. If we assume that bonding is anisotropic we can write

$$
\begin{align*}
& g_{\|}=2\left|\sin ^{2} \beta-\left(1+K_{\|}\right) \cos ^{2} \beta\right|  \tag{6}\\
& g_{\perp}=2\left|\sqrt{2} K_{\perp} \sin \beta \cos \beta+\sin ^{2} \beta\right|
\end{align*}
$$

where

$$
\mathrm{K}_{\|}=\langle+1| \mathrm{L}_{z}|+1\rangle \quad \text { and } \mathrm{K} \perp=\sqrt{ } 2\langle+1| \mathrm{L}_{\mathrm{x}}|+0\rangle
$$

From above equations we can estimate the nature of bonding inVO ${ }^{2+}$ ion doped different lattices with the help of EPR data and parametric angle $\beta$.

## 2. Results \& Discussion

The covalent bonding parameters $K_{\|}$and $K_{\perp}$ were determined with the help of EPR data of $\mathrm{VO}^{2+}$ ion doped in different single crystals given in Table $1[13,14,15]$. The values of these parameters $K_{\|}$and $K \perp$ with the parametric angle $\beta$ shown in Table 2 satisfy the experimental $g$ values.

In the presence of tetragonal crystalline field the covalent bonding parameters are less than 1 as there is no shifting of doublet in $\mathrm{t}_{2 \mathrm{~g}}$ and higher doublet $\mathrm{e}_{\mathrm{g}}$. The result shows that the value of one covalent bonding factor $\mathrm{K} \perp$ should be less than 0.048 in order to have a better fit to the experimental $g$ value [12]. The covalency is inversely proportional to the $g$ value [16] and the value of $g \|$ depends on the $K_{\|}$. If $K_{\|}$decreases, $g_{\|}$increases and covalency decreases showing that, the character of the complex will be more ionic. $g_{\perp}$ depends on the $K \perp$ and is directly proportional to it. Hence, its value will increase if $K_{\perp}$ increases; giving different nature to the complex as far as bonding is concerned

|  | 0.811 | 0.011 | 94.30 |

The rate of decrease of $K_{\|}$is more than $K_{\perp}$ so that the compound can be approximately considered to be more ionic. Thus electron will migrate to neighboring atom suggesting that the net amount of charge transfer should also be considered in the crystal field theory of ionic complex.

## 3. Conclusion

The nature of bonding of $\mathrm{VO}^{2+}$ ion doped in different single crystals has been evaluated. This result shows that the value of one covalent bonding parameter should be less than 0.048 in order to have a better fit to the experimental g value. The rate of decrease of $K_{\|}$more than $K_{\perp}$ shows that the compound can be approximately considered more ionic.
