Prevention of Pediatric Obesity: Focus on the First Two Years Lyndsey Gallagher, Kimberly Brown, MD¹, Clare Lenhart, PhD, MPH², Colleen Dempsey-Rex, RD, LDN¹

BACKGROUND

- 18.5% of children aged 2 to 19 are obese.¹
- Obesity rates are **disproportionately higher** in Hispanic and African American populations, and families of lower socioeconomic status.^{1,2}
- The Allentown zip code 18102 has the highest childhood obesity rates (22.7%) for LVHN's entire population.
- Rapid weight increases in the first 6 months of life are associated with obesity at 3 years of age.³
- There is a 70% chance that a child who is overweight or obese will remain obese in adulthood, leading to chronic health conditions.^{4,5}
- This study investigated whether enhanced dietary information at well visits from birth to 24 months would affect BMI.

CONCLUSION

No statistical differences in 24 month BMI between

Statistical significance between research patients and nonstudy clinic control patients for 12 month weight for length average percentile and 24 month average BMI percentile.

• There are 20 patients that still need their 2 year well visit to

Study barriers included patient no-shows, scheduling limitations, and change in scheduling personnel.

 Interventions focused only on education are ineffective against community conditions, cultural and nutrition habits,

 Increase community outreach in high need areas through partnerships with community organizations

 Focus on school-based and community-based interventions to bring healthy foods and nutrition
