Abstract. The purpose of this system is the application of lightweight slabs in mid-floor construction. In the case of a conceptual hotel design, which currently is predicted to be built in a classical mid floor reinforced construction, the practice of COBIAX lightweight construction without beams will highlight the advantages of this system. The system uses circular or oval hollow spheres, which are placed in the slab. This results in the creation of a lightweight slab, due to the reduction of mass, also a considerable reduction of columns, avoiding beams, reduction of the foundation plate thickness, decrease in floor height, etc. In this case, the architects will have the opportunity to design large and spatial structures, where the distance between the columns can reach up to 20 m. Reducing the amount of concrete of lightweight slabs in the COBIAX system, affects directly the reduction of CO₂(carbon dioxide) emission. Based on studies made by a German research organization, each m³ of concrete replaced with COBIAX, reduces approximately 210 kg of CO₂ emission, which makes COBIAX method an ideal system for eco designers. 1. Hollow spheres are placed in neutral axis where concrete has less shear or compression forces, reducing the volume of concrete. 2. Reducing of the concrete mass that is under tension force up to 35 %, has a positive impact in the whole structure which enables saving building material. The Slab thickness varies from 240 mm to 600 mm. While most standard slabs, transmit stress forces in two or one direction, lightweight COBIAX slab system distributes the stress forces in several direction. COBIAX slab needs up to 40% less load bearing columns, which offers architects better flexible opportunities in design.

Key words: stability, flexibility, economic cost, ecology, feasibility.

1 Introduction

Cobiax system has been applied in numerous structures in Europe, validating the acceptance of this system in Europe. This system of construction in our country (Kosovo) for the first time began to be applied in 2011/2012 in to a building called "World Trade Center" WTC-Pristina. It was used in a specific building: in the Commercial Center, while the rest of surrounding buildings such as: housing and administration are being built in classical system (slabs of reinforced concrete). To elaborate the advantages of this system we took a case study-a conceptual design of a hotel which is supposed to be built in the center of Pristina. This project was intended to be built in a classical system and the classical construction was replaced with Cobiax system. Various attempts were made in the past in order to reduce the weight of concrete slabs without reducing the flexural strength of the slab. Reducing the own weight in this way would reduce deflections and make larger span lengths achievable. Idea- *The essence of structural design is the appropriate usage of material. Unnecessary weight is created by materials that are not significantly contributing to a structure's stability.* A bird can fly because its bones are made of a hard shell with struts placed inside. The bone's weight is optimized and at the same time the bone is stable. Cobiax slabs differ in three ways from traditional solid flat plate slabs ;
*Reduce dead load due to the concrete displacement of the void formers. The bending moments and column reactions are reduced consequently
*Reduced stiffness of the slab due to the presence of the void formers. The deflection of the slab is influenced consequently.

*Reduced shear capacity of the slab due to the presence of the void formers. This requires the identification of the slab areas with too high shear in which the void formers mustn't be placed.

The Cobiax slab is dimensioned with the methods used for traditional flat slabs and compatible with any concrete design code.

1.1. Typology of Products

There are two types of Cobiax cage modules, the “Slim- Line” and “Echo- line”;

Slim Line

* Void former height 100 to 220 mm

*Slab depths 20 to 35 (+) cm

Echo- Line

*Void former height 225 to 450 mm

*Slab depths 35 to 60 (+) cm

Void formers, positioned between the bottom and top reinforcement layers - displaced concrete. They are used when the distance between the columns is large ie., when we have strain in which case concrete works more in pressure (98%) and less in traction. (cobiax Engineering; 2010).

It should be mentioned some points regarding this system;

a) Bending – The bending strength of Cobiax slabs was investigated in laboratory tests using various slab depths and void former sizes. The bending behaviour has been proved to be comparable with the one of solid slabs.

b) Stiffness – The void formers in Cobiax slab reduce its stiffness compared with solid flat slabs.

c) Shear – According to current standards, calculation of the shear strength for traditional one – way spanning hollow core slabs is based on the smallest available web width of a hollow cross section. With such criteria used for two-way spanning voided slabs, the resulting shear strength for Cobiax flat slab would only be about 10 % of the shear strength of a solid flat slab with same thickness.

d) Punching – Due to shear force limitations areas with high shear force concentration such as around columns heads are to be executed without Cobiaxcage modules. The critical perimeters that are relevant for the punching shear design are located within these solid areas. The punching shear considerations in these areas are therefore as for solid flat slabs. It is recommended to explicitly verify that the determining perimeter for punching is located inside the solid zone as shown on below drawing. Should this not be the case, the solid zone has to be increased accordingly. The reduced dead weight of the Cobiax flat slab decreases the column reactions and allows optimizing the necessary amount of punching reinforcement.

Fig 2 The realization of cobiax slab with sections

Source: Engineering Manual - Cobiax

e) Fire protection – Fire tests in specialized laboratories with Cobiax slab specimens have shown that above parameter and criteria can be applied with no limitation to Cobiax flat slabs and that they can withstand fire in the same way as solid flat slabs. The current fire rating of Cobiax slabs stands for 180 minutes issued by the German Authorities (report P-SAC 02/III – 187 done by MFPA)

f) Acoustic Insulation – Acoustic Insulation tests were conducted on Cobiax slabs with specimens in specialized laboratories as well as in completed buildings. The aim was to evaluate the acoustic insulation capacities of Cobiax slabs compared to solid flat slabs and to define an appropriate acoustic insulation rating method. Interpretation of these acoustic insulation measurements show that for a Cobiax slab the same acoustic insulation evaluation methods can be used as per solid flat slab.

g) Various technical issues – Compared to a solid slab of same thickness, Cobiax slab has an improved vibration performance. Cobiax flat slabs have higher natural frequencies for common practice live loads compared to solid slabs due to their reduced dead load.

1.2. Execution

Cobiax slab can be executed in traditional in-situ concrete or in combination with semi-precast elements.

In-situ concrete

Application of concrete slabs in site, is done through placements of void forms in between lower and upper steel reinforcement. First are placed 1.frames, 2. distance holders 3. reinforcement nets, 4.void formers, 5.concreting

Fig 3 Realization of the slab in workplace

1.cables for strain

1.frames, 2. distance holders,
3.reinforcement , 4.void forms,
5.reinforcement

Combination with semi-precasted elements

In this case void forms are placed in factory in a prefabricated slab and together are brought instantly into a construction site. In both cases void forms are placed in between lower and upper steel reinforcement.

Fig 4 Application of prefabricated slabs in site

Source: Cobiax Technologies

The advantage of this system is noted on the possibility of establishing installations on mid-floor slab construction, in which case we can remove any sphere without causing any constructive problem.

It is notably a suitable system for seismic countries. Concentrated masses are reduced without losing construction stiffness, and loads in foundations are reduced significantly by 15 %

2 Methodology

2.1. Case Studies

Fig 6 Several views of the building

Fig 7 Location

of the building in site

Source: ©Ertan Sylejmani

As a case study a conceptual hotel design was chosen. This building has 3 floors underground, a ground floor and 16 floors with a total height varying from 46,5 to 50,2 meters. This building is designed in a location chosen at the very center of the city of Prishtina known as Center 1. The reason why we have chosen this building as a case study is because during the design phase, the interior columns could create functional problems. These types of columns were not possible to be eliminated since the building was intended to be built by using a classical construction system. However, the application of void forms has enabled us to eliminate a considerable number of columns, the elimination of launching beams all in all, as well as reducing the floor-floor height.

Fig 8 Typical floor layout

Fig 9 A view of building construction

Source: ©Ertan Sylejmani

2.2. Comparisons

Knowing that with the application of void forms, the distance between the columns can go up to 20 m, we have decided to eliminate the selected columns highlighted in colour red, to achieve higher commodity and functionality.

Fig 10 Plan-comparison before and after

Source: ©Ertan Sylejmani

- a) Existing layout- where the distance between the columns was 7m
- b) Layout with columns that will be eliminated, where the distance between the columns will be 14m

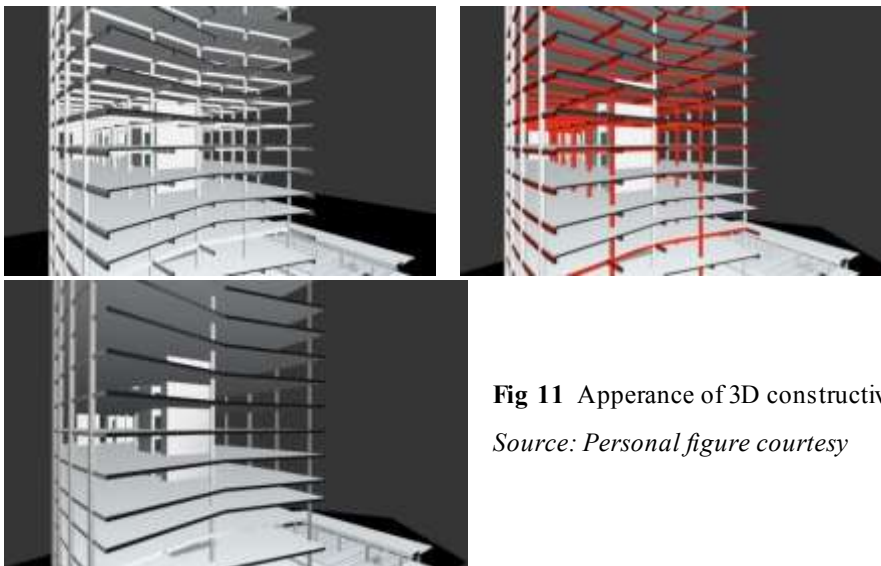

Fig 11 Apperance of 3D constructive system

Source: Personal figure courtesy

By replacing a solid slab with an agile type of slab (cobiax) as shown in the Figure nr. 12 results: in the elimination of the columns by producing new neat spaces and by eliminating launching beams floor-floor height is reduced. In an architectural aspect , it facilitates architects with great opportunities in floor flexibility and the execution of the building is easier.

Optimized with Void formers

2.3. Calculations

Fig 13 Layout where the surface from reinforced concrete is seen and the extension of void formers

Source: Personal photo courtesy

In the conceptual design the entire surface of slabs is with reinforced concrete with a 20cm height.

$$\begin{aligned}
 S &= a \times b \dots && (m^2) \\
 V_{\text{slab}} &= S_s \times h_s \dots && (m^3) \\
 V_{\text{columns}} &= S_c \times h_c \dots && (m^3) \\
 V_{\text{issued beams}} &= S_{ib} \times h_{ib} \dots && (m^3) \\
 V_{\text{foundation}} &= S_f \times h_f = \dots && (m^3) \\
 V_{\text{total}} &= V_s + V_c + V_{ib} + V_f = \dots && (m^3)
 \end{aligned}$$

For our project we have chosen the following; Void former height – 220 mm
 Void former horizontal diameter – 315 mm, and slab thickness from 350 mm, when dead load reduction per m² is 2.80 kN/m², concrete displacement per m² is 0.112 m³
 Number of void formers per m² is 8.16
 Width of the hidden beams is acquired 100 cm, the inner and the perimetric 60 cm (according to calculations), there are times when it is realized with sector as shown in Figure 2

$$\begin{aligned}
 V_{\text{slab(cobiax)}} &= S_s \times h_s \times 0.888 \dots (m^3) \\
 V_{\text{hidden beams}} &= S_{hb} \times h_{hb} \dots (m^3) \\
 V_{\text{columns}} &= S_c + h_c \dots (m^3) \\
 V_{\text{foundation}} &= S_f \times h_f = \dots (m^3) \\
 V_{\text{total}} &= V_s + V_{hb} + V_c + V_f = \dots (m^3)
 \end{aligned}$$

0.888 – amount of concrete slab of mid-floor

0.112 – amount of cobiax spheres

3 Results and Discussion

Slab surface is; $S=2\ 073.13\ m^2$

$h_s=20\ cm$

$V_{slab.} = 2\ 073.13 \times 0.2 = 414.62\ m^3$

$V_{columns} = 41.11\ m^3$

$V_{issude\ beams} = 84\ m^3$

$V_{foundation} = 3\ 768.83\ m^3\ hf = 1.6\ m$

$V_{p,sh,t} = 539.62\ m^3 \times 18\ floors = 9\ 713.16\ m^3$

$V_{total} = 13\ 481.99\ m^3\ concrete$

Concrete is selected with C25/30 class

Solid area; $S = 424.94\ m^2$

Cobiax area; $S=1648.19\ m^2$

$h_p=35\ cm$

$V_{slab} = 1648.19 \times 0.35 = 576.86 \times 0.888(\text{void formers}) = 512.25\ m^3$

$V_{hidden\ beams} = 424.94 \times 0.35 = 148.72\ m^3$

$V_{columns} = 21.79\ m^3$

$V_{foundation} = 2\ 753.4\ m^3\ hf = 1.2\ m$

$V_{s,c,b} = 689.72\ m^3 \times 18\ floors = 12\ 289.68\ m^3$

$V_{total} = 15\ 043.08\ m^3\ concrete$

Concrete is selected with C40/50 class, which affects the reduction of cross-cutting elements and contributes to a greater construction life length.

Static spaces $l_x 14$ and $l_y 7$ formers could be realized but this is more difficult to height would go to 1.4 and this floor-floor height impose us suspended column dimensions from slab height will be 10 cm, height would rise to hf. 160 hf. 120 cm.

m beside by using void also with ribbed system, be realized. The beam 1.0 m and as a result of would rise and would ceiling, it would increase 30 x 60, to 40 x 80 cm, while the foundation cm, while previously was

Beam 1- 40 – 140 cm

Beam 2 - 20 – 100 cm

$$2073.13 : 98 = 21.15$$

$$V_{\text{issued beam}} = 35.27 \times 21.15$$

$$V_{\text{slab}} = 207.313 \text{ m}^3$$

$$V_{\text{columns}} = 36.64 \text{ m}^3$$

$$V_{\text{issued beams}} = 745.96 \text{ m}^3$$

4 Conclusions

From these tests we can conclude that the application of void forms enables distances between columns up to 20 meters and by this we achieve 40% reduction of original planned columns with classical system of construction. It should be noted that these void spheres are manufactured using recycled materials. It contributes also in a shorter period of implementation, reduces cross-cuttings of vertical elements, achieving lower floor heights. By achieving lower floor heights, suspended ceilings are not required

resulting in lower foundation height as well. It contributes also in achieving a more affordable building costs, by reducing cubic meter volume of concrete from the local price of 200 euros to 130 euros.

In designing inner spaces, gypsum card boards could be applied, and they play a feasible role.
