INTRODUCTION

Burning mouth syndrome (BMS) is characterized by a continuous sensation of burning or heat in the oral cavity, mainly on the tongue, palate and/or gingiva¹⁻³, in the absence of a primary cause^{4,5}. Systemic diseases, such as diabetes mellitus or anemia, must be ruled out³. It is most common among postmenopausal women and causes intense discomfort and suffering.

There is no defined etiology for BMS other than precipitating causative factors, and it is still considered idiopathic. One of the most widely accepted theories is that the partial or total loss of chorda tympani (facial) nerve function disinhibits the trigeminal nerve, resulting in pain along trigeminal pathways, as both taste and pain systems are regulated by interneurons of the central nervous system (CNS)⁶⁻⁸. This theory is based on evidence of neuropathic mechanisms⁹⁻¹⁰, including the loss of small fibers in oral tissues¹¹, salivary and somatosensory abnormalities^{8-10,12-14}, reduced corneal reflexes¹⁵, and peripheral nerve degeneration¹¹⁻¹⁶. Despite the known interaction between smell and taste¹⁷, we found no studies that investigated it in relation to BMS.

Thus, the objective of this preliminary study was to determine tactile, pain, thermal, gustative and olfactory thresholds in a group of patients with BMS as compared with controls.

METHODS

This research was approved by the Ethics Committee of Hospital das Clinicas, Medical School, University of Sao Paulo (HC-FMUSP), and all patients provided informed consent. Twenty consecutive patients with BMS, diagnosed according to the International Association for the Study of Pain (IASP) criteria¹⁸, were evaluated by the HC-FMUSP orofacial pain team between August 2007 and January 2008 and then compared with 30 normal subjects. All patients had BMS for more than 3 years and had no oral infections or

other lesions and no diseases included in the exclusion criteria.

Inclusion criteria: The study included 20 patients newly diagnosed with BMS who had not begun pharmacological treatment and 30 healthy controls with no complaint of facial or intraoral pain within the last 6 months who were consecutively selected from patients receiving dental treatment at the Dentistry Division of the hospital.

Exclusion criteria (for patients and controls): Exclusion criteria included Sjögren syndrome, rheumatological diseases (i.e., fibromyalgia and rheumatoid arthritis), diabetes, anemia, hyper- or hypothyroidism, generalized pain, and history of surgery in the facial/oral region. The patients and controls underwent a systematized evaluation by the hospital's general physician to investigate the presence of systemic diseases. In addition to the clinical exam, a hematological evaluation of thyroid hormones, glycemia, rheumatoid factors, including reactive C protein and hemodimentation velocity, and hemogram values was performed.

All subjects underwent a standardized superficial facial sensibility protocol applied to distinct areas of the face (bilateral trigeminal branches) and oral mucosa (superior and inferior arches)¹⁹ in the following order.

- (1) Thermal sensibility (using an electrical device designed at the Functional Neurosurgery Division of HC-FMUSP) at a temperature range between 0°C and 50°C.
- (2) Mechanical/tactile sensibility (using microfilaments from von Frey) ranging from 0.1 g/mm² to 10.0 g/mm².
- (3) Pain sensibility/superficial algometry (using Micromar[®], Diadema, São Paulo, Brazil).

Each thermal and mechanical stimulus was applied three times, and the threshold was established when the subject recognized at least two of the three applications. If this did not happen, the next stimulus in crescent order would be applied to avoid a tolerance effect. Algometry was performed with a superficial device and a disposable 0.7×15-mm needle. The ophthalmic branch (V1) was evaluated 1 cm above the eyebrow, and the maxillary branch (V2) was evaluated 1 cm to the side of the nose wing. Finally, the mandibular branch (V3) was evaluated 1 cm below the angle of the lips.

Table 1 - Age and gender of BMS patients and controls (N = 50).

Groups	Age (\pm standard deviation) <i>P</i> = 0.0033	Gender (female)
BMS	60.95 (\pm 12.21)	16 (80.0%)
CG	68.86 (\pm 9.79)	10 (33.3%)

BMS: Burning mouth syndrome; CG: Control group.

(4) Gustative thresholds were set according to the following molar concentrations²⁰⁻²².

- Sweet (glucose): 0.01; 0.032; 0.1; 0.32; 1.0.
- Sour (citric acid): 0.01; 0.032; 0.1; 0.32; 1.0.
- Salty (sodium chloride): 0.01; 0.032; 0.1; 0.32; 1.0.
- Bitter (urea): 0.01; 0.032; 0.1; 0.32; 1.0.

A single drop of each concentration was applied and swallowed by the patient; the results were compared to results from a single drop of distilled water. When the stimulus was not perceived, the next concentration was applied. The patient's mouth was washed with distilled water between different tastes.

(5) Olfactory threshold with isopropanol solutions (9.9; 15; 23.3; 32; 48; 53; 70%)²³⁻²⁴. Each concentration was offered to the patient along with a bottle of water, and the patient was asked to choose the bottle containing the substance three times. The threshold was established when the patient correctly chose all three times. If the patient chose incorrectly, the next concentration was offered along with a bottle of water.

All subjects were evaluated in the sitting position, with the head resting on a flat surface and the Frankfurt line parallel to the ground. All evaluations took place at the same time of day (between 1 and 4 pm) in a silent room with acoustic protection on the walls and with the door closed. Only the patient and the researcher were in the room during evaluations. All patients were evaluated by the same researcher. The subjects received the same instructions after being positioned, which were to keep their eyes closed during the exam and to identify and report whether they felt the stimuli being applied to the face (by saying "yes" or "no") and what they felt (by naming the stimulus). Only the researcher knew the order in which the stimuli would be presented. Finally, all findings were tabulated and statistically analyzed.

Statistical analysis

For age and algometry, we used the one-factor ANOVA and Tukey's test. The Kruskal-Wallis test was used to

Table 3 - Between-group comparison of the superficial algometry means for all trigeminal branches. Thresholds at V1 and V2 (N = 50) were higher.

	V1 (<i>p</i> = 0.289)	V2 (<i>p</i> = 0.132)	V3 (<i>p</i> = 0.143)
BMS	31.900 \pm 20.83*	28.067 \pm 9.36*	25.067 \pm 8.93
CG	24.733 \pm 9.73	23.000 \pm 12.50	22.350 \pm 7.88

*One-factor ANOVA and Tukey's test (*p* < 0.05)

analyze facial and oral sensitivity. Finally, gustative and olfactory thresholds were evaluated with the Kruskal-Wallis test followed by Dunns test. The level of significance was *p* < 0.05.

RESULTS

Demographic characteristics

The mean age of subjects was 60.95, and there were 16 women and 4 men in the BMS group. There was a significant age difference between groups (Table 1).

Somatosensory findings

There were no between-group differences in the somatosensory results for the ophthalmic branch, and similar cold thresholds were noted between the groups. The BMS patients had higher tactile thresholds at the maxillary branch (*p* = 0.001) and higher warm thresholds at the maxillary (*p* = 0.032) and mandibular (*p* = 0.001) branches (Table 2). The BMS patients had higher pain thresholds at the ophthalmic and maxillary branches (*p* < 0.05) (Table 3). There were no intraoral sensibility differences between the studied groups (*p* = 0.87).

Gustative evaluation

The gustative evaluation showed significant differences in all basic tastes (sweet *p* < 0.001; salty *p* = 0.004; sour *p* = 0.001; bitter *p* = 0.001). The BMS patients had higher salty, sweet and bitter thresholds but lower sour thresholds (Figure 1). Neither group exhibited difficulties with taste identification.

Olfactory evaluation

The BMS patients had higher olfactory thresholds (Figure 2).

DISCUSSION

This study presents evidence that supports the theory that the neuropathic mechanisms underlying BMS involve the somatosensory, gustative and olfactory pathways. To our

Table 2 - Between-group comparison of superficial sensibility in all modalities (cold, warm, and tactile) given the three trigeminal branches. Thresholds for the warm (V2 and V3) and tactile (V2) modalities were higher (N = 50).

Modalities	V1			V2			V3		
	BMS	CG	<i>p</i>	BMS	CG	<i>p</i>	BMS	CG	<i>p</i>
Cold	1.35 \pm 0.67	1.27 \pm 0.45	0.467	1.35 \pm 0.67	1.10 \pm 0.31	0.793	1.40 \pm 0.68	1.27 \pm 0.45	0.076
Warm	1.45 \pm 1.76	1.00 \pm 0.01	0.097	1.40 \pm 0.75	1.01 \pm 0.01	0.032*	1.45 \pm 0.78	1.00 \pm 0.01	0.001*
Tactile	1.40 \pm 0.50	1.03 \pm 0.18	0.064	2.40 \pm 0.50	1.03 \pm 0.18	0.001*	1.40 \pm 0.50	1.03 \pm 0.18	0.095

knowledge, this is the first time the olfactory threshold of BMS patients has been investigated, and the findings show abnormalities in the trigeminal, gustatory and olfactory

systems. Thus, these findings support the notion that central sensitization is involved in the physiopathology of this disease⁶⁻⁸. The pathophysiology is complex because of the

overlapping of cortical areas that receive afferents with trigeminal and gustative inputs²⁵. Furthermore, taste perception includes olfaction, and olfaction also requires somatosensory input²⁶. These three sensory systems (i.e., trigeminal, gustatory and olfactory) show abnormal interactions in patients with BMS.

Our results are similar to those of previous studies that show decreased somatosensory perception in BMS patients, including higher tactile and thermal thresholds in all trigeminal branches^{8,9,12}, higher taste thresholds^{10,13,14} and a delay in the blink reflex¹⁵. Thermal abnormalities in the orofacial region that only pertain to the perception of warmth might be associated with the burning sensation these patients describe, and it has been reported that abnormal functioning of the warmth-perceiving pathways can induce burning pain sensations²⁷. It is possible that in BMS, there is a malfunction in warmth detection that leads to a pain sensation and, when it becomes chronic, induces other somatosensory, gustative and olfactory disturbances through central mechanisms, including neuroplasticity at the cortical areas responsible for sensory interaction²⁶. Abnormal taste has been described as a consequence of the loss of warmth detection²⁷. In this sense, BMS could be described as a phantom sensation of heat on the tongue.

In the gustative evaluation, the sweet, salty and bitter tastes had higher thresholds, but the sour taste had lower thresholds. Sour is the taste that involves the activity of H⁺ ions directly through channels in the receptor membranes, which also can activate small pain fibers. In addition to peripheral nerve degeneration^{11,16}, a more sensitive perception of acids (for taste and pain) could be a peripheral mechanism of BMS.

A limitation in this study is the small sample size. Larger studies are necessary to confirm the reported results. Although there was an age difference between the groups, the implications of this difference are controversial, especially for gustation and olfaction, which apparently does not differ by age or gender²⁸.

In conclusion, this preliminary study shows evidence of abnormal thresholds for pain, tactile, warmth perception, olfaction and gustation. Given these results and previous results in the literature, we propose a phantom heat sensation involving central pathophysiology as a mechanism in BMS.
