Physiotherapy

ABSTRACT

Background and purpose: Huntington's disease (HD) is a neurodegenerative, progressive disorder of the central nervous system which causes significant gait and balance disturbances. This is a pilot study which aims to determine the effects of a physiotherapy programme with use of Proprioceptive Neuromuscular Facilitation (PNF) on gait and balance in HD patients.

Material and methods: 30 HD patients aged 21–60 with genetically confirmed diagnosis participated in the study. Participants followed a 3-week-long PNF-based physiotherapy programme. Gait and balance were evaluated twice in each participant: first at baseline and then after the course of physiotherapy. The following methods were used for gait disturbances: Tinetti Gait Assessment Tool, Up and Go Test, Timed Walking Tests for 10 m and 20 m (TWT10m, TWT20m). Balance was assessed with use of Berg Balance Scale, Pastor Test and Functional Reach Test.

Results: There was a significant improvement in all measures of balance and gait.

Conclusion: PNF-based physiotherapy is effective and safe in HD patients.

1. Introduction

Huntington's disease (HD) is a neurodegenerative, progressive disorder of the central nervous system inherited in an

autosomal dominant trait. HD is clinically manifested by cognitive impairment, behavioural signs and a variety of movement disorders including chorea, dystonia, ataxia or parkinsonism [1]. All of these movement disorders cause gait disturbances and increase the risk of falls [2]. The typical

features of gait disturbances in HD are as follows: reduction of gait velocity and frequency, extended gait cycle, prolonged double support phase, shortening of the step length, and large variability in the length and height of steps [3–6]. The mechanism of gait disturbances in HD is still unknown. Involuntary movements seem to play minor role and their treatment does not improve gait [6]. Another symptom of HD is balance disturbances. Recent study shows that HD patients produce more sway than control subjects during standing. Furthermore, they have slower reaction and more falls while unexpected or sudden rotation of the support surface [7]. Gait and balance dysfunction occur in an early stage of the disease [8]. So far there have been several papers on gait and balance disorder in Huntington disease, most of them included small numbers of participants and showed positive results of rehabilitation and physical therapy [9–11] and none of them used a special physiotherapeutic technique. There is no established pharmacotherapy of gait or balance disturbances in HD therefore physiotherapy appears encouraging therapeutic option [12,13]. Physiotherapy techniques constitute the primary treatment approach in the management of gait and balance disturbances irrespectively of the cause. Proprioceptive Neuromuscular Facilitation (PNF) is one of widely used methods of physiotherapy. It is a complex technique of neuromuscular re-education [14] which is based on the maximal stimulation of proprioceptive and external (touch, verbal, visual) receptors aiming at activation of impaired structures of the nervous system. PNF was previously found effective in the treatment of gait and balance disturbances in Parkinson's disease (PD) [15,16]. This study aims to determine the effects of the PNF physiotherapy programme on gait and balance of patients with Huntington's disease.

2. Material and methods

The study was conducted between October 2009 and May 2010 according to the Declaration of Helsinki and was approved by the Local Ethical Committee. The inclusion criteria were as follows: mutation in the *HTT* gene in genetic testing, HD motor manifestation (chorea, dystonia, and/or gait disturbances) at baseline neurological examination, stable pharmacotherapy for at least one month prior to inclusion, the patient's informed consent to participate in the study. The exclusion criteria were: severe disability (stage 5 of the Shoulson and Fahn scale [17]), significant cognitive dysfunction or psychiatric symptoms (e.g. aggression, psychosis, depression) that prevented effective cooperation between the patient and physiotherapist, any orthopaedic condition (e.g. fractures, sprains) impeding movement. Participation in the study was offered to 34 consecutive HD patients admitted to the Department of Neurology, Outpatients Clinic. Two patients refused to take part in the study. The remaining 32 patients were included in the study, followed baseline examination and entered the physiotherapy programme. Two patients were excluded during the course of physiotherapy because of an outburst of impulsive behaviour. The characteristics of the study group are shown in Table 1. The intervention was a 3-week-long intensive physiotherapy programme. Physiotherapy was provided five days a week (15 sessions). During each

Table 1 – Characteristics of the study group.

Patients	Mean	Standard deviation	Range
Age (years)	43.4	13.8	20–60
Number of CAG repetitions	46.6	6.0	40–62
Disease duration (years)	7.0	5.8	2–10
UHDRS cognitive	123.9	43.31	10–186
UHDRS motor	40.8	20.0	10–78
UHDRS functional assessment	17.6	4.6	7–25
UHDRS independence scale	76.67	13.2	50–100
TFC	7.7	3.1	3–13

UHDRS – unified Huntington's disease rating scale; TFC – total functional capacity.

session the treating physiotherapist applied all the main techniques and principles of facilitation (e.g. slow approximation, timing for emphasis, bilateral reciprocal patterns) according to the PNF concept and used mainly the closed kinematic chains. Each session was 90 min long and consisted of three parts:

- introductory part (10 min) which included: warm-up, education of a correct body awareness and respiratory pattern,
- main part (70 min) which included: improvement of balance reactions, mat activities (rolling/prone on elbows/bridging/side sitting/quadruped/kneeling/half-kneeling/standing), exercises in a sitting position (rocking/scooting), gait training (weight shifting/one leg standing/walking forward, backward, sideways/braiding),
- end part (10 min) which included relaxation techniques.

Pharmacotherapy was not changed during the study period. Gait and balance were evaluated twice in each participant: first at baseline and then immediately after the completion of the physiotherapy programme. The following methods were used for gait assessment: Timed Walking Test for 10 m (TWT10m) and Timed Walking Test for 20 m (TWT20m) [18,19], Up and Go Test (TUG) [20], Tinetti Gait Assessment Tool [21]. Balance was assessed with use of the Functional Reach Test (FRT) [22], Berg Balance Scale (BBS) [7] and Pastor Test [23]. Statistical analysis was done in the group of 30 patients who completed the course of physiotherapy and final examination. The analysis was performed using STATISTICA® 9 Statsoft. The non-parametric Wilcoxon test (matched pairs) was used. For correlation analysis Spearman's rank correlation coefficient was used.

3. Results

The improvement of static and dynamic balance was seen in a clinical scale (BBS) as well as in anticipatory balance tests (FRT, Pastor Test). The improvement of gait was significant in all tests. Gait and balance improvement seem to be higher in patients with more advanced gait disturbances. Unwanted effects of PNF were not identified. The two patients who were excluded from the study because of behavioural disturbances had had episodes of impulsive behaviours in the past, therefore we do not regard behavioural outbursts as an

adverse event of PNF. The mean values of gait and balance measures before and after the course of physiotherapy as well as the mean difference are presented in Table 2.

4. Discussion

Previous studies show that rehabilitation (physiotherapy, occupational therapy, speech therapy) appears effective in the improvement of gait, balance, mobility and physical capability in HD and enhances patients independence [10,24,25]. The efficacy of physiotherapy alone was evaluated in a single study by Bohlen in 12 HD patients. The patients were provided physiotherapy twice-weekly over 6 weeks. Significant improvements after physiotherapy were seen in TUG and BBS [11]. Improvement of motor disturbances after various antidopaminergic drugs is known in HD. However, there is sparse data in the literature on pharmacotherapy of gait and balance disturbances [26]. As compared to the data on the efficacy of PNF in PD patients, the improvement in gait and balance in our HD sample is rather small [15]. The possible explanation for the remarkably lower efficacy of PNF may be the cognitive impairment and behavioural disturbances of the HD patients. Although patients with severe dementia were excluded, the executive dysfunction of the participants might have affected therapy. Nevertheless physiotherapy of patients with cognitive impairment is possible and may be effective as shown in a study in Alzheimer's disease [27]. Another potentially confounding factor affecting treatment is behavioural disturbances. Apathy defined as lack of motivation seems to be the most common and troublesome behavioural symptom in HD [28]. Neither cognitive dysfunction nor behavioural disturbances were analysed as confounders of PNF efficacy in the present study.

The assessment of the efficacy of any therapeutic intervention is an extremely important part of its development

and implementation. We have identified three groups of methods that may be applied to formal efficacy assessment: global functional scales or specific scales for gait, posture or neurologic signs assessment (e.g. TFC, UHDRS, BBS), functional tests (e.g. FRT, TWT10m) or instrumental methods, e.g. 3-D gait analysis. So far, none of the mentioned methods has been regarded as a gold standard of gait or balance assessment. The methods of gait and balance assessment applied in this study provide reliable and multidimensional information on gait and balance disturbances [1] and have been previously used in the assessment of a therapeutic interventions on gait or balance [29,30].

Some limitations of the present study should be raised. First, the sample was small, thus it was not possible to stratify the results to disease severity, cognitive impairment, behavioural disturbances or drug allocation. Second, the sample was quite inhomogeneous in terms of the severity of symptoms and baseline measures of gait and balance. Another weakness of the study was lack of a delayed assessment of gait and balance following the final assessment. However, taking into account the study by Zinzi et al., who showed that there is a continuous effect of rehabilitation in HD after two years [10], we believe that PNF may also provide an unfading effect.

It is a matter of debate whether use of a protocol with a no-physiotherapy control group provides any additional information. We assume that the prerequisite of stable pharmacological treatment throughout the study and one month prior to inclusion excludes confounding effects of medication on the results of the study.

The efficacy of PNF should now be estimated in a group of early stage HD patients, and long-term effects should also be evaluated. Further research is also needed to predict the best responders to this method and compare PNF with other physiotherapeutic methods and pharmacologic therapy.

Table 2 – Descriptive statistics for measurements before and after PNF therapy.

Test		Me	Q ₁	Q ₃	Mean (range)	Standard deviation	Mean difference (range)	Standard deviation of difference	p-Value
Berg Balance Scale (score)	BA	50	43	53	46.9 (19.0–30.0)	8.6			
	FA	52.5	50.0	56.0	52.5 (38.0–56.0)	5.3	–5.6 (–20–0)	5.7	0.000008

Me – median; Q₁ – first quartile; Q₃ – third quartile; BA – baseline assessment, FA – final assessment.

5. Conclusion

The present study shows that gait and balance in HD patients improved after PNF therapy. PNF is based on the concept of stimulation of the brain in order to employ the compensatory mechanisms and neuronal plasticity to restore the lost function. The efficacy of PNF in HD demonstrates that the brain of a HD person which is globally burdened, may still be successfully stimulated. We suggest that physiotherapy based on the PNF concept should be used in HD as a complementary method to pharmacotherapy because it is safe and efficient.
