## SUMMARY

### Section I

#### Primarily Data From Hand-Harvested Tests

There was a significant difference in lint yield among varieties each year at each location. There was a variety x location interaction each year. Early-maturing varieties such as Hancock and Auburn M were more consistent in lint yield than some of the later-maturing varieties. Some varieties such as Empire W.R. 61 ranked low consistently in lint yield. Stardel did well at Jackson and Ames Plantation but very poorly at Fort Pillow.

Yarn strength of lint samples obtained from mechanically-harvested cotton that had been ginned on a commercial gin at Jackson in 1966 averaged less than that of hand-picked samples that were ginned on a 10-saw laboratory gin.

### Section II

#### Advanced Strains Test

Significant differences among varieties were obtained each year. Early strains usually (but not always) performed well in the advanced strains test. Some experimentals possess special attributes such as superior fiber properties or glandless seed. Unfortunately, the strain exhibiting the most desirable fiber properties frequently does not yield competitively with varieties that possess shorter and weaker fibers.

Hancock (tested as T-59-134), Deltapine 45A, Deltapine 16, McNair 1032, and Coker 201 are some of the recent varietal releases that were evaluated in the advanced strains tests before release.

### Section III

#### Mechanically Harvested Cotton

There was a statistical difference in lint yield among varieties in every test except at Ames Plantation in 1963.

Deltapine Smooth Leaf, Dixie King II, and Auburn M gave the highest average acre value return at Milan. Also Deltapine Smooth Leaf and Dixie King II gave the highest 3-year average return at

Ames Plantation. Deltapine Smooth Leaf and Rex Smoothleaf consistently graded one grade better than Dixie King II. Yarn strength of lint samples obtained from a commercial gin averaged less than that of hand-picked samples which were ginned on a 10-saw laboratory gin.

The length (2.5% span length) and strength ( $T_1$ ) were lower, in general, where the mechanically-picked cotton had been ginned on a commercial gin when compared to hand- or machine-picked samples that had been ginned on a 10-saw laboratory gin.

## DEFINITIONS AND TERMS USED IN THIS REPORT

*Seed cotton yield*—is reported in pounds per acre.

*Total lint yield*—is reported in pounds per acre and determined by multiplying seed cotton pounds per acre by percent lint for hand picked cotton. The mechanically-harvested seed cotton yields per acre were multiplied by gin turnout to get total lint yield.

*Percent*—1st picking — is calculated by dividing the lint yield at first picking of a given variety by its total lint yield.

*Earliness Index*—was determined by expressing the yields at first picking as a percentage of the yield of Auburn M at 1st picking.

*Bolls per pound*—was determined by:

$$\frac{\text{Number of bolls in sample}}{\text{Weight of seed cotton sample}}$$

*Percent lint*— $\frac{\text{Weight of ginned lint from sample}}{\text{Weight of seed cotton sample}}$

*Gin turnout*— $\frac{\text{Weight of lint from commercial gin}}{\text{Weight of mechanically-harvested cotton}}$

*Ginning loss*—Weights of lint plus seed were subtracted from machine-picked cotton weights.

*Classer's staple length*—Length given in 32nds of an inch to samples submitted to the Board of Cotton Examiners, Memphis Classing Office, Memphis.

*Acre value*—(Lint + seed values) Lint values were based on the Memphis Spot Market. Seed values were based on Cottonseed Review South Central area.

*50% Span Length*—The 50% span length is a measure of the distance from a base line spanned by 50% of the fibers in the sample.

*2.5% Span Length*—The 2.5% span length is a measure of the distance from a base line spanned by 2.5% of the fibers in the sample.

<i>2.5% Span Length</i>	<i>Staple</i>
<1.00—1.00	15/16—1 1/32 (33/32) short
1.01—1.10	1 1/16 (34/32)—1 3/32 (35/32) average
1.11—1.20	1 1/8 (36/32)—1 3/16 (38/32) medium long
1.21—1.30	1 7/32 (39/32)—1 9/32 (41/32) long
1.30+	1 5/16 + (42/32) extra long

**UHM** (Upper half mean)—UHM is another measure of length and it approximates classer's staple and also 2.5% span length.

**Mean**—Mean is the average length in inches of all fibers longer than 1/4-inch.

**Micronaire**—Micronaire is a relative measure of fiber fineness or coarseness; higher readings indicate coarse fibers and low readings indicate fine fibers.

#### *Micronaire*

6.0+	Very coarse
5.0—5.9	Coarse
4.0—4.9	Average
3.0—3.9	Fine
3.0	Very fine

**Yarn Skein Strength (YS)**—The yarn skein strength is the force in pounds as an average of 20 determinations required to break a skein. This breaking strength has been corrected to a yarn number of 27.0 tex and is in terms of the standard skein. The corrected standard skein strength is the observed miniature skein strength converted to standard skein strength and corrected to a yarn number of 27.0 tex. The equation is as follows:

$$\text{corrected standard} = \frac{\text{Min. skein strength} \times 1.84 \times 27.0}{\text{skein strength} \quad \text{observed yarn number}}$$

**Fiber Strength (T<sub>1</sub>)**—Fiber strength is the force required to break a bundle of fibers on the Stelometer with two jaws holding the fiber bundle separated by a 1/8-inch spacer. Strength is expressed in terms of grams per tex. High readings indicate fiber of greater strength and low readings indicate fiber of lesser strength.

#### *Fiber Strength (T<sub>1</sub>)*

22.5+	Very strong
20.1—22.4	Strong
17.6—20.0	Average
15.1—17.5	Fair
15.0 or less	Weak

**E<sub>1</sub>**—The percentage elongation at break of the fiber bundle measured for T<sub>1</sub> strength on the Stelometer. High readings denote greater elongation.

## DESCRIPTION OF RECOMMENDED VARIETIES

### *Auburn M*

*Maturity:* Very early.

*Growth Habit:* Determinate to semi-determinate.

*Bolls per lb.:* 63.

*Disease Reaction:*

- a. Resistant to fusarium wilt, root knot nematode complex.
- b. Moderately tolerant to verticillium wilt.

*Lint Percentage:* 36 to 38.

*Fiber Properties:*

- a. Length: 2.5% span length (1.08)<sup>1</sup>.
- b. Strength: T<sub>1</sub> (1.75).
- c. Fineness: Micronaire (4.24).
- d. Spinning quality: skein strength of 27 tex yarn, range (107-123), average (113).

### *Auburn 56*

*Maturity:* Medium-late.

*Growth Habit:* Erect, vigorous, medium height, variable in growth habit, high degree of storm resistance.

*Bolls per lb.:* 68.

*Disease Reaction:*

- a. Resistant to fusarium wilt, root-knot, nematode complex.
- b. Has some tolerance to verticillium wilt.

*Lint Percentage:* 36 to 38.

*Fiber Properties:*

- a. Length: 2.5% span length (1.07).
- b. Strength: T<sub>1</sub> (1.78).
- c. Fineness: Micronaire (4.33).
- d. Spinning Quality: skein strength of 27 tex yarn, range (104-124), average (114).

### *Rex Smoothleaf*

*Maturity:* Early.

*Growth Habit:* Shorter than other commonly grown southeastern varieties. Determinate.

*Bolls per lb.:* 62.

*Disease Reaction:*

- a. Resistant to fusarium wilt.
- b. Resistant to one race of bacterial blight.

<sup>1</sup> All fiber properties are average values for a number of years.

*Lint Percentage:* 35 to 37.

*Fiber Properties:*

- a. Length: 2.5% span length (1.09).
- b. Strength: T<sub>1</sub> (1.75).
- c. Fineness: Micronaire (4.07).
- d. Spinning Quality: skein strength of 27 tex yarn, range (108-119), average (114).

*Stardel*

*Maturity:* Early.

*Growth Habit:* Tall.

*Bolls per lb.:* 75.

*Disease Reaction:* Not recommended where wilt is a problem.

*Lint Percentage:* 36 to 38.

*Fiber Properties:*

- a. Length: 2.5% span length (1.09).
- b. Strength: T<sub>1</sub> (1.92).
- c. Fineness: Micronaire (4.36).
- d. Spinning Quality: skein strength of 27 tex yarn, range (109-130), average (122).

*Carolina Queen*

*Maturity:* Late.

*Growth Habit:* Tall open plant, and uniformly-spaced bolls.

*Bolls per lb.:* 68.

*Disease Reaction:* Resistant to fusarium wilt.

*Lint Percentage:* 36 to 39.

*Fiber Properties:*

- a. Length: 2.5% span length (1.11).
- b. Strength: T<sub>1</sub> (1.83).
- c. Fineness: Micronaire (4.44).
- d. Spinning Quality: skein strength of 27 tex yarn, range (103-129), average (117).

*Dixie King II*

*Maturity:* Medium-early.

*Growth Habit:* Medium size, upright plant. Plant retains leaves longer than most other varieties tested.

*Bolls per lb.:* 58.

*Disease Reaction:* Tolerant to fusarium wilt.

*Lint Percentage:* 35 to 37.

*Fiber Properties:*

- a. Length: 2.5% span length (1.08).
- b. Strength: T<sub>1</sub> (1.77).
- c. Fineness: Micronaire (4.36).
- d. Spinning Quality: skein strength of 27 tex yarn, range (104-124), average (114).

*Stoneville 213*

*Maturity:* Medium-late.

*Growth Habit:* Similar to Stoneville 7A. Medium height.

*Bolls per lb.:* 71.

*Disease Reaction:* Shows some tolerance to verticillium wilt.

*Lint Percentage:* 36 to 39.

*Fiber Properties:*

- a. Length: 2.5% span length (1.08).
- b. Strength: T<sub>1</sub> (1.80).
- c. Fineness: Micronaire (4.64).
- d. Spinning Quality: skein strength of 27 tex yarn, range (107-124), average (114).

*Hancock*

*Maturity:* Very early.

*Growth Habit:* Semi-determinate, medium height, leaves of the "Empire type" and the fruiting branches are short and angle upward presenting a semi-cluster appearance.

*Bolls per lb.:* 63.

*Disease Reaction:* Unknown.

*Lint Percentage:* 37 to 40.

*Fiber Properties:*

- a. Length: 2.5% span length (1.06).
- b. Strength: T<sub>1</sub> (1.78).
- c. Fineness: Micronaire (4.33).
- d. Spinning Quality: skein strength of 27 tex yarn, range (111-125), average (117).

## COTTON VARIETY TESTING PROGRAM

The cotton variety testing program consists essentially of two parts or phases. The first phase is the advanced strains test. The cotton breeder conducts this phase which includes the most promising experimental strains of cotton from Tennessee and experiment stations in adjacent states and from commercial companies. If a variety performs well in the advanced strains test, it is then entered in the state variety testing program. Varieties are evaluated for 3 years in the state variety tests before they are considered for recommendations by the Experiment Station.

Results reported here are from tests conducted at Jackson, Fort Pillow, Ames Plantation, and Milan.

The Fort Pillow test is located on bottom land with soils of Morganfield and Adler silt loam types which has a wilt disease complex. No disease problem was noted at any of the other locations. Jackson and Ames Plantation tests were conducted on upland soils such as Loring, Grenada, and Memphis silt loam. The tests at Milan were conducted on Collins silt loam, a bottom soil.

The University of Tennessee Agricultural Experiment Station participates in the Regional cotton variety testing program by including the National and Regional standard entries at two locations. Fort Pillow represents the Delta region and Jackson represents the Eastern region.

This report is divided into three sections. The first section is a summary of hand-harvested cotton variety tests in Tennessee from 1963 through 1966. Also included in this section are data for spindle picked tests at Jackson and Ames Plantation for 1966.

The second section consists of data obtained from the advanced strains tests at Jackson. These tests were hand picked.

Section three includes data for several varieties which were mechanically harvested with a spindle picker and ginned on commercial gins at Ames Plantation and Milan.

Section I  
Primarily Data From Hand-Harvested Tests  
Procedure

A randomized block design was used each year for each test. Two-row plots, each 60 feet long, were used at Jackson and Ames Plantation in 1966. All other tests reported in this section consisted of 2-row plots, 35 feet long. The test at Ames Plantation in 1966 contained 6 replications and all other tests contained 8 replicates. Recommended cultural practices were followed in each test and were the same for all entries in any given test.

Two 160- or 150-boll samples were taken from each variety immediately before first picking of all tests. These samples were ginned on a 10-saw laboratory gin. Gin, seed, and fiber data were obtained from these samples.

The cotton variety tests in 1966 at Jackson and Ames Plantation were harvested with a spindle picker. Four replicate samples of each variety were taken from the mechanically-harvested cotton at Jackson and three at Ames Plantation. These samples were fractionated to determine the percent trash for each variety. These fractionated samples were combined by variety and ginned on a 10-saw laboratory gin to determine the percent lint. The percent lint and the percent trash for each variety were used to calculate lint yields at these two locations.

Varieties are listed in order of descending dollar value per acre (lint + seed). The lint values each year were based on the Memphis Spot Market for middling inch cotton. Seed values were based on Cottonseed Review, South Central area. Acre value, yield, and other characteristics of the varieties are presented in Tables 1 through 24. Fiber data are presented in Tables 25 through 42.

## RESULTS AND DISCUSSION

There was a significant difference in lint yield among varieties each year at each location (Tables 4 through 7). There was a variety x location interaction each year. Part of this variety x location interaction was due to the wilt disease complex at Fort Pillow. Some varieties were more tolerant to wilt than others. In Table 8 it can be seen that Hancock ranked first in lint yield 6 out of 9 times in these tests from 1963 through 1965. Using a 4-year average, Hancock ranked first 7 out of 12 times. The 1966 data were not presented in this table because Ames Plantation yields in 1966 were so low. Hancock was consistent in its yielding ability, whereas varieties such as Carolina Queen and Deltapine Smooth Leaf which are late-maturing varieties did not consistently produce high yields in Tennessee. However, under favorable conditions such as early planting and good weather, these varieties did perform well. Stardel did well at Jackson and Ames Plantation but very poorly under wilt conditions at Fort Pillow. Hancock and Auburn M, both early-maturing varieties, were among the top four varieties in acre value at all locations as shown in Tables 1 through 3. Empire W.R. 61 ranked low consistently in lint yield and acre value.

Dixie King II, Stoneville 213, Auburn M, and Auburn 56 were fairly consistent in yield.

Deltapine Smooth Leaf gave about the same acre value at all locations except at Jackson. It ranked last at this location.

Data from hand-picked samples (ginned on a 10-saw laboratory gin) and mechanically-harvested samples (ginned on a commercial gin) are presented in Tables 28 and 29. It can be seen from data in Table 28 that yarn strength of lint samples obtained from a commercial gin averaged less than for hand-picked samples. All other fiber data in this section were obtained from hand-picked samples. These data are presented in Tables 30 through 42.

Table 1. Acre value, yield, and other characteristics of cotton varieties tested at Jackson from 1963 through 1966

Variety	Acre value	Yield lint	Earliness	Yield at 1st picking	Lint percent

## Section II

### Advanced Strains Test

Promising advanced experimental strains from the Tennessee breeding program, adjacent states, and Southeastern commercial breeders were tested at Jackson each year. Two recommended commercial varieties, one early and one late, were included as checks. Entries inferior to the commercial checks were replaced by newer strains from year to year. Experimentals are rarely evaluated in the advanced strains tests for more than 3 years. Poorly-performing strains are eliminated from the test and the best strains from the Tennessee program are entered in the state variety tests. Also those strains which show promise from other institutions which are released as named varieties are entered in the state variety tests.

#### Procedure

A randomized block design with 8 replications was regularly used in the advanced strains tests. Two-row plots 35 feet long were common to the tests. All advanced strains tests were harvested by hand.

A 160-boll random sample was taken from each entry immediately before first picking of each test. The 160-boll samples were composited from 20-boll random individual plot samples. The samples were ginned on a 10-saw laboratory gin. Gin and fiber data were obtained from these samples.

#### Results and Discussion

Yields and other agronomic characteristics are presented in Tables 43 through 46; fiber and spinning data are presented in Tables 47 through 50. Varieties are listed in order of decreasing lint yield.

Significant differences among varieties were obtained each year. Early strains usually (but not always) yielded well in the advanced strains tests (Tables 43-46). No earliness data were obtained in 1965.

Several experimentals in the 1966 advanced strains test had longer and stronger fibers than those in earlier years (Tables 47 through 50). Unfortunately, the strains exhibiting the most de-

sirable fiber properties frequently did not yield competitively with varieties that possess shorter and weaker fibers.

Experimental strains frequently yielded more than recommended commercial varieties (Tables 43 through 46). Some experimentals possess special attributes such as superior fiber properties or glandless seed. The entries in the advanced strains tests represent the best from several breeding programs.

Hancock (tested as T-59-134), Deltapine 45A, Deltapine 16, McNair 1032, and Coker 201 are recent varietal releases that were evaluated in the advanced strains tests before release.

### Section III

#### Mechanically Harvested Cotton Tests

#### Procedure

Several cotton varieties were spindle picked at Milan (1965-1966) and Ames Plantation (1963-1965). The experimental design was a randomized complete block with 6 replications. Each plot consisted of four rows 100 feet long. All varieties were spindle picked twice each year. A two-row cotton picker was used and all four rows of each plot were harvested. After weighing each plot separately, seed cotton (including trash) for each variety (both pickings) was bulked and ginned on a commercial gin. Lint and seed were weighed after ginning. "Ginning losses" were determined by subtracting weight of seed + lint from seed cotton (including trash) for each variety.

In 1963, 1965, and 1966 before the first picking, a composite 150-boll sample was obtained from each variety. These will be referred to as "hand-picked boll samples." A 2-pound seed cotton sample (including trash) was collected from each variety from each of the two mechanical pickings. A lint sample was taken after each variety was ginned on a commercial gin.

In 1964 at Ames Plantation three lint samples of each variety were obtained at random after ginning; however, in the analysis they were treated as replicates. The hand-picked boll samples and 2-pound seed cotton samples were ginned on a 10-saw laboratory gin. All samples were classed by the Board of Cotton Examiners, USDA, Memphis Classing Office, Memphis, Tennessee. The fiber measurements were made by the USDA Cotton Fiber Laboratory, Knoxville, Tennessee.

#### Results and Discussion

Mechanically-harvested cotton yields, acre values, and other data are shown in Tables 51 through 55. These represent 2 years' data at Milan (1965 and 1966) and 3 years' data at Ames Plantation (1963 through 1965). There was a statistical difference in lint yields among varieties in every test except at Ames Plantation in 1963.

Deltapine Smooth Leaf, Dixie King II, and Auburn M gave the highest average acre value returns at Milan. Deltapine Smooth Leaf and Dixie King II also gave the highest 3-year average returns at Ames Plantation. Deltapine Smooth Leaf and Rex Smoothleaf

consistently graded one grade better than Dixie King II. In most cases Dixie King II out-yielded Deltapine Smooth Leaf in lint, but when other factors—such as grade—were considered, the acre values became close.

The fiber data are presented for each year along with the acre value, yield, and other characteristics.

Yarn strength of lint samples obtained from a commercial gin averaged less than that of hand-picked samples which were ginned on a 10-saw laboratory gin (Table 56). These data on yarn strength are similar to the data obtained at Jackson in 1966 (Table 28). The 2.5% span length (upper half mean length in 1963) was lower in general where the mechanically-picked cotton had been ginned on a commercial gin when compared to hand-picked samples that had been ginned on a 10-saw laboratory gin (Tables 56, 57, 60, 63 and 66). In some cases, the data also indicated that cotton fiber that has been ginned on a commercial gin is lower in strength than hand-picked or machine-picked cotton which had been ginned on a 10-saw laboratory gin (Tables 56, 58, 61, and 67).

THE UNIVERSITY OF TENNESSEE  
AGRICULTURAL EXPERIMENT STATION  
KNOXVILLE, TENNESSEE

Agricultural Committee

Board of Trustees

Andrew D. Holt, President

Clyde M. York, Chairman

Ben Douglass, Harry W. Laughlin, Wassell Randolph  
W. F. Moss, Commissioner of Agriculture

STATION OFFICERS

Administration

Andrew D. Holt, President

Webster Pendergrass, Dean of Agriculture

E. J. Chapman, Assistant Dean

J. A. Ewing, Director

Eric Winters, Associate Director

J. L. Anderson, Budget Officer

Department Heads

S. E. Bennett, Agricultural Biology

T. J. Whatley, Agricultural  
Economics and Rural Sociology

J. J. McDow, Agricultural  
Engineering

Harold J. Smith, Agriculture,  
University of Tennessee at Martin

L. F. Seatz, Agronomy

C. S. Hobbs, Animal Husbandry-  
Veterinary Science

Ruth L. Highberger, Child Develop-  
opment and Family Relationships

J. T. Miles, Dairying

Gracey E. Goertz, Foods and  
Institution Management

M. R. Johnston, Food Technology

J. W. Barrett, Forestry

Myra L. Bishop, Home Management,  
Equipment, and Family Economics

B. S. Pickett, Horticulture

R. L. Hamilton, Information

Mary R. Gram, Nutrition

K. L. Hertel, Physics

O. E. Goff, Poultry

Anna J. Treece, Textiles and Clothing
