## **THE AUTHORS**

**ALVIN R. WOMAC**, principal investigator, is an assistant professor in the Department of Agricultural and Biosystems Engineering, The University of Tennessee.

**JILL C. GOODWIN** is a former research assistant in the Department of Agricultural and Biosystems Engineering, The University of Tennessee. Ms. Goodwin is now with John Deere and Company.

**WILLIAM E. HART**, who served as collaborator in this project, is an associate professor in the Department of Agricultural and Biosystems Engineering, The University of Tennessee.

The authors may be contacted at The University of Tennessee, 308 Agricultural Engineering Building, Knoxville, Tennessee 37996-4500

## **ACKNOWLEDGEMENTS & NOTES**

Support by the Tennessee Agricultural Experiment Station, the Tennessee Soybean Promotion Council, and *Successful Farming* magazine made this project possible.

X-77 is a registered trademark of Valent U.S.A. Corporation of Walnut Creek, California. Agridex is a registered trademark of Setre Chemical Company of Memphis, Tennessee. Use of these names and the selection of nozzles used in this study neither state nor imply an endorsement of a specific commercial product or firm.

On the cover, a drawing by John J. Conroy, a graduate research assistant in the Department of Agricultural and Biosystems Engineering, depicts a spray system in operation in a field of soybeans.

## **Tip Selection for Precision Application of Herbicides: A Look-Up Table of Drop Sizes to Assist in the Selection of Nozzles**

### **INTRODUCTION**

Proper selection of spray nozzle tips is one of the first steps to reduce off-target drift during spray applications of pesticides and other treatments. Drift can occur during applications in windy conditions and temperature inversions, especially with improper sizing of drops. By selecting spray nozzle tips appropriate for the liquid being sprayed and pressure of the system, growers can minimize the production of small drops that lead to drift. Proper selection of nozzles allows a greater percentage of spray to reach its target while reducing the risk that drift can pose to nearby crops, particularly during applications of postemergence herbicides.

Interest in precision application of pesticides and other sprays has resulted in a proliferation of drift reduction tips available on the market, along with competing claims of performance. Many of the tip assessments reported by manufacturers are based on test sprays of water and simply report a volume median diameter of drop size, a percentage of droplets smaller than 100 µm (microns) or a broad spray class. *However, each nozzle tip actually produces a wide range of drop sizes at any given pressure. The drop spectrum varies with every combination of tip size, operating pressure, and spray liquid.*

The portion of the spray with drops less than 100 to 200 µm has the greatest potential of herbicide drift because the fine spray is easily blown off target by the slightest breeze and is prone to evaporate very quickly. The issue of evaporation is critical to drops in two ways: First, the water in the drops evaporates, which may result in very fine particles of herbicide formulation that do not settle to the target. Second, the solvents and active ingredients of some herbicides may directly evaporate from the drops, meaning that

while some spray may reach the target, its efficacy may be diminished. Evaporation of both types is more prevalent in smaller drops because the smaller the drop, the greater the surface area on that drop relative to its volume, which subjects the spray to excessive evaporation.

To minimize the production of small drops, growers need to be able to correlate tip performance with operating conditions and the liquid to be sprayed. Drop spectrum data have not been widely available for making side-by-side comparisons between tips from different manufacturers, especially as operated with different liquids. This study aims to fill that gap through data gathered in controlled conditions using a laser diffraction instrument.

## OBJECTIVES

The objectives of this study were:

1. To identify the set of currently available drift reduction tips and other conventional tips (such as extended range) that are appropriate for ground application by high clearance sprayer or 3-point hitch sprayer
2. To identify the range of nozzle operating pressures unique to each tip design
3. To measure the in-flight size of spray drops produced by selected nozzle designs, nominal size ratings, operating pressures and test liquids of water, a water-surfactant mixture, and a water-crop oil concentrate mixture
4. To tabulate volume median diameter, volume percentage of spray in small drops, and other drop spectrum details

## DROP SIZING

Drop size was measured with a laser diffraction instrument (Malvern 2605 L/c drop/particle size analyzer with 800-mm lens). Spray output discharging downwards was traversed several times (6 to 8) completely through the laser beam while the drop size detector was polled 10,000 sweeps per test run. Daily checks of instrument consistency were performed at the beginning and end of the day with a selected nozzle and operating condition.

A representative tip of the reported tests was chosen based on prescreening several tips of a given brand, size, and type. Drop size data for the representative tip are reported for a minimum of three (3) replicate drop size runs. The reported runs were selected based on a consistent, repeatable response by the instrument. Over 5000 measurement test runs were conducted for the study.

## TEST MATRIX

Specific combinations of tips, sizes, and pressures were tested with three test liquids. These combinations are outlined in **Table 1**.

## Look-up Table of Drop Sizes

The look-up table is organized by test liquid:

1. Water
2. Water + 0.25% v/v X-77 surfactant
3. Water + 1.0% v/v Agridex crop oil concentrate

Data within each test liquid are arranged by nozzle manufacturer:

- |                |                     |
|----------------|---------------------|
| 1. CP Products | 4. Lurmark          |
| 2. Delavan     | 5. Spraying Systems |
| 3. TurboDrop   |                     |

Data within each manufacturer are arranged by nozzle tip design and pressure, as outlined in the following test matrix.

**Table 1. Test matrix of specific combinations of test liquids, tips, sizes, and pressures.**

## DROP DATA DESCRIPTIONS

A wide range of drop sizes exists in any given spray discharge. Indicators of this range are expressed in terms of the spray "volume." Descriptions of terms are as follow:

Spray volume (%) < 44 µm - percentage of spray volume in drops 44 µm and smaller

Spray volume (%) < 91 µm - percentage of spray volume in drops 91 µm and smaller

Spray volume (%) < 191 µm - percentage of spray volume in drops 191 µm and smaller

The spray volume in drops smaller than about 200 µm is usually considered as "driftable" fines depending on weather conditions and location of release relative to the canopy.

$D_{v0.1}$  (µm) - 10% of the spray volume in drops less than the indicated  $D_{v0.1}$

$D_{v0.5}$  (µm) - 50% of the spray volume in drops less than the indicated  $D_{v0.5}$

- also called Volume Median Diameter (VMD)

- *not* mean (average) drop size

$D_{v0.9}$  (µm) - 90% of the spray volume in drops less than the indicated  $D_{v0.9}$

Span - relative span that indicates the range or dispersion of drop sizes

-  $(D_{v0.9} - D_{v0.1}) / D_{v0.5}$

A micron (µm) is a unit of length measurement that indicates  $1 \times 10^{-6}$  meters. 25,400 µm equals 1 inch. A human hair is about 50 µm in diameter.
