Copyright © Mark L. Burton, 1991 All rights reserved This dissertation is dedicated to my father, H. P. Burton, my mother, Sally D. Burton, my brother, Dr. Newt Burton, and to the thousands of men and women who for over a hundred years made the St. Louis - San Francisco Railroad the finest railroad in America.

ACKNOWLEDGEMENTS

There are a large number of individuals and institutions without whom this effort would not have been possible. First and foremost, I wish to thank John Mayo for his patient direction, boundless encouragement, enthusiasm and friendship. I wish to acknowledge and thank the other members of my committee--Sidney Carroll, Henry Herzog, Pete Patton and particularly David Mandy whose relentless attention to detail and insistence on accuracy has made this a better piece of research. I owe many thanks to Larry Bray and Juan Gonzalez of the Tennessee Valley Authority both for their assistance in acquiring funding and for their helpful comments. I wish to thank The Center for Business and Economic Research and Department of Economics at the University of Tennessee--in particular Kathy Davis and Susan Bott. I owe much to my peers and with to offer my special gratitude to Carlos Martins-Filho, Margaret Ray, and Deborah Vaughn Nestor for their assistance and enlightened comments. I am grateful to recognize the extremely valuable comments of Jim MacDonald from Rensselaer Polytechnic Institute. On a personal note, I wish to thank Mr. and Mrs. Donald Charles for their friendship and support. And finally, I must thank Cheryl Jurgens whose love and encouragement sustained me. Though all of these and many others have contributed to this research, any remaining errors are solely my responsibility.

ABSTRACT

This investigation first provides a highly disaggregated study of deregulated railroad rates for seventeen commodities. The results indicate that the Staggers Rail Act fundamentally altered the way in which rail carriers price their services. Rates now adhere more closely to incurred costs and exhibit a heightened sensitivity to the presence of both intermodal and intramodal competition. The model is then extended to accommodate the possibility of shipper responses to changed carrier behavior. The results of this extension suggest that shippers have responded eagerly to altered railroad behavior by changing the characteristics of their shipments. Together, the changes in railroad behavior and shipper responses to these changes have produced lower railroad rates for the movement of many commodities. At the same time, there is no evidence that rates for even a single commodity have been made higher by deregulation.

CHAPTER I

INTRODUCTION AND MOTIVATION

It has been suggested that two focuses within economics contributed to the wave of federal deregulation evident in the 1970's and 1980's. Stigler's "Economic Theory of Regulation" (1971) caused a general reconsideration of the economic motivations and effects of regulation. At the same time, Baumol, Panzar, and Willig (1982) and a collection of other economists directed renewed attention to what Joe Bain has termed the "conditions of entry". Together, these advancements provided the academic motivation and the means for a reexamination of the presence of federal regulation in a number of industries.¹

Within the broadly defined arena of transportation, there was movement toward the deregulation of all prevalent modes of both passenger and freight carriage in the 1970's. The first measure to afford any industry significant relief from rate regulation came in 1978 when the Civil Aeronautics Board was abolished and domestic airlines were allowed to freely select routes and fare structures. The reasoning which has emerged in defense of this deregulation has rested heavily on the belief that in the absence of sunk costs or other barriers to

¹This is not to say that academics were the sole or even principal force behind the deregulation wave. Indeed, the Economic Theory of Regulation would suggest that shifting "political economy" determinants underlying varying interested groups were central to the deregulation movement. See Peltzman (1989).

entry, the simple threat of intramodal competition was sufficient to insure an economically efficient outcome.

The same reasoning has supported the decision to deregulate motor carriage. Sunk costs are viewed as negligible, so that the only barrier to the sort of hit and run entry prescribed by contestability was Interstate Commerce Commission regulation. Further, there was tangible evidence which suggested that both organized labor and the trucking industry opposed deregulation because of an awareness of its potentially competitive effects. Indeed, Stigler's work helped to motivate the Motor Carrier Act of 1980 just as Baumol's efforts have since served to justify it. This act brought nearly complete deregulation to the trucking industry.

Empirical investigations to determine the effects of these deregulation measures have been plentiful and, while there have been disappointments and surprises in both industries, deregulation has generally had its intended effect.

There has been massive entry and exit in both industries.² At the same time, prices have fallen substantially without any evidence that either the availability or quality of service has been harmed.³

²The president of the Sante Fe Railroad was quoted as saying, "Deregulated trucking means that anyone with a rebuilt Kenworth, a packet of road maps and a thermos of coffee can enter the industry."

³For a full discussion of the impacts of motor carrier deregulation see Winston, Corsi, Grim and Evans (1990).

The railroad industry, however, exhibits a structure which sharply contrasts those of the airline and trucking industries. The federal government neither owns nor directly maintains the infrastructure necessary to provide rail service. Rather, the tremendously large physical plant central to railroad operations remains in the hands of private firms who are responsible for its upkeep and who, for the most part, determine its use. The costs of constructing new rail lines are both large and largely unrecoverable, so that they constitute a formidable sunk cost. Hit and run entry by other railroads in response to economic profits is virtually impossible for this reason. If markets for rail transport are defined to exclude other possible modes of transport and if railroad trackage and facilities are not open to all potential users, there is no way these markets may be considered contestable.⁴

Accordingly, advocates of railroad deregulation did not rely on such arguments in their attempts to have rate making freedoms returned to rail carriers. Instead, proponents suggest that deregulation would affect the industry in three ways. First, it was hoped that a loosening of operational controls (particularly with respect to mergers and abandonments) would allow railroads to reduce costs and, at the same time, offer more attractive services. Secondly, new rate making freedoms would give the railroads the ability to adjust more quickly to new traffic opportunities. Lastly, it was argued that intermodal competition - competition from trucking and barge - would be sufficient to generate further cost

⁴For a full discussion of railroads and contestability, see Baumol and Baily (1984).

reducing measures and to insure that deregulated carriers would be unable to capture economic rents.⁵

At the time of these discussions, the rail industry was ailing so that concerns about the continued availability and adequacy of rail service, combined with an inherent suspicion of nationalization greatly enhanced the attractiveness of the deregulation perspective. The 1970's witnessed a number of legislative attempts to reform and reduce railroad regulation. These efforts were capped in 1980 by the Staggers Rail Act which effectively eliminated the regulation of railroad rates and significantly reduced all other rail regulation.

The impacts of deregulation on railroad operations and costs have been wide ranging and often pronounced, but most often these effects have been readily recognized and agreed upon. However, the manner in which deregulation may or may not have influenced rail rates, though central to all questions of future policy, has not been appropriately treated. The research presented here seeks to correct this inadequacy by employing the Interstate Commerce Commission's annual Carload Waybill Sample in a highly disaggregated analysis of railroad rates. It is only through such a comprehensive analysis that the full impact of Staggers on the consumers of rail services can be seen.

In those transport industries where sunk costs are low and rapid entry is often possible, deregulation has produced the predicted results, but can this

⁵It was widely believed that the railroad industry was a virtual paragon of X-inefficiency.

favorable conclusion be extended to include an industry where intermodal competition is the primary enforcement device? Has deregulation, as the railroads would contend, simply leveled the field, so that they may now compete effectively or does the improved financial health of America's railroads owe to an increased capacity to capture monopoly profits? If rates have fallen, have they fallen proportionately for all customers, or may some shippers have benefitted more than others? Do railroad rates more accurately reflect the costs of providing service or are more captive shippers now forced to pay a disproportionate share of common costs? These are the questions which must be addressed if policy makers are to reasonably treat the continued calls for reregulation of some rail rates. This research approaches these question in the following way. Chapter II presents a regulatory history of the railroad industry and an analysis of the Staggers Rail Act. Chapter III summarizes the existing research describing the impacts of deregulation with particular emphasis on rate effects. Chapter IV provides a model of railroad pricing behavior which is refined for empirical estimation, so that any effects of deregulation or railroad rates may be detected. Empirical results are explained and discussed in Chapter V. In Chapter VI, the model is further refined to allow changes in shipper behavior as a response to carrier changes. Finally, Chapter VII integrates the results with findings from past studies in a discussion of future rail policy.

CHAPTER II

THE INSTITUTIONAL SETTING

The Interstate Commerce Act and Revisions

There is no consensus regarding the precise course of events which lead to the passage of the Interstate Commerce Act in 1887 or the formation of the Interstate Commerce Commission in 1889. There are, however, a number of prominent factors which somehow worked together to produce these measures. First, the agricultural community, feeling that unfair railroad pricing practices had contributed to declining real farm incomes, lobbied hard for both state and federal regulation of rail rates. There is also the common view that rail carriers favored federal regulation as a means of curbing destructive competition. However, Chandler (1977) suggests that, while there was a desire on the part of the carriers for federal intervention, the sort of regulation embodied in the Interstate Commerce Act was not at all what the carriers sought a decade earlier.

Prudent analysis suggests that there are elements of truth in each approach.

In any case, the act to regulate commerce and to establish the Interstate

Commerce Commission was passed into law in 1887. Table 2-1 summarizes the regulated activities and enforcement devices attributed to this legislation.

¹See Robertson (1964).

²See Gilligan, Marshall and Weingast (1989) for a discussion of this view point.

However, as noted by Fair and Guandolo (1979), the law was found lacking in early legal tests. While the original legislation made unfair rates illegal, a series of court decisions made it clear that the ICC did not have the power to impose either maximum or minimum rates. The Hepburn Act (1906) first gave the Commission explicit power to establish maximum "fair" rates. The power to establish minimum rates was conferred by the Transportation Act of 1920. The 1920 act marked a watershed in transportation policy. Prior to World War I, railroad regulation had been designed simply to constrain anti-competitive practices. The ICC only possessed power to fix maximum rates. Amendments to the ICA prior to 1920 garrisoned this power, but did not state or imply any broader concern for a stable transportation network. However, by the war's end motor carriage was coming to be seen as a truly viable alternative means of transport and it was reasonably clear that railroad expansion had peaked. The war had also made it clear that an extensive and stable national transportation network was central to the public interest. More and more transportation policy began to reflect this realization. While the 1920 act did place additional constraints on rail carriers, many of these constraints were designed to enhance stability within the industry.³

³Specifically, the law recognized that rates should guarantee a fair rate of return. Also, the act contained the sorts of provisions aimed at reducing destructive competition which had been desired by the carriers forty years earlier.

Appendix I outlines the more prominent pieces of transportation legislation enacted between 1887 and 1970. The amendments to the original Interstate Commerce Act and other legislative measures largely reflect the intent to maintain a stable and adequate surface transportation network in the face of a rapidly changing transportation environment. However, it is unarguable that these additions had taken both the depth and scope of railroad regulation far beyond that envisioned by its original proponents.

The Regulatory Environment in 1970

By the end of the second world war, nearly every facet of railroad operation was strictly regulated. The ICC maintained full rate making power, the

power to approve or disapprove mergers, abandonments, and service discontinuance, the power to control car flows, prescribe safe operating procedures, and equipment standards. The Commission was able to confer trackage rights, control the use of joint facilities, and prescribe the rules of interchange. With the exception of a few measures designed to reduce the burdens imposed by passenger operations, these regulations remained unchanged until the decade of the '70's. The following paragraphs outline the scope of these regulations in each of the areas mentioned above. Together, these regulations summed to form the institutional environment which existed in the ten years immediately prior to the passage of Staggers.

Combinations and Control

In approving railroad acquisition, merger, or control of another railroad, the ICC was called upon to consider, (1) the effect upon adequate service to the public, (2) the effect upon the public interest of the inclusion, or failure to include other railroads in the territory, (3) the total fixed charges resulting unless the ICC

⁴This list of regulated functions is by no means exclusive and is limited only to the ICC, the ICA, and its amendments. Other statutes and regulatory bodies maintained control of various aspects of railroad operation. For example, unlike any other industry (regulated or otherwise) the Federal Employers Liability Act (FELA) dictates carriers' responsibilities toward injured employees. Repeal of the FELA is the number three legislative objective of industry lobbyist, preceded only by the maintenance of Staggers and newly passed legislation providing for mandatory, random drug testing.

⁵This review of railroad regulation is substantially that of Fair and Guandolo pp. 49-59, edited and revised for readability.

finds that such increase would not be contrary to public interest, and (4) the interest of the carrier employees affected so that for a period of four years from the effective date of the authorization, the employees of the railroads involved will not be in a worse position with respect to their employment.

The regulatory attitude exuded by the ICC in the years prior to Staggers was as important as these statutory constraints in dissuading large scale consolidation. The Commission subscribed to a particularly broad definition of "public interest", so that any potentially detrimental effects to even the most peripherally affected party received Commission consideration. Therefore, prospective merger partners were forced to quell the concerns of innumerable groups as a part of the application process or face its almost certain refusal. A case in point is the Penn Central disaster. The research and formulation of merger plans of the New York Central and Pennsylvania Railroads took place in the middle 1960's. From that point forward, the proposed partners negotiated fervently with affected communities, shippers, competitors, and labor unions to gain the support necessary to secure Commission approval. This process produced a myriad of concessions to these parties and took years to accomplish. The prolonged nature of the approval process coupled with the forced concessions is routinely mentioned as a factor which contributed to the resulting Penn Central disaster.6

The Railroad Revitalization and Regulatory Reform (4R) Act amended

⁶For a full discussion of the Penn Central bankruptcy see Daughen (1971).

Section 5 and 5(2), giving the Secretary of Transportation broad authority regarding plans and proposals for railroad unification and coordination projects. The 1976 act called on the Secretary to make a comprehensive study of the possible restructuring of the railway system, to respond to and pass upon request of carriers regarding mergers or joint use of facilities and to conduct informal hearings on such and to report these to the ICC. The Commission still retains final authority for approval of all proposals and agreements, but prior to a recommended decision, the ICC must request the views of the Secretary of Transportation, the Secretary of Labor and the Attorney General. The same act prescribed detailed procedural and time requirements for disposing of railroad applications. The Regional Rail Reorganization (3R) Act grants authority to the ICC to direct a carrier to operate under certain conditions over the lines of another carrier and to adjust the compensation involved.

Section 5(15) of the Interstate Commerce Act (hereafter ICA) prohibited railroad control of any common carrier by water operating through the Panama Canal or of a water carrier elsewhere with which the railroad applicant might compete for traffic. Railroad acquisition or control of motor carriers under Part II of the ICA, according to Section 5(2) (b), was not permitted unless the ICC found that the result would be: (1) consistent with the public interest and will enable such carrier to use service by motor vehicle to public advantage and (2) the resulting operations would not unduly restrain competition. The ICC interpreted these conditions to mean that the motor freight operations of railroads

ordinarily should be auxiliary to and supplemental of rail operations. However, the Supreme Court ruled that the ICC might authorize operations not so restricted if warranted by facts showing public need.

Discontinuance and Abandonment

Among the four modes of regulated transport (air, water, rail, and motor carriage) only railroads own facilities other than terminals. Railroads could not abandon all or any portion of the way facilities operated, or discontinue service on any or all way facilities except after 60 days notice to the ICC and the Governor of each state involved, and after obtaining a certificate from the ICC to do so. As in the case of consolidations, the regulatory burden was strengthened by a perennial hesitancy on the part of the Commission to grant the certificates which allowed abandonments.

Exempt Traffic

All revenue traffic of railroads was subject to regulation until 1976 when Congress passed the 4R Act, providing in Section 207 that the ICC, after notice and hearing and for a specified period could exempt transactions and services that meet certain conditions. These conditions were that transactions be limited in scope, and that the regulation of these transctions placed an undue burden on persons or classes of persons or on interstate or foreign commerce and were not necessary to effectuate the nation's transportation policy. By the time the 4R Act

was passed, the disposition of the ICC had changed sufficiently to allow wide spread use of the rule for exemption.

Interchange of Traffic

Railroads were (and are) required to afford all reasonable, proper and equal facilities for interchange with other railroads and with water carriers subject to Part III of the ICA.

Joint Use of Terminals

The ICC could order a railroad to permit a second railroad to share in the use of terminal facilities including main line track for a reasonable distance outside of such terminal if it is found, (1) to be in the public interest, (2) to be practicable, (3) and not to substantially impair the ability of the owning railroad to handle its own business.

If the carriers cannot agree on terms of the necessary agreement, the ICC could prescribe reasonable terms.

Rate Regulation

Prior to deregulation in 1980, the basic elements of rate regulation were common to all regulated transportation. These included requirements that rates be just and reasonable, not be discriminatory or give undue preference or advantage to any shipper. Lawful rates were to be published in tariffs and approved by the appropriate administrative agency. Joint rates between two or more carriers were also to be approved.

The 4R Act of 1976 prescribed criteria for the ICC to use in passing upon rail rates as distinct from other carriers. These applied to calculations of costs and valuation factors and to consideration of competitive conditions. Specifics were given in regard to charges in single and joint rates and the bases and terms for suspension of proposed rates. Time limits and procedures were included. These specifics were not applicable by law to other transport modes.

There were a number of other features which pertained only to railroad regulation, and not to the other modes under the ICC, CAB or FMC.

- 1. Aggregate of Intermediates. Railroads and water carriers were not allowed to charge a through rate which was greater than the aggregate of intermediate rates. Motor carriers were never subject to this restriction.
- 2. Intrastate Rates. With respect to intrastate railroad rates, the ICC could, after full hearing, find that a rate, fare, charge or classification caused undue or unreasonable advantage preference or prejudice with respect to competitive interstate traffic or that such rates or practices place an undue burden on interstate commerce or discriminated against foreign commerce. If such a finding was made, the ICC could forbid use of such rates or practices and could prescribe the rate or the maximum and minimum rates to be charged.
- 3. Long and Short Haul Rates. The Fourth Section of the ICA prohibited railroads under Part I and water carriers under Part III from charging more for a shorter than for a longer distance on a given route and in the same direction.

Under certain conditions, the ICC could give "Fourth Section Relief" if the

charge to the more distant point was compensatory. But such relief to railroads was restricted. Water competition in the more distant movement used to support application for relief must have actually existed and not have been just potential. Furthermore, rate reduction to meet such water competition could not be subsequently set aside and rates raised without specific permission of the ICC.

4. Through Rates and Joint Rates. Railroads were required as a duty to establish through routes and joint rates and charges with other common carriers by water and rail. Where one of the parties to a through route was a water carrier, the ICC prescribed such reasonable differentials with respect to such rates, and the all rail rate for the route, as it found justified. A railroad could not be required, in establishing a through route, to embrace in such a route substantially less than its entire line, including lines it controlled or managed, unless it was unreasonably long compared to another practical through route, or the ICC found that the proposed through route was needed to provide adequate, more efficient and more economic transportation. But subject to public interest, the ICC was required to give reasonable preference to the originating carrier and no through route could be established to help meet financial needs of a given carrier.

The authority of the ICC to prescribe the division of joint rates incident to the establishment of through routes and rates was complete and comparable in all three parts of the Act except that in respect to rail and water common carriers, the ICC in deterring the division among rail carriers in a rail route or water carriers in a water route could consider, (1) efficiency, (2) revenue required to pay

respective operating expenses including taxes, (3) a fair rate of return and (4) relative importance of the services of the respective carriers in the public.

Routing by Shipper

If two or more through routes were available, railroads under Part I were required to strictly observe the choice of route made by a shipper if given in writing at time of delivery to the carrier. All railroads in the route were equally bound to observe this choice.

The Staggers Act

President Jimmy Carter signed the 1980 Staggers Rail into law on October 14, 1980. As pointed out in an early release by the Association of American Railroads, the Act did not provide "wholesale deregulation," but it did substantially reduce the amount of rate regulation in particular. *Railway Age* provides the following summary of the rate provisions.⁷

Rate Regulation

Nearly two-thirds of rail rates (based on 1980 traffic levels) were freed from any form of ICC regulation. Under Staggers, the ICC can prescribe maximum rates where railroads have market dominance, but it is the burden of the shipper to demonstrate that this is the case. Further, market dominance is not

⁷See <u>Railway Age</u>, January 26, 1981, pp. 56-73.

defined by market share or other like measure. Rather, a carrier may be judged to be dominant only if the rates it charges are deemed excessive. Initially, the ICC could investigate rates only if the shipper could demonstrate that the rates exceed variable costs by at least 160%. This threshold was increased to 180% in 1984.

For the first four years, all rate increases attributable to increases in the rail cost index (up to 6% per year, but not to exceeded a total of 18%) were automatically exempt from ICC control. After 1985, such increase have been limited to 4% per year and are reserved primarily for carriers with financial problems.

Any rate reduction by which the resulting rate exceeds average variable costs is automatically exempt from ICC control. As noted by Boyer (1987), the exemption of rate reductions had been the trend since the middle seventies. However, this provision once and for all removed rate decreases from bureaucratic control.

General rate increases were limited to joint rates until 1984, then eliminated entirely. Even for the years 1981 - 1984, general increases could not exceed the level of inflation.

Rate bureaus were no longer allowed to discuss or vote on single line rates and discussion or voting on joint rates was limited to carriers which could reasonably participate in the haul. Beginning in 1984, this provision was made even stronger. Now, discussion of joint rates must be limited to the carriers

forming a particular route. This provision clearly reduced carriers' ability to legally collude in the fixing of rates.

Contract rates, which the ICC had gradually come to embrace, were made, in all cases, legal.

The time frame for the suspension and investigation of a rate was reduced. In order to get a suspension, a shipper must demonstrate likelihood that it will win on the merits of its case, that it will suffer substantial injury though application of the rate, and that a refund would not be adequate protection.

These provisions confer tremendous latitude to carriers in the setting of rates. However, the restrictions on rate bureau activities, the abandonment of general rate increases, and the full freedom to confidentially contract all serve to encourage adherence to costs and heighten competition among carriers.

Car Service

On matters related to car service, ICC orders are restricted to emergency situations with national or regional importance. At the same time, the commission's powers to require joint use of terminals during emergencies were increased. The legislation also provides that premium charges may be levied for special services to improve car utilization. It eliminates incentive per diem and it authorizes shippers to try to reach agreement among themselves on private-car compensation and then to negotiate with the carriers. The ICC serves only as a court of last resort.

Additional Provisions

In addition to these provisions, the law contained measures which substantially expedited merger and abandonment procedures. It also gave added support to efforts to spin off to smaller carriers (either public or private) lines which were previously targeted for abandonment. Staggers extended the support to Conrail which was originated by the 3R and 4R Acts and finally, in what Railway Age calls the most controversial provisions, the 1980 act made provision for the entrance of the Union Pacific and Chicago & Northwestern into the Powder River Basin of Wyoming by authorizing the construction of new rail line and by ordering trackage rights over the Burlington Northern.

A comparison of the regulatory changes under Staggers to the regulatory framework already in place in 1980 reveals that the railroad industry is still under substantial statutory control. However, as mentioned above, the legislation signaled a marked change in Congressional mandate. It is important to realize that the 1980 Rail Act not only loosened the degree of specific control, it also profoundly affected the way in which the Interstate Commerce Commission interprets and enforces remaining regulation.

-

CHAPTER III

LITERATURE REVIEW

Railroad Pricing Under Deregulation

To date, there have been five efforts to forward any sort of comprehensive evaluation of the effects of deregulation on all rail rates. These include the works of Grimm and Smith (1986), Boyer (1987), Barnekov and Kleit (1988), McFarland (1989), and Winston, Corsi, Grim, and Evans (1990). The earliest of these works summarizes a shipper survey conducted in the years immediately following deregulation. Boyer, Barnekov and Kleit, and McFarland each present an aggregate econometric analysis of post-Staggers rates. Only the newly published work of Winston et al offers the sort of broad ranging, more highly disaggregated analysis of deregulated rail rates which is necessary to answer the questions of policy alluded to in the introduction of this work.

The results of Grimm and Smith's Shipper survey were interesting and shipper satisfaction should not be ignored, but the fact that a majority of shippers feel that rail rates and rail service has improved does not provide the sort of conclusive evidence needed to underpin future transportation policy. Further their survey was biased in that they only contacted large volume shippers, so that the results of this research are even more limited than they appear.

The three aggregated studies offer much greater precision and do begin to answer some policy questions. Unfortunately, there is no consensus among these

authors as to the impact of deregulation on rail rates. More importantly, the high level of aggregation obscures much of the information needed to treat the perennial cries for reregulation of selected rail rates. In each case, average annual rail rates are the dependent variable, so that no distinction is made between commodities or regions.

Boyer concludes that the decline evident in rates in the years since Staggers is the result of improved technology and that deregulation has been largely innocuous in its effects. Because this study was the first to offer an econometric analysis of the effects of deregulation on rates, it has received considerable attention. Subsequent works (aggregate and disaggregate alike) have confirmed the important contribution of improved factor productivity to lower rail rates. However, the conclusion that Staggers has not affected rates certainly has found no consensus and is openly disputed by many of the later studies cited above. Again, the aggregated nature of the Boyer study may account for this controversy. While improved utilization of technology may predict lower rates for some commodities, the results offered below suggest that carrier response to deregulation has been the driving force behind lowered rates for the movement of other goods. This sort of intercommodity variation disappears when millions of individual movements are averaged into seventeen observations.

McFarland's efforts and those of Barnekov and Kleit closely parallel that of Boyer, but the results are substantially different. Barnekov and Kleit determined that rates are lower as a result of deregulation. McFarland's conclusion is that rail

rates are unchanged, but that there have been significant service improvements attributable to Staggers, so that in a hedonic sense shippers have benefitted by getting more product for the same price.

Winston et al use data from the deregulated era to construct counterfactual rate deflators for a wide range of commodities. The authors conclude that
rates for some commodities have declined due to deregulation, while other rates
have been increased. When the dollar values of these changes are aggregated,
the conclusion is that the total expenditure on rail shipment has been made
slightly higher than it would have been in the absence of deregulation. The
authors admit however that this final conclusion is the conservative case estimate
and that their conclusion is violated if assumptions regarding shipper response to
rate changes are relaxed.

In addition to the broad based studies outlined above, there have been some works which thoroughly analyze the impact of Staggers on rates for a few particular commodities. Robert J. Hauser (1987) uses data from 1978-1983 to look at the impact of deregulation on rail rates for export grain across seven regions of the U.S. Hauser finds that deregulation has significantly reduced these rates, but that the degree of both intramodal and intermodal competition is still important in determining rate levels. There are two weaknesses in this work.

¹Because the authors do not <u>report</u> the results, it is not possible to determine estimated rate changes for the full range of commodities. However, it is noted that rates for grain appear to have been lowered by Staggers while rates for the movement of coal appear to be higher.

First, the six year period of investigation is regrettably short, particularly given the volatility of export grain markets during this period. More importantly, Hauser based his analysis on "rates collected from public rate tariffs, rate books of region grain cooperatives and rate books of grain exchanges." There is strong evidence to suggest that the majority of shipments do not move under published rates.

James MacDonald (1987, 1989) also has analyzed the impact of deregulation on railroad rates for export grains. He does not conduct an explicit regional analysis, but because he distinguish between corn, soybeans, and wheat, some region conclusions may be drawn. MacDonald, like Huaser, finds that competition from other railroads and from water transport significantly affects rail rates. The 1987 study utilizes data from 1983 only and, thereby, shares the first weakness cited in the Hauser work. However, in both studies, MacDonald uses data from the ICC's annual Carload Waybill Sample, so that his results more accurately reflect the actual rates under which shipments moved.²

In their analysis of coal transport rates, Garrod and Miklius (1987) use a method quite different from that of MacDonald or Hauser. They use mine mouth rates and delivered rates as reported to the federal government to reconstruct the actual rates for coal shipments to public utilities. By this method, they avoid many of the problems which contract rates pose for users of other data sources. They

²Given the prominence of grain as a fraction of total rail traffic the findings of MacDonald represent an important contribution to overall efforts to analyze the behavior of deregulated rates. Further, MacDonald (1987) demonstrates and Winston (1990) confirms that the data contained in the carload waybill sample are not significantly biased by the existence of contract rates.

use the methodology of Zimmerman (1979) to determine whether or not carriers of western, low sulfur coal are attempting to capture the maximum available economic rents. Garrod and Miklius conclude that railroads were not constrained by the potential use of alternative fuels, but were limited in their pricing by the availability of coal from other geographic locations, so that they apparently captured less than twenty percent of available profits. The chief weakness in this effort is that it employs rates from one point in time only. Furthermore, the date selected was July 1, 1983. This date falls within a period when electricity usages had undergone a record decline, so that there is, at least, the possibility that the railroads' unwillingness to try to capture rents may have only reflected the softness in the market for coal.

Quality of Service

Two of the studies outlined above give considerable attention to the improvements in rail service. As mentioned, McFarland concludes that shipper welfare has improved under Staggers even though he detected no statistically significant decline in aggregates. The basis of this conclusion is improved quality of service. Winston, Corsi, Grim and Evans further substantiate this conclusion by offering an estimation of the welfare gain to shippers which has resulted from faster, more predictable service. The authors conclude that rail transit times have improved by over thirty percent in the years since Staggers and that the improvements in the variability of these times is even greater. They estimate that

this has resulted in a \$4.69 billion gain in welfare for shippers. It is worth noting, however, that the authors conclude this gain and the increased profits of carriers merely represent a transfer of welfare from rail labor and do not, therefore, represent any real economic gain.

Regulation During Transition

There have been two works which address the difficult regulatory issues which remain in Staggers' wake. Both of these focus on the position of "captive shippers". Staggers provides regulatory support for such shippers if they can demonstrate that railroads are charging excessive rates. In a 1986 working paper Ann Friedlaender uses simulation analysis to investigate whether the "cost-ceiling" approach for residual regulation is more or less efficient than some form of Ramsey pricing. She concludes that in nearly all cases, the cost-ceiling approach as implemented is allowing railroads to extract rents from captive shippers which are in excess of what might be necessary for the carriers to earn a normal profit. Further, by examining the movement of average rail rates for the movement of manufactured commodities, she asserts that the railroads are using profits from captive shippers to compensate for losses from pricing below costs in "competitive" markets.

Merrill Roberts (1987) evaluated the ICC method of rail costing as it applies to the 180 percent rule. This discussion centers on the technical aspects of this costing model, but the paper does provide a solid overview of the pitfalls

inherent in any rail costing model. One of his more interesting assertions is that railroad capital was significantly over-valued under regulation, causing railroad returns to appear lower than they really were.

Non-Price Behavior

Two very interesting efforts have been published discussing the problem of vertical foreclosure in the regulation of railroads. Henry McFarland (1987) provides a compelling theoretical argument. He concludes that carrier aversion to interchange evidenced since deregulation is generally not anti-competitive and, more often than not, represents attempts to avoid unnecessary costs. However, Grimm and Harris (1988) contend that unwillingness to interchange traffic is not the only form of vertical foreclosure practiced by railroad who have some degree of monopoly power over shippers. They contend that such railroads may compel the shippers to short-haul rival railroads with threats of poorer service over the portion of the route which the monopoly carrier controls. Grimm and Harris use a route choice model to provide empirical evidence for their case. Their estimations employ pre-Staggers data to determine the frequency in which shippers choose a single line routing when a multi-line would offer better (nonprice) service. They indeed find that some shippers tend to behave less than optimally by choosing less desirable routings to maintain single line service. Further, they find this propensity increases as the monopoly share of the routing increases. Finally they assert that if this sort of vertical foreclosure was present

prior to deregulation, it must be even more pronounced in its wake. There are several characteristics of this work which may be troubling to some, not the least of which is their exclusion of differential rates from the analysis. Also, evidence suggests that the shippers for whom quality of service is most important are exactly the same shippers who could most easily be lost to alternative modes of transportation, so that one must wonder why these shippers would endure this manipulation.

Abandonments and Regional Railroads

John Due (1987) offers a thoroughly detailed chronology of the resurgence of regional and local railroads as an alternative to branch-line abandonments. However, this work contains very little analysis. In particular, Due does not mention the strong regional patterns evident in the characteristics of newer carriers nor does he consider the implications of these variations for the survival of these lines.

Survey Literature

Nancy Rose (1987) has assembled a well crafted survey of current literature describing the effects of surface freight deregulation. It is valuable not only because of its literature summaries, but also because of its concise description of the current regulatory debate.

Finally, Clifford Winston (1985) provides a thorough evaluative survey of transportation economics. This work does not explicitly treat railroad deregulation, but it does provide a comprehensive view of the techniques and issues evident in all transportation research.

CHAPTER IV

MODEL, DATA, AND ESTIMATION

This chapter develops a model of railroad pricing behavior which borrows heavily from existing models of railroad costs and the demand for railroad services. These elements are then combined and refined to produce a reduced form equation suitable for statistical estimation. Next, there is a full description of the data available from the ICC's annual Carload Waybill Sample and a delineation of the means by which this data was assembled with other available information to form the final data set. Finally, this chapter outlines the econometric technique which combined the theoretical with the observed to estimate the impacts of deregulation on railroad rates.

The Theoretical Model

First, it is assumed that rail carriers acted to maximize firm profits throughout the period of this research. Because the Interstate Commerce Commission had the ability to alter, delay or fully reject any application for rate changes, some have found this assumption to be unacceptable (see MacDonald, 1989a). However, there are four precepts which justify its use here. First, as Boyer (1987) notes, most applications for rate decreases were exempt from ICC ruling, so that rates were substantially free to move downward throughout the period under investigation. Secondly, applications for rate increases were

routinely granted without alteration, albeit in a sometimes less that timely manner. It is important to realize that rate regulation was originally instituted to insure that rates were representative of incurred costs and that rail carriers did not earn excessive profits. Railroad earnings had been chronically low for two decades prior to the passage of Staggers, so there was no need to suppress rates. Next, there is no a priori reason to assume that even the most constrained firm will not attempt to earn the most money possible. Indeed, the regulation literature is replete with scenarios which depict rate of return regulated firms engaging in various practices intended to maximize profits. Finally, the empirical specification to be presented at the end of this chapter allows for the confirmation or refutation of this assumption. The variables emerging from the profit maximizing model are substantially the same as those generated by other models of firm behavior.

Therefore, the parameter estimates provide a means to test the assumption.

Considering first individual firm demand for freight transportation, it is likely that such demand functions are largely discontinuous, particularly in the short run. It is improbable that a potential shipper will vary either the quantity to be shipped or the distance of the movement in response to a change in rail price. Instead, the shipper will continue to purchase the same amount of rail transportation (measured in ton-miles) until price has climbed to some reservation rate sufficiently high to induce the shipper to switch to a different rail carrier, a different transport mode, or to abandon the shipment altogether.

Given this situation, the profit maximizing rail carrier, if it possessed perfect information, would engage in first degree price discrimination, setting the rate for each shipment marginally below that rate which would cause the shipper to abandon the railroad's services. However, in reality railroads do not possess the degree of information necessary to engage in such practices. Rather, carriers distinguish between the demands of different groups of shippers by observing important characteristics. These various groups of customers are defined by two primary considerations - the availability of rail and non-rail transport substitutes as defined by geographic characteristics and the characteristics of the shipped commodity. Finally, while individual demands for transportation services may be discontinuous, collections of shippers grouped by discernably different demand elasticities exhibit demand functions which are largely continuous.

Ann Friedlaender and Richard Spady (1981) observe:

In analyzing the demand for freight transportation it is important to realize that it is used as a factor of production. Consequently the specified demand function should be able to be related to the underlying cost and production functions...

Therefore, the characteristics of a down stream production process and the characteristics of the commodity shipped to facilitate this process work together to determine of the demand for the transport of that particular commodity. The demand for the transport of commodities which are bulky or which are less essential to down stream production will be more responsive to price changes than will the transport demand for a highly valued non-bulk commodity. And again, these are characteristics which are easily observed by rail carriers.

While the commodity characteristics are the primary determinant of the appropriateness of transport alternatives, geographic considerations often dictate the availability and pricing of rail and non-rail transportation alternatives. With regard to possible water transport, certain regions of the country are favored with an abundance of navigable water ways, while other regions have none. Motor carriage is ubiquitous, but, the fact that trucking costs (and the resulting prices) escalate sharply with increased distances makes this mode of transport prohibitively expensive for origin destination pairs which are remote.

Friedlaender and Spady's work, as well as that of Richard Levin (1981) spans only a short time period, so that cyclical variations in transportation demand were given only passing consideration. However, this study spans a significantly longer period of time so that it must be assumed that changes in the level of aggregate economic activity might also affect the demand for transportation by affecting the demand for final goods. This possibility is given consideration here.

Based on the above discussion, the demand for transportation services is specified as:

(4.1)
$$Q = f(P, M, K, A)$$

where Q is the quantity of railroad services (measured in ton-miles) that is demanded by some catagory of shipper in a given time period. P represents the own price of rail service. M is a vector of variables describing the availability and relative prices of rail and non-rail transportation alternatives. K is a set of

commodity characteristics such as weight to value, perishability, etc. And A is some aggregate measure of overall economic activity. There is no theoretical reason to assume a specific functional form for this demand equation. It is simply assumed for the purposes of further analysis that this function is well behaved and exhibits those properties typically associated with market demand functions.

The cost of providing railroad services to the various groups of customers is given by:

(2)
$$C = g[f(P, M, K, A), S, R, F]$$

Here, C represents the total cost (in dollars) of producing some quantity of rail services for a specific catagory of shipper. P, M, K, and A retain their above definitions. S is a vector of shipment characteristics including weight, distance, number of loads, special equipment requirements, etc. R represents a set of route characteristics such as the number of line interchanges and the overall density of traffic along the route. Finally, F denotes factor prices and productivity.

The consideration of traffic density introduces a confounding situation in the analysis of individual or grouped rail costs. Railroads provide a number of distinct products represented by the transportation of different commodities between various origins and destinations. However, most fixed facilities (including right of way) are important to the provision of many if not all of these services

and, therefore, present large common costs which are not easily apportioned among the different products (shipments) which the railroad sells.

The initially high average fixed costs associated with railroad trackage and terminal facilities decline rapidly as the number of trains using them increases. This is typically referred to as "Economies of Density". These economies cause the average cost of providing one product to decline as the carrier sells more of that product, but these costs also decline if the carrier sells different products which require use of the same trackage or facilities. If rail prices were set simultaneously, the quantity of each product sold would affect the costs of all shipments and their consequent prices by affecting the overall traffic density. This renders all rail pricing decisions interdependent so that the optimal vector of prices can be obtained only by solving a simultaneous system, containing an equation for each of the services which the railroad provides.

Fortunately, the verities associated with actual rail pricing suggest that simultaneity, far from being a necessary component of any model, is inappropriate. Available anecdotal information suggest that traffic density is important in rail pricing decisions, but that this density is considered as exogenous when individual rate decisions are made. Theoretically, each pricing decision in period "t" has the capacity of affecting the costs and prices of all other services provided in this period. However, the tremendous variety of shipments over tens of thousands of potential routes which converge and diverge over various route segments makes explicit consideration of these interdependencies by the carriers as they set prices

impossible. Therefore, this research mirrors actual carrier behavior by assuming that traffic density is exogenously determined by the level of traffic in period "t-l". Further, the impact of pricing in period "t" on future traffic density is ignored. That is to say that carriers attempt no sort of intertemporal optimization.

Factor prices and productivity are present as an argument in equation (4.2). However, the reader will note that the empirical model considered below includes only those variables which determine the quantity of factor use. It does not take explicit account of factor prices or factor productivity. From a cross-sectional vantage, this is immediately defendable. Neither factor prices nor their productivity vary substantially across commodities or regions in any given time period. There are several reasons this is true. Throughout the period of this investigation labor represented the largest of all variable costs. Also during this period, carriers continued to band together and negotiate all labor contracts on a national basis, so that union wages and labor requirements are invariant across carriers.¹ The second largest expenditure was on diesel fuel. While there may have been cross sectional variations in fuel prices, there is little reason to believe that these variations were pronounced or in any way systemic across regions. Further, the very prominence of diesel makes it less likely that fuel sellers could successfully engage in any form of price discrimination.² Finally, any examination

¹For example in 1982, labor costs represented over sixty percent of all operating expenditures on the Burlington Northern.

²Bradburd (1982) demonstrates that all else being equal, it is more difficult for a seller to extract monopoly profits when the commodity represents a significant

of locomotive fleet records will reveal that there are only marginal cross sectional variations in the level of fuel efficiency for any time period.

The intertemporal aspects of factor prices and productivity are a bit more troublesome. Both Boyer (1987) and McFarland (1989) attribute continually falling rail prices to improvements in technology and factor productivity. Virtually all information indicates that the capital in place on Class I railroads in 1987 was significantly more fuel efficient and less labor intensive than was the physical plant of 1973. Boyer makes no explicit notice of factor prices in his analysis of aggregate rail rates. He does, however, use average train length as a proxy for technological improvement. McFarland, on the other hand, accounts for factor prices by use of a factor price index. However, his work does not directly include a measure of technological progress. Both of these studies include a trend measure as a general means of considering changes in factor productivity and factor pricing. This is the approach which is adopted here. The empirical estimation includes a trend variable to reflect intertemporal changes in factor productivity and prices

Combining equations (4.1) and (4.2) generates the profit function:

(4.3)
$$\pi = f(P, M, K, A)^*P - g[f(P, M, K, A), S, R, F]$$

This function represents the profits obtainable by the sale of transportation services to distinct groups of customers which are again defined by the commodity

portion of the buyers input expenditures.

characteristics and by the origin and destination of the shipment. The revenues generated from sales to each group are obviously independent and, because the impact of current sales on traffic density must be ignored, carriers behave as if the costs associated with each class of movement are also independent. Thus to maximize total firm profits, the carrier need only maximize equation (4.3) for each group of customers.

Again, there is nothing to suggest that equation (4.3) might exhibit any perverse qualities, so it is assumed to be at least twice and continuously differentiable and strictly concave. These assumptions combined with the implicit function theorem allow for differentiation and solution for an own price, P, which by concavity is guaranteed to represent the profit maximizing price, P, where:

(4.4)
$$P' = h(M, K, A, S, R, F)$$

It is this equation which forms the basis for the empirical estimation designed to evaluate the rate impact of the Staggers Rail Act.

The Data

The principal data source for the estimation of equation (4.4) was the Interstate Commerce Commissions annual Carload Waybill Sample (CWS) for the years 1973 through 1987 excluding 1975.³ The CWS is a one percent stratified

³ALK Associates, the firm which handles the distribution of the Carload Waybill sample is unable to produce a public use tape for 1975.

sample of all rail movements within the United States. Full documentation for this sample is available in Appendix II. As noted earlier, rail carriers are assumed to set prices for like sets of customers based on commodity characteristics and origin - destination pair. The expanded records were, therefore, aggregated by commodity, quarter, and origin - destination to accommodate this assumption. This formulation yields a pooled cross section and time series data set where the shipments of a particular commodity are represented cross sectionally by a variety of origin - destination pairs which are then pooled to form the quarterly time series.

The origin and destination information on the public use sample is given by state to preserve carrier and shipper confidentiality, so that for each commodity in each quarter, there are a possible 2,304 observations. Note this construction allows shipments from origin "i" to destination "j" to be considered separately from shipments originating in "j" and terminating in "i". Still, the geographic aggregation of this portion of the data mandates only very general analysis of the regional impact of deregulation.

Confidentiality also restricts the level of commodity disaggregation. The sample contains commodity descriptions for all shipments at the two digit Standard Transportation Commodity Code (STCC) level. STCC definitions are given in Table 4.1. Many of the records contain much more specific commodity information (up to a five digit level), but confidentiality concerns prohibit this additional information from being made available for all shipments. This loss of

information appears inconsequential for some commodity groups, but for others it is much more troublesome. For example STCC number 10 indicates non-metallic ores, a commodity for which more specific information would be of only limited use. However STCC number 37 indicates transportation equipment and contains records for the movement of everything from bicycles to space shuttle components. The reader is, therefore, advised to be mindful of these definitions when examining the empirical results.

TABLE 4.1
STANDARD TRANSPORTATION COMMODITY CODES

STCC	Commodity
10	Metallic Ores
11	Coal
14	Non-Metallic Ores
20	Food and Kindred Products
24	Lumber
25	Furniture and Fixtures
26	Pulp, Paper and Paper Products
28	Chemicals
29	Petroleum and Coal Products
30	Rubber and Plastic Products
32	Clay, Concrete, Glass and Stone (CCGS)
33	Primary Metal Products
34	Fabricated Metal Products
35	Machinery
36	Electrical Equipment
37	Transportation Equipment
10	Waste or Scrap Material

Again, the CWS data are aggregated by commodity, origin - destination, and quarter, so that the value of a particular variable in an observation represents a mean figure. For example in a sample observation, the variable MNINT might represent the mean number of line interchanges for the shipment of some commodity, perhaps lumber, between some origin and destination pair, say Alabama and Oklahoma, in some quarter and in some year such as the fourth quarter of 1978.

The format of the origin - destination information in the CWS was changed in 1986. For 1986 and 1987 this information is given by BEA area of which there are approximately two hundred. Unfortunately, confidentiality and the more specific nature of this information necessitated the elimination of origin destination information altogether for some records. For some STCC's all records were complete, for others as many as forty percent contained deficient information. Even for those commodities where a significant portion of the records did not contain the necessary origin - destination information, an attempt was made to salvage and use those records which did contain this information. For each commodity where a problem existed the mean values of both the dependent and all independent variables were calculated for the group of records which did contain the origin - destination information. Next, similar means were calculated for those observations with the missing data. If these two means were statistically different for even one of the variables, the 1986 and 1987 data was eliminated entirely for that commodity. If, however, the group means for each

variable were not statistically different at a ninety-five percent level, the observations which contained the origin - destination information were retained.

Appendix III indicates the method by which BEA areas were converted to state to state data.

Finally, there has been some controversy regarding the validity of the revenues reported in the CWS for the years 1981 through present. The discussion focusses on the existence of contract rates which are allowed under Staggers. In the scheme of railroad tariffs three echelons of reporting must be considered. First, there are published tariffs. Few if any movements occur under these rates. Next, there are the billed rates. These are the rates which are reported on the waybills which accompany the shipment. Prior to 1981, the billed rates represented the actual charges associated with a shipment. Since 1981, railroads have been able to establish contract rates with shippers and it is the reporting of these rates which sits at the center of the controversy over the CWS. Carriers are not required to report contract rates on the waybills. Rather, they may report the rate at which the movement would occur if there was no contract in force. Further, there is nothing on the bill (and consequently, nothing in the CWS) which identifies the shipment as a contract move, so that it is impossible to separate those records for which the rate information may be misleading.

Some, such as Professor Boyer, have argued that the possible corruption of the line haul revenue field of the CWS makes this sample unusable. Others, including MacDonald (1987 and 1989a) and Winston (1990) have demonstrated

that prudent use of the sample is still quite possible. MacDonald (1987), by direct comparison, first establishes that way-bill rates are not simply tariff rates as some have argued. Next, he compares total grain revenues as reported by the Association of American Railroads with grain revenues derrived by expanding the CWS. These figures were not statistically different, indicating that the way-bill rates, in the aggregate, closely reflect the rates at which shipments actually moved.

In his later (1989a) research, MacDonald adopts a methodology similar to the "mine mouth" strategy of Garrod and Miklius. He compares mean way-bill rates to mean price spreads between for grain at distant origin/destination pairs. MacDonald argues that these price spreads should encompass the true rates. As in his 1987 research, the 1989 results indicate that way-bill figures closely track the price spreads.

Winston, Corsi, Grim, and Evans performed a similar test for coal rates and found that the billed 1985 rates for movements of coal were not significantly different than actual coal rates.⁴ An overwhelming majority of contract movements are shipments of grain or coal.

The implication, then, is that even though railroads are not required to report contract rates, they are doing so in most cases. An explanation of this behavior may lie in the structure of the contracts. In most cases the rates charged to contract shippers are not substantially less than those charged to non-contract

⁴This test (similar to MacDonald (1987)) consisted of comparing the total coal revenues as reported by the Association of American Railroads with the total coal revenues generated by an expansion of the Carload Waybill Sample.

customers. However, the contracts specify rebates to be paid to (or penalties to be paid by) the shippers if the volume of traffic meets (or fails to meet) required levels specified by the contracts. MacDonald (1989b) contends that, in the case of penalties, carriers report for billing purposes the rate they expect to receive. This would not include the amount of any penalty. Further, it seems the value of any payable rebates is not substantial enough to statistically differentiate contract rates from billed rates.⁵

There are three commodities for which contracts are in wide use. The first of these is grain. MacDonald's work is sufficiently complete so that this commodity is not considered here. The second commodity is coal, which leads all other goods in terms of the percentage of shipments moving under contract. Coal contracts are typically structured in the same manner as grain contracts, so that the billed rates are assumed to be equally valid. The final commodity for which contracting is prominent is lumber. Approximately nineteen percent of all lumber shipped by rail moves under contract. The reader should be mindful of the possible impact of contracts when considering this commodity.⁶

Data describing the number of rail carriers operating between each origin and destination pair were compiled by use of the Interstate Commerce

⁵Again, a word of personal thanks is owed to Jim MacDonald for his explanation of the operation of railroad contract rates and his clarification of the tests which he performed to compare contract and way-bill pricing.

⁶Because most contract rates offer rebates for volume shipping, it is possible that the waybill rates for lumber are actually higher than the effective contract rates.

Commission's Annual Report, the Association of American Railroads' Yearbook of Railroad Facts, and The Official Railway Guide. These data are annual. A rail carrier was defined as offering service between two states in a particular year if it operated in both states. In a few isolated cases this method is misleading. For example, the Burlington Northern operates in both North and South Dakota, but provides no direct rail link between these states. Still, such examples are rare. In the period between 1973 and 1987 the number of Class I railroads was reduced from thirty-five to sixteen through a series of failures and consolidations. Effort was made to account for this activity even to the point where supplementary information was used to distinguish between the year of approval and actual merger consummation.⁷

Data describing the availability of inland water transport was assembled in a similar manner. Where two states were connected by a single inland watery system, water transport was identified as possible. As in the case of rail service, the physical possibility of water transport may be misleading in that no such movements may ever be undertaken. Still, in the vast majority of instances, this proved a reliable method. Coastal water transportation was not considered as an alternative.

The implementation of deregulation was initially indicated by a zero-one dummy variable, STAGG. Though the Staggers Rail Act was passed in October

⁷It should also be noted that the computation method allowing this construct made it necessary to exclude all <u>intra</u>state movements from the data set.

of 1980, it was assumed to have no impact on rail pricing until 1981. The original specification implied that the full impact of deregulation was felt immediately. This hypothesis was tested by interacting the dummy variable for deregulation with time. This interaction term was statistically significant in five of seventeen estimations. Therefore, STAGG was redefiend as the product of the original zero/one dummy variable and a time trend term (Year minus 1980).

Because the data set retains a high level of disaggregation the summary statistics describing the data for each commodity in each year are presented in Appendix IV rather than in the text.⁸

Econometric Technique

Equation (4.4) is estimated separately for each of the seventeen two digit STCC's defined in Table 4.1. This method of analysis eliminates the necessity of including commodity characteristics in the estimation. Instead, inter-commodity comparisons may be made by comparing the values of the other coefficients for each of the STCC's. Variables to proxy M, A, S, and R, as well as the variables designed to detect the impact of deregulation, are defined in the following way:

(M) The availability and pricing of other Transport Modes

Three primary variables are used to represent M. First, the zero-one dummy variable WATER described earlier, is used to indicate the possibility of

⁸Summary statistics were calculated by year even though the actual data are quarterly.

water transport between the particular origin and destination, with a value of one indicating that water transport is viable. If carriers possess any degree of monopoly power, profit maximization implies rate differentials based on varying price elasticities. In such cases, one would expect a negative correlation between the availability of water transport and railroad rates for the movement of bulk commodities.

Similarly, motor carriage is assumed to be everywhere available. However, because trucking costs escalate rapidly with distance, and because motor carrier rates are commonly assumed to be highly reflective of costs (See Levin (1981), trucking is often inappropriate for long distance movements. To measure the effect of this phenomena on rail rates, the variable MMILES is included. Rail rates which are positively related to this variable indicate that carriers respond to the fact that trucking is less appropriate for long distance shipments by charging higher prices for such shipments, all else being equal. However, it is typically assumed that average transport costs decline with distance, so that if rates adhere to costs the coefficient estimates for this parameter should be negative rather than positive. In this way MMILES captures two opposing effects. It is regrettable that these effects can not be isolated. However, it is at least possible to determine which is dominant.

The actual estimation also includes MMILES2 which is the square of the mean distance of shipments between "i" and "j" in period "t". If terminal costs are positive and the marginal cost of providing transport is constant in distance, then

average cost of service (per ton-mile) will fall asymptoticly toward the level of marginal cost as distance increases. Thus, there is reason to suspect that costs do not vary linearly with distance. The quadratic term is included to accommodate this suspicion

Finally, the variable DIRSRV is included as a measure of intramodal competition. It is defined as the number of carriers offering service between the origin, "i", and destination, "j", in period "t". In a perfectly competitive environment, this variable should have no impact on rates. However, in an oligopoly setting, one would expect rates to decline as the number of firms increases. The ideal measure of intramodal competition would not only take into account the number of direct (meaning non-interchange) routes between origins and destinations, but would also account for possible interline routings and the additions in shipping times, distances, and variability associated with such routings. This sort of measure was contemplated in this research as an index which included the number of direct routes and the weighted number of indirect routes between the origin and destination. The weight would have lied between zero and one depending on the additional distance associated with the route. However, the computational problems stemming from the (literally) millions of

⁹In a non-cooperative setting, the Cournot model of oligopoly behavior predicts precisely this result. In a more cooperative framework, attempts to collude are commonly believed to be more successful when the number of firms is small. See Blair and Kaserman (1985).

possible routings between each possible origin and destination lead to the abandonment of a search for a preferable measure.

(A) Aggregate Economic Activity

Because the level of aggregate economic activity affects final demands, it is assumed to affect the level of transportation demand as well, and thereby has the potential to influence rates. However, it is possible that this occurs with a lag. The variable AVPROD is included to reflect this possibility. AVPROD is defined as the simple mean of the quarterly index of manufacturing production for periods "t" and "t-1". Ignoring the possibility of mode switching, it is hypothesized that transport demand becomes less elastic during periods of accelerated economic activity and more elastic as the economy cools. Accordingly, it is expected that this variable will be positively correlated with rail rates.

(S) Shipment Characteristics

At least two of the shipment characteristics overlap other variable categories. As noted above, the distance variable, MMILES, determines the appropriateness of motor carriage, but it also is a key determinant of average rail costs. Another shipment characteristic - the need for specialized equipment - is assumed to be commodity specific, so that its presence may be viewed as a partial explanation for the disparity of coefficient values for the different STCC's. The

¹⁰If shippers switch transport modes as a result of changing inventory needs, the impact of shifting aggregate demand may be dampened.

primary shipment characteristic included in the estimation is MLOADS which is defined as the mean number of loads for shipments of the particular commodity between "i" and "j" in period "t". As noted by Patton (1988), any given shipment may require as many as four switch moves by the carrier. The costs of these moves are fairly constant with respect to the number of loads, so that average pick up and delivery costs per load decline as the number of loads increases.

Therefore, a negative coefficient estimate for this parameter indicates that rates more accurately reflect costs. On the other hand, larger volume shippers face considerably higher costs if they wish to adapt receiving and loading facilities to accommodate another mode. Presumably, this results in more inelastic demand. Thus, a positive correlation between MLOADS and rates may indicate a carrier's attempt to capture additional profits.

(**R**) Route Characteristics

Two primary variables were included as a reflection of route characteristics. The first of these, MNINT, denotes the mean number of line interchanges for the movement of some commodity between origin and destination in period "t". This variable is directly related to the level of total costs because of the terminal activities associated with interchange. Therefore, rail rates will be positively correlated with the number of interchanges if rates adhere to costs. However, the variable MNINT may take on a negative sign as well. Carriers forming a joint route (as suggested by interchange) must also agree on how rates are to be apportioned. Further, there may be a number of joint routes serving a single

origin destination pair. This suggests a high level of strategic interaction between carriers in the creation and division of joint rates. A negative sign for MNINT would indicate that this interaction is dampening carriers' attempts to secure the maximum available profit.

The second route characteristic, DENSITY, is defined by the overall volume of rail traffic between "i" and "j" in period "t". For a number of reasons, this is an inferior proxy for the route density. However, the state to state origin-destination information makes the development of a more appropriate measure impossible. Braeutigam et al (1984) suggests that any real economies in rail shipping are the result of density not scale. Accordingly, rail costs should decline as DENSITY increases until some minimum efficient density is attained. Beyond this optimal level, DENSITY may have no impact or may even indicate increasing costs if the rail infrastructure is be pressed beyond capacity. Most would argue that, ignoring seasonal car shortages, rail capacity is seldom taxed, so that the parameter estimates for density should be negative if rates reflect costs.

(F) Factor Costs

As noted earlier, there is no reason to suspect any cross-sectional variation in factor costs, either with respect to commodity or origin - destination pair. The intertemporal improvements in factor productivity are captured by the variable TIME which is a period measure ranging between one (the first quarter of 1973) and fifty-six (the final quarter of 1987).

(P*) Profit Maximizing Price

The dependent variable in each estimation is defined as the revenue per ton-mile, RTM. The value of this variable is calculated directly from the line haul revenue, net tons, and milage fields of the CWS. The values are then placed in real terms by use of the quarterly Producer Price Index.

The above may be combined to obtain:

(4.5a)
$$RTM_{ijt} = \beta_0 + \beta_1(MNINT_{ijt}) + \beta_2(MLOADS_{ijt}) +$$

$$\beta_3(MMILES_{ijt}) + \beta_4(MMILES2_{ijt}) + \beta_5(DIRSRV_{ijt}) +$$

$$\beta_6(DENSITY_{ijt}) + \beta_7(WATER_{ijt}) + \beta_8(AVPROD_{ijt}) +$$

$$\beta_9(TIME) + \epsilon_{iit}$$

which explains rail rates in the absence of any regulatory change.

To capture the effects of deregulation, the estimation contains the previously defined variable (STAGG) and a set of interaction variables defined as the product of STAGG with the right-hand-side variables in equation (4.5a). With the exception of DENSITY for which SDENS is the corresponding interaction term, these secondary terms are simply represented by the original variable name preceded by the letter "S" to indicate the effect of Staggers. The final model to be fitted for each commodity is then:

$$(4.5b) \qquad \text{RTM}_{ijt} = \beta_0 + \beta_1(\text{MNINT}_{ijt}) + \beta_2(\text{MLOADS}_{ijt}) + \\ \beta_3(\text{MMILES}_{ijt}) + \beta_4(\text{MMILES2}_{ijt}) + \\ \beta_5(\text{DIRSRV}_{ijt}) + \beta_6(\text{DENSITY}_{ijt}) + \beta_7(\text{WATER}_{ijt}) + \\ \beta_8(\text{AVPROD}_{ijt}) + \beta_9(\text{STAGG}_{ijt}) + \beta_{10}(\text{SMNINT}_{ijt}) + \\ \beta_1(\text{SMLOADS}_{ijt}) + \beta_{12}(\text{SMMILES}_{ijt}) + \\ \beta_{13}(\text{SMMILES2}_{ijt}) + \beta_{14}(\text{SDIRSRV}_{ijt}) + \\ \beta_{15}(\text{SDENS}_{ijt}) + \beta_{16}(\text{SWATER}_{ijt}) + \\ \beta_{17}(\text{SAVPROD}_{iit}) + \beta_{18}(\text{TIME}) + \varepsilon_{ijt}$$

where the combination "ij" represents a particular origin - destination pair for some time period "t".

This interaction specification allows three forms of analysis. First, by examining the coefficient estimates for B_0 through B_8 , it is possible to determine the effects of the various parameters on rail rates during the regulated era. That is, where STAGG equals zero, the value of the interaction variables equal zero, leaving equation (4.5a). Secondly, the value for STAGG when combined with the slope interaction variables depicts the way in which deregulation changed carriers' responses to the independent variables. Finally, by setting, the value of STAGG to zero, one can predict what rates might have been charged in the absence of Staggers and compare these predictions to the actual observed rates for the various commodities. Figure 4.1 and an example will illustrate this technique. Assume that the number of interchanges alone is responsible for the observed rail rate. Rates could then be modeled as:

(4.6a)
$$RTM_i = \beta_0 + \beta_1 (MNINT)_i + \epsilon_i$$

Hypothetically, estimation might yield the regression line plotted in Figure 4.1. Next, assume that for some set of additional observations after deregulation, the relation between MNINT_i and RTM_i is fundamentally different than it was for the original set of observations. These additional observations are denoted by a value of one for a zero/one dummy variable, STAGG. For all other variables STAGG has a value of zero. This structural difference is depicted in the following model:

(4.6b)
$$RTM_i = \beta_0 + \beta_1 STAGG_i + \beta_2 MNINT_i + \beta_3 (STAGG_i * MNINT_i) + \epsilon_i$$

When STAGG has value of zero the fitted regression will have the same parameter values as in (4.6a). However, when STAGG takes on a value of one, the intercept for the regression becomes $B_0 + B_1$ and the slope becomes $B_2 + B_3$. The difference between the effect of MNINT on RTM in the deregulated era is simply B_3 . Further, given the observed values of MNINT in the years since deregulation, it is possible to predict what RTM would have been by setting the value of STAGG to zero.

There is no theoretical indication for support of any particular functional form with the exception of the quadratic relation between the optimal price and shipment distance, so that a linear form was initially assumed. Other functional forms were tested with no substantial improvement in fit. Therefore, the linear form is retained for its simplicity.

INTERACTION SPECIFICATION EXAMPLE

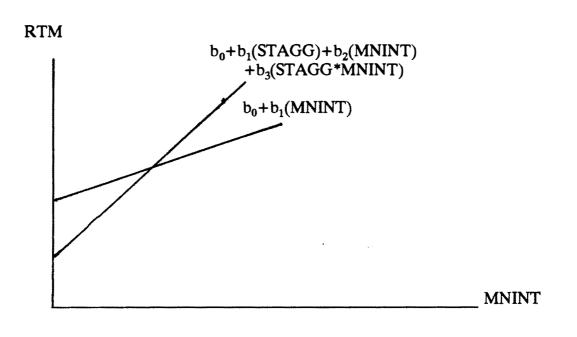

FIGURE 4.1

Consistent with accepted econometric practices, 11 the estimation technique corrects for autocorrelation and heteroskedasticity. It is assumed that the disturbance for each origin - destination pair, ϵ_{ijt} is serially correlated with the disturbance for the same routing in period "t-1". The model also recognizes that the disturbance for different origin - destination pairs within any particular period may exhibit different variences. The error structure may be written as:

(4.7)
$$E(\epsilon^2_{ijt}) = \sigma^2_{ij}$$
 (heteroskedasticity)

(4.8)
$$E(\epsilon_{ijt}\epsilon_{ikt}) = 0$$
 (j * k) (cross sectional independence)

(4.9)
$$\epsilon_{ijt} = p_{ij}\epsilon_{ij,t-1} + u_{iit}$$
 (autocorrelation)

where:

$$(4.10) u_{iit} \sim N(0,\sigma_{uii}^2)$$

(4.11)
$$\epsilon_{ij1} \sim N(0, \sigma^2_{uij}/(1-p^2_{ij}))$$

(4.12)
$$E(\epsilon_{ii,t-1}u_{ik}) = 0$$
, for all j,k

Kmenta (1986) fully outlines the development of this error specification.¹²

¹¹See Kmenta (1986) and Hsing and Chang (1980).

¹²There are really two cross-sectional elements within the data set, the commodity and the origin-destination pair. Cross-sectional independence was assumed with regard to both. The latter is explicit in the above specification, while the former implies that estimation of each commodity separately is appropriate, rather than some simultaneous estimation technique.

CHAPTER V

ANALYSIS OF RESULTS

Appendix V presents a full reporting of regression results from the estimation of equation (4.5b) for the seventeen STCC's. Actual coefficients and significance levels appear in the text only as they are necessary to support the inferences offered. The results are revealing; first because they provide a reasonable explanation of rail rates during the regulated era, as well as some measure of regulatory efficacy. Second, these findings provide solid evidence of enhanced competition which is directly attributable to deregulation. Finally, in direct contrast to some of the early findings, the results suggest that nearly two thirds of all rail traffic moves under rates which are lower than they might have been in the absence of deregulation.

Rail Rates Prior to Deregulation

The picture of railroad pricing prior to Staggers is one of sluggish (and possibly joint) profit maximization. Regulators were unsuccessful in forcing rail rates to reflect even those costs which are identifiable and easily associated with particular services. At the same time, the regulatory environment constrained carriers from responding fully to the presence or lack of intermodal competition.

Finally, it appears that rate regulation may have dampened any tendency toward intramodal rivalry by facilitating tacit collusion.

An examination of the coefficient estimates in Table 5.1 shows a muted sensitivity to both intermodal and intramodal competition in the years prior to Staggers. The variable DIRSRV appears negative and statistically significant for only four of the seventeen STCC's, indicating that prior to deregulation, the presence of alternative rail carriage did not routinely act to lower rail rates. This result may be explained two ways. If rail rates were highly competitive, one would expect similar rates regardless of the number of operating firms. However, since the results to be discussed below suggest that rates did not closely reflect costs, this scenario is unlikely. An alternative explanation of the result is that the regulatory setting facilitated some form of tacit collusion. The parameter estimates for WATER, also in Table 5.1, show that rail rates for several commodities were lower in those areas where water transport was available. However, the broad range of commodities for which this is true suggests that this is more likely the result of a regulatory bias in favor of southern states than any attempted discrimination on the part of rail carriers. Finally, the coefficient estimates for MMILES and MMILES2 in no case indicate a pricing response to the more appropriate nature of truck transport over shorter distances. The remaining demand-side variable in equation (4.5b) is AVPROD, the measure of cyclical activity.

¹Water transport is more available in southern and mid-western states. Friedlaender and Spady (1981) also found evidence of this same bias.

TABLE 5.1

PRE-STAGGERS IMPACT OF DEMAND-SIDE VARIABLES

•			

As expected, rail rates for each of the commodity groups were pro-cyclical.

The means by which incurred costs were reflected in rail rates prior to Staggers is often curious, but seldom indicative of strong competition or effective regulation. See Table 5.2. For example, the number of interchanges would be expected to increase rates because of the associated terminal costs. However, prior to deregulation, this was true for only one third of the commodities,² and for five commodities more interchange appears to have lowered rates. The former of these results simply reflects the inability of regulators to establish rates that reflected incremental costs. The negative correlation between interchange and rates may indicate the difficulty for carriers of negotiating the level and division of joint rates. In contrast to interchange, an increased number of loads within each shipment would be expected to lower average costs. However, ten of the seventeen commodity estimates yielded coefficients for MLOADS which were positive and statistically significant. Again, if rates were being accurately determined by the Interstate Commerce Commission or if a significant degree of competition existed, one would not predict this result. Instead, the positive relation between the number of loads and the per ton-mile rate in the years prior to Staggers probably reflects attempts to exploit the captive nature of larger

²Interestingly, it was primarily bulk commodities for which rates reflected the increased costs of interchange.

shippers who were (and are) less able to switch transport modes because of the higher costs of retro-fitting receiving and loading facilities.³

One of the most often noted determinants of rail costs is the traffic density of the selected route. Because of the dispersement of fixed costs over more and more shipments, it is expected that average costs will become lower as density increases until the capacity of the rail infrastructure comes into question. Yet, an examination of the coefficients for the variable DENSITY suggests that these economies of density were only reflected in the rates for movement of four of seventeen commodities prior to deregulation. Further, for a number of primarily bulk commodities, the sign for DENSITY is positive and significant.

Only two cost-side variables routinely displayed signs consistent with any sort of cost influenced pricing. It has long been assumed that average transport costs decline as the distance between origin and destination increases (See Chapter IV). The parameter estimates for MMILES and MMILES2, as reported in Table 5.1, suggest these cost savings were evident in rail rates even in the years prior to deregulation. The reader will recall that MMILES and MMILES2 also reflect the way in which rail rates are influenced by the appropriateness of motor carriage. It was hypothesized that, for shipments of longer distance where trucking might be less appropriate, rail rates might be higher. However, the

³For example, shippers who ship or receive large numbers of carloads at one time usually have extensive on-site switching facilities. The costs of replacing these facilities with those which are appropriate for another transport mode would be extensive.

results indicate that it is the impact on costs of longer shipment distances which influences rates. Finally, the estimates for TIME indicate that the technological improvements alluded to by other authors did play a role in lowering rail rates for the movement of all seventeen commodities throughout the years between 1973 and 1980.

Pricing Under Deregulation

The results indicate that deregulation substantially altered carriers' responses to the profit determining variables as described above. In nearly every case, rates tended to better reflect the level of incurred cost and the presence of transport alternatives.

The interaction specification permits a detailed analysis of deregulation's effects on carrier responses to values of the independent variables in the years since Staggers. The coefficients for the interaction variables provide a measure of the *change* in response attributable to deregulation. The sum of the interaction coefficient and the original coefficient represent the total carrier response to particular variables in the post-deregulation era.

Table 5.3 provides the coefficient estimates for the interaction variables SDIRSRV and SWATER, the sum of these coefficients with their corresponding independent variable coefficients, and the results of joint tests for significance. First, it is apparent that rail carriers are now much more sensitive to the presence of other rail carriers than they were prior to Staggers. The sum of the coefficients

for DIRSRV and SDIRSRV is negative for ten of the thirteen commodities where this sum is statistically different from zero. In three cases, the negative value of SDIRSRV serves to reenforce an already existing relationship between rail rates and the number of carriers offering direct service. For two of the remaining seven commodities, the values for SDIRSRV reverse a positive relation. Finally, there are five commodities for which rates are now negatively affected by the presence of rail alternatives where there was no previous relationship.

The parameter estimates for SWATER confirm two hypotheses. First, they suggest that rail carriers are more responsive to transportation alternatives in setting rates since Staggers. Secondly, the results support the suggested regulatory bias which favored southern states. Again, prior to deregulation, a number of commodities moved under rates which were lower when water transport was available. However, the diversity in the nature of these commodities suggests that the rates were really lower because of a regulatory bias which only coincidentally favored states where water transport was available. If this hypothesis is true, one would have expected rates to return to "normal" levels when regulatory control of rates was abandoned. An examination of Table 5.3 (together with Table 5.1) indicates that this is precisely what happened. Rates for commodities which are not appropriately moved by water lost their sensitivity to the availability of water transport when Staggers was put into place. On the other hand, commodities for which water transport presents a reasonable alternative continued to move under lower rates when barge transport was available. For these commodities, demand

considerations replaced the regulatory bias as the impetus for lower rates.

The extreme adherence of rates to the cost savings associated with longer shipment distances has been maintained in the years since Staggers, so that any difference in the way rail carriers react to possible motor carriage is somewhat obscured. If such differences exist, they may be uncovered in the commodity by commodity analysis which is to be presented later.

Railroad deregulation has dampened, but certainly not eliminated carrier responses to the level of cyclical activity. Table 5.4 contains coefficient estimates for SAVPROD, the sum of these coefficients and those for AVPROD, and the test statistic to determine whether this sum is different than zero. It is clear that the impact of deregulation was to reduce the influence of cyclical activity on rates for most commodities. Given that sensitivity to other demand side factors has been made greater by deregulation, this result may seem a little curious. It is, however, explained by the change in the mix of commodities which are shipped by rail. Recall that prior to deregulation the rates for all commodities tended to be pro-cyclical. Further, this tendency was more pronounced for manufactured goods than for raw materials. An examination of total car loadings reveals that raw materials (predominantly bulk commodities) have increasingly dominated the mix of commodities traveling by rail. These are precisely the commodities for which transport demand has always been less cyclical. Next, as manufactured commodities represent a continually smaller fraction of total rail traffic, the rewards to carriers from adjusting rates to reflect cyclical change becomes smaller

73

too. Cyclical variations in commodity demands simply no longer hold a potential for gains sufficient to warrant variations in rates.

From the standpoint of economic efficiency, the changes in carrier response to demand side variables may be interpreted two ways. First, the ability of railroads to charge differential rates based on demand characteristics implies that these carriers possess some degree of market power. If rate regulation had been effective in inhibiting this power, and if prescribed rates had accurately reflected costs, then one could associate a loss of efficiency with the implementation of Staggers. There is, however, an alternative perspective. The discussion in Chapter IV suggests that carriers had substantial rate making freedoms prior to deregulation, yet the evidence presented in this chapter indicates that the rates which they set were not particularly sensitive to the presence of other rail carriers. Taken together, these results suggest that regulated rail carriers depended heavily on the Interstate Commerce Commission to protect them from intramodal rivalry. Neither contract rates nor any other confidential devices were allowed under ICC regulation. Therefore, each firm was constantly aware of the rates being charged by its rivals. At the same time, it would have been difficult for the Commission to sanction differential rates which were not the product of differing costs. Railroads were, therefore, assured that their competitors would not be offering substantially lower rates or, at very least, that any such behavior would be immediately detectable. Stigler (1971) makes it clear that regulation may confer economic benefits to its targets. In the case of American railroads, it appears that

regulation facilitated cartel-like behavior. That rail carriers are now more sensitive to the presence of other carriers, indicates that this tacit collusion has been replaced with a new sense of rivalry.⁴

Presuming that deregulation did heighten intramodal rivalry and recognizing the constant pressures imposed by motor carriage, one would expect that deregulated rail rates would better reflect the ever falling costs of providing rail service. This is, in fact, what the evidence obtained here suggests.

First with regard to shipment characteristics, it was noted earlier that there are significant switching costs associated with pulling and delivering shipments.

These costs are largely invariant to changes in the number of loads, so that shipments containing more loads are switched at a lower per ton cost. The number of loads which shippers routinely ship or receive is also assumed to give some indication of the importance of the commodity to the shipper and the potential cost of switching to an alternative form of transportation. Presumably shippers transmitting or receiving larger shipments are more captive. 5 Prior to

⁴The reader may ask why an industry which was dependent on rate regulation to enforce cartel behavior would actively support the removal of that regulation. The answer would seem to be that most railroads realized the true threat to their welfare did not come from other railroads, but from the motor carrier industry. With prolonged regulation, each carrier could be assured of the behavior of its rival, but such regulation was simply too costly because of the way it inhibited any response to intermodal competition.

⁵While it is the absolute size of the shipment which determines the cost and appropriateness of switching to another transport mode, the degree to which the shipper is "captive' is also a function of how important the shipment is to the shippers

the implementation of Staggers, rail rates for larger shipments were higher than those for shipments containing fewer loads. Perhaps this too represents some form of regulatory bias in favor of small shippers. Possibly this result is an indication of carrier attempts to discriminate against more captive shippers. In any case, it is clear that under regulation rail rates responded perversely to the number of loads within the shipment. Deregulation reversed this pattern, so that now rail rates for twelve of seventeen commodities are negatively influenced by increasing the number of shipment loads. Table 5.5 provides the coefficient estimates for SMLOADS. It also contains the sum of this variable and MLOADS. Further examination of Tables 5.1 and 5.5 reveals that it is bulk commodities for which the negative relationship is the most prominent. This is consistent with railroad operations in which unit trains containing bulk commodities are often roaded and delivered directly with no switching costs.

Just as an increased number of loads lowers average costs, an increase in the number of interchanges should raise them because of more terminal activity. Recall that, prior to deregulation, only one third of the commodities moved under rates which were positively affected by the number of interchanges, so that cost savings associated with fewer interchanges were not being incorporated into rates. Table 5.5 presents the parameter estimates for SMNINT and the sum of SMNINT and MNINT. Clearly deregulation has produced rail rates which better indicate the costs of interchange. In the wake of Staggers, nine of seventeen commodities

over-all business.

display rates which are positively correlated with the number of interchanges. It is also worth noting that prior to deregulation four STCC's actually displayed a negative correlation between rates and the number of interchanges. This number was reduced to three by Staggers.

Table 5.6 contains the coefficient estimates for SMMILES and SMMILES2. Prior to deregulation, rates for the movement of all seventeen commodities reflected the hypothesized reduction in average costs which is associated with longer shipment distance. Deregulation tended to dampen this relation in some cases and enhance it in others, but in no case does the relationship disappear or is it reversed.

Model Predictions

The general conclusion at this point in the analysis must be that deregulation has lead to more intramodal rivalry, more real attention to intermodal challenges and rates which better reflect the costs of providing services. While it is evident that rail carriers still possess some market power, the net effect of the Staggers Rail Act on the degree of efficiency in railroad transportation seems to be positive. Theoretically this positive outcome stands independent of the effects of deregulation on the actual levels of rail rates. However in the arena of public policy, this more efficient pricing behavior pales to concerns over how the level of deregulated rail rates compares to those rates which might have been in evidence if regulation had persisted.

The interaction specification allows the prediction of rates under the scenario of continued regulation. However, as with any out of sample prediction, the confidence attached to these predictions diminishes greatly as the predictions move through time away from the regulated era. Further, it was necessary to aggregate the predicted values across origin destination pairs in order to obtain a workably small set of predictions for analysis. Finally, the predictions offered are based on the transformed values of the independent variables which were generated through the Generalized Least Squares estimation technique.

Therefore, they may only be appropriately compared with the transformed values of rates which were actually observed. Thus all inference regarding the changes brought by deregulation appear in percentage terms rather than absolute terms.

For the purpose of this analysis a rate was considered to be higher or lower than the predicted rate if it was above or below the bounds of the 95% prediction interval surrounding the predicted rate.⁶ Inspection of Table 5.7 below reveals

The Generalized Least Squares approach allows the variance-covariance matrix to deviate from the form assumed in an Ordinary Least Squares estimation. Specifically, in the research presented here, both the diagonal and off-diagonal elements may take on values representative of the cross-sectionally heteroskedastic and time-wise autoregressive error structure assumed in Chapter Four. When the true parameters of the error structure are known, data may be transformed, so that the variance-covariance matrix conforms to the OLS assumptions. Thus, the OLS estimators retain all desirable properties as do any predictions based on estimated values. When the true parameters of the error structure are not known, values for the transformation matrix may be estimated. In such a case, the OLS estimators retain all desirable properties. However, an examination of prevailing econometric theory provides little insight into the way in which prediction intervals are established for small samples in this latter case. For the purpose of this research, the values for the transformation matrix were estimated. However, given the absence of applicable econometric theory, predictions were conducted as if the values of the elements

that railroad deregulation has produced rates which are lower than they might have been for some commodities in some years. Further, this table suggests that rail rates have in no case been made higher by the implementation of Staggers. Examination of table 5.7 in conjunction with the coefficient estimates and summary information (See Appendix IV) for each commodity yields very interesting results.

First, we see that there was notably less movement away from predicted rates in 1982 and 1983 than in other years. This result owes primarily to the reduced cyclical nature of rates and the sharp decline in aggregate business activity during those years. Rates were falling at this time which certainly corresponds to their prior cyclical nature. However, when business conditions improved, the decline in rail rates did not reverse itself as it might have in the past.

Next, while the level of intramodal competition was largely invariant across commodities, changes in the degree of sensitivity to this sort of competition often contributed to the proportion of movements traveling under lower rates. Eight of the nine commodities for which over ten percent of rates appear lower display negative coefficients for the variable SDIRSRV. Moreover, when these coefficients were ranked by magnitude, seven of the ten most negative were associated with commodities which had a significant number of shipments moving at lower rates after deregulation. The obvious implication is that when Staggers

within this matrix were known.

TABLE 5.7
PROPORTION OF RATES ALTERED BY STAGGERS

This table indicates the proportion of traffic which moved under rates which were significantly different than those predicted had regulation continued.

enhanced sensitivity to intramodal competition the result was that a substantial amount of traffic moved under lower rates.

Interestingly, there seems to be little real correlation between the proportion of rail rates which declined based on the bulk/non-bulk nature of the commodity. By 1987, rates for nearly thirty percent of all shipments of scrap were lower than the prediction had regulation continued. Similarly, over twenty-four percent of the movements of nonmetallic ores were moving at significantly lower rates by 1985. However, rates for metallic ores, coal, and CCGS appear virtually unchanged. Conversely, the proportion of rail rates for machinery, for rubber and plastic products, and for fabricated metal products which appear to be lowered by Staggers is moderate to none. Yet the proportion of transportation equipment, electrical equipment, food products, and lumber traveling at lower than predicted rates is substantial.

Rather than conforming to any specific inter-commodity pattern, the percentage of rates for each commodity which are lower under deregulation seems to be a function of that commodity's own demand and cost characteristics. For example, rates for the movement of scrap material appear particularly sensitive to the availability of water transport in the years since Staggers. It may also be noted from the summary statistics in Appendix IV that the percentage of such shipments in regions where water transport is readily available is particularly high. Thus, the rates for a large number of such shipments have fallen significantly. On the other hand, the observed rates for the movement of machinery do not

appear to have been significantly lowered by deregulation. In this case, whatever rate reducing forces may exist are offset by a strong new sensitivity to the number of interchanges.

Any attempt to examine the welfare implications of deregulated rail rates must consider the magnitude of individual rate changes as well as the overall quantity of those changes. Again, the estimation technique dictates that rate changes be calculated in relative rather than absolute terms. It is also desirable that the impact of the individual rate changes reflect the size of the shipment for which they applied. Therefore, the following method was used to calculate the average difference in rate for each observation on each commodity.

$CHANGE = \underbrace{RTM - PREDICTED}_{PREDICTED} \times \underbrace{MLOADS}_{LDSBAR}$

Where RTM is the rate predicted by the model when STAGG equals one, PREDICTED is the rate predicted when STAGG was set to zero, MLOADS is as defined above and LDSBAR is the mean number of loads in for all shipments of the particular commodity. Further, in analyzing the magnitude of the rate changes, it is imperative that the reader be constantly mindful that many observed rates were not statistically different from the rate predicted in the absence of Staggers. The margin for error in the predicted rates is extremely high. Still, the data in Table 5.8 provides some measure of magnitude for those rates which have changed.

TABLE 5.8

MAGNITUDE OF RATE CHANGES

The following table presents aggregated estimates of the magnitude of change in rail rates for the seventeen commodities. WChange represents a weighted change. This measure was constructed by weighting the predicted change in rate by the number of car loads in the shipment.

It is clear from the outset that the magnitude of change is, in general, higher for bulkier commodities. This pattern weakens during the 1982-1983 recession, but re-emerges even stronger in the period between 1984 and 1987. A notable exception to the pattern described above is coal. Coal rates appear as high or higher than predicted through 1983. However, they fall substantially below predicted levels for the years 1984 and 1985. In fact, the percentage deviation from the predicted rates for coal is greatest for both these years. Unfortunately, coal is one of the commodities for which the 1986 and 1987 data is unusable.

As with the percentage of movements for which rates were significantly lower, the magnitude of changes are sharply correlated with cyclical activity. The magnitude of rate reductions for virtually all commodities is reduced during the 1982 - 1983 recession, Again, this owes to the fact that rates did not obey the cyclical pattern which they displayed prior to deregulation. Figure 5-1 illustrates what may be considered a typical pattern for the deviation of observed rates from the rates which might have been evidenced in the absence of Staggers.

Table 5.8 provides estimates for the magnitude of rate changes. However, this table does not provide the results of statistical tests aimed at establishing a confidence region for these changes. Such intervals are not established because the predicted rates are based on values for the independent variables which would

have been *predicted* in the absence of the act of deregulation.⁷ In the place of such tests, Table 5.9 contains the results of "F" tests which conclusively refute the hypothesis that the coefficients for the interaction variables and the deregulation term STAGG are simultaneously zero. These test suggest that those rate predicted under Staggers are statistically different from those predicted in its absence for fifteen of the seventeen commodities.⁸

In summarizing the results from the estimation of the empirical model for the seventeen commodities, there are three conclusions which stand most clearly. First, rail rates in the years since Staggers better reflect the costs of service than they did during the regulated era. Next, Rail carriers are much more sensitive to the availability of intramodal and intermodal competition than they were prior to deregulation. Finally, as much as thirty percent of movements of some commodities occur at rates which are measurably lower than they might have been had regulation persisted. The importance of this result is amplified by the knowledge that no single commodity appears to move under rates which are

⁷A considerable effort was made to determine an appropriate method for establishing appropriate prediction intervals. However, none was discovered. This gap in econometric methodology seems both unfortunate and somewhat unbelievable. Efforts to determine an appropriate technique will continue, so that subsequent research may contain these prediction intervals.

The SAS procedure for testing such hypothesis failed for "Lumber" and for "Furniture and Fixtures". This does not mean that the null hypothesis could not be rejected. Instead it means that the statistical package was unable to carry out the specified test for these two commodities. An examination of the appropriate coefficient estimates and associated standard errors provides no insight as to why this failure may have occurred.

higher as the result of Staggers. The policy implications of these results will be discussed in the following chapter. However, it seems clear that the results obtained here move economists much closer to a definitive opinion regarding the effectiveness of railroad deregulation.

TYPICAL CHANGES IN RAIL RATES

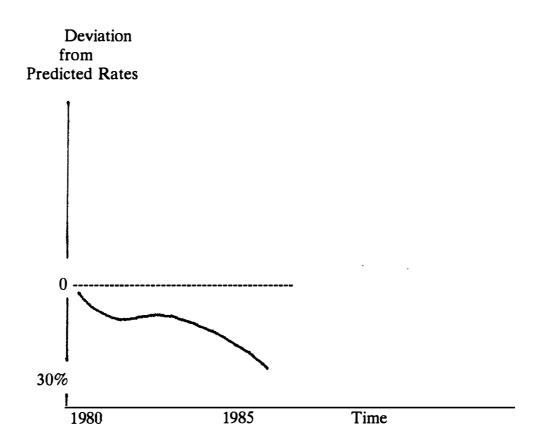

FIGURE 5.1

CHAPTER VI

SHIPPER RESPONSE

Motivation and Model Refinements

There is some indication in the preceding chapter that deregulation not only changed the manner in which railroads operate, but that these changes in turn led to changes in the composition and characteristics of the traffic which has moved by rail in the years since Staggers. The consideration of this possibility holds the potential for a set of even richer results. This chapter first describes the reasons why deregulation and the changes it brought to carrier behavior might have also altered the characteristics of rail traffic. Next, a simultaneous, recursive model is proposed to represent the relationship between Staggers, carriers, and shippers. This is followed by a description of the estimation results and an analysis of their importance to the overall evaluation of railroad deregulation.

An exhaustive description of the ways in which the Staggers Rail Act affected railroad behavior is beyond the scope of this work. However, as mentioned in the introduction, nearly every facet of railroad operation, marketing, finance, and organization changed radically and rapidly in the wake of deregulation. In the first two years following Staggers' passage, the number of mergers, branch-line sales and line abandonments was so extreme that any

¹I am particularly grateful to Jim MacDonald for recognizing this avenue of additional analysis and for his suggestions as to how it would best be pursued.

maintenance of an accurate national rail map was impossible. Even during the recession years of the early 1980's capital spending by the nation's railroads reached all-time record levels. The product of these investments was a vastly improved quality of transportation service. Not only were railroad right-of-ways improved, but carriers invested in a new generation of locomotives and rolling stock. Together, these changes allowed for the introduction of many new services which were aggressively marketed to existing and potential customers.

Innumerable changes were made in operations, so that the costs of providing these new services declined. Further, as evidenced here, the structure of railroad rates changed significantly as the structure of the industry changed.

To this point, it has been assumed that none of these changes affected the levels of the independent variables in equation (4.5b). In some cases this assumption is palatable. For example, the changes to the railroad industry had no capacity to change the availability of water transport as it is measured here.² It is even more unlikely that the changes within the railroad industry have measurably affected the aggregate level of business activity within the national economy, so that the variables AVPROD and WATER are appropriately treated as entirely exogenous. However, the exogeniety of the other right-hand-side variables from equation (4.5b) may be more of an issue.

²It is, however, possible that a more precise measure of the availability of water transport might eventually reflect some change attributable to rail deregulation. That is to say that those who make decisions with regard to maintaining and improving navigation facilities certainly consider projected barge traffic and these projections are highly dependent on projected rail rates.

Consider first the average number of loads in the shipment of a particular commodity. The intramodal rivalry attributable to Staggers caused an acceleration in the introduction of larger, more dependable freight cars and many shippers moved quickly to the use of this new rolling stock.³ At the same time, the railroads certainly did not discourage the increased use of shipper-owned and maintained equipment.⁴ Together, these deregulation related changes brought about an increase in the average capacity of freight cars. Given that the average tonnage per shipment did not change radically, one would expect use of larger equipment to result in fewer loads per shipment. Examination of the summary information for the variable MLOADS indicates that this was in fact the case, so that operating changes caused by Staggers in turn caused a change in shipper selection of equipment.

Evidence from Chapter V indicates that deregulated rail rates favor shipments where there are fewer interchanges. The potential impact on shipper behavior owing to this deregulation induced change in rate structures is obvious. However, the rate effect is only one component of the way in which Staggers may have changed shippers' selections of rail routes. Since 1981, carriers have introduced an array of new services designed to enhance the quality of rail service. When the number of carriers involved in a route is small, it makes it much easier

³Larger equipment means fewer loads and less expense in loading and unloading. The newer equipment was significantly more dependable, so that it also reduced the variability of transit times attributable to equipment failure.

⁴This was particularly true in the case of coal movements.

for shippers to take full advantage of these new services.⁵ Therefore, a decline in the number of interchanges is not unlikely.

The quality of railroad service which shippers have received may also be related to the traffic density along the selected route. The Chapter V results provided no strong association between Staggers, the variable DENSITY, and the rates for the movement of most commodities. However, this does not mean that Staggers did not induce changes in the values of this variable. Grim and Smith (1986), McFarland (1989), and Winston et al (1990) point to significant improvements in railroad service. Much of this improvement is related to reduced variability in shipping times. This advancement is, in part, due to improvements to way and structures. Since, 1980, Class I carriers have invested billions of dollars toward the rehabilitation and improvement of trackage and related facilities. However, these efforts have not been uniform across the entire national rail system. Instead, carriers have focussed on core main lines. Many carriers have sold secondary mains to regional carriers or, at least, have not worked to improve the condition of these lines. Further, very few railroads have acted to slow the decay of branch lines. This pattern of simultaneous rehabilitation and neglect is a direct result of deregulation. Prior to Staggers, carriers did not have nearly the freedom that they now possess to focus on those operations where traffic

⁵Railroads may cooperate in offering improved service for the shipment of commodities which might be moved by truck. Thus, there have been a number of newly introduced joint piggy-back operations. However, when the perceived competition is primarily intramodal, intramodal rivalry emerges.

potentials are greatest. Also, prior to deregulation, the level of intramodal rivalry was not sufficient to motivate improved service on primary routes. Given the improved quality of service on densely used lines and the continued abandonment of more peripheral operations, one would expect that since Staggers, shippers would be even more inclined to use high density routes where possible.

The potential for shippers to have responded to Staggers induced changes by altering the distance over which they ship by rail is a bit more limited. As noted in Chapter V, there has been a long standing propensity for rail rates to favor shipments of longer distance. This was evident before deregulation and remains the case today. Staggers increased this tendency for the movement of some commodities and dampened it for the shipment of others. All in all, deregulation did not greatly alter the role that distance plays in the formulation of rates. Therefore, there was less of a Staggers provoked change to which shippers might have reacted. Further, individual shipment distances are seldom changeable.⁶ This means that any observed change in average shipment distances would necessarily be the result of some shippers either abandoning or converting to rail service. One could only expect that this sort of change would come more slowly.⁷

⁶Recall the Chapter Four discussion in which it was asserted that individual demands for railroad services are largely discontinuous.

⁷To the extent that switching modes may involve significant costs related to facility conversion, a considerable time might pass before an individual firm would opt to abandon rail service.

Much as with the case of shipment distance, individual shippers have little capacity to affect the number of rail carriers offering direct rail service between a particular origin and destination. However, unlike the case of distance, the way in which the variable DIRSRV impacts rail rates was changed significantly by Staggers. It is hard to envision how shippers may have reacted to this change, but there was certainly a sufficiently significant change in carrier behavior to warrant some reaction.

Taken together, the possibilities for shipper reaction to Staggers induced changes in railroad operations and pricing behavior demand consideration if the analysis of railroad deregulation is to be complete. The next task then is to modify the Chapter IV model to accommodate such possibilities.

Equation (4.5b) is reproduced here as equation (6.1)

$$(6.1) \quad RTM_{ijt} = \beta_0 + \beta_1(MNINT_{ijt}) + \beta_2(MLOADS_{ijt}) + \\ \beta_3(MMILES_{ijt}) + \beta_4(MMILES2_{ijt}) + \beta_5(DIRSRV_{ijt}) + \\ \beta_6(DENSITY_{ijt}) + \beta_7(WATER_{ijt}) + \beta_8(AVPROD_{ijt}) + \\ \beta_9(STAGG_{ijt}) + \beta_{10}(SMNINT_{ijt}) + \beta_{11}(SMLOADS_{ijt}) + \\ \beta_{12}(SMMILES_{ijt}) + \beta_{13}(SMMILES2_{ijt}) + \\ \beta_{14}(SDIRSRV_{ijt}) + \beta_{15}(SDENS_{ijt}) + \\ \beta_{16}(SWATER_{ijt}) + \beta_{17}(SAVPROD_{ijt}) + \beta_{18}(TIME) + \epsilon_{1ijt}$$

This model continues to adequately represent the way in which railroad deregulation affected the structure of railroad rates. Hover, allowing for the

possibility of shipper reaction to changes in operations and pricing requires the model must be expanded to include a set of structural equations which describe this shipper response. Finally the resulting *system* of equations must be appropriately estimated.

The first question to be resolved is whether the exogenous variables in equation (6.1) are better expressed as a function of rail rates or as a more general function of deregulation. This issue has already been addressed above.

Necessarily, any shipper response to deregulation encompassed a reaction to the rate structure which was demonstratively altered by Staggers. However, Staggers did much to the nature of rail service which is not reflected in the changes to rates. These non-price Staggers-induced modifications in the character of railroad service must be captured as well. Therefore, the structural equations representing shipper response are modeled as a function of STAGG rather than RTM.

Given that several of the exogenous variables in equation (6.1) are hypothesized to be a function of STAGG, we must next determine whether or not their are other explanatory variables which should be included to explain *variations* in the observed levels of MLOADS, MNINT, MMILES, DENSITY, and DIRSRV. Using MNINT as an example, the structural variable explaining the number of interchanges evidenced in shipments of a particular commodity between a specific origin destination pair is presently specified as:

(6.2)
$$MNINT_{iit} = \beta_0 + \beta_1 STAGG + \epsilon_{iit}$$

which assumes that the number of interchanges would have remained constant at a level of B_0 had it not been for the implementation of Staggers. This is not an entirely untenable assumption for this particular variable. However, for at least two of the other variables which require structural equations, this assumption is less acceptable.

In the case of MLOADS, two opposing forces worked both prior to and after deregulation to change the average number of loads in a particular shipment. First, the size of most classes of rail cars has continually increased, so that, all else being equal, we might expect fewer loads in the shipments of some commodities. At the same time the increased use of unit trains for the movements of coal, grain, automobiles, and intermodal movements was growing steadily well in advance of deregulation. This latter phenomena would indicate an increasing trend in the number of loads for the shipment of those commodities. Similarly, railroads had long been engaged in programs to abandon low density lines. Therefore, independent of any regulatory response, we would expect values for DENSITY to have been declining over time. Quite simply, the only services which remained available to shippers were increasingly over lines with greater traffic density.

Similar arguments might suggest intertemporal changes in the values of the remaining two exogenous variables for which structural equations are indicated (MMILES and DIRSRV). Each of which would be linked primarily to continual

⁸This is precisely the argument of Jim MacDonald in his July, 1990 correspondence.

changes in the available technology. Though perhaps a more precise measure is desirable, this analysis will proceed under the hypothesis that these technological changes are adequately captured by the trend variable TIME, so that the resulting structural equations to be estimated in conjunction with equation (6.1) are:

(6.3a) MLOADS_{iit} =
$$\beta_0 + \beta_1(STAGG) + \beta_2(TIME) + \epsilon_{a,ijt}$$

(6.3b) MNINT_{ijt} =
$$\beta_0 + \beta_1(STAGG) + \beta_2(TIME) + \epsilon_{b,ijt}$$

(6.3c) MMILES_{ijt} =
$$\beta_0 + \beta_1(STAGG) + \beta_2(TIME) + \epsilon_{c,ijt}$$

(6.3d) DENSITY_{ijt} =
$$\beta_0 + \beta_1(STAGG) + \beta_2(TIME) + \epsilon_{d,ijt}$$

(6.3e) DIRSRV_{ijt} =
$$\beta_0 + \beta_1(STAGG) + \beta_2(TIME) + \epsilon_{e,ijt}$$

Before equations (6.1) and (6.3a) - (6.3e) can be estimated, some assumptions must be made regarding the relationship which may exist between the six individual error terms and these and between these error terms and the explanatory variables in the structural equations. To expedite the estimation process and because there is no a priori reason to assume otherwise, it is assumed that the error terms in the structural equation are independent of each other and also independent of the error term in equation (6.1). According to Kmenta (1985), violation of this assumption would not lead to biassed estimators for the

various model coefficients. It would, however, result in a loss of efficiency. Independence was *not* assumed between the individual error terms and the independent variables or between the error term in period t and period t-1.

Empirical Results and Implications

Full regression results for equations (6.3a) - (6.3e) are not reported here. However, these results are summarized in Table 6.1. The hypothesis that shippers responded to Staggers-induced changes in the structure of rail rates is clearly supported by these results. In every case where shippers could adjust shipment characteristics to take advantage of this new structure they did so. In fact, shipper response in the wake of deregulation was just as important as the change in price structure in providing the lower average rates which were previously outlined.¹⁰

Chapter V results indicate that rail rates now reflect the costs attributable to shipment interchange. This was not the case prior to Staggers. At the same time, Table 6.1 indicates that the number of interchanges for the shipment of fourteen commodities declined. Detractors from deregulation might argue that

⁹It is likely that any subsequent re-estimation of this system will utilize a more complex estimation technique which is capable of accommodating a relationship between the error terms.

¹⁰With regard to the specification of the structural equations, "Regression Specification Errors (RESET) Tests" were performed at the time of estimation. The results of these tests indicate that the simple specification of equations 6.3a - 6.3e may suffer from omitted variables bias. Accordingly, future research should include attempts to more fully specify these equations.

this behavior could indicate increased vertical foreclosure, that higher rates for interchanged traffic and the associated shipper response, simply reflect new carrier power to oppress captive shippers. However, the evidence in Table 6.1 refutes such claims. The three commodities for which the variable STAGG was not statistically significant were Coal, Chemicals and Metallic Ores. Certainly two if not all three of these commodities are transported for shippers who are extremely captive in terms of rail/non-rail alternatives.

Table 6.1 also indicates that STAGG was a significant and positive predictor of DENSITY for ten of seventeen commodities. The reader will recall that the variable DENSITY did not perform particularly well in the estimation of equation (4.5b). However, there is other evidence that this variable is tremendously important in determining rail costs. Chapter V contains some speculation seventeen commodities dropped significantly with the implementation of the act to deregulate. No doubt, part of this change is attributable to the number of post-Staggers mergers, but it is unlikely that mergers are responsible for the full amount of change. The indication is that shippers, recognizing the change in about why this variable failed in the earlier model. This centered on

¹¹See Brautigam, Daugherty and Turnquist (1984).

¹²As indicated earlier, there were a number of large mergers in the two or three years after Staggers. To the extent that these mergers were parallel mergers, the number of direct serve routes would be reduced. For example, the Frisco-Burlington Northern merger reduced the number of direct rail routes between Missouri and Kansas. However, to the extent that the mergers were end to end the number of direct serve alternatives was increased. For example, the same Frisco-BN merger created a new direct rail alternative between Nebraska and Florida.

the means by which it was constructed. However, this construction does not inhibit the ability of the model in equations (6e) to detect the change in density attributable to Staggers. Ten of seventeen commodities moved in corridors (if not on specific routes) where traffic was more dense than it had been prior to deregulation. As in the case of interchange, carrier behavior may have contributed somewhat to this result. Consistent with the provisions of Staggers, branch-line abandonments have increased in the years since deregulation. However, many of the Class I carriers have chosen to sell the larger of their unprofitable lines to regional carriers rather than abandon them, so that service on many low density lines is still available. The implication is that shippers have either re-routed shipments over routes with greater volumes of traffic or, when this is not possible, chosen an alternate mode of transport.

Sixteen of seventeen commodities moved over routes in which the implementation of deregulation was associated with a positive and statistically significant increase in the number of carriers providing direct service. The results from Chapter V have indicated that post-deregulation rail rates strongly favor shippers who have larger numbers of rail alternative. Just as movements now travel over routes which are denser, shipments are also moving over routes where there are a larger number of railroads offering direct service. In the above discussion of interchange, it was noted that the merger activity in the early 1980's

¹³The reader will recall that the origin - destination information is state to state. Thus, the density measure is state to state rather than route specific.

affected the number of direct routes between many origin and destination pairs. However, it is clear that since deregulation shippers are either routing shipments in corridors where there is more rail competition or they are shipping by another mode. In this way both the post-Staggers rate structure and shipper response to this new structure are producing lower observed rail rates.

Of the variables over which shippers have control, the observed levels for MMILES seemed the least responsive to the implementation of Staggers. Average shipment distances changed for only seven of the seventeen commodity groups and where a Staggers related change was observed, it was typically small and negative. At the same time the time trend coefficient estimates were positive and significant for fifteen of the seventeen commodities. Little explanation can be offered for the six cases in which STAGG was negative. However, it appears that, overall, shipment distances for most commodities are continuing to slowly increase. 15

The coefficient estimates for the impact of deregulation on MLOADS are the only results in table 6.1 which are immediately inconsistent with the hypothesis that shippers reacted to the changed price structure. In Chapter V it was noted that rail rates now reflect the lower car load costs which are associated with multiple car load shipments. One would, therefore, expect to see shippers move

¹⁴The shift in shipment distances was usually in the neighborhood of one to two percent.

¹⁵The discussion in Chapter Four suggested that individual shippers were reluctant or at least slow to change either the volume which they shipped or the distance over which it traveled. The results here seem very consistent with this assertion.

toward fewer shipments with more cars. This is not at all what table 6.1 indicates. The imposition of Staggers was associated with fewer loads per shipment for sixteen of the seventeen commodity groups. ¹⁶ Kenneth Boyer (1987) and James MacDonald ¹⁷ both have offered discussions which explain this seemingly perverse result. The number of loads in typical shipments has declined sharply because of the use of larger equipment. There are tremendous cost savings associated with the use of such equipment. These cost reductions have resulted in lower rates and, therefore shippers are inclined to distribute a constant tonnage over a smaller number of the larger freight cars.

Chapter V established that railroad deregulation changed the way that carriers set rates. Aggregate (average) rates have fallen and rate characteristics now more accurately reflect underlying cost characteristics. In this chapter, we have seen that changes in railroads' rate setting and operational behavior have led to significant responses by shippers which. These responses have led to a noticeable alteration of rail shipment characteristics in the post-Staggers period. As a consequence, the total welfare gain to consumers resulting from deregulation is the result of (1) lower average rail rates and (2) savings due to reconfigure shipment characteristics.

¹⁶The one commodity which is not included is Coal. The extensive use of unit trains in the movement of this commodity certainly explains this result.

¹⁷In a written commentary on this work, James MacDonald suggested that the variable MLOADS might be reconsidered for this very reason. He suggested that the number of tons in the shipment might be a more appropriate measure.

CHAPTER VII

CONCLUDING REMARKS

Economic theory suggests as appropriate the regulation of industries when the production technology and the configuration of firms within and contiguous to the industry are such that a stable and efficient equilibrium is impossible.

Somewhere, imbedded in the thrust for such regulation is the belief that unconstrained firms will be capable of earning positive economic profits, or that destructive competition may ensue. However, when the scenario is devoid of the potential for normal, much less excessive, returns, the problem facing policy makers becomes entirely convoluted. This latter situation was epitomized by the circumstance of the U.S. railroad industry as it entered the final quarter of the twentieth century.

Certainly, when market demand is insufficient to sustain the regulated, as well as the ungoverned, firm the first and most obvious option is to simply allow the industry to disappear. Indeed, American railroads could have been allowed their continued decay until the mode was extinct. However, to have done so would have drastically increased factor costs for a host of other industries, imposing considerable hardship on those industries which are most efficiently served by rail. From a policy perspective, the abandonment of railroad freight service was simply unacceptable.

Given that railroad freight transportation was deemed essential to the national interest and yet apparently incapable of self-preservation under regulation, the second option was that of nationalization. If costs exceeded potential revenues, some form of subsidization could have been combined with extant governance to produce a viable national rail system. The 3R Act aptly demonstrated the federal government's willingness to commit large sums toward the preservation of rail transport. However, the magnitude of the problem when taken at a national rather than regional level, combined with an inherent and long standing distrust of nationalized enterprise, made this option unattractive.

From an economic vantage, the problem was two fold. Railroad costs might be reduced or demand for the mode's services might be increased so that potential revenues would be adequate. However, history dictated that any steps toward either of these ends must be accompanied by the assurance that solvent carriers would be incapable of capturing excessive profits. Deregulation might work, but it would only be an acceptable solution if policy makers, shippers and the public were convinced that it did not imply renewed monopoly power. Winston Churchill once vowed that, "The Hun is at our feet or he is at our throat." Even as the U.S. railroads entered their third decade of pronounced decay, those who would have revived them found it difficult to escape the effects of their tainted (and once well earned) reputation.

The Staggers Rail Act of 1980 offered nearly total relief from rate regulation. If rates for the shipment of higher valued commodities had been held

artificially high by regulation, they might be lowered. Traffic levels could thereby be restored and the industry spared extinction. Proponents of railroad deregulation argued (probably without need) that operational and rate making freedoms would foster viable intermodal competition while enhancing intramodal rivalry. The concerns of more captive shippers, though loudly voiced, were muted by the distress of the railroad industry.

It will be decades before any final evaluation of Staggers is agreed upon.

Still, transport policy makers are faced daily with demands to refine, overhaul, or overturn the act of deregulation. If the status quo is to be preserved or if new policies are to be adopted in its stead, those charged with the decisions must have the benefit of whatever amount of knowledge the academic community can offer. It is in this spirit that this research was undertaken.

The paramount ambition of the act to deregulate was to guarantee the well-being of the railroad industry. It was reasoned that rate making freedom would restore rail's share of intercity traffic and, thereby, accomplish this end. Rail's share has not increased. Still, there is every evidence that the industry is much more sound than it was even a decade ago. After a wave of consolidation in the early 1980's, the configuration of Class I carriers has remained largely constant. The remaining firms have offered financial returns which at least approach the levels that the ICC judges as adequate.

Operating costs have been substantially reduced. Carriers have eliminated the use of cabooses from most trains, negotiated smaller crew sizes and more

flexible work rules. Carrier owned service facilities have often been replaced by contract service agreements. More fuel efficient locomotives have replaced aging second and third generation diesels. Low density branch-line operations have either been abandoned or sold to short-line operators.¹ The cost of producing one ton-mile of railroad service is by all means less in the wake of Staggers. Still, very little in what is described above seems directly attributable to rate deregulation. Further, there is nothing in this to guarantee that lowered costs have not been combined with pricing freedoms to generate economic profits.

Since the act to deregulate, most railroad returns have increased so that they are of a level considered adequate by the Interstate Commerce Commission, but none have exceeded this standing. The link between railroad deregulation, cost reductions, and continually falling rail rates is the intramodal rivalry which has been spawned by Staggers. Evidence presented above clearly supports the contention that rail carriers are much more sensitive to the presence of intramodal competition than they were prior to 1981. Individual carriers have pushed to lower costs and to effectively market rates which reflect these reductions. This owes to the pervasive belief that all railroads must now compete with each other if they wish to maintain their own share of even the traffic for which they need not compete with other modes. This sort of expectation has been reenforced by the activities of the Interstate Commerce Commission. The reader will recall that one

¹As an example of the degree of force reductions, employment on the Burlington Northern dropped from approximately 65,000 in 1980 to 30,000 in 1987 during a period where coal traffic in particular increased substantially.

of the original provisions of Staggers granted trackage rights to two other carriers over the Burlington Northern's route into the Powder River region of Wyoming.

Additionally, the ICC has been particularly aggressive in imposing other trackage rights agreements in conjunction with merger approvals.²

Prior to 1981, rate regulation effectively eliminated intramodal rivalry.

Railroads collectively competed against other modes of transport, but within the industry there was very little competition. Rates were set at levels which were largely independent of costs and which were vulnerable to the biases of the regulators. In the wake of deregulation, rail carriers are fiercely aware of intramodal alternatives. Rates better reflect costs and the biases, once evident, have been eliminated. Actual rate levels have not moved dramatically. Still, significant portions of numerous commodities move at rates which are lower than they would have been had regulation persisted. At the same time, there is no evidence that rail rates for even a single commodity have been made higher by Staggers.

The evidence suggests that railroads set rates which are different for various classes of customers without respect to existing cost differentials.

Therefore, one may assume they retain some amount of market power. This does not necessarily mean that rail carriers are earning economic profits. McFarland (1989) maintains that declining average costs for the provision of some services

²For example, the Commission granted extensive trackage rights to the Denver, Rio Grand & Western when it approved the merger of the Union Pacific, Western Pacific, and Missouri Pacific railroads.

may make it necessary for some rates to exceed marginal costs. Winston, Corsi, Grim and Evans estimate the additions to welfare which would result if all rail rates were set at marginal cost, but in their policy conclusions suggest that railroad profits are mow only adequate. Therefore, they do not advocate any change in the present regulatory setting. The results presented here suggest that the structure and formulation of rail rates is more efficient than it was prior to deregulation. At the same time, both the physical and fiscal state of the railroad industry is better than it has been for decades.

That carrier expectations about rivals' behavior may change, that railroads will learn to undertake tacit collusion is possible. Even in the least concentrated rail markets, the number of available carriers is not sufficiently large to preclude that possibility. Neither is intermodal competition always adequate to guarantee that colluding rail carriers could not extract significant economic profits. However, from a policy perspective, the first decade of deregulated rail service has demonstrated that ungoverned intramodal and intermodal forces can provide a satisfactory outcome. If it becomes necessary for the federal government to refine existing transport policy, those refinements should be aimed at strengthening the forces of competition rather than reimposing direct rate regulation.

APPENDICES

APPENDIX I

RAILROAD REGULATORY LEGISLATION

The following is an abridged list and explanation of railroad regulatory legislation through 1976 based on the more expansive treatment of Fair and Guandolo (1979). The list is confined to regulatory acts which explicitly govern railroad behavior and does not include more general antitrust legislation even though such laws are often applicable to rail carriage.

- The Interstate Commerce Act (ICA) was the initial act to regulate commerce. It applied to common carriage by rail, as well as transport which included partial use of either mode. The purpose wasto regulate individual rates and through rates, pooling arrangements etc. The bill sought to prevent rate discrimination and to eliminate long and short haul practices. The act was to be administered by the Interstate Commerce Commission (ICC).
- 1889 This amendment to ICA clarified original provisions relating to tariffs.

 More importantly, it gave the ICC the power to enforce the provisions of the ICA.
- 1903 The Elkins Act provided that published tariffs must be observed. It strengthened the provisions against rebates by making carriers liable for the receipt thereof. It also dealt more forcefully with the practice of rate discrimination.
- 1906 The Hepburn Act gave the ICC explicit power to impose maximum and minimum rates. This act also included pipe line operators under ICC jurisdiction. The act allowed the Commission to impose a system of accounting and reports and it was given the power to administer oaths, examine witnesses, and receive evidence, so that hearings might be held.
- 1906 The Amnesty of Witnesses Act provided that amnesty stemming from compulsory could only be extended to individuals, not to corporations.
- 1910 The Mann Elkins Act gave the ICC the power to suspend and investigate rates on its own behalf. It also added the "aggregate of intermediates" clause. Finally the legislation brought telephone, telegraph, and cable companies under the ICA.

- 1912 The Panama Canal Act prohibited the ownership of water carriage by railroads when this might be injurious to competition. It also authorized the ICC to establish through rates for rail water combinations.
- 1917 The Esch Car Service Act expanded the ICC's ability to investigate and, if necessary, modify car service agreements. It also gave the Commission express power to suspend car service agreements and directly control car supply during times of nation emergency.
- 1918 By Presidential Order the United States government began to directly operate the nation's railroads. This continued until 1920.
- The Transportation Act of 1920 returned railroads to private ownership. The act also defined "fair" rate of return, gave the Commission authority to direct operation of one carrier by another, and directed the ICC to develop a plan for merging the nation's railroads into a smaller number of systems. The act also gave the ICC explicit control of intrastate rates which discriminated against interstate commerce and the commission was also given control of railroad securities. Additionally, the ICC gained the power to enforce the division of joint rates and to force the installation of safety equipment.
- 1933 The Emergency Transportation Act established new rules for the making of rates, directed and encouraged carriers to examine ways to eliminate the duplication of services and expenses, and directed the Federal Trade Commission to develop a plan for improving all modes of transport.
- The Transportation Act of 1940 further broadened the Commission's powers regarding car usage agreements. This act also made it expressly illegal to discriminate against or in favor of regions and territories. The act expanded demands on carriers for acceptance of interchange and also defined motor carriage incidental to rail carriage.
- 1942 The Freight Forwarder Act brought freight forwarders under ICC control.
- 1948 The Mahaffie Act made it possible for rail carriers to reorganize without the necessity of bankruptcy.
- 1964 The Urban Mass Transportation Act made grant money available for planning of mass transit. The act also provided low interest loans for undertaking improvements.

- 1966 The Department of Transportation Act established the Department of Transportation (DOT) and transferred safety matters to this agency.
- 1970 The Rail Passenger Act mandated the creation of a nation rail passenger network (AMTRAK).
- 1973 The Regional Railroad Reorganization Act provided financing for U.S. Railway Association to create a final plan for the operation of freight service in the northeast.
- 1976 The Railroad Revitalization and Regulatory Reform Act began to reduce the degree of rate regulation. This act also imposed strict time limits on the length of certain regulatory processes.

APPENDIX II

DATA DOCUMENTATION

Below, is the documentation for the Interstate Commerce Commission's public use tapes derived from the annual Carload Waybill Sample. As this documentation indicates, the format of the public use tapes was changed in 1986.

1973 through 1985

<u>Position</u>	Description
1	Waybill Quarter
2	Waybill Year
4	Number of car loads in shipment
8	AAR mechanical car type
12	TOFC Plan
13	Number of TOFC/COFC loads in shipment
17	Standard Transportation Commodity Code
22	Net tons in shipment
29	Line haul revenue
38	Interstate/Intrastate flag
39	Transit Code
40	All rail/Intermodal flag
41	Actual shipment distance
45	Strata
46	Subsample
47	Origin State
50	States of interchange (up to nine)
68	Termination State
70	Origin ICC rate territory
71	Termination ICC rate territory
72	Expansion factor
75	Expanded number of car loads
.81	Expanded number of tons
90	Expanded revenue
101	Expanded number of TOFC/COFC units

1986 and 1987

Position	Description
1	Waybill date
7	Accounting period
11	Number of car loads in shipment
15	Car ownership (rail or private)
16	AAR car type
20	AAR mechanical designation
24	ICC car type
26	TOFC/COFC plan
29	Number of TOFC/COFC units
33	TOFC/COFC unit ownership
34	TOFC/COFC type
35	Hazardous or bulk material in boxcar flag
36	Standard Transportation Commodity Code
41	Billed weight
48	Actual weight
55	Line haul revenue
64	Transit revenue
73	Miscellaneous revenue
82	Interstate/Intrastate flag
83	Import/Export flag
84	All rail/intermodal flag
85	Type of move via water
86	Outbound transit code
87	Substituted truck for rail service
88	Rebill code
89	Estimated miles
93	Stratum identification
94	Subsample number
95	Strata count
100	Theoretical expansion factor
103	Number of interchanges
. 104	Origin BEA area
107	Origin ICC rate territory
108	Interchange state
126	Termination BEA area
129	Termination rate territory
130	Waybill reporting period length
131	Car capacity

136	Nominal car capacity
139	Tare weight of car
143	Outside length of car
148	Outside width of car
152	Outside height of car
156	Extreme outside height
160	Type of wheel bearings and brakes
161	Number of axles
162	Draft gear
164	Number of articulated units
165	AAR error codes
215	ALK bad routing code
216	Expanded number of car loads
222	Expanded number of tons
231	Expanded revenue
242	Expanded number of TOFC/COFC units

APPENDIX III

B.E.A. TO STATE CONVERSIONS

Below is a listing of BEA areas, their description and the state with which they were associated for the purpose of matching 1986 and 1987 with that from earlier years.

Origin/Destination State	BEA's	Origin/Destination State	BEA's
Maine	1-2	Vermont	3
Massachusetts	4	Rhode Island	5
Connecticut	6	New York	7-12
Pennsylvania	13-18	Maryland	19
District of Columbia	20	Virginia	21-23
North Carolina	24-30	South Carolina	31-34
Georgia	35-40	Florida	41-46
Alabama	47-50	Tennessee	51-55
Kentucky	56-58	Vest Virginia	59-60
Ohio	64-70	Michigan	71-74
Indiana	75-82	Illinois	83-88
Wisconsin	89-94	Minnesota	95-97
Iowa	98-104	Missouri	105-108
Arkansas	109-111	Mississippi	112
Louisiana	113-118	Texas	119-135
Oklahoma	136-138	Kansas	139-141
Nebraska	142-145	South Dakota	146-148
South Dakota	149-152	Montana	153-155
Wyoming	156	Colorado	157-159
New Mexico	160	Arizona	161-162
Nevada	163-164	Utah	166-167
Washington	168-171	Oregon	172
California	174-181		

APPENDIX FOUR

SUMMARY STATISTICS

This appendix contains a set of summary statistics describing eight variables and seventeen commodities. Even though the data are quarterly, these summary figures were computed annually

Metallic Ore

VARIABLE	N	MEAN	STANDARD	MINIMUM	MAXIMUM
			DEVIATION	VALUE	
			MYEAR=74		
RTM	408	0.031163	0.018438	0.00157352	0.1833

APPENDIX V

CHAPTER V REGRESSION RESULTS

The tables which follow report the full regression output from the Generalized Least Squares estimation technique outlined in Chapter V.

The second portion of the reporting process for each commodity contains the "F" statistics and hypothesis tests for the null hypothesis that the sum of the pre-Staggers independent variable and the corresponding interaction term is equal to zero.

VITA

Mark Burton was born in Tulsa, Oklahoma in 1959, but moved to Springfield, Missouri in that same year. He was graduated from Springfield's Kickapoo High School in 1977. The following fall he entered the University of Missouri at Columbia, earning the Bachelor of Arts degree in Economics in 1981.

After his undergraduate work, Mark accepted employment in the Law Department of the Burlington Northern Railroad. where he worked for three years.

In 1985, he returned to Columbia, Missouri to begin graduate study. Two years later he transferred his work to the University of Tennessee at Knoxville where he earned the degree of Doctor of Philosophy in Economics in 1990. Upon completing his degree, Mark accepted the position of Assistant Professor of Economics at Lafayette College in Easton, Pennsylvania.
