Background Increased atmospheric concentrations of fossil and biogenic derived greenhouse gases CO₂, CH₄ and N₂O affects global temperature and precipitation patterns. Such climatic and environmental changes will alone and in combination have strong effects on the terrestrial ecosystems with consequences for their future structure and functions.

In 2005 a project focusing on biological effects of climate change (Mikkelsen et al., 2007) was initiated with the aim to improve our understanding of how climatic and environmental changes in concert will affect biological processes in terrestrial ecosystems. One task is the examination of biosphere-atmosphere exchange of biogenic GHGs under future climatic conditions.

Methods. The study site is on a shrubland dominated by the evergreen *Calluna vulgaris* and grasses *Deschampsia flexuosa*. Soil is characterized by a sandy moraine. The fluxes of CO₂, CH₄, and N₂O are measured in a full factorial design with CO₂, temperature and drought as treatment variables. Analysis of soil samples for potential denitrification, nitrous oxide reductase activity and presence of denitrifying enzymes (*nirK*, *nirS* and *nosZ*) is conducted at regular intervals.

Results. Observations on GHGs were initiated in June 2006. Generally emission rates of N₂O were small (<10 µg N⁻² h⁻¹) and much scattered. A trend in data suggests reduced N₂O emissions as well as increased CH₄ oxidation in response to particularly the drought treatment. Increased temperature also seems to reduce N₂O emissions, but when combined with elevated CO₂ the results do suggest that both drought as well as temperature effects are alleviated by the CO₂. In the 2nd growing season the environmental manipulations did not affect N₂O emissions, however, peak emission rates were observed after heavy rainfalls.

Potential denitrification activity is significant in the top soil (30-300 ng N g⁻¹ h⁻¹) Nitrous oxide reductase activity is negligible in this community suggesting that N₂O is the final product from denitrification. PCR-amplification of the *nirK*, *nirS* and *nosZ* gene fragments has so far not been successful.
