Introduction

The Arboretum in Hørsholm (55°52' N, 12°30' E) is attached to the Danish Centre for Forest, Landscape and Planning, under the Faculty of Life Sciences, and part of The University of Copenhagen. The Arboretum has an extensive collection of woody plant species of known origin. There are approximately 2000 woody plant taxa in the collection, representing 295 genera and 101 plant families. This collection is used to study how plants from different parts of the world thrive in response to the Danish environment. A study of the potential of plants spreading from the arboretum to the surrounding area was made to understand how well the collection's plants were adapted to the Danish environment (Nielsen & Leverenz 2002). It was also made to check if there were any potential problem-species that needed to be studied in more detail, or if control programs were needed. In this study of the area within 2 km in all directions from the Arboretum, we found no plant species that were definitely spreading from the Arboretum collection. This was a surprising result, but it became clear that we needed to know if the plants were producing flowers (pollen) and fruit (seed) in order to have a clearer understanding of the negative results. As a first step we have begun to record if, and when, the taxa in the collection produce flowers (and thus pollen), and fruits (and thereby seed).

Furthermore, as a more popular perspective, both professional and amateur-gardeners would be very interested in a tool for prolonging the season with beautiful flowers in gardens.

In this working paper we present the results from three (four) years survey. The first year (2003/2004) of this project was funded in part by the »Estat-sråds Georg Bestle og Hustru's Mindelegat«. The second and third years (2005 and 2006) were funded by G.B. Hartmanns Familiefond. The third year 2006 was also funded by G.B. Hartmanns Familiefond. Furthermore, in 2010 flowering of many Rhododendron species was measured in connection with a project also funded by G.B. Hartmanns Familiefond. Those flowering data are included in this workingpaper. In 2010 fruiting was not studied.

Dendrologist Jerry W. Leverenz started the flowering and fruiting project in 2003, and was responsible for the data collection in 2004, 2005 and 2006. Furthermore Jerry W. Leverenz was responsible for the writing of the two first Working papers: No. 7-2005: *Timing and abundance of flowering and fruiting in the Hørsholm Arboretum from september 2003 to october 2004* and No.15-2006: *Timing and abundance of flowering and fruiting in the Hørsholm Arboretum-results from the first two years*. Jerry W. Leverenz has not contributed directly to this Working paper and the data analysis.

Figure 1: *Prunus triloba* flowering late April 2003

Methods

Although botanists would not call the sexual reproductive organs of gymnosperms »flowers«, the term will be used, in this paper, for both gymnosperms and angiosperms for ease of writing. Likewise the term fruit will be used in a broad sense.

This project has utilized student helpers to carry out the bulk of the field work and has also been used to educate students at the Royal Veterinary and Agriculture University. For the students involved, contact with the Arboretum's living collection over an extended period greatly increased their knowledge and appreciation of the many different woody taxa and their variable responses to the seasons.

Every year, each area of the arboretum was walked through about once every week. Often more than one calendar day within a week was used to go through the entire arboretum. In the first 3 years the survey included »the entire collection«. The fourth year (2010) only Rhododendron-species was scored. In between we have data from 2008, but those data still need some work before comparison is possible.

Flowering and fruiting dates and abundance were recorded on a list of the plants sorted by their positions within the collection.

Identification tags on the plants were marked in pencil when a record was made (»X« for flowering, »O« for fruiting). Because the tags were not always marked, double recordings occasionally occurred. In such cases, only the first date was entered into the database. Flowering week number was recorded along with the flowering date to add security in the records.

The precision of the observations was plus or minus one week (Leverenz *et al.* 2005) and therefore ‘week’ numbers are used in all data analyses.

Flowering dates were determined to occur for a plant when 50% or more of the flowers on a plant had opened. Occasionally it was judged that the flowers had opened the week before but were overlooked (on rarer occasions even several weeks before) and the observation was then backdated and a note made of the backdating. Forward dating was also done when plants were very close to flowering. However, forward dating was not done in the winter or early spring months, because a week of below zero weather could completely stop development of the plants. For plants with separate male and female flowers, flowering date was judged from the male flowers. For catkin producing plants this was done in most cases by tapping the catkins or shaking the branches and looking for pollen release. It was difficult to get a clear sight of the crown of tall trees, and therefore binoculars, or spotting scope, were used to observe the flowers. Even so, the tall trees could not be observed with the same accuracy as the plants with flowers near eye level. The spotting scope was only used for problem trees as it took extra time to use.

Fruiting date was judged by when 50% or more the fruit had ripened based on colour. Opening of cones or woody capsules was not used as this can be delayed for a considerable time in some species. The timing of the opening of ripe cones is an adaptation to local environments and can vary from provenance to provenance for a given species (Frankis & Lauria 1992).

Fleshy fruits and some conifer cones tended to be removed by birds and other animals before we would have judged them to be ripe. Because of this the students were asked to record fruit ripening dates a bit early, especially, if they noticed that the fruits were being consumed. Nevertheless some fruits were probably missed as all the fruit were observed to disappear over a period of a few days in some species like for example *Pinus pumila* and *Podocarpus nivalis*. We also can not rule out the possibility of harvesting by visitors. People collecting in the arboretum are supposed to ask permission first but this does not always occur. Errors caused by the loss of fruits by predation are probably at most only a few percent of the whole collection, but for individual taxa this error could be misleading. For some species like *Hamamelis* species, *Larix* species or some *Pinus* species cones are held on the tree for several years. This also made it difficult to judge the fruit production, especially in tall trees where it was difficult to see the age classes, and probably added some error in the numbers of fruits recorded.

Some taxa, for example *Sinocalycanthus chinensis* produced fruit with only empty seed. These were still counted. It would be impossible for a study of this type to determine the viability of the seed for all the species studied. Thus the observation of fruiting only indicates the potential for viable seed

production and is not a guarantee that viable seeds were produced.

The Arboretum include more than 3000 taxa and the applied methods has not allowed a detailed and exhaustive set of flower and fruit observation.

Fruiting plants may have been overlooked, and fruits on many plants can be hidden by the foliage. In many cases significant underestimation of the number of ripe fruits can therefore have occurred (Leverenz 2006). Still the data were quite valuable for a positive identification of plants that have produced fruits in the years of observation.

The abundance of both flowers and fruits was registered in the following four abundance classes: 0 to 9 flowers or fruits, gave a score of 1, 10 to 99 gave a score of 2, 100 to 999 gave a score of 3, and 1000 or more a score of 4. This abundance data is not presented here, but incorporated into the Arboretum electronic database for easy access.

Results and discussion

Figure 2, shows the average number of taxa flowering over the 4 years (2004, 2005, 2006 and 2010) as well as the average number of fruiting taxa (2004, 2005 and 2006).

Average number of taxa flowering or fruiting
during the four year period.

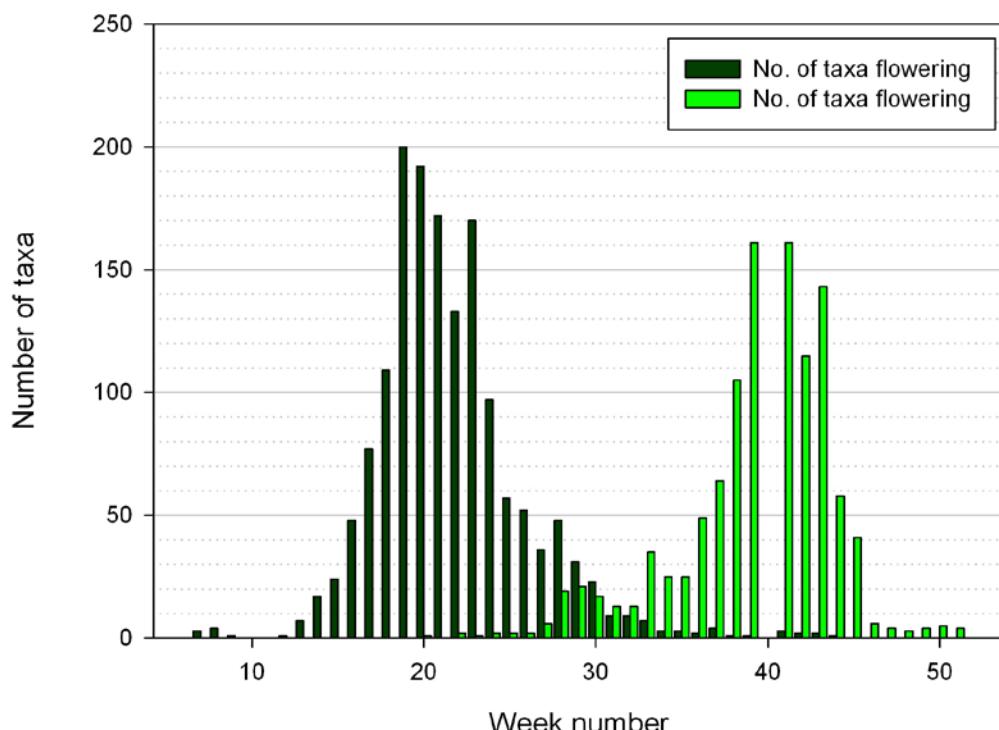

Figure 2: Average number of plants flowering in the Arboretum collection during four years study.

In appendix A, the data shows the flowering intervals of the four years: »first flower week«, »last flower week« and »mean flower week«. The data also shows »mean flower number«, »mean fruit week«, »mean fruit number« and sample size for both flowering and fruiting.

Statistical analysis of data shows that there is highly significant difference between average first flowering week, between most years as shown in table 1.

Year	Mean first flower week	2004	2005	2006	2010	Temperature sum over 5°C until 15. April
2004	21,28	-	S	S	NS	71
2005	20,95	S	-	S	S	85
2006	21,66	S	S	-	NS	23
2010	21,64	NS	S	NS	-	71

Table 1: Mean first flowering week is highly significant different (S) between most years beside 2004/2010 and 2005/2010 (NS). The difference can probably be explained by temperature sum f.ex. over 5c until the 15. of april.

Even though the dataset is limited by only 4 replications (years) it is most likely that the differences in flowering week is explained by the heat sum until a sudden date, f.ex heat sum over 5°c until the 15th of april as shown in table 1. In the future we will repeat this project and by then, statistical analysis will be more extensive.

Analysis also shows that the order of species flowering is almost the same every year, with an average correlation of 0,9 between years. This is botanically not surprising, but underlines that data collection has been made homogeneous and carefully, even though many students were implicated in this process.

Future aspects

In this paper results and data from a huge fieldwork are only briefly presented.

The dataset presents a unique opportunity to investigate into details about, for example, special families and how weather influence on timing af flowering and/or fruiting.

The flower observations of *Corylus sp* and *Betula sp* is especially interesting due to the allergenic effects of the pollen from these species. Data on *Corylus* has already been used by a BSc student to calculate the temperature sum needed for the species to flower, and study how the length and intensity of the pollen season is influenced by the weather conditions. Presently a study of the *Betula* complex is also planned, and links to the likely effect of climate change can be an important outcome. The studies will lead to scientific publications in relevant journals, but also publications that target a wider public audience with interest in the allergenic aspects.

Temperature recordings from 2004 and up to 2010 will be used to explain differences between flowering and fruiting week from 2004-2010. Furthermore in the future these recordings will be compared to climatic data when flowering and fruiting are measured again. This should be done in 5 to 10 years to see what effect the global warming and more extreme weather conditions have on the collection of woody plants in the Hørsholm Arboretum. Connected to another G.B. Hartmann Familiefond funded project we now have about 10 temperature sensors allocated in most parts of the Hørsholm Arboretum (installed october 2010). Until now climatic data has been provided by the nearest national weather station which is placed approximately 15 km. away.

The use of our own temperature sensors will reveal whether the Arboretum has a different microclimate than the surroundings. Experience from professional gardeners indicates that it tends to be colder in the Arboretum than places only 5 km away. Furthermore data from the winter 2010/2011 show that there are temperature differences within the Arboretum of up to 8 degrees on very cold nights. Therfore a temperature grid of the Arboretum will be very usefull in further analysis of the flowering data, as an explaining factor in statistical analysis.
