Content

C08.01 Applied Geography

C08.01-01 - Launch of the Applied Geography Commission's 3rd Edited Book - Applied Geography and Spatial Analysis: Addressing Real World Issues...	11
C08.01-02 - Sessions on Applied Geography Topics 1	12
C08.01-03 - Sessions on Applied Geography Topics 2	13

C08.02 Arid Lands, Humankind, and Environment

C08.02-01 - Human-Nature Interaction in Arid Lands and their Margins 1	15
C08.02-02 - Human-Nature Interaction in Arid Lands and their Margins 2	17
C08.02-03 - Human-Nature Interaction in Arid Lands and their Margins 3	19
C08.02-04 - Human-Nature Interaction in Arid Lands and their Margins 4	21
C08.02-05 - Human-Nature Interaction in Arid Lands and their Margins 5	23

C08.03 Biogeography and Biodiversity

C08.03-01 - Climate Change and Land Use Effects on Species, Communities and Ecosystems 1: Indian Subcontinent and the Himalayas	25
C08.03-02 - Climate Change and Land Use Effects on Species, Communities and Ecosystems 2	27

C08.04 Climatology

C08.04-01 - Applied Climatology in the 21st Century	30
C08.04-02 - Climate change and variability in different spatial and temporal scales 1....	32
C08.04-03 - Climate change and variability in different spatial and temporal scales 2....	34
C08.04-04 - Climate change and variability in different spatial and temporal scales 3....	36
C08.04-05 - Climate change and variability in different spatial and temporal scales 4....	38
C08.04-06 - Climate change and variability in different spatial and temporal scales 5....	40
C08.04-07 - Climate change and variability in different spatial and temporal scales 6....	42
C08.04-09 - Potential Impacts of Climate Variability and Change on Agriculture: Historical Variations 1	44
C08.04-10 - Potential Impacts of Climate Variability and Change on Agriculture: Climate Projections and Assessment Strategies 2	46
C08.04-11 - Potential Impacts of Climate Variability and Change on Agriculture: Changes in Productivity 3.....	49
C08.04-12 - Potential Impacts of Climate Variability and Change on Agriculture: Economic Considerations 4	51
C08.04-13 - Urban climates 1	53
C08.04-14 - Urban climates 2	55
C08.04-15 - Weather and Climate Extremes 1	56
C08.04-16 - Weather and Climate Extremes 2	57

C08.05 Coastal Systems

C08.05-01 - Coastal Systems - Beaches and dunes.....	60
C08.05-02 - Coastal Systems - Coastal erosion and management 1	62
C08.05-03 - Coastal Systems - Coastal erosion and management 2	64
C08.05-04 - Coastal Systems - Coastal erosion and management 3	66
C08.05-05 - Coastal Systems - Coastal erosion and management 4	68
C08.05-06 - Coastal Systems - Coastal monitoring 1	70
C08.05-07 - Coastal Systems - Coastal monitoring 2	72
C08.05-08 - Coastal Systems - Coastal monitoring 3	74
C08.05-09 - Coastal Systems - Coastal monitoring 4	76
C08.05-10 - Coastal Systems - Rocky coasts 1	78
C08.05-11 - Coastal Systems - Rocky coasts 2	80
C08.05-12 - Coastal Systems - Sea-level rise and impacts 1	82
C08.05-13 - Coastal Systems - Sea-level rise and impacts 2	84
C08.05-14 - Coastal Systems - Sea-level rise and impacts 3	86

C08.06 Cold Region Environments

C08.06-01 - Contextualising climate change: methodological, institutional and regional responses	89
--	----

C08.07 Cultural Approach in Geography

C08.07-01 - Cultural Approaches in Social and Geographical Theory 1	92
C08.07-01 - Cultural Approaches in Social and Geographical Theory 2	94
C08.07-02 - Cultural approaches to sacred spaces in the global era 1.....	96
C08.07-03 - Cultural approaches to sacred spaces in the global era 2.....	98
C08.07-04 - Cultures and sustainability	100
C08.07-05 - Cultural identities 1: The globalizing East Asia	102
C08.07-06 - Cultural identities 2: Historical places in East Asia	104
C08.07-07 - Cultural identities 3: The urban and rural places of East Asia	106
C08.07-08 - Multilocality: symbolic and material constructions of space in societies of mobile individuals 2	108
C08.07-09 - Multilocality: symbolic and material constructions of space in societies of mobile individuals 1	110
C08.07-10 - Spatialities of art: between policy and politics 1.....	112
C08.07-11 - Spatialities of art: between policy and politics 2.....	114
C08.07-12 - The Uses of Art in Public Space 1	116
C08.07-13 - The Uses of Art in Public Space 2	118

C08.08 Dynamics of Economic Spaces

C08.08-01 - Emerging Economic Spaces in Globalizing Worlds.....	121
C08.08-02 - Universities, Clusters, and Industry Emergence	123
C08.08-03 - Resource-based Economies.....	125

C08.08-04 - Emerging Economic Spaces in Europe.....	127
C08.08-05 - Emerging Economic Spaces in Asia	129
C08.08-06 - Emerging Economic Spaces Europe	131
C08.08-07 - Economic Geographies of Entrepreneurship	133
C08.08-08 - Global Value/Commodity Chains and Economic Governance	135

C08.09 Environment Evolution

C08.09-01 - Human-Environment Interactions and Evolution in the Late Pleistocene and Holocene 1	138
C08.09-02 - Human-Environment Interactions and Evolution in the Late Pleistocene and Holocene 2	140
C08.09-03 - Human-Environment Interactions and Evolution in the Late Pleistocene and Holocene 3	142
C08.09-04 - Human-Environment Interactions and Evolution in the Late Pleistocene and Holocene 4	144
C08.09-05 - Human-Environment Interactions and Evolution in the Late Pleistocene and Holocene 5	146
C08.09-06 - Human-Environment Interactions and Evolution in the Late Pleistocene and Holocene 6	148

C08.10 Gender and Geography

C08.10-01 - Gender and Geography 1: Everyday, home and mobility.....	150
C08.10-02 - Gender and Geography 2: Work and society.....	152
C08.10-03 - Gender and Geography 3: Migration and transnationalism.....	154
C08.10-04 - Gender and Geography 4: Planning and development.....	156
C08.10-05 - Gender and Geography 5 - Panel Discussion: International practices in gender geography: bridges and barriers.....	158

C08.11 Geographical Education

C08.11-01 - Education for Sustainable Development & Global Learning 1	160
C08.11-02 - Education for Sustainable Development & Global Learning 2	162
C08.11-03 - Education for Sustainable Development & Global Learning 3	164
C08.11-04 - Examples of Best Practice in Geography Education and Teacher Preparation 1	166
C08.11-05 - Examples of Best Practice in Geography Education and Teacher Preparation 2	167
C08.11-06 - Examples of Best Practice in Geography Education and Teacher Preparation 3	169
C08.11-07 - Higher Education.....	171
C08.11-08 - Innovative Learning - New & Traditional Media.....	173
C08.11-09 - Preconceptions in Geography and Geography Education.....	175
C08.11-10 - Spatial Thinking I.....	177

C08.11-11 - Spatial Thinking II.....	179
C08.11-12 - Standards, Concepts and Experience 1	181
C08.11-13 - Standards, Concepts and Experience 2	183
C08.11-14 - State of the Art in Geography Education 1	185
C08.11-15 - State of the Art in Geography Education 2	187

C08.13 Geography of Governance

C08.13-01 - Governance - key theoretical and methodological issues, main research directions 1	190
C08.13-02 - Governance - key theoretical and methodological issues, main research directions 2	192
C08.13-03 - Governance - key theoretical and methodological issues, main research directions 3	194
C08.13-04 - Governing development in regions, cities and rural communities 1	196
C08.13-05 - Governing development in regions, cities and rural communities 2	198
C08.13-06 - Governing development in regions, cities and rural communities 3	200
C08.13-07 - Governing development in regions, cities and rural communities 4	202
C08.13-08 - Governing development in regions, cities and rural communities 5	204
C08.13-09 - Innovations in public sector - public administration reforms, public sector reorganizations, local finance and progress in planning	206

C08.14 Geography of the Global Information Society

C08.14-01 - Global Information Society: Mobility, Society and Network Connectivity 1	209
C08.14-02 - Global Information Society: ICT, Knowledge & Media 2	211
C08.14-03 - Global Information Society: Urban and Regional Development 3	213
C08.14-04 - Information and communication technologies for development and human well-being 1	215
C08.14-05 - Information and communication technologies for development and human well-being 2	217

C08.15 Geography of Tourism, Leisure, and Global Change

C08.15-01 - Global Change and Tourism: Socio-Cultural Issues	220
C08.15-02 - Sustainable Tourism 1	222
C08.15-03 - Sustainable Tourism 2	224
C08.15-04 - Tourism Development and Management.....	226
C08.15-05 - Sustainability Related with Second Homes.....	228
C08.15-06 - Tourism sustainability with GIS and zoning systems	230
C08.15-07 - Tourism and Global Environmental Change: Climate Change Issues	232
C08.15-08 - Tourism and Regional Development 1	234
C08.15-09 - Tourism and Regional Development 2.....	236
C08.15-10 - Tourism and Regional Development 3.....	238
C08.15-11 - Tourism Mobilities and Urban Space.....	240

C08.15-12 - Transforming Tourism Geographies in the Global South	242
--	-----

C08.17 Global Change and Human Mobility

C08.17-01 - Global climate change and human mobility in coastal areas: the SECOA Project 1	245
C08.17-02 - Global climate change and human mobility in coastal areas: the SECOA Project 2	247
C08.17-03 - Global climate change and human mobility in coastal areas: the SECOA Project 3	249
C08.17-04 - Global climate change and human mobility in coastal areas: the SECOA Project 4	251
C08.17-05 - Global climate change, economic crisis and human mobility 1	253
C08.17-06 - Global climate change, economic crisis and human mobility 2	255
C08.17-07 - Global climate change, economic crisis and human mobility 3	257
C08.17-08 - Global climate change, economic crisis and human mobility 4	259

C08.18 Hazard and Risk

C08.18-01 - Earthquake and Tsunami special session	262
C08.18-02 - Hazard and risk for future mitigation 1	264
C08.18-03 - Hazard and risk for future mitigation 2	266
C08.18-04 - Hazard and risk for future mitigation - Poster session	268
C08.18-05 - Vulnerability and Resilience 1	270
C08.18-06 - Vulnerability and Resilience 2	272

C08.19 Health and Environment

C08.19-01 - Access to Care 1	275
C08.19-02 - Access to Care 2	277
C08.19-03 - Access to Care 3	279
C08.19-04 - Global Health and Disease Surveillance	280
C08.19-05 - Ground truths: Advancing children's geographies through including children as researchers 1	282
C08.19-07 - Health Geography and Public Health 1	284
C08.19-08 - Health Geography and Public Health 2	286
C08.19-09 - Health Geography, Vulnerability and Global Risk	288

C08.20 History of Geography

C08.20-01 - Society and Environment: Conceptions and representations of nature(s) in the history of geography 1	291
C08.20-02 - Society and Environment: Conceptions and representations of nature(s) in the history of geography 2	293
C08.20-03 - Society and Environment: Conceptions and representations of nature(s) in the history of geography 3	295

C08.20-04 - Society and Environment: Conceptions and representations of nature(s) in the history of geography 4	297
C08.20-05 - Society and Environment: Conceptions and representations of nature(s) in the history of geography 5	299
C08.20-06 - Society and Environment: conceptions and representations of nature(s) in the history of geography 6	301

C08.22 Islands

C08.22-01 - Human/Nature-Interaction on small islands – an integrative geography perspective. Co-supported by the IGBP/IHDP core project LOICZ which explores coastal vulnerability and sustainability in the context of global change and human dimensions	303
C08.22-02 - Human/Nature-Interaction on small islands – an integrative geography perspective. 2 Co-supported by the IGBP/IHDP core project LOICZ which explores coastal vulnerability and sustainability in the context of global change and human dimensions	305
C08.22-03 - Human/Nature-Interaction on small islands – an integrative geography perspective. 3 Co-supported by the IGBP/IHDP core project LOICZ which explores coastal vulnerability and sustainability in the context of global change and human dimensions	307

C08.23 Karst

C08.23-01 - Human impacts and environmental changes in karst	310
C08.23-02 - Management and conservation of karst landscapes 1	312
C08.23-03 - Management and conservation of karst landscapes 2	314

C08.24 Land Degradation and Desertification

C08.24-02 - Land Degradation and Desertification in the context of Global Environmental Change: Management, Vulnerability, and Policy 2	317
C08.24-01 - Land Degradation and Desertification in the context of Global Environmental Change: Management, Vulnerability, and Policy 1	319
C08.24-03 - Land Degradation and Geomorphology: Monitoring, Assessment, and Theory Development 1	321
C08.24-04 - Land Degradation and Geomorphology: Monitoring, Assessment, and Theory Development 2	323
C08.24-05 - Land Degradation and Geomorphology: Monitoring, Assessment, and Theory Development 3	325
C08.24-06 - Land Degradation and Geomorphology: Monitoring, Assessment, and Theory Development 4	327

C08.25 Land Use and Land Cover Change

C08.01

Applied Geography

C08.01-01 - Launch of the Applied Geography Commission's 3rd Edited Book - Applied Geography and Spatial Analysis: Addressing Real World Issues

Chair: Robert J. Stimson, Kingsley E. Haynes, Edward Elgar

Introducing the book

Robert Stimson (University of Melbourne)

Brief presentations by a selection of chapter authors

Graham Clarke (University of Leeds)

John Lombard (Old Dominion University)

Robert Baker (University of New England)

Maria Lucinda Fonseca (University of Lisbon)

Eliahu Stern (Ben-Gurion University)

Pablo Osses McIntyre

C08.01-02 - Sessions on Applied Geography Topics 1

Chair: Kingsley Haynes, Robert Stimson

**The role of culture on the management of immigrant-related diversity:
Lisbon in comparative perspective**

*Maria Lucinda Fonseca (University of Lisbon), Alina Esteves (Centre for
Geographical Studies)*

Estimating small area visitor expenditure for grocery store location planning

*Andy Newing (School of Geography), Graham Clarke (University of Leeds),
Martin Clarke (University of Leeds)*

Demographic sustainability as a base for rural development policy

Eliahu Stern (Ben-Gurion University)

C08.01-03 - Sessions on Applied Geography Topics 2

Chair: Kingsley Haynes, Robert Stimson

Next step: on the validation of the Q index to identify optimal locations for economic activities

Stephane Joost (EPFL)

Socioeconomic segregation and travel time: New criteria's for decision-makers in social housing location, for the areas of expansion at the Metropolitan Area of Santiago de Chile (AMS)

Pablo Osses McIntyre

Ageing - an increasing process in western societies: The case of Portugal

Diogo Abreu (Centro Estudos Geográficos)

Global animal husbandry and its impact on the environment

Sergey Govorushko (Pacific Geographical Institute)

C08.02

Arid Lands, Humankind, and Environment

C08.02-01 - Human-Nature Interaction in Arid Lands and their Margins 1

Chair: Olaf Bubbenzer, Mahmoud Ashour

Influence and causes of discharge variability of the Tarim River, Xinjiang China, and related effects on the lower Tarim-Ecosystem

Andreas Ginau (University Frankfurt a. M.), Christian Opp (University of Marburg), Sun Zhandong (Chinese Academy of Sciences), Ümüt Halik (University of Eichstätt-Ingolstadt / Xinjiang University)

The study site is located within the 'Riparian Ecosystem' along the lower reaches of the Tarim River (Xinjiang, China). The Tarim itself is the longest inland river in China. It is an important source for plants and trees within the flood plains of the Taklamakan Desert, thus forming a 'green corridor' within the desert surrounding the Tarim River. Irrigated farmland expansion and construction of water reservoirs along the Tarim River have caused permanent water deficit problems within the lower reaches of the Tarim River since the 1950s and increased the mineralization of the river water. This development reached its climax with the desiccation of the Taitema Lake and severe degradation of the 'Riparian Ecosystem'. All these developments led to the initiation of the 'emergency ecological water transfer project'. The objective of this project is to ensure a constant water supply to the lower reaches of the Tarim River by the transfer of water from the Bosten Lake catchment and Tarim's upper and middle reaches. The processes and trends of the vegetation change during the period of intermittent water transfer have been ruled out by Sun et al. (2010) on the basis of remote sensing data (SINDVI). Their results show that with the transfer of water the 'Riparian ecosystem' is revitalizing. Yet vegetation changes are assumed to depend mostly on factors directly controlling the groundwater level, which are the distance to the river, river behavior such as its volume and ebbing frequency and the height of the groundwater table. The composition and properties of soils and sediments underlying this ecosystem might be another important factor that on the one hand supports the ecosystem especially its forest, and on the other hand counterbalances negative effects caused by the frequent ebbing of the Tarim River. We like to present preliminary results of our 2010 and 2011 studies. Soil profiles along two transects within the study region have been analyzed in the field and laboratory. Results comprise grain size measurements, pore size distribution, organic content and data from XRD-measurements on the soil's mineral composition. These parameters allow conclusions about water storage and water transfer features of the studied soils and sediments as well as their ability to support and protect the 'Riparian Ecosystem' of the lower Tarim area.

Carbon Dynamics of Apocynum along the Tarim River, Xinjiang, Northwest China

Rouzi Aihemaitijiang (University of Greifswald), Niels Thevs (University of Greifswald)

Due to vast land reclamation along the Tarim River in Xinjiang, Northwest China to grow cotton, native plant species are facing a severe competition for water which is essential to survival. This paper explores possibility of *Apocynum Pictum* is an alternative plant to substitute cotton which is hypothesized as much more water saving and economically profitable to expand in the area to preserve natural populous *euphratica* forest. Finding out overall carbon output of the plant is essential to prove this hypothesis. There for above and below ground biomass of *Apocynum pictum* in two locations and two transect sites for each location along the Tarim River are measured respectively. In this paper, Point center square method is used for sampling the above ground biomass to measure height, crown diameter and fresh weight of the plant on site, later air and oven dry methods is utilized to measure air dry and oven dry weight of stem and leaf of *Apocynum pictum*. Subsequently lab analysis made to measure C, N content of the samples. In the mean time, below ground biomass of *Apocynum*, ground water level and electric conductivity are also measured. Finally overall carbon output for per hectare is calculated and allometry formula is obtained which shows carbon dynamics of *Apocynum* and its relation with environmental parameters such as ground water level and soil salinity. Key Words: *Apocynum*, Tarim River, Carbon Dynamics, Allometry

The Study of Relationship between Environmental Change and Catholic Mission beyond the Great Wall in Northern China(1865-1952)

Xiaohong Zhang (Fudan University)

The Great Wall of China locates on the transition belt from subhumid region to arid/semiarid region, so that it had been as the boundary between farm area and nomadic area in northern China over 2000 years. However, in middle of 18th century, the farming land began to cross the Great Wall and entered the nomadic region before. Then the farming-pastoral boundary started moving northward and westward substantially and resulted in environmental change happened along the Great Wall belt. In the historical process, the Congregation of the Immaculate Heart of Mary (CICM), a congregation had preached in Inner Mongolia since 1865, played an important role. Based on the date from local archival, Christian documents and investigation, the research aims to study how the Catholics influenced the local environment beyond the Great Wall and what the relationship between religion mission and environmental change was. Since the congregation entered Inner Mongolia, they obtained land from Mongolian and lent land and farm facilities to Han Chinese people in order to convert them and to maintain the mission well. As a result of intensive land management by the Catholic mission, the arid/semiarid landscape, formerly used as grazing lands, was changed to more intensive

agricultural use. The study shows that the Catholic Church became a strong force in pushing the farming-pastoral boundary northward and westward in late Qing Dynasty because of its authoritarian religious organisation.

Human-Nature Interaction in the Eastern Pamirs of Tajikistan - The nexus of natural resources, pasture use, and energy consumption

Kim André Vanselow (University of Erlangen), Tobias Kraudzun (Universität Berlin)

This paper deals with the relations between the natural resources, the grazing practices, and the energy demand in the Eastern Pamirs of Tajikistan. The study area is a high plateau with elevations between 3,500 m asl and more than 5,000 m asl. The orographic environment and its altitudinal location cause low temperatures throughout the whole year, with an annual average of only minus 1° C in the valleys. Furthermore, this region is characterized by a distinct aridity with precipitation values partly below 100 mm per year, caused by high mountain ranges which shield the plateau from the precipitation of the Westerlies and the Indian summer monsoon. Hence, the Eastern Pamirs can be described as a cold high mountain desert that is characterized mostly by scattered, slow growing vegetation. Based on these natural preconditions, pastoralism with extensive livestock herding is a prime adapted land use strategy under the region's harsh environment. Therefore, the Soviet administration allocated the production of meat as the main region's task and installed collective (kolkhozy) and state farms (sovkhozy). Here, a well-balanced and sustainable utilization of all pastures of the Eastern Pamirs was fostered by imports of fuel and forage resources, and an elaborate management plan, usually with four seasonal pasture camps. However, the dissolution of the Soviet Union and the independence of Tajikistan resulted in significant structural changes for the Eastern Pamirs. Most notably, the end of the Soviet subsidy system stopped the provisioning of the region from outside. Without the external inputs of the Soviet economy, bridging long distances between the seasonal pastures poses a major problem to most smallholders. Furthermore, the limited supply and high cost of imported fossil fuels induced the increased use of dwarf shrubs - mainly teresken (*Krascheninnikovia ceratoides*) - as a substitute energy resource. However, they are also important forage plants, particularly in winter when fodder resources are scarce. The aim of this paper is to provide a well-founded overview of the pasture and firewood resources and the spatiotemporal variability of the actual pasture use with the associated livestock numbers, in order to make assertions on overuse in particular areas. It could be shown that the mono-seasonal pasture utilization of the Soviet state farms contrasts with a distinct multi-seasonal present-day use. Consequently, pastures close to villages are used all year round, particularly in winter, and are heavily overgrazed. Grazing pressure on summer pastures is much less than on winter pastures. However, also several distant summer pastures show high livestock numbers, which indicates that they are not underused, as it is argued in other studies. Furthermore, it could be demonstrated that the actual

degradation of dwarf shrub vegetation is still far from the numbers mentioned in reports and literature.

Transformation of livestock grazing and land degradation in the Kyrgyz Pamir

Teiji Watanabe (Hokkaido University), Jie Liu (Hokkaido University), Shigeru Shirasaka (Teikyo University), Ikuko Miyahara (Miyagi University), Tetsuya Komatsu (Hokkaido University), Takanobu Sawagaki (Hokkaido University), Kazuo Mizushima (Nihon University), Yasuhiro Ochiai (Nihon University)

Transhumance of livestock animals has been a long tradition in the Pamir since the former Soviet era. After the independence from the Soviet Union in 1991, the countries such as the Kyrgyz Republic are believed to have severe land degradation. This study first examined the degree of land degradation on grazing slopes in the Alai valley, southern Kyrgyz. The study area is characterized by heavy dependency on transhumance. The degree of land degradation was examined by the method of Howard and Higgins (1987): a relationship between slope angle and the average height of grazing steps on slopes indicates the degree of grazing intensity. About half of the examined slopes indicate overgrazing, but the rest has grazing space for more livestock. The onset of the land degradation was examined by interview surveys (N=21 families residing near the main road). All families realized the land degradation on the slopes, and many residents feel that the grazing slopes are getting drier although we do not have any supportive evidence. They notice that many of the soil-erosion scars had occurred before the 1991 independence. This suggests that the land degradation in the area is related to the transhumance in the former Soviet era, but not to that after the 1991 independence. Interview surveys also showed that some families began to use the grazing slopes in summer seasons after the independence, especially after 2000. Such additional land use might cause future land degradation, showing a necessity of continuous monitoring.

Dynamiques des terres humides du domaine semi-aride en Tunisie

Gammar Amor (Université de Manouba), Karray Mohamed Raouf (FSHS Tunis), Chaouach Mondher (FLAH Manouba), Majbri Abdellatif, Mahjoub Mohamed Raouf

Cette contribution présente les types d'édifices humides du domaine semi-aride de la Tunisie et discute de leur conservation et de leurs dynamiques récentes. La sécheresse estivale et la configuration du relief du domaine semi-aride de la Tunisie favorisent la formation des milieux humides. Les terres humides les plus vastes se trouvent dans les bassins intérieurs et les plaines ouvertes sur la mer à l'est du pays. En montagne et sur

les piémonts, les terres humides ont une répartition ponctuelle, mais leur conservation est meilleure. Alors que la partie humide du pays se distingue par ses lacs et mares acides, la partie semi-aride présente des sebkhas, des lagunes, des merjas et garas non ou légèrement salées. Les exemples analysés ici montrent l'ampleur des destructions des terres humides par le drainage systématique des aires inondables et marécageuses au profit de l'agriculture (plaines de Grombalia, de Goubellat...). Ils montrent aussi d'autres dynamiques récentes directement et indirectement dues à de puissantes formes d'interventions humaines. Le défrichement des bassins versants, les aménagements hydrauliques, les déversements et bouleversements liés aux villes aboutissent à une suralimentation des basses terres et se traduisent par la régénération des édifices humides (El Gouréa?), leur résistance et leur extension malgré le drainage (Delta de la Mejerda, Sebkha d'Essijoumi), le transfert des terres marécageuses vers l'aval (Sebkha de Slimène)... mais souvent avec des problèmes de pollution et d'artificialisation des milieux et des risques d'inondation des rives. Dans ce domaine semi-aride de la Tunisie, les actions de conservation des terres humides paraissent assez tardives par rapport aux mutations rurales et urbaines responsables des destructions et d'une forte anthropisation des milieux. Cependant, la diversité des dynamiques offre des chances réelles pour espérer la restauration des sites majeurs et retrouver des sites en bon état ou en voie de régénération qui représentent une grande valeur pour la conservation de la biodiversité.

Land degradation - Balancing ecosystems services and stakeholders use of agro-forestry systems in North of Cameroon

Burghard Meyer (Institute Geography Leipzig), Ernest Fongwa (Brandenburg University), Tsi Evaristus (University of Dschang)

Land degradation (LD) and desertification are among the greatest world challenging problems, especially in the Sahel region with droughts and high yearly variability of rain. Desertification is defined according to UNCCD as land degradation in arid, semi-arid and dry sub-humid areas resulting from various factors, including climatic variations and human activities. ES are the benefits that humans obtain from the ecological functions of the natural ecosystems (MEA, 2005). They need to be maintained and preserved in order to balance environmental processes and functions by adaptive and mitigation land management measures. The talk methodically links scientific objectives of interdisciplinary investigations by using new integrative entrances to the LD problem in the Sahel of Cameroon. This is when combining the modelling of ES as social categories and market management schemes for agro-forestry (AF) and the management of sustainable wildlife in three main objectives dealing with AF by investigations: on Landscape Degradation by the widening the systematic knowledge about LD by exploring the landscape system, the multi-functionality of land uses by indicators, the carrying capacity of main ES as linkage from landscape functions to ES and to investigate their linkages to AF protective measures. on Modeling Ecosystem Services by a) the exploitation of the relationship between ES and LD for adaptive management support systems for dry landscapes; b)

the encouragement of stakeholder participation for balancing ES by introduction of business development schemes and by modelling of ES using innovative techniques and c) by the provision of motive schemes to support stakeholder participation in preserving ES and by development of a market management scheme through community-based financial participation. on Sustainable Wildlife and Agro-forestry by the (1) the exploration of insights into the wildlife in terms of ES; (2) the investigation on impacts of wildlife in land use systems and AF also by running field plot experiments. The planting of native tree species contributes to management of sustainable wildlife also by zone planning based on land functions. This is when modelling the optimal adaptation of selected wildlife to natural resources use, which is endangered by landscape degradation. The talk is primarily linked to the scientific methods development and LD problems in terms of ES, landscape functions and wildlife management. It applies thematically wide investigations about AF systems by market orientated management of ES and wildlife in the local farming and nomadic systems. The expected results should be seen as management support systems for policy improvement, which aim at providing strategies towards rehabilitation of degraded landscapes, and the protection of abiotic and biotic resources.

Environmental change and vegetation succession along an ephemeral river, the Kuiseb River in the Namib Desert

Kazuharu Mizuno (Kyoto University)

The Namib Desert is located along the western coast of Namibia and is affected by the cold Benguela Current. Forests line the course of the Kuiseb River, an ephemeral river in the Namib Desert, and several areas of these forests are characterized by high concentrations of tree death. We sought to clarify the relationship between recent environmental changes and such tree deaths in the region. The reason behind extensive tree deaths along the Kuiseb River has been investigated near Gobabeb since 2001. In Gobabeb, although the annual rainfall is only 27 mm, fog-water precipitation is 31 mm. Tree deaths were concentrated on river banks where sands from dunes had been thickly redeposited by flooding. *Acacia erioloba* was abundant in these areas. Although *Faidherbia albida* germinated more commonly than *Acacia erioloba* on the river banks, the former was less likely to survive than the latter. In an effort to explain the deaths of so many mature *Acacia erioloba*, the environmental conditions were analyzed. *Acacia erioloba* extends its main roots deep into the moist, fine-grained soil layer immediately after germinating and absorbs water through lateral roots there. When these seedlings become mature trees, they are likely to extend a great number of lateral roots in the shallow depth and absorb water seeping into the shallow layer of land. Fog often arises in the morning around Gobabeb, and the shallow roots absorb water brought by the fog. Flooding occurred frequently until the early 1970s but has become less common since then. The groundwater level also dropped due to the decrease in flooding. Although successive floods used to bring and deposit fine-grained materials from the upper reaches of the river, such materials are becoming scarcer. It is reasonable to conclude

that the cause of extensive tree death was a lack of water caused by this lack of deposition of fine materials and the attendant drop in the groundwater level, both of which made it difficult for the shallow tree roots to absorb water at depth. The findings and considerations so far in this study have implications for human activities in this area. The livelihood of the Topnaar people is highly dependent on the fragile forests along the Kuiseb River. Forests provide shade, firewood, and building materials to the people, and food to livestock. If flooding continues to decrease, it is likely that trees deaths will increase, which will negatively affect the livelihood of the local people.

Water management contradictions and social crisis in the oasis of Tafilalet (Morocco)

Thierry Ruf (IRD)

The history of the Moroccan oases is marked by political breaks and climate change. The oasis of Tafilalet was the front door of the Islam in Morocco and the city of Sijilmasa was one of the most important of Africa for the Middle Ages. The current royal dynasty was born in the plain of Tafilalet. Irrigated by two Saharan rivers, Ziz and Gheris, the plain was considered for a long time as small western Mesopotamia. It lived on important but irregular contributions of water. Resistant in the colonization, the plain was also rebel towards the central power after the independence of the country. But an exceptional floods ravaged it and it had to enter in a new era: it depends now on a big dam, which is built very far from the plain and from the new town of colonial creation, Errachidia. The communication is centered on the history of the public actors and the rural society in the management of water resources that are regulated by the dam. We also study the resources that are escaping the powers of the water engineers : those resulting from floods of side rivers or from Gheris river (which has no dam) and the resources that are coming from draining galleries, khetaras (qanats : they are always flowing in spite of years of droughts between 1975 and 2005. What is interesting in this region, is the phenomenon of massive return of rains since 2005 that led to fill completely the dam of Ziz and to renew watertables. It reactivates tens of khetaras dried up in the previous years. The relationships between the actors become complex with the return of the water : in front of the objective of the new expansion of irrigated zones with modernist models, there are peasants' resistances.

Traditional water use at the desert margin – water harvesting strategies on the Karak Plateau, Jordan, with special regard to old cisterns

Barbara Brilmayer Bakti (Heidelberg University), Olaf Bubenzer (Heidelberg University), Arwa Hamaideh (University of Jordan)

Jordan is one of the ten poorest countries in the world regarding its water resources. During its long settlement history dating back to Neolithic times, various adaption strategies for water use and management evolved. These come into focus again today as water scarcity increases due to high population growth rates, changes in lifestyle and climate change. One of these traditional strategies of water use that has been practiced in the eastern Mediterranean and the Middle East since ancient times, is the collection

and storage of surface run-off generated during the wet winter season in anthropogenic underground holes in the rock (cisterns). Thereby the surplus of the winter months is used to improve scarce water resources during the dry and hot summer months. The collected water can usually be used for all purposes including drinking water supply because of its good quality. Therefore, the old cisterns on the agriculturally important Karak Plateau, which are very likely to be of ancient age (Nabatean, Roman, Byzantine), represented the first benchmark for studying the surface water resources of the area and their potential for sustainable use. The Karak Plateau, situated at 800 - 1200 m above sea level east of the Dead Sea, reflects the transitional character of the whole country of Jordan on a small scale, lying between the Mediterranean in the west and the deserts in the east. With the smooth transition between its central parts influenced by a Mediterranean climate to the desert located immediately east of it, the Karak Plateau can be characterized a desert margin. In addition to mappings and ground checks, especially remote sensing techniques were applied to study the land cover and existing cisterns on the northeastern part of the plateau in an area of approximately 200 km². A very high resolution satellite image (GeoEye-1) was implied in conjunction with object-based remote sensing software (Feature Analyst®) to extract the roof tops of modern settlements, which could be used as run-off collection areas for the ancient cisterns. The data of hydrologically relevant parameters such as climate, land use, geology, soil and relief were integrated into a data base for subsequent GIS analyses which completed the study of the local surface water resources and environmental conditions. Land use classification and analysis of soil properties were performed implying the satellite image, a high resolution DEM, ground checks, and a small-scale soil survey including soil sample analyses in order to evaluate spatial variances in surface run-off generation under recent climate conditions. Based on these results, recommendations can be made for the siting and construction of microcatchments with which surface run-off can be collected and stored in cisterns or reservoirs or used directly for agricultural purposes.

Water processes in arid and semi-arid Central Asia: IWRM implementation in Uzbekistan and Kazakhstan

Andrea Zinzani (University of Verona/University of Fribourg)

Water processes in arid and semi-arid Central Asia: IWRM implementation in Uzbekistan and Kazakhstan The importance of water resources management in drylands cannot be overestimated, be it from a social, political, environmental or economical point of view. Since the Dublin's declaration in 1992, the international 'wisdom' seeks to mainstream the IWRM (Integrated Water Resources Management) approach. In this context, a paramount role is attributed to irrigated agriculture, representing by far the most water consuming human activity. It is therefore very relevant to inquire what is happening today in arid and semi-arid regions considering irrigation features and their relations with land tenure. This paper aims to discuss these issues on the example of post-Soviet Central Asia, one of the regions in the world where irrigation is of crucial importance to state

economies and people's livelihoods. The collapse of USSR and the subsequent decentralisation and decollectivization processes strongly affected water management and irrigation dynamics. At the end of the 90's, Central Asian countries were induced by the World Bank and other Organizations to adopt the IWRM international norms in order to improve their water management conditions. But due to specific economic, social and political conditions, the countries' implementation of IWRM showed differing trajectories. The question therefore arises whether we can speak of a distinctly 'national path' to IWRM in Central Asia? In the present paper, this question is discussed on the example of water management and irrigation transfer in Uzbekistan and Kazakhstan.. The two countries expose some similarities(e.g., reliance on allochtonous rivers originating in the Tian-Shan mountains, climatic conditions, agricultural crops, recent historical background), but they also considerably differ in terms of state endowment of natural resources and socio-political processes during the post-Soviet period. Data used for this paper stem from field work in the middle Zeravshan valley (Uzbekistan) and the Arys valley (Kazakhstan) in 2011. The paper analyses National IWRM programmes in order to inquire the two countries' official IWRM policies as well as their actual implementation at the local level in irrigated agriculture.

Anthropogeneous influence on water ecosystems

Arsen Grigorian (YSU)

Ecosystem is loose concept and is one of the bases of modern ecology. At last years is a serious problem the appreciation of anthropogeneous changes of hydrological regime of water ecosystems and control of water ecosystems' state depending on sharp increasing of sweet water requirement and intensive change of natural landscapes. At present, the hydrological regime of water ecosystems in the most densely populated regions of planet determines not only by natural changes of meteorological elements, but also by different anthropogeneous factors. At that, the role of lasts in each year becomes more considerable. The quantitative and qualitative appreciation of economic activity influence becomes complicated that in each basin or river part are observed different anthropogeneous factors at the same time which have some influence on water and thermal regimes. By practical point one of the main aspects of anthropogeneous influence on water ecosystem is change of water quality. The entrance of formed runoff water into water objects in urban populated area makes thermal pollution, which is spread on all over the river runoff. Now should be pay an attantion to issues of changes discovering and appreciation of water ecosystems generated because of anthropogeneous effects on water ecosystems. The influence of anthropogeneous factors on water ecosystems is expressed by two directions: 1. change the characteristics of hydrological regime of water ecosystems 2. change the quality of natural waters. Changes generated by influence of anthropogeneous factors on water ecosystems and theirs discovering are very important for sanitary state protection of water ecosystems. On water ecosystems of the Republic of Armenia influences the

following anthropogeneous factors: building of reservoirs and other water technical objects entrance of agricultural, industrial, communal-domestic runoff water into the water ecosystems. The building of reservoirs and water technical other objects are change not only hydrological, but also thermal regime of water ecosystems. Theirs building influences on microclimate, water fauna and flora of water ecosystems of coastal zone, are generate preliminary conditions of fish-breeding breach and are affect on fish industry. The irrigation, industrial and communal-domestic water supply are influence on water contant of rivers, in consequence of it is being observed breach of water and thermal regimes. Thermal pollution of water ecosystems became serious problem at last decannials. Thermal pollutant are thermal and nuclear electric stations', industrial, communal-domestic runoff water. They breach biological regime of ecosystems, increase microbes, in summer increases the evaporation, suffers damage ground fauna, becomes poor the kind of plants and animals, decreases their development and biological productivity and etc.

Study of archaeological features in the Samarkand region, Uzbekistan using satellite imagery

Noboru Ogata (Kyoto University)

This presentation offers the result of examination about the location and form of archaeological sites in the Samarkand region, Uzbekistan. Samarkand occupied important position in the Silk Road region throughout the historical ages. Using CORONA intelligence satellite photographs - acquired in the 1960's and declassified in 1995, we detected a number of archaeological features. These features mostly take form of mounds and fort ruins, but are various in size and shape. Typically, mounds and fort ruins are found along the boundary of arable land (oasis) and arid zone (desert). In August 2000, we traveled around the region to identify the detected archaeological features. A local archaeologist who guided us told us that most of these features are settlement ruins. Since 2000, higher resolution satellite imagery has been available. But we can observe that CORONA imagery of lower resolution offers more useful information about the original situations of the archaeological sites. Most of the archaeological sites have been influenced by agricultural development in the recent decades. Through comparing the CORONA photo taken on October 20, 1964, and QuickBird image taken on June 28, 2010, we can observe that Chimqurgon Tepa near Shakhrisabz is affected by the construction of a dam. Moreover, CORONA photos offer availability of stereoscopic pairs. However, CORONA photos are geometrically so distorted that we have difficulty in stereoscopic view. I used QuickBird image as the template to rectify the CORONA photos to enable stereoscopic views. Through the stereoscopic observation, I made morphological overview of Kok Tepa, the most important archaeological site in the region, to find that the site has complex structure consisting of higher and lower levels. As for Chimqurgon Tepa, we can observe that it is a ruin of a huge fortification with double enclosure. The outer enclosure (moat) uses cliff of the fluvial terrace for the north side and small wadi for the west side. East side of the moat is apparently artificial. I conclude that CORONA imagery of the 1960's offer valuable source for studying archaeo-geography of settlements, forts and tombs.

Aeolian sediments and human impact on the landscape in central and southern Mongolia

Frank Lehmkuhl (RWTH Aachen), Jörg Grunert (Department of Geography), Alexandra Hilgers (University of Cologne), Daniela Hülle (University of Cologne), Christian Stolz (Universität Flensburg)

Aeolian sediments including paleosols preserve valuable information on Holocene environmental change. These archives were used to reconstruct the landscape history in the upper Orkhon Valley close to the former capital Kharkhorin, Central Mongolia. For comparison, aeolian and lacustrine records were investigated in the Gobi desert, southern Mongolia. By using luminescence and radiocarbon dating, phases of landscape change, indicated by soil formation and sedimentation, could be identified in the upper Orkhon Valley at around 6.5-6 ka. Since 3 ka, especially within the last two millennia of Historical Time (300 B.C. - present), a more intensified human occupation in the Upper Orkhon Valley occurred in this region. This included a more densely grazing of cattle to supply the growing population demands of the Uighurs and Mongols. This overgrazing caused an increase in erosion and the formation and deepening of fluvial gullies, together with soil deflation and subsequent deposition of aeolian sediments. Human activity, in addition to climate, has been dominant in driving landscape evolution of this region since the late Holocene. Contrary to the Orkhon the South Khangay rivers in the second study area drain to the WNW - ESE running endorheic depression zone of the Gobi Lakes with arid climatic conditions. Lake sediments at different heights above the modern levels provide evidence of higher lake level stands indicating more humid periods and dated mainly to early and mid Holocene periods. Since 3 ka the climate became significantly arid well detectable by fossilized lake deposits indicating continuous lake regressions. The modern lake status dated to 1960 has been well documented by Russian topographic maps. Since then, a dramatically drop of the level of the Orog Nuur and several other lakes in the northern Gobi occurred which should not be misinterpreted as consequence of the global climate warming. It is clearly due to human interventions into the hydrology by creating irrigation projects during the socialist period and, after that, by the quick growing of the now private nomadic herds since 1991. Although the irrigation projects have been mostly abandoned, meanwhile the overgrazing has become a severe problem visible in the field by the widespread reactivation of normally fixed dunes. Concerning the nomadic economy, this has catastrophic consequences for the herds as documented by more than 5 millions of died animals during the winter 2009/10. Today the exclusively man-made desertification all over the country has become a national problem. Mongolian politicians interpreted it as a consequence of the global climate change which has been caused by the industrialized nations. Therefore they claim financial satisfaction to restore the deserted steppe environments.

From archaeological patterns to superimposed large-scale climate mechanisms

Bertil Mächtle (Universität Heidelberg)

Geoarchaeological studies offer new scientific questions for the participating disciplines and new insights are emerging, namely in Archaeology. Likewise also Geography is enriched, discovering archaeological archives as a new proxy for past environmental changes. Based on this added value of interdisciplinarity, this study points out the close link between environmental change and cultural dynamics for the last two millenia in southern Peru, and forms a new hypothesis for the dynamics of large-scale circulation mechanisms in the context of climatic oscillations, which affected both man and environment. The findings show that pre-Columbian prosperity, land-use and adaption measures were closely tied to an adequate land-use potential, which shifted several times between the desert margin along the Peruvian coast and the cold and more humid Andean highlands to the east as well as meridional between the Titicaca region and the Palpa-Ayacucho region further north. These spatial dynamics are obvious in the archaeological records, and this insight was the nucleus to hypothesize about the climatic mechanisms behind: Meridional shifts in the mean position of the Intertropical Convergence Zone (ITCZ) and the Bolivian High (BH) seem to offer a conclusive explanation for the archaeological pattern. Evidence of these shifts can be found in several proxy data from cushion peatlands near Palpa, lake Titicaca sediments or marine records off Peru as well as in more distant geoarchives as the Cariaco basin record, Galapagos lake sediments and corals from the western Pacific warm pool. The occurrence of contemporaneous changes points to (global) coupled climate mechanisms behind, which controlled pre-Columbian dynamics in southern Peru. The same pattern of the ITCZ-BH can be found also for the early-mid Holocene, which shows that the controlling mechanisms are not incidentally or bounded by the specific conditions of the last two millenia.

Holocene palaeoenvironmental changes in the Central Sahara

Jens Brauneck (Universität Würzburg), Roland Baumhauer (Universität Würzburg)

Surveys by the Universities of Würzburg and Berlin, starting in the 1970's have revealed the existence of palaeolakes in remote areas in Niger. Initial research has shown that the sediments found are suitable for reconstructing its late quaternary palaeoenvironment. The aim of the interdisciplinary research project 'LIMNOSAHARA' was and still is to review existing evidence and to fill stratigraphic gaps within the Holocene palaeoenvironmental history of the Central Sahara. For this purpose, two expeditions in 2005 and 2006 headed to the north-eastern parts of Niger to investigate the remains of palaeolakes. At the sebkha of Seggedim, a core of 15 meters length could be extracted which revealed a composition of high-resolution sections. Radiocarbon dates set the beginning of the lacustrine stage at about 10,600 cal BP, with an exceptionally stable freshwater regime to about 6,600 cal BP. There, a major change in the sedimentation regime of the basin is recorded in the core, indicating a change from freshwater to sebkha conditions. The results obtained from the core are compared with lacustrine sediments from outside the depression, situated further to the north. Within the plateau landscape of Djado, Mangueni and Tchigai, two sites containing lacustrine deposits were investigated for palaeoenvironmental reconstruction. Depending on the geographical setting, these sediment archives were of shorter existence than the lake, but reveal additional information about the palaeoenvironmental changes from Early to Mid Holocene. In the Enneri Achelouma, lacustrine pools developed around 9,500 cal BP, initiated by former landsliding that had dammed up the valley. Contemporaneously, lacustrine conditions existed in the Fabergé basin. The investigated archives at both sites evidence only short time lacustrine sedimentation during Early Holocene. Contrary to the palaeoenvironmental archives at Seeterrassental and Fabergé, the information obtained from the freshwater lake sediments at the Seggedim depression showed no noticeable signs of climatic variation until Mid Holocene. Evidence of frequent fires found in the investigated archives raises the question of their cause. Despite the irregularities in the radiocarbon record, the dates from translocated and redeposited charcoal pieces at Seggedim can be narrowed down to a tight time span of 1,200 cal years, during which the regular burnings appear to have occurred. Beside the theory of natural fires caused by lightning, the intentional burning of reed beds may be an alternative explanation, at least for the Seggedim depression. This method is still a regular procedure among traditional Sahelian herdsman, in order to provide access to water for their animals when

the pond is enclosed by vegetation. Whether the fires originated in manmade fire or in lightning cannot be determined.

Anthropogenic Biomes: Regional Response to Global Climate Change Modeling

R.B. Singh (University of Delhi)

Humans have achieved ecological dominance through series of long and precedent steps and have fundamentally altered local as well as global patterns of biodiversity and ecosystem processes. As of now the existing systems for representing these global patterns, including biome classifications, either ignore humans altogether or simplify human influence. This paper is an attempt to analyse the anthropogenic biomes (anthromes). Anthropogenic biomes may also be termed "anthromes" to distinguish them from conventional biome systems, or "human biomes" (a simpler but less precise term). Anthropogenic biomes offer a new way forward by acknowledging human influence on global ecosystems and moving towards models and investigations of the terrestrial biosphere that integrate human and ecological systems. Indian anthropogenic transformation of terrestrial biomes patterns were assessed at 5 resolution by comparing potential natural vegetation maps with anthrome maps at century intervals from 1700, 1800, 1900, 2000 and 2010 using a rule-based anthrome classification, overlay analysis and other geographic information system (GIS) software tools. Anthrome classification adopted on the basis of study done by Netherlands Assessment Agency (NAA) and Maryland Centre. The model applied to gridded global data acquired by GTAP and Hadley Center (NASA) data provided by McGill University since 1700 for human population density, agricultural and urban land use. The study would present the first characterization of terrestrial biomes based on global and regional patterns of sustained, direct human interaction with Indian ecosystems. Eighteen "anthropogenic biomes" were identified through empirical analysis of regional population, land use, and land cover. In 1700, nearly half of the terrestrial biosphere was wild, without human settlements or substantial land use. Most of the remainder was in a semi natural state (45 per cent) having only minor use for agriculture and settlements. By 2000, the opposite was true, with the majority of the biosphere in agricultural and settled anthromes, less than 20 per cent semi natural and only a quarter left wild. More than 75 per cent of Earth's land showed evidence of alteration as a result of human habitation and land use, with less than a quarter remaining as wild lands, supporting just 11 per cent of terrestrial net primary production. Keywords: Anthropogenic biomes; land use change; feature-based mapping and modelling; long-term ecological change; GIS; India.

The Permafrost Transect - Effects of Climate Change and Land Use on Permafrost and Carbon Dynamics in Soils along a Climate Gradient across the Tibetan Plateau

Thomas Scholten (University of Tübingen), Dirk Wagner (Alfred Wegener Institute), Michael Schlöter (Helmholtz Zentrum München), Peter Kühn (University of Tübingen), Corina Dörfer (University of Tübingen), Julien Ollivier (Helmholtz Zentrum München), Sizhong Yang (Alfred Wegener Institute)

Our work focuses on the impact of climate change and human activities on the sensitive permafrost-affected geoecosystems on the Tibetan Plateau. We assume that permafrost dynamics are largely controlled by precipitation and temperature as well as land use changes and have a central impact on soil degradation, soil microbial activities and consequently on carbon sequestration, and greenhouse gas emissions. Our geoecosystem-based approach will determine carbon dynamics and greenhouse gas fluxes on three different spatial scales, namely landscape, plot and pedon. Soil temperature, soil moisture, and soil redox potential are main drivers along the 1,500 km transect at altitudes between 4,600 and 5,100 m ASL. The allocation of 10 study sites along the permafrost transect includes different monsoon dynamics and thus, distinct temperature and moisture regimes. Our research is divided into (i) permafrost dynamics, pedogenesis and soil organic carbon stocks, variability and turnover, and (ii) formation of methane and carbon dioxide (methanogenesis and methane oxidation). The presentation will show results from the 2009 and 2011 expeditions integrating an indicator-based interpretation across scales from molecular biology to plot and landscape scale. Feedback mechanisms and the resultant risk potential related to material fluxes and greenhouse gas emission are of particular interest in the scope of a warming Earth.

Land Degradation and Changing Ecosystem in Central Aravalli Hilly Range: A Case Study of Tonk District, Rajasthan, India

Rama Prasad (University of Rajasthan)

Himalayan forest-cover changes over the past two centuries: a review of spatial and temporal aspects

Udo Schickhoff (University of Hamburg)

Historical forest-cover changes are often not sufficiently taken into consideration when discussing forest degradation and de-forestation in the Himalayas. This paper examines the historical dimension of forest-cover changes using case studies of particular localities and regions and summarizes the emerging picture for the entire Himalayan mountain system. Historical patterns of forest conversion and deforestation are related to present-day rate of forest changes. In many Himalayan valleys potential forest areas have decreased by c. 50 %. The historical transformation processes from forests into farm-

and rangelands can be differentiated into several periods with varying degrees of intensity. It turns out that landscape alteration processes are heavily dependent on the general socio-economic conditions. Until the beginning of the 19th century Himalayan valleys were very thinly populated. Substantial changes in the distribution of forests and agricultural lands occurred in many valleys in the first decades of British rule in the 19th century. The protective influence of the Forest Department, founded in 1864, considerably slowed down these transformation processes. Up to the turn of the century the scenery of the present-day cultural landscape has been created in its basic patterns. This holds also true for Nepal where the present-day forest to non-forest ratio in most of the middle and high mountain regions has not substantially changed during the 20th century. However, the Terai lowlands as well as some mountain regions such as the Northern Areas of Pakistan showed a considerable decrease in forest areas in the past decades. About one-third of all Himalayan districts have experienced a significant decline of forest areas in recent decades. Negative structural alterations within the forest stands and along the forest margins rather than large-scale deforestation characterize recent changes in Himalayan forest condition.

The priority for the European mountain biodiversity conservation in Russia

Tishkov Arkady (Russian Academy of Sciences), Elena Belonovskaya (Russian Academy of Sciences), Elena Belonovskaya (Russian Academy of Sciences), Elena Belonovskaya (Russian Academy of Sciences), Elena Belonovskaya (Russian Academy of Sciences)

The priority for the European mountain biodiversity conservation in Russia The mountains occupy nearly 50 % of the territory of Russia. Due to the palaeogeographical factors, geographical position, massiveness and dominating heights mountains are characterized with a high biodiversity at all levels: specific, ecosystem, landscape. For example, the Caucasian flora in total consists of 6350 vascular plants' species and only 433 of them are spread on the abutting plains and don't rise above the level of low mountain belt. More than 75 % of terrestrial animals inhabits the mountain ecosystems and there are nearly 50 % of the former USSR fauna in the Greater Caucasus. The degree of endemics is higher in the mountains than on the plains. Mountains of the middle latitude with moderately warm climate are characterized with high level of species richness and endemism. In the Greater Caucasus 1600 plant species, which introduce 25.2 % of the total amount of species, are usually identified as endemics. 13.5 % of endemics are revealed in the mountains of the Southern and Central Sibiria. The mountains are characterized by increased ecosystems diversity per unit of area, high nature borders saturation and biotic complexes patchiness. The complexity of altitudinal zonality structure in many respects depends on the combination of warm and moistening. For example, on the Greater Caucasus 8 types and 7 variants of altitudinal zonality could be differentiated. Due to high environmental instability and biotic systems vulnerability great amount of rare and endangered plant and animal species, mentioned in the Red data books of Russia are met in the mountains. Among these 533 plant species there are 282 mountain ones and among 415 animal species - 95. Nowadays there are only preliminary data about quantity of the rare plant communities in the mountains of the former USSR. Meanwhile only 100 mountain communities of various ranks, chosen by various criteria, are called rare and endangered. Favourable environments, high diversity of high-yield ecosystems have been attractive for man during all time. Thus, human economic activity remains an important factor, which influences on the trend and intensity of changes in primary mountain ecosystems. Nearly 70 % of the whole mountains area of Russia is occupied by transformed ecosystems. The high degree of mountain species endemism, great amount of the rare and endangered species and ecosystems strengthen the value of mountain regions for territorial biodiversity conservation and increase their nature-conservative status. For increasing of the Russian mountain territories biodiversity

conservation efficiency, besides the realization of the principle of the ubiquity of the environmental conservation it is necessary develop the adequate protected areas ecological network as a part of Pan-European ecological network (the Emerald network).

Spatial-Temporal Variability of Apple Orchards in Response to Environmental Change in Himachal Pradesh (INDIA)

Inder Jeet (University of Jammu)

In Himachal Pradesh agro-climatic conditions are suitable for the cultivation of variety of fruit crops. The development of fruit crops has greatly fulfilled the needs and objectives of socio-economic growth in the state. Among various fruits grown in the state apple dominate in area as well as production. Himachal Pradesh is the second largest producer of apple in India. But due to environmental change some areas are experiencing decline in the productivity of apple in the state. The area undertaken for present study is Kotgarh village in Shimla district of Himachal Pradesh, which also experienced the impact of environmental change on apple orchards with reference to space and time. The diffusion of delicious apple in the state has been started from Kotgarh in earlier 20th century, as first time the delicious varieties of apple were introduced by Samuel Nicholas Stokes in 1918 in this village. The present study is an attempt to analyze the changes in the growth of apple orchards in terms of space and time in response to changing environment. The study will be based on primary as well as secondary data. One time Kotgarh was known for best quality apple in the country but now apple have become uneconomical, nonviable, less profitable and even unproductive in such a short period. Over the years, fruit growers in the study area have observed significant variations in climate. This awareness of climate change is based mainly on the associated impacts on the apple crop especially on blossoming, fruit setting, yield and increased incidences of pests and diseases. Over all the climate is described as being much warmer and people perceive a definite reduction in snowfall over time. Not only has the actual amount of snowfall decreased but changes in timing of snowfall have also been noticed. Snowfall in December and January has become rare and the period of snowfall now extends through the months of February-March. As a result to maintain an apple orchard has been become an uphill task. New trees simply don't survive and older ones are dying fast and the farmers have switched over to other fruits and vegetables. Key Words: Environmental Change, Spatial, Temporal

Distribution of aloe vera in semi-arid region (Khetri), Rajasthan

Dharmender Chauhan (University of Rajasthan)

The present paper discusses the distributional potentiality of natural vegetation i.e. Aloe Vera. The area under investigation is semi-arid region (Khetri), popularly known as historical heritage, geographical and cultural zone in Rajasthan. Besides this zone has unique combination of beautiful ecosystems via; riverine ecosystem, sandy plain

ecosystem, sand dunes ecosystem and stony and rocky ecosystem. It is located in the South-eastern part of Jhunjhunu district, Rajasthan with geographical extension between 27° 40' 24" to 28° 17' 12" N latitude & 75° 39' 59" to 76° 12' 59" E longitude. The district consists of three seasonal rivers- Basai, Kantli & Chandravati. All these rivers fall under the pattern of internal drainage system of the district. The area is facing the problem of excess of fluoride contents in the water which has average volume of 7.5 ppm & people are suffering from the disease of Fluorosis at many places in the study area. The plant covers a vast area of Tropical America, West Indies, Egypt, Netherlands, Southern Mediterranean region, Cape Verde, Islands, and Canary Islands etc. In India it has specific distribution covering Madhya Pradesh, Rajasthan i.e. in western and central India. The plant belongs to the family - 'Liliaceae'. It is known Ganwarpatha, Grithkumari, Ghigwar, Barbados Aloe etc. locally. It falls under the group of 'Under Shrubs' There is no abundant locality of phytogeographic distribution in the region. Although it's favorable habitat is stony & rocky (hilly patches of the area). Surrounding these patches a wide distribution of gravel formation with compact soil is found at many places which makes favorable eco-climatic conditions for its growth. Being a phyto-geographer, the best efforts have been made in this research paper to conserve and analyze decreasing natural vegetation in Rajasthan. Further, one can visualize the results of the efforts made by Department of Forest and public awareness, the forest land through implementation of successful afforestation and plantation programmes. The results suggest taking up immediate steps to adopt the improved forest management technologies with people's participation to minimize the effects of decreasing natural vegetation in the region. Further the results of the study can be utilized by the planners, bio-scientists, botanists, phytogeographers, naturalists and policy makers to evolve suitable forest management and strategies to the bio-conditions of the region.

How well do meteorological indices explain forest fire occurrence in Germany?

Anne Holsten (Potsdam Institute for Climate Impact Research), Anto Raphael Dominic (Potsdam Institute for Climate Impact Research), Luis Costa (Potsdam Institute for Climate Impact Research), Jürgen P. Kropp (Potsdam Institute for Climate Impact Research)

Meteorological forest fire risk indices have been developed to forecast the risk of fire occurrence and aid forest managers to take suitable preventive measures. We evaluate five meteorological fire risk indices and relevant meteorological variables for their predictive capacity against monthly fire statistics for German states between 1993 and 2010. The indices with best explanatory power were, in increasing order, the German modified M-68, the Canadian Fire Weather Index and Angström. However, mean relative humidity stands out as the best overall predictor for most of the states for the recorded number of fires, especially for the most fire prone states. For the same time period, we investigated correlations for daily fires for the state of Brandenburg. In this case, the performance of fire indices and relative humidity were more similar than at the monthly level. Climate projections under different temperature and moisture conditions consistently indicate a monthly decrease in relative humidity until 2060, particularly in the summer months. Future monthly values of M-68 denote also a considerable increase of fire risk in the summer. The increase in fire risk at the beginning and end of the fire season points to a possible extension of the current fire season. Our results reveal that mean relative humidity is sufficient to describe observed fire occurrences in Germany at both monthly and daily scales. Correlation coefficients were robust at state, country, monthly and daily analysis. Due to its predictive power and simplicity of calculation, relative humidity is a valid, if not better, alternative to the investigated fire indices in describing climate fire conditions in Germany.

Characteristics of a thermal belt on a mountain slope observed by a Terra/ASTER thermal infrared image in the western region of Kanto plain

Shohei Konno (Tokyo University)

Kanto plain is the largest stretch of flat land in Japan, with the north and west sides surrounded by mountain ranges of 1000-2000 m height. During clear and calm winter nights, a thermal belt is formed on the mid-slope of mountain ranges in accordance with the development of temperature inversion on the flat area and cold drainage flow from the mountain slopes. As the night temperature drop on a thermal belt is smaller than that on the plains, mid-slope of the mountain ranges are used for pomiculture, especially to grow

mandarin oranges. Therefore, study of thermal belts is one of the most important subjects in the field of agricultural meteorology. The recent advancements in remote sensing technology have enabled the acquisition of high-resolution information on surface temperature, which is also utilized for the investigation of thermal belts. In this study, through the analysis of a thermal infrared image derived from Terra/ASTER satellite on a clear and calm night (December 27, 2010) by overlaying a digital elevation model, vegetation map, and distribution of vegetation index (normalized difference vegetation index, NDVI), the characteristics of the thermal belt on the Kanto mountain ranges, west of the Kanto plain, were investigated in terms of topographical relief, tree species, and amount of vegetation coverage. These characteristics have not been addressed in previous studies. The resolutions of the thermal infrared image, digital elevation model, vegetation map, and distribution of vegetation index were 90, 10, 100, and 250 m, respectively, and hence, these datasets were converted into grid data of 100 m for the analysis. In addition, the relationship between the thermal belt and location of mandarin orange orchards was investigated by overlaying the thermal infrared image on the location map of mandarin orange orchards. All these analyses were conducted using ArcGIS, which is comprehensive software for designing, analyzing, and managing geographical information datasets. A clear thermal belt was formed on the mid-mountain slope at 200-400 m altitude. The surface temperature at the geomorphological ridge area in the thermal belt was 2-4 °C and 8-10 °C higher than those at the valley and flat areas, respectively. In contrast, tree species and the amount of vegetation coverage had no significant relation with surface temperature. Since the surface temperature derived from the thermal infrared image corresponded with the measured temperature, the surface temperature distribution is considered to be strongly influenced by in situ air temperature. Furthermore, the location of mandarin orange orchards corresponded fairly well with high temperature areas of the thermal belt, indicating that local residents utilize the thermal belt areas for mandarin orange cultivation.

Health and climate - good motivation to implement urban sustainable planning policies

Ana Monteiro (Porto University)

The promotion of sustainable urban planning policies have always enormous obstacles partially because they mean, for citizens, losing some "well being". Nowadays, scientists need to help society and decision makers to make an effort to review the two concepts - city and sustainability. It is urgent to discuss how they might, at least, seem incompatible. Since cities came into existence, they have managed to survive because societies have been able to withdraw from the ecosystem a vast amount of products at a much faster rate than they can be replaced due to scientific and technological advancements. The city implies accommodating a diversity of groups of people and activities in a very restricted space. Within the current paradigm focused on well-being, the demands of the modern city go far beyond the acceptable boundaries of its

ecological footprint, requiring substantial modifications to the biogeophysical structure. Therefore, unless our concept of city is radically changed, bringing these two ideas together will prove a difficult task, since one is anchored in profit rates and the other is based on respect for the rhythms of ecosystems. Health and climate demonstrate a good opportunity to motivate people to rethink their patterns of "well being" and to transform what they understand as a "loss" into a "profit". If we manage, like we have done at Porto, to show that there are close relationships among asthma crisis, climate context and atmospheric pollution, we will be able, for instance, to help the implementation of pedestrianization areas.

Spatial and temporal dynamics of duration of growing periods for crops in a thermally extreme climate: the case of the Russian Far East

Elena Grigorieva (Russian Academy of Sciences), Chris de Freitas (University of Auckland)

Plants have adapted to grow best above certain temperatures. Typically, in general assessments of thermal impact on crops, 0, 5, 10 and 15°C are taken as threshold temperatures due to their close relationship with the onset of various stages in crop development. The research examines the duration of period between thresholds as an agro-climate indicators as applied in a thermally extreme climate of the southern part of the Russian Far East and looks into spatial and temporal patterns in these data. The regions examined are Khabarovsk Krai, Primorsky Krai and Jewish Autonomous Region (JAR) using mean daily climate data for the period 1966 to 2005. In the shoulder seasons of spring and autumn, daily mean temperatures can rise above the threshold for a few days then fall again. To circumnavigate false starts or endings to the period with temperatures above the threshold chosen, the following approach is used. The start of the period is taken as the first day (in spring) after which the sum of positive temperature sums (between daily temperature and the base threshold) is higher than the sum of negative temperature differences. In the same fashion, the end of the period is the last day (in autumn) on which the sum of negative temperature differences is higher than the sum of positive sums using daily data for each of the four base temperature thresholds. The results show that growing season (GS) using the 10°C threshold increases from north to south of the study area, as might be expected, but the mean GS varies considerably from one location to another. Marginal thermal conditions are observed in the north, and both in the elevated areas and in the coastal regions. Three geographic regions are identified. The Northern region has a GS less than 130 days and is located north-west of Khabarovsk Krai. The main crops grow here are oats and soybean. The Central region is located at the southern part of Khabarovsk Krai, at JAR and the northern part of Primorsky Krai, where the GS is 130-145 days. The main crops here are wheat, soybean, oats, potatoes and etc. The Southern region has a GS of more than 150 days and is located in the south-western part of Primorsky Krai. This is the best region for agriculture in that a range of heat-demanding crops can be successfully cultivated, even

rice. The length of the spring and autumn transition seasons are examined using the threshold of 15°C and 0°C, respectively. The longest transition season is near the ocean in the coastal region of Primorsky Krai, while the shortest is in the continental interior of Khabarovsk Krai and JAR. Generally the spring transition period is longer. The continental part of Khabarovsk Krai region has the longest summer season (period above 15°C threshold). Year-to-year fluctuations of GS vary greatly from the period-mean values, with greatest variation in coastal areas. Overall, the results indicate no significant temporal trends in GS in any part of the study region.

Chair: Professor Nigel Tapper

Warm water events in the southern Atlantic - Benguela Niños

Karin Lutz (University of Augsburg), Joachim Rathmann (University of Augsburg), Jacobelt Jucundus (University of Augsburg)

In correspondence to the Pacific counterpart El Niño, anomalous warm water events in the upwelling regions of the Atlantic Benguela Current are called Benguela Niños (BNs). An increase of sea surface temperatures (SSTs) off the coast of Angola has remarkable effects on regional rainfall patterns and on the west coast ecosystem and fisheries. Although BNs have already been studied in detail based on data for short periods in recent years, long-term studies are still lacking. This contribution is based on long-term data sets and focuses on regional influences of BNs on precipitation and also on regional and global interactions in terms of teleconnections. It is based on monthly observational data since 1870, including HadISST1.1 (1°x1° spatial resolution) and HadSLP2 (5°x5°) from the UK Hadley Centre as well as gridded precipitation data (CRU TS3.0) from the Climatic Research Unit (Norwich, UK) and daily station data for precipitation from the Global Historical Climatology Network (GHCN). All data were high-pass filtered to remove trends. Rotated s-mode Principal Component Analysis (PCA) was applied to derive coherent centres of SST and SLP variability and to define regions of similar rainfall variability. Time coefficients from the SST PCA and additionally Angola/Benguela region SST mean values were used to define a particular BN-index (BI). Based on this BI, composite analysis is used to study relationships between SST anomalies in the Benguela current and precipitation in Southern Africa as well as between SSTs and sea level pressure (SLP). To study the influence of Atlantic Ocean SSTs on precipitation in Southern Africa in more detail, the PCA time coefficients for SST and precipitation were used in bivariate correlation analyses and in Canonical Correlation Analyses (CCA). To study interactions on regional and global scales, the previously defined Benguela Index was related to the South Atlantic atmospheric and oceanic centres of variability (represented by their PCA time coefficients) and to different teleconnection indices (e.g. Trans Polar Index (TPI), Antarctic Oscillation (AAO), Southern Oscillation (SOI)).

Climate extremes or weather extremes? Little Ice Age megafloods in the Namib Desert, Namibia, climate oscillations and solar irradiance

Klaus Heine (Universität Regensburg), Jörg Völkel (Universität München)

The purpose of our paper is to review recent advances that have been made in the study of palaeofloods in the Namib Desert and the developments associated with

reconstructions of climate features from sedimentary archives. Global environments are known to have varied over the past millennia, but the spatial patterns have remained poorly defined. We used palaeoflood sediments to reconstruct rainfall patterns over the last 500 years (Little Ice Age, ca. AD 1350 - 1850). The Little Ice Age is found to show palaeofloods that exceeded those of the millennium prior to the Little Ice Age in the northern Namib Desert and the Orange River catchment, but which fell well below post-Little Ice Age levels. The magnitude of the palaeofloods decreases from North to South. The most extreme palaeoflood events occurred during the relative cool phase of the Little Ice Age, the so-called Maunder Minimum (ca. AD 1640 - 1710). Our data show that the palaeofloods were extreme but short-lived flood events (hours, days) which originated in westward shifts of the Tropical-Temperate-Troughs (TTTs) between the southwestern Indian Ocean and the southeast Atlantic Ocean. Precipitation events in connection with TTTs over southern Africa result in certain patterns of anomalous low-level moisture transport. The synoptic scale TTT events are often controlled by large-scale planetary circulation patterns. Even in the 'high-sun' (summer) rainfall areas of the southern hemisphere, the westerlies are important for the development of rain-bearing disturbances, which take on a 'hybrid' character and combine features of tropical and mid-latitude systems. Tropical and extra-tropical dynamics are involved in producing these TTT cloud bands over southern Africa. These atmospheric dynamics influence the regional occurrence of the TTTs and, hence, the distribution of rainfall in the Namib Desert. The TTTs make only a small contribution to wet and dry months (and years). Thus, studies of rainfall variability over months or years do not detect these TTTs, even though they may be a major cause of the flashfloods observed in the sedimentary record. The data presented emphasize the value of palaeoflood records (slackwater deposits) as an indicator of past weather patterns. Correlations are apparent between marine and terrestrial records, indicating the relationship between the Benguela upwelling system and regional weather patterns. We conclude that the patterns of hydrological change recorded in the Namibian slackwater deposits imply dynamical responses of rainfall to solar irradiance forcing changes involving Benguela El Niño oscillation; these hydrological changes can be correlated with records from many other places. We present weather phenomena that must not be confounded with climate changes. During the Little Ice Age, the shifts of the TTTs correlate with a weakening of the solar irradiance during the Wolf, Spörer and Maunder Minima.

East African rainfall and vegetation dynamics in response to a changing El Niño

Tim Appelhans (University of Marburg)

In recent years, a number of studies have presented evidence that toward the end of the 20th century El Niño events exhibit a significant change in both spatial location of maximum SSTs and tropical-midlatitude teleconnections. Classical El Niño events, characterised by warm SST anomalies in the eastern Pacific, are considered to be the

most important cyclic climatic feature on interannual time scales and have been shown to influence regional climates worldwide. However, over the last two decades, maximum Pacific SST anomalies have been more frequently observed in the central Pacific. These anomalies are generally flanked by cooler SSTs towards the east and west and it has been shown that the nature of associated teleconnection patterns differs from those associated with classical El Niño events. Furthermore, a continued frequency increase in these central Pacific El Niño events has been projected for the 21st century. Here, we investigate whether changes in response patterns to such a shift in El Niño can be observed over tropical East Africa. There is a wealth of studies in the international literature that establish clear links between climatic and ecological dynamics of the eastern African equatorial region and El Niño. It has been shown that Indian Ocean SST dynamics are closely linked to SST dynamics of the equatorial Pacific. Furthermore, precipitation and vegetation dynamics in the region respond clearly to El Niño (and La Niña) events. Therefore, it can be expected that a change in the inherent characteristics of El Niño will affect climatic and ecological responses in equatorial East Africa. In a novel approach we investigate whether such effects are observable and quantifiable. Space-time characteristics, such as classical correlation, principal components, decadal and seasonal trends and empirical orthogonal teleconnections of Indian Ocean SSTs, precipitation and vegetation greenness at various spatial resolutions are investigated over a period of 30 years (1980 - 2010). To identify potential changes over time within this period (whether continuous or abrupt), a moving-average-like approach is applied. Starting with the first observation datum, we analyse ten years of monthly observations of the aforementioned parameters in a fixed spatial domain. We repeat this analysis successively by moving the ten year window forward in time through the complete 30 year time period. The window is moved forward at annual steps so that the analysis is carried out for 21 successive time intervals (1980 - 1989, 1981 - 1990, 1982 - 1991, ...). Each instance of the moving window application produces a standardised set of results. Statistics of these results (e.g. the slope of slopes of the OLS trends) are investigated as to whether a change over time can be characterised qualitatively and quantitatively.

Southern Hemisphere regional climate variability during the Holocene: evidence from New Zealand rivers

Jane Richardson (Massey University), Ian Fuller (Massey University), Mark Macklin (Aberystwyth University), Katherine Holt (Massey University), Nicola Litchfield (GNS)

New Zealand, located in the Southern Hemisphere westerly circulation zone, is influenced by both the El Niño Southern Oscillation (ENSO) and the Southern Annular Mode (SAM), and its rivers exhibit sensitivity to hydrological changes in response to these oscillatory climate systems. In this paper we present a probability-based reconstruction of Holocene river activity at a national and regional scale derived from the meta-analysis of 401 14C samples obtained from fluvial units representing river activity and flooding in New

Zealand. Probability-based records of Holocene river activity, compiled for the North and South Island, show that episodes of river activity in the two regions have exhibited a predominantly out-of-phase relationship. During the Holocene, 12 multi-centennial length episodes of river activity were identified in northern New Zealand (North Island), and 11 periods of river activity were detected in the southern New Zealand (South Island) record. These records of river behaviour are compared with independent hydro-climate proxy data representing regional, tropical and polar influences on Southern Hemisphere climate. It is proposed that variability in atmospheric circulation is the major driver of New Zealand river activity. In southern New Zealand episodes of increased Holocene river activity were driven by enhanced westerly atmospheric circulation associated with the negative phase of the Southern Annular Mode (SAM). In contrast, river activity and flooding in northern New Zealand is thought to have coincided with increased meridional atmospheric circulation coinciding with the positive mode of SAM and by La Niña phases of the Southern Oscillation.

Variability of temperatures and precipitations during an early phase of the Little Ice Age in central Spain

Teresa Bullon (University de Madrid)

This study presents the results of a historic reconstruction based upon documentary sources of temperatures, precipitations and floods during the period 1550-1610 in Central Spain. According to the evidences that have been founded as well as the references of previous researches, in this period occurred a climatic crisis that is known as an early phase of the Little Ice Age. Although this cold oscillation in Spain has not been totally defined, the data presented in this paper may help to identify its timeframe, the characteristics of the thermal decline, the precipitation - drought sequences associated to it, and the related environmental consequences. In order to carry out this research, we consulted a large number of historical documents that are stored in many different Spanish archives. These documents belong to the institutions that administered the study area during the time period. We used data from primary sources, contemporaries to the events, rather than compilations or secondary references. We arranged the data according to the intensity and significance of the meteorological phenomena described and, subsequently, we assigned ordinal indexes to these values. The severity of intense extreme cold was more pronounced in the years 1550-1610 than they are today. On the other hand, in accordance with this temperature changes, precipitation or drought regimes gave rise to a contrasted interannual concentration of flood events in the rivers belonging to the basins headed in the mountains of the study area, and, in general, to a decrease in the harvest productions due to a fall in spring precipitations. Temperatures and precipitations suffered changes independently. The interconnection between them produced several temporal sequences, with cold-humid or cold-dry periods. This climatic variability helps to understand better how a natural climatic oscillation happens, and explains the reaction of environment and society to these changes.

Temperature and rainfall oscillations and trends in Israel since 1975 and their environmental implications

Hadas Saaroni (Tel Aviv University), Baruch Ziv (University of Israel), Pinhas Alpert (Tel Aviv University), Roee Pargament (Tel Aviv University)

The research analyses temperature and precipitation data from Israel, attempting to identify trends and oscillations occurring since the beginning of the continuous present global warming, in the mid 1970's. In order to point at dynamic forcing which can explain

climate variations, we explored changes in the occurrence of the regional synoptic types, based on the semi-objective synoptic classification of Alpert et al (2004) and variations in the dominant large-scale atmospheric oscillations. The results indicate a significant rise in the yearly temperature all over Israel, being most noticeable in the hot months, June-October. The temperature rises also in the winter months, in contrast to the cooling trend observed until the mid 1990's. In the coastal region and the flat areas the rise of the minimum temperature was higher than that of the maximum, whereas in the mountains the rise in the maximum temperature was higher. The rapid warming of the summer nights in the coastal plain, which is heavily populated, means an increase in the nocturnal heat stress, with its implied health and other environmental effects. This nocturnal warming may be explained, at least partly, by the Urban Heat Island. Moreover, the heat spells in Israel has become more frequent and longer in duration. At the same time, a decrease in the number of nights with frost potential was noted, but long frost events still occur. The rain regime in Israel is characterized by high inter-annual variations, which makes it hard to identify long term trends in a period of few decades. This study indicates that the region undergoes variations, in a decadal scale, being associated with variations in the occurrence of Cyprus lows, the regional rain producing system, and in the large-scale oscillations, the Nino 3_4, the East Atlantic-Western Russia and the North Sea-Caspian Sea Pattern. The large-scale oscillations are responsible, both directly and indirectly (through the Cyprus lows), for rainfall increase between the end of the 1970's and the beginning of the 1990's and a decrease since the mid 1990s. This decrease is accompanied by shortening of the rainy season and lengthening of the dry spells separating between rain events. In addition, the 200mm and 300mm aridity lines shifted northward, so that the area characterized by Mediterranean climate became smaller, while the arid area grew larger. Based on the Köppen climate classification, a rise in annual temperatures means an increase in the values defining the borders of arid region. This implies that the rising temperatures, observed and predicted, results in actual movement of aridity lines northward and westward more than that are based on changes in rainfall alone. However, the recent decrease of the rainfall is, at least in part, a reflection of regional natural climatic variations.

Climate Change During the Last Glacial and Early Holocene: Causes and Consequences Viewed from the Eastern Mediterranean

Ulrich Müller (Goethe-Universität), Jörg Pross (Universität Frankfurt a.M.), Ulrich Kotthoff (University of Hamburg)

Climate change during the last glacial and early Holocene was by factor 10 larger and faster than what has been measured since 1850 AD (NGRIP members 2004). Such extreme amplitudes of climate response help to identify underlying mechanisms like orbital forcing, abrupt mode shifts of Atlantic meridional overturning circulation (AMOC), Dansgaard-Oeschger (D-O) events, and atmospheric circulation changes. We present a continuous, high-resolution pollen record (>500 samples) of climate and environmental

change in the eastern Mediterranean during the last glacial to early Holocene interval (73 to 7 kyr BP) based on a new core from the famous site Tenaghi Philippon (e.g. Tzedakis et al. 2006) in NE-Greece. The chronology of the record is based on 20 AMS ¹⁴C dates and two tephra age markers. All age data yield a consistent age-depth model. The Tenaghi Philippon pollen record shows a general dominance of dry steppe biomes in the eastern Mediterranean during the last glacial. This dominance was interrupted by a series of interstadials characterized by a short-term expansion of tree populations. The early Holocene interval shows the spread and subsequent prevalence of Mediterranean forest but also a row of drastic climate set-backs. The pollen data indicate eastern Mediterranean climate was generally much dryer during the last glacial than during the Holocene. The short-term expansion of tree populations during interstadials was most likely facilitated by interim increases of precipitation that interrupted the otherwise arid environments of the eastern Mediterranean during the last glacial. Our record shows a one-to-one match with the D-O climate variability known from Greenland $\delta^{18}\text{O}$ ice-core records. Greenland interstadials were linked with expansion of tree populations in the eastern Mediterranean whereas Greenland stadials were linked with aridity. We argue this is because the resumption of the AMOC and the associated strong increase North Atlantic sea-surface temperature at the onset of Greenland interstadials facilitated an enhanced moisture load of the westerlies on their track into Europe. The similarity to Greenland was highest during the early Holocene, including the 8.2 kyr BP event (Pross et al. 2009) and the interval of classic Dansgaard-Oeschger variability during early to mid MIS 3 (Müller et al. 2011). This suggests that high obliquity intervals are well suited to direct consequences of abrupt AMOC mode shifts to the eastern Mediterranean; probably via intensity changes of the Siberian High. Climate Change and Variability in the North Atlantic Region

Alexander Polonsky (Marine Hydrophysical Institute)

This is a brief review of the works devoted to the investigation of the regional manifestations of global warming, Atlantic Multidecadal Oscillation (i.e., of the quasiperiodic natural variations of the ocean-atmosphere system in the North Atlantic with typical time scales of 50-100 yrs.) and thermohaline catastrophe (i.e., shutting down of thermohaline circulation in the North Atlantic). The typical scale of the Atlantic Multidecadal Oscillation is determined by an adjustment of meridional oceanic circulation in the North Atlantic to the changes of the surface conditions there. The analyzed oscillation affects various climatic characteristics: air temperature, river discharge in the European and North-American regions, the number and intensity of tropical cyclones in the Atlantic Ocean, and the parameters of mid-latitude cyclones and anticyclones in the

Atlantic-European region. The main mechanism by which the Atlantic Multidecadal Oscillation affects the climatic characteristics of the regions neighboring with the North Atlantic is the atmospheric response to the thermal anomalies in the ocean leading to a shift of the centers of atmospheric action and to the changes in the intensity and predominant directions of propagation of atmospheric cyclones and anticyclones. By using the results of long-term instrumental observations carried out in Eastern Europe and the data array of reconstructed temperature in the Alpine region, it is shown that the Atlantic Multidecadal Oscillation accounts for a significant proportion of low-frequency variations of temperature in Europe. This fact confirms the potential predictability of the regional atmospheric manifestations of the Atlantic Multidecadal Oscillation on the decadal-scale. The rate of quasi-periodical regional warming/cooling of surface air temperature due to Atlantic Multidecadal Oscillation can exceed the regional temperature rising due to global warming. In particular, the fast warming of the North Atlantic region during the last three to four decades of 20th century is due to coincidence of human-induced trend and transition from negative to positive phase of the Atlantic Multidecadal Oscillation. Realization of thermohaline catastrophe for the recent climatic epoch is unlikely because of circulation stability to imposed typical thermohaline fluctuations due to possible surface changes in the North Atlantic.

Vanishing winters - trends in soil frost dynamics and snow cover in Germany

Juergen Kreyling (University of Bayreuth), Hugh Henry (University of Western Ontario)

Current climate models are very capable of projecting trends in mean winter temperature. However, other ecologically relevant parameters, such as snow cover and soil frost dynamics are less well investigated. Changes in these parameters are expected to have strong ecological implications, especially in the temperate zone, where the question arises if snow and soil frost will occur at all with any regularity at some point in the future. We explored trends in days with snow on the ground (snowdays), minimum soil temperature (MST), and number of soil freeze thaw cycles (FTC, i.e. changes in sign from negative to positive at any pair of consecutive soil temperature records at -5 cm) at 177 German weather stations. Future trends were explored by statistical modelling based on climatic and topographic predictors. Snowdays decreased uniformly at a rate of 0.5 days per year. This trend is projected to continue to a point where significant parts of Germany will no longer exhibit snow cover regularly in the future. MST has already been increased and is projected to do so in the future, mainly in southern Germany. FTC have been decreasing uniformly in the recent past. No evidence for increased FTC or decreased MST with decreasing insulation due to missing snow cover was found. FTC are projected to decrease over-proportionally in the north-east where frequencies in the past were higher. Ecological implications of the strong decrease in occurrence and magnitude of the studied climate parameters include changes in nutrient cycling, productivity and survival. Ecological research is clearly needed, as the effects of diminished winters on ecosystems are not well understood. Kreyling J, Henry HAL (2011) Vanishing winters in Germany: soil frost dynamics and snow cover trends, and ecological implications.

Spatial and temporal shifts in climatic regions in Slovakia

Marian Melo (University in Bratislava), Milan Lapin (University in Bratislava), Hana Kapolkova (University in Bratislava), Jozef Pecho (Academy of Sciences of the Czech Republic), Anna Kruzicova (University in Bratislava)

Spatial and temporal shifts in climatic regions in Slovakia Melo Marian 1, Lapin Milan 1, Kapolkova Hana 2, Pecho Jozef 3, 4, Kruzicova Anna 2 1 Comenius University Bratislava, Faculty of Mathematics, Physics and Informatics, Mlynska dolina, 842 48 Bratislava, Slovakia 2 Comenius University Bratislava, Faculty of Natural Sciences, Mlynska dolina,

842 15 Bratislava, Slovakia 3 Institute of Atmospheric Physics, Academy of Sciences of the Czech Republic, Bocni II, 1401, 141 31 Prague, Czech Republic 4 Technical University of Liberec, Faculty of Science, Humanities and Education, Voronezska 1329/13, 460 01 Liberec 1, Czech Republic The paper deals with the evaluation of territorial and temporal climate change in Slovakia. Our aim is to specify climate regions and sub-regions using the Köppen and the Konec climatic classification schemes and to identify the shifts in their boundaries in Slovakia during the 20th century and at the beginning of the 21st century. Generally, the Köppen's classification is very appropriate for illustrating climatic conditions of larger regions. Analyses based on the Konec's method (developed for the Central Europe) are among the most frequently used climatic classifications in Slovakia. Climatic characteristics calculated only from 30-year or longer periods are representative for the given site or region. In case of climate change and variability analysis also 11-year or longer moving averages can be used. Temporal climate trends based on the Konec's moisture index during the 20th century and at the beginning of the 21st century show that the climate in Slovakia has varied relatively substantially during this time. Climate has become warmer and more arid in the southern part of Slovakia, particularly in the Danubian Lowland, while the northern part (the Orava Region) has become warmer and more humid (in terms of precipitation totals). According to these classifications, certain territorial shifts in climatic regions and sub-regions towards the higher altitudes and to the north were registered in Slovakia during this period as well. (Acknowledgement. The Science and Technology Agency (Slovakia) under contract No. APVV-0015-10 supported this study.)

Recent trends in temperature over Oltenia Plain, Romania

Alina Vladut (Universitatea din Craiova)

The study of regional temperature trends gains in importance as global warming is not linear either in time or in space. Temperature patterns have registered clear changes over southern Romania both in terms of mean values (mean, mean maximum, and mean minimum temperatures) and extreme events over the past five decades. The upward trend, both at annual and seasonal level, is supported by deviations (most of them positive in the last 20 years), linear regression, and 5-year, 8-year, and 10-year running averages. Generally, the mean temperature increased with 0.2-0.7°C from one decade to another. The slope of the 20-year increasing trend has consistently been steeper than that recorded over the 1961-1990 period. Comparing the last two decades, the temperature increase reached 0.30-0.50°C within most of the analysed region. There was also noticed a differentiated temperature increase per seasons, which is generally consistent with present temperature patterns over Europe. According to the analysed data, temperatures have increased more in spring and summer and less in winter and autumn. However, during the 20th century (1901-2000), researchers mention that the seasons warming most rapidly are winter and summer, while trends in spring are the lowest. Winter is presently the season that displays the less obvious upward trend, in

spite of certain peaks reached in the last decade (for example 2007, more than 3°C). Thus, the study emphasizes a clear rate of temperature increase, which will surely trigger important modifications of the vegetation cycle and great impact on water reserves, agriculture, and human health.

precipitation related) and edaphic (compound topographic index or wetness index, terrain concavity/convexity) were used in the model construction.

Consequences of Past Environmental Changes in the Phylogeography of Peat-Bog Taxa in Europe

Miguel Geraudes (University of Lisbon), Carlos Neto (University of Lisbon), João Paulo Fonseca (ISPA - IU), Tiago Monteiro-Henriques (ISA - UTL)

Phylogeography includes potential tools which might turn the multi-proxy approach towards palaeoclimates more effective. Former glacial refugia are revealed by the persistence of high genetic diversity today and can have contributed to Mediterranean biodiversity hotspot, being critical in spatial planning policies and conservation strategies as significant reservoirs of biodiversity. We have identified refuges for *Drosera rotundifolia* L., *Genista anglica* L., *Gentiana pneumonanthe* L., and *Cirsium palustre* L. in the Iberian Peninsula, as well as in the Apennine and the Balcanic Peninsulas. They may have acted as glacial refugia for species of present-day wide distribution in Europe such as those. The peaty ecosystems of southern Europe are, other than the mountain ones, relict ecosystems from past colder climates. Their communities communities of specialists were fragmented into a disjunctive biogeographical distribution, especially the low-altitude sub-littoral bogs, decontextualized from current climate. The genetic structure of populations within such communities encompass signatures of the major climatic oscillations of the last million years. To understand this, the combination of different approaches was used: (1) morphological and phytosociological data, (2) palaeobotanical and palynological data and (3) phylogeographic analyses, using genetic information from AFLPs and DNA sequences from nuclear introns and chloroplast markers. More than 20 populations of each target species will be sampled in the Iberian Peninsula, in Central Europe, in the Italian Peninsula and in the Balkan Peninsula. The population structure of the 4 species within the Iberian Peninsula was thoroughly analyzed; and the relationship between northern populations, which went extinct during glacial advances, and southern refugial populations was tested. Different rates of molecular evolution were covered, trapping the genetic signal in a broader time scale. The within-population genetic diversity and phylogeographic patterns among populations is under evaluation, including the relationship and the level of historic gene flow among them. Using a species distribution model, the environmental envelope of the studied species was projected into future climatic conditions according to the available climate change scenarios constructed by the different research centers that take part on the IPCC (e.g. www.worldclim.org). Therefore, the likelihood of species presence/absence was estimated according to the referred future scenarios, and final maps are being produced in a geographic information system (ESRI ArcGIS). Environmental variables such as climatic (temperature and

Long-term changes of heavy precipitation in Japan

Jun Matsumoto (Tokyo University), Kotaro Kamimura (Tokyo University), Hayato Suzuki (Tokyo University), Hideo Takahashi (Tokyo University)

Long-term changes of heavy precipitation in summer on a daily basis at 50 stations all over Japan for 110 years from the beginning of the last century, and that in the whole year on an hourly basis at approximately 100 stations in the Kanto Plain region, Central Japan for 32 years from 1979 are investigated in order to examine the long-term changes of heavy precipitation in Japan. It was found that during the recent 110 years in summer, the occurrence of heavy rainfall, defined by the Rainfall Characteristics Index (RCI) to show the relative contribution of heavy precipitation to the total precipitation, presents no specific long-term trend and presents decadal-scale variations in a regional scale in most parts of Japan. It is noted that decreasing trend is predominant in the 21st century. On the other hand, warm season (May-October) hourly precipitation in the Kanto Plain region shows increasing trend in southern part of the Kanto Plain where Tokyo and other major cities are located, implying some effects of urbanization on short-term heavy precipitation occurrences in recent 32 years. No such trends have been detected in cold season (November-April).

Drought disaster and its driving mechanism in northwestern China over the past millennium

Harry Lee (University of Hong Kong)

North Atlantic Oscillation (NAO) plays an important role in the Northern Hemisphere climate system. Although there is growing interest in the connection between NAO and precipitation change in China, there are few studies concerning that connection in northwestern China. Based on fine-grained historical drought disaster records and NAO proxies, we explored quantitatively their possible connection in northwestern China over the past millennium at the multi-decadal to centennial timescales. Statistical results show that NAO and drought disaster were negatively correlated, as positive modes of NAO caused northward-displaced, stronger-than average mid-latitude westerlies with an enhanced latitudinal water vapor gradient into the central Asian drylands, resulting in reduced drought frequency and intensity in northwestern China. But, their correlation was out-of-phase during the Little Ice Age because of the southward shifting of monsoons, westerlies, and the East Asian Jet Stream brought by long-term land surface cooling. As it has been indicated that the precipitation in northwestern China is also determined by El

Niño-Southern Oscillation and North Atlantic sea surface and air temperature aside from NAO, further studies are needed to evaluate their individual roles and combined impacts upon the drought disaster there.

Moisture Variations on the Northeastern Tibetan Plateau during the last Millennium and Possible Forcing Factors

Xiaohua Gou (Lanzhou University), Yang Deng (Lanzhou University), Fahu Chen (Lanzhou University)

Six moisture-sensitive tree-ring width chronologies were used to reconstruct moisture variations over the past millennium on the northeastern Tibetan Plateau (NETP). A strong consistency between chronologies was found through the correlation analysis and the shared growth variability in the NETP has therefore been interpreted as a common response to a regional climate signal. Principal component analysis was used to extract the common signals in the tree ring chronologies. The first principal component (PC1) correlated well with regional precipitation and can thus be used as a regional moisture indicator. Wet spells were identified from AD 1081 to 1086, 1231 to 1244, 1359 to 1408, 1554 to 1586, 1743 to 1754, 1765 to 1773, 1892 to 1912, 1970 to 1985, whereas dry periods occurred AD 1121-1159, 1279-1309, 1451-1507, and 1696-1723. Decadal-scale variations of the PC1 and the Pacific Decadal Oscillation (PDO) show a consistent pattern during the 11th to 12th, 14th, and 16th to 19th centuries. An anti-phase relationship between the PC1 and the PDO during the 15th century may have been caused by a southward migration of the intertropical convergence zone (ITCZ). The PC1 also shows some coherent patterns with variations in solar activity. Multi-taper spectral analysis demonstrates that there exist significant periodicities of 205, 73, 51, 39, 33 years, and some 2-8 year cycles. The 50-70 year cycle may be linked to the PDO, whereas the ~205 and 35 years cycles and the 2-8 year cycle may be related to variations in solar activity and the ENSO pattern, respectively.

Palaeoenvironment Reconstructions of the middle to late Holocene in a high-resolution sediment core from Tianchi Lake on Liupan Mountains, China

Aifeng Zhou (Lanzhou University)

The Asian monsoon is a key component of the earth's climate system that directly affects the livelihood of 50 million people on the loess plateau of central China. At the far edge of monsoonal influence, this region is especially vulnerable to future changes in temperature and evaporation/precipitation. Therefore, paleoclimatic information on the natural sensitivity of the region to changes in monsoon driven aridity is crucial. Here we present multiple proxy records from Tianchi Lake, one of the few nature lakes on the western loess plateau. The chronology is well constrained by a high-resolution radiocarbon age-model, spanning the past 6000 years. Here we present Glycerol dibiphytanyl glycerol tetraethers (GDGTs), lake macrophytes (paq) and plant-wax hydrogen isotope to

reconstruct regional climate change during the middle to late Holocene. Evidence from n-alkane Paq , C/N and $^{13}\text{C}_{\text{org}}$ data suggest increasing relative abundance of macrophytes over past 6000 years, which we interpret as decreasing lake-level. Plant macrofossils and other environmental parameters suggest that the vegetation in the catchment was decreased from 6000 cal yr BP and then more rapidly from 2200 cal yr BP. This is coeval with documentary records of increasing local population density and infers historical human impact on the catchment. Using Sun et al (2011) regional calibration we derive mean annual GDGT based temperatures (MBT/CBT-MATs) with reasonable ranges. Our temperature reconstruction closely correlates on millennial to centennial timescales with the independent D/H measurements on C28 fatty acid ($^{13}\text{C}_{28}$), whose signal is assumed to derive primarily from terrestrial plant waxes and the $^{13}\text{C}_{28}$ values to reflect local changes in precipitation. Synchronous evolution of reconstructed temperature (MBT/CBT-MAT) and precipitation ($^{13}\text{C}_{28}$) from Tianchi Lake suggest that the climate on western loess plateau shifted between 'warm/wet' and 'cold/dry' during the middle to late Holocene. Comparisons of our independent GDGT temperatures and plant-wax $^{13}\text{C}_{28}$ records with stalagmite ^{18}O records from the monsoon region and NH summer insolation suggest strongly that our record reflects regional changes in monsoon strength forced by NH summer insolation. Superimposed on the longer-term insolation driven changes are centennial scale variations, recorded by both the independent reconstructions of precipitation ($^{13}\text{C}_{28}$) and temperature (MBT/CBT-MAT). Trade-wind driven of the frequency/intensity of ENSO cycle on the longer-term scale and the SST changes of the western tropical pacific might be the key point of the monsoon strength variations in study area.

Long-term variability of selected agricultural climate conditions in Central and Eastern Europe and their impact on the fruit industry

Agnieszka Wypych (Jagiellonian University), Tadeusz Niedzwiedz (University of Silesia), Zbigniew Ustrnul (University Krakow), Lukasz Malarzewski (University of Silesia)

The rate of climate change is a broadly discussed subject today and affects human activity to a significant extent. Agriculture is the sector of the economy that is most vulnerable to climate change. Reported mean temperature increases as well as significant changes in precipitation amounts and the increasing frequency of extreme weather events are symptoms of changing climate conditions, which are increasingly affecting crop yields across the globe. The primary purpose of the paper is to describe the effect of climate change on agriculture based on the example of the fruit industry. The paper analyzes the tart cherry, which is highly sensitive to climate extremes and threshold events and requires long-term investment. Hence, the tart cherry appears to possess strategic economic value. Three European countries where tart cherry production is growing were analyzed: Germany, Poland, Ukraine. Data from seven meteorological stations representing different agricultural regions were used. Daily temperature data and precipitation totals covering the time period of 1951-2010 were obtained and used to calculate selected agricultural indices with thresholds critical for the tart cherry. The temperature characteristics of the study area were assessed and compared to those of Central and Eastern Europe in general. The paper then proceeds to analyze long-term changes in agricultural climate conditions with respect to tart cherry production. The paper further looks at the effect of atmospheric circulation on temperature in the study area. Changes in agricultural climate conditions are compared to changes in the intensity of North Atlantic circulation for the study period. Atmospheric circulation is a key determinant of contemporary climate change. This is especially true in temperate climate zones where changes in the advection of air masses can result in unfavorable weather conditions - some of which may be described as extreme.

The Siberian High: Teleconnections, extremes and association with the Icelandic Low

Amit Tubi (University of Jerusalem), Uri Dayan (University of Jerusalem)

A 60-yr minimum temperature record of 11 stations in inner Eurasia enabled the characterization of the variability in the Siberian High (SH) intensity. The decline in the SH

intensity is observed in tandem with the positive mode of the Arctic Oscillation (AO), both increasing in recent years and highlighting the rate of warming over Siberia. The coldest 1968-9 winter in the 60-yr period corresponds with the lowest AO annual index value. Spatial correlation analyses indicate that enhanced cyclogenetic conditions over the eastern flank of the Icelandic Low (IL) are associated with a milder SH. Seasonal composite analyses of the circulation pattern during the coldest 1968-9 winter are characterized by a retreat of the IL, allowing a westward expansion of the SH cold core. A robust methodology, assuring an adequate representation of extremely cold spells in both their extent and duration was developed. This methodology yielded three exceptional events, the most severe one lasting 10 days and affecting all stations in the SH domain. Analyzing this event on a fine temporal resolution enabled the detection of short-term synoptic scale processes, such as the polar air mass penetration, resulting in a mean minimum temperature of -40 °C over the whole domain. This short-term polar air incursion and its termination featuring this spell as modulated by the location of the IL, point at its important role in modifying the SH.

Natural seasons and their variations in Iran

Bohloul Alijani (Kharazmi University)

Seasons are natural indicators of the climate variability which are accepted by the people to adapt and plan their life and activities on their length and variability. This research has tried to define start, end, and duration of the seasons and study their variations in Iran. In order to define the natural seasons, the daily data of temperature, precipitation, relative humidity, wind speed, and sunshine hours were obtained from the Meteorological Organization of Iran for the weather stations of Iran for the period 1982-2007 period. This period was chosen because most of the stations had complete data. The data were analyzed in three steps. First, the daily mean of the period was calculated and then the mean values were clustered to get the homogenous climate periods of the year. Second, the start, end, and duration of the seasons for each year of the study period were determined according to the thresholds obtained from the first phase of the study. The results showed that winter starts with minimum temperatures below zero Celsius, spring begins when daily minimum goes above 14C. Summer begins with daily maximum above 25C and fall starts at maximums below 14C. This research showed that the natural seasons are not equal in Iran. The longest season is summer in most of the country. The spring has the shortest duration all over the country. Winter is getting longer from south to north while summer is very long in the south of the country. The annual analysis of the seasons showed that their characteristics have changed during the study period. Summer has become longer and warmer. But winter has become shorter and milder. Key words: seasons, seasonal variations, Iran, natural seasons, seasons in Iran.

Recent spatial variability of air temperature in Tunkinskaya intermontane hollow

Elena Istomina (Russian Academy of Science), Nadezhda Voropay (Russian Academy of Science)

Climate changes can be evaluated best-attested with the use of meteorological stations data. But meteorological stations in Tunkinskaya intermontane hollow are situated in a flat open places. It is difficult to investigate the climate of mountain regions on the base of this data. To study detailed spatial-temporal variability of air temperature of a territory the space images (far-infrared band) and electronic temperature sensors (thermochrones) were used. In 2007 the microclimatic studies of the air temperature regime of key areas of Tunkinskaya Hollow (the Republic of Buryatia, Russia) were started. The Hollow is located 200 km to the west from Lake Baikal. The 20 electronic temperature sensors (thermochrones) were used for measurement of air temperature in the field. The sensors recorded air temperature every 3 hours simultaneously with routine measurements at meteorological stations. Choice of key areas was made taking into account the landscapes characteristics. We study a cross-section through the Tunkinskaya Hollow that includes the bottom of the Hollow and its mountainous border - the Tunkinskiy Ridge and the Khamar-Daban Ridge. Thermochrones located at an altitude of 806 m to 2119 m. Along with climate observations the complex landscape research being conducted. Geographic information system was developed for the study area. The GIS contains topographic maps, digital elevation model (SRTM), different-time satellite images Landsat 5 and 7, SPOT 4, and available geological and landscape-scale maps of the area. Complex landscape descriptions of more than 100 points was made. Descriptions were performed on specially designed forms, including the main characteristics of the Geosystems components: lithogenic base, soil and vegetation. The main emphasis is on quantitative characteristics. The landscape map of the area with scale 1: 100 000 was created. This allows us to study the climatic features of the territory in the context of a landscape approach. Series of the Landsat space images were used for extrapolation of the data of point observations and for reconstruction of air temperature field taking into account the emissive ability of different types of surface. The algorithm of calculation of air temperature with using of space images was developed. The maps of air temperature for different points of time were made. On the base of this unique data, the details of a temperature variability of the territory are shown, e.g. temperature inverse in winter season and others.

Development and validation of 1936-2008 year monthly gridded temperature and precipitation data set for use in global climate change assessment for Georgia

Marika Tatishvili (Georgian University)

The development and validation of the 25kmX25km gridded monthly mean temperature and precipitation data set for Georgia that covers period 1936-2008 and accounts for the complexity of the Georgian terrain has been presented. The temperature and precipitation data set have been passed on quality control and missed data were restored using several methods. The obtained data sets were checked on homogeneity. For interpolation Spline with Barriers procedure has been used. The 25 resolution grid with 112 nodes has been created for global climate change assessment for Georgia. Some results have been presented.

Climatic dimension of the Caspian Sea level fluctuations

Natalia Lemeshko (Saint Petersburg University), Ekaterina Fomicheva (Saint Petersburg University)

The Caspian Sea is a unique element of Earth's landscape. It is a closed sea-lake with a huge catchment area whose topography is plain in the north and mountainous in the southeast, which makes the Caspian Sea a reliable moisture integrator reflecting both long- and short-term climate fluctuations within a vast territory. The contemporary idea about the Caspian Sea level fluctuations are based on the structure of the Sea water balance that is determined by the climatic factors. Throughout more than a hundred-year observational period significant Caspian sea-level fluctuations have been recorded. The amplitude of the sea level fluctuations does not exceed 4 meters during the instrumental period (from the highest level (-25.2 m BS) in 1882 to the lowest level (-29.1 m BS) in 1977). Whilst the amplitude mounted to 8-10 meters during the New-Caspian transgression, some estimates suggest 12-19 m. Three warm climatic periods have been investigated: the Holocene climatic optimum (6.2 - 5.3 KA B.P.), the warming of 1930-es and the last three decades of the 20 century & first decade of 21 century which were accompanied by the global warming and the growth of the Caspian Sea level, in order to research ranges of the Sea level fluctuations. The peculiarity of regional climate changes has been examined for all seasons in 1990s with an increase in the mean global air temperature. The temperature and precipitation anomalies have been compared for 1991-2000 and the Holocene optimum. It has been concluded that quantitative estimates

of the air temperature and precipitation agree between themselves for the larger regions of the Eurasia territory. It means that the climatic optimum of the Holocene should be used for the near future climate scenarios as well as for assessment of the Caspian Sea level change. The paleoclimatic reconstruction-maps for winter and summer air temperature and annual precipitation for global warming on 1°C have been used as predicting scenarios of climate conditions in the beginning of 21 century. Based on the heat-water balance method and scenario a hydrological model has been developed to calculate the changes in climate and hydrological parameters with the progress of global warming. This model allows us to calculate changes in annual river runoff and evaporation for the Caspian Sea catchment. Some additional assumptions have been made to adapt this method for empiric scenario of climate change. The water balance approach and method of historical analogy (using instrumental data of the Sea water balance components) have been used for the assessment of the Caspian Sea level with global warming.

Marmarik rivers runoff in global warming climate conditions

Varduhi Margaryan (YSU)

We studied the runoff of Marmarik River in conditions of global warming climate, because the Marmarik in comparison with, other rivers stands out comparatively by big natural runoff. Toward this end have been studied physiographic main factors stipulator the river runoff, available literary sources, have been collected, worked out and estimated observation data of hydrological and meteorological points and stations of basin, which are archived in Armstatehydromet, is being covered some peculiarities of runoff in climate change conditions. For studying, analyzing and estimating of water resources have been used physical-statistical and mathematical models. In the river basin hydrological and meteorological studies have been done in 20 th century beginning from 30 th. Deficiency is that the basin is studied very bad by meteorological observation. In the basin in different years worked one meteorological station (Hankavan) and two points (Aghavnadzor and Meghradzor). At the present time (2010) in the river basin works only one meteorological station, Hankavan also during some period was as a point (that is there were only precipitation and snow cover observation) and as a meteorological station later, at the same time did not save continuity of observations range. That is why we have been used date of observations of neighbour meteorological station Hankavan. Now (2010) in the basin work only three water measuring points: Hankavan (1956-2010) and Aghavnadzor (1396-2010), which situate on Marmarik river and Meghradzor (1935-2010), which situates on the tributary of Marmarik, Gomur. The rivers of Armenia, Marmarik also, characterize with spring flood, summer-autumn and autumn-winter shortage of water phases. Spring floods, as a rule, begin from the end of March-beginning of April and continue until the end of June-first decade of July, and during these periods often passes maximum runoff of river. During the flood (IV-VI) by the river passes 65-80 % of annual runoff. In Aghavnadzor point in 1936-2008 in I, II, V-XII months are being observed

decreasing of runoff volume, in May greatly, but in March and April, although lightly, but it increases. As a result of decreasing of runoff is being observed as during spring flood, as well as in shortage water phase, therefore, during the year. The volumes of maximum runoff are decrease also. At Hrazdan meteorological station is being noticed air temperature increasing, in January and February greatly. And it is a very reason of runoff changes. The changes of atmospheric precipitation of Hrazdan meteorological station are ignored, because distribution of precipitation has local character mainly and cannot characterize the situation right. At the same time precipitation is increases by height, but Hrazdan situates near the lower flow of river. Thus, global warming climate effect on river runoff volumes and runoff decreases.

Climate Change Impacts and Coral Reef Ecosystems

Abdollah Esmaeili (National Iranian South Oil Company)

Climate change impacts threaten coral reef ecosystems by increasing ocean temperatures, storm activity, ocean acidification, and sea-level rise. These physical ocean changes lead to coral bleaching and diseases. Increasing atmospheric carbon dioxide has already begun to reduces calcification Increasing atmospheric carbon dioxide reduces calcification rates in reef-building and reef-associated organisms by altering sea water chemistry through decreases in pH (ocean acidification). In the long term, failure to address the impacts of rising temperatures and ocean acidification could make many other management efforts futile. Reducing greenhouse gases (primarily carbon dioxide) will be required to avoid irreversible climate-change effects. Therefore it is essential that we not only reduce emissions, but take urgent actions to reduce the impact of elevated greenhouse gases on coral reef ecosystems. In this paper, we will briefly discuss these subjects.

C08.04-09 - Potential Impacts of Climate Variability and Change on Agriculture: Historical Variations 1

Chair: Julie A. Winkler

Understanding climate change from rice cultivation: Lessons from local farmers in Assam, India

Haruhisa Asada (Tokyo University)

Impact of climate change on agriculture is one of the biggest challenges in the modern society. The effect of future climate change on crop production is estimated by computer simulation combining both climate model and crop model, which has a significant uncertainty. Furthermore, estimating future crop production is not simple as it largely depends on social and economic conditions. Therefore, it is necessary to know the local cropping system, which climatologists often neglect. In this sense, knowledge of local farmers will be useful for scientists to understand the relationship between climate and local cropping system including socio-economic factors. This study tries to understand climate change from the farmers' view who is engaging with rice cultivation in Assam, northeast India. Northeast India is widely known as the rainiest place in the Monsoon Asia, and rain-fed rice is traditionally cultivated in the low-lying Brahmaputra floodplain without modern irrigation. Field work was carried out during rainy season from May to November 2009 in the study village in eastern Assam, and farmers' responses to rainfall variation were investigated by hearing survey and field observation. In the study village, three kinds of responses for rainfall variations of different time scales were found among farmers. In the first case of rainfall shortage during 2009 monsoon season, influence of intra-seasonal variation of rainfall on rice yield was very limited for farmers using traditional cropping technologies. Farmers did not take any measures for rainfall shortage, but harvested sufficient rice production. In the second case of significant decrease of monsoon rainfall around 2000, farmers had to change existing cropping pattern as water level of paddy fields significantly declined caused by decadal variation of monsoon rainfall. Farmers gave up growing broadcast rice suitable for deep water condition and increased the area of transplant rice which has higher yield. They completed this dynamic change of cropping pattern without introducing modern cropping technology. In the third case of recurrent flood years during the early 1970s, farmers could not cultivate rice due to deep flood water, and had to migrate to other place seeking for new cultivable lands. This affected land holding pattern in the study village which eventually caused cropping pattern changes. These results suggest that the effect of climate change on agriculture varies with cropping technology available for local farmers. Rainfall amount is not the sole factor, but socio-economic conditions of local farmers also plays important role for crop production. Climatologists who tend to consider climate effect in macro scale, should have farmers view in micro scale. In order to understand ongoing climate change,

farmers' knowledge, experience and even memory should be utilized as well as meteorological observations.

Phenological Models to Project Changes in the Beginning of Tart Cherry Blossom across Europe and North America

Frank-M. Chmielewski (Universität zu Berlin), Philipp Matzneller (University Berlin), Klaus Blümel (Universität zu Berlin), Jeffrey Andresen (Michigan University), Geza Bujdosó (Research Institute for Fruit Growing), Peter Hilsendegen (Rheinland-Pfalz, Dienstleistungszentrum Ländlicher Raum), Amy Iezzoni (Michigan State University, Department of Horticulture), Robert Kurlus (Poznan University), Lukasz Malarzewski (University of Silesia), Tadeusz Niedzwiedz (University of Silesia), Nikki Rothwell (Northwest Michigan Horticultural Research Center), Costanza Zavalloni (University of Udine)

In order to study the impact of climate change on agriculture and horticulture such as tart cherry production, phenological models are of great importance. They can act as separate models to investigate possible shifts in the timing of phenological events or they can be inserted as subroutines in complex management models. These integrated models are essential to investigate the impact of climate change on late frost hazard, yield formation, irrigation, pest and disease infestation etc. For these applications, phenological models must be able to project shifts in plant development not only for present climate conditions but also for possible future conditions up to 2100. Our studies have shown that the original, commonly used Growing Degree Day (GDD) model shows several systematic deficits. If one uses physiologically meaningful values for the starting date of temperature accumulation (t_1), which also operate for future climate conditions (relatively early starting dates, due to rising temperatures), and for the base temperature (TBF), the models exhibit a built-in trend for the beginning of blossom (t_2) with increasing temperature level, which cannot be influenced by the model parameters itself and which is too large in absolute value. As a consequence, large root mean square errors (RMSE) between observed and simulated blossoming stages emerge. Implementation of an additional daylength term in the GDD models eliminates these problems almost entirely, and markedly reduces the RMSE at verification. Additionally, this term automatically leads to physiologically meaningful model parameters. Moreover, the model optimized and verified for one tart cherry growing location in Germany, could be successfully applied to calculate the beginning of blossom in other regions in Europe and in North America, mainly for strictly standardized phenological observations in the Global Phenological Observation Programme (GPM). We developed combined chilling-forcing (CF) models for the beginning of tart cherry blossom which based on the chilling hour (CH) or chilling portion (CP) accumulation and on a modified GDD approach with an additionally daylength term. The phenological blossoming models were optimized for two major tart cherry growing regions in Germany (Rhineland-Palatinate), on the basis of gridded phenological and temperature data (14 km x 22 km grid) between 1961 and 2009. For

the internal verification of the models the dataset was spited into two halves. The even years were used to optimize the models and the odd years to verify them. For an external verification, phenological observations from different experimental sites (study regions in CLIMARK) and phenological gardens (GPM Programme) in Europe and North America were used. The internal and external verification of the combined CF-models was acceptable, so that we were able to use these models to project possible shifts in the beginning of tart cherry blossom due to climate change.

Impact of land use changes as a result of global warming on soil erosion, soil organic carbon and greenhouse gas emissions to atmosphere

Andrey Zhidkin (Moscow University), Alexander Gennadiyev (Moscow University), Valentin Golosov (Moscow University), Kenneth Olson (University of Illinois), Maxim Markelov (Moscow University), Roman Kovach (Moscow University)

If climate change did occur in the northern hemisphere and the mesic-frigid line was to move north, then it is likely that forest and prairie lands would be cultivated or pastured. The goal of our research was to assess the impact of global warming on land use conversion of forest land in the frigid temperature regime of the northern hemisphere to agricultural crop use and effects on soil erosion and deposition, soil organic carbon storage (SOC) in the landscape and greenhouse gas emissions (CO₂). Our approach required the selection of study sites including 2 in Russia (Tula and Belgorod regions) and three sites in the USA (Albany, Hanover and Knoxville areas, IL). The soils of 30 transects studied were sampled and investigated in laboratories. The soil erosion rates were determined using USLE and RUSLE equations, as well as new method of magnetic tracer (spherical magnetic particles) and method radioactive tracer (cesium-137). At the Knoxville site the cropland retained 59.7 Mg C/ha or 87% as much as the timberland, at the Albany site cropland retained 31.8 Mg C/ha or 52% as much as the timberland, at the Hanover site the cropland retained 54.7 Mg C/ha or 69% as much as the timberland, at Tula the cropland retained 20.7 Mg C/ha or 107% as much as the timberland and at the Belgorod site the cropland retained 12.9 Mg C/ha or 75% as much as the timberland in the upper 0.5 m of the soils. Approximately 20% of SOC in timberland was oxidized during the first 40-50 years of land use change and after initial cultivation. The amount of soil erosion over the last 150 years was determined at all sites, the SOC content of the sediment was determined with 70% of the sediment and SOC retained on the landscape, an additional 20% released to atmosphere as CO₂ and 10% transported to rivers. Using the method of different-age tracers characterizing the soil erosion/deposition during the last 140-150 years (magnetic tracer) and during the last 20-25 years (radioactive tracer), the spatial and temporal features of the redistribution of the drifts on typical slopes in different parts of the forest-steppe zone of the East-European Plain were established. Data on the rate of the erosion-accumulation processes within the slopes studied on key sites in Tula, Kursk, and Belgorod oblasts were analyzed. A clear trend of an decrease in the soil erosion rate in this zone during the last 20-25 years was revealed compared to

the average rate for the last 140- to 150- year long plowing period, which was related to the climate warming, an abrupt reduction of the surface runoff during the spring snowmelt period, and the increasing soil-protecting role of the agricultural plants in the crop rotations because of the decrease in the proportion of row crops.

Changing Pattern of Rainfall and Agriculture in Assam (India)

Bimal K Kar (Gauhati University), Pahari Doley (Gauhati University)

Rainfall, an important element of climate, which greatly influences the agricultural practices in an area, has been undergoing change as a part of the global phenomenon of climate change. This is no less true in the case of Assam, a state in India's eastern periphery mostly surrounded by eastern Himalayan foothills, where the economy is primarily based on agriculture. As a matter of fact, the amount of both annual and monsoon rainfall has been witnessing a declining trend in most parts of the state during the last few decades or so. Such a situation appears to have significant bearing in agriculture system in the state in respect of area coverage, cropping intensity and crop yield rate including that of rice production patterns and changes in crop calendar. It has also necessitated the increased provision for irrigation so as to overcome the deficit in natural supply of water and also to keep agricultural production process uninterrupted even due to slight change in crop calendar. With the above background, an attempt is made in this paper to analyse the patterns of annual rainfall including its seasonal variation, agricultural status in terms of area coverage, cropping intensity, irrigation and rice production, and their prevailing interrelations in six selected districts of Assam, viz. Dhubri, Kamrup, Nagaon, Dibrugarh, Karbi Anglong and Cachar, using secondary data obtained mainly from the Directorate of Economics and Statistics and Directorate of Agriculture, Govt. of Assam for the period 1991-2010. The data so obtained have been analysed and presented with the help of some simple but meaningful quantitative and cartographic techniques. The analysis reveals that although the declining but fluctuating trend of rainfall in the state has affected the agricultural production pattern, the prevailing rainfall-agriculture relationship in the state has not been so simple. Moreover, increased uncertainty in monsoon rainfall has not only resulted in gradual changes in crop calendar but also increased diversification in cropping pattern.

C08.04-10 - Potential Impacts of Climate Variability and Change on Agriculture: Climate Projections and Assessment Strategies 2

Chair: Julie A. Winkler

Sensitivity analysis for agriculture using growing degree-days as a climate warming impact indicator for a region with extreme annual air temperature amplitude

Chris de Freitas (University of Auckland), Elena Grigorieva (Russian Academy of Sciences)

The thermal component of climate is a key factor in agriculture, thus any change, whatever the cause, will affect the value of the resource. The problem is we are unable to adequately predict future climate. Sensitivity assessment circumnavigates this problem and informs planning decisions without knowing precisely the magnitude of climate change that might occur. The impact of change will depend on the climate of the region in question. For example, an average 1oC air temperature rise may be of little consequence where high temperatures are common and prevail over extended periods. Conversely, marginal climates for agriculture may be highly sensitive and respond dramatically to even the smallest change in thermal conditions in an already short growing season. The concept of growing degree-days (GDD) is used as a measure of the agricultural potential of climate on a regional scale. Typically, in general assessments of thermal impact on crops various base threshold temperatures are used due to the close relationship of these thresholds with the onset of various stages in crop development. The current study uses GDD for these thresholds as applied in the thermally extreme climate of the southern part of the Russian Far East and examines spatial patterns in these data using mean daily climate data for the period 1966 to 2005. Daily maximum and minimum air temperatures are used for calculating GDD at 17 locations using threshold base air temperatures of 0, 5, 10 and 15oC, with a high-temperature threshold cut-off of 30oC. Sensitivity changed thermal conditions of +1, +2 and +3oC are examined using a sensitivity index defined as the percentage change in GDD for each of the three warming scenarios. Generally, the results show GDD sensitivity decreases from north to south of the study area, but the mean GDD sensitivity varies considerably from one location to another. Marginal thermal conditions are observed in the north, both in the elevated areas and in the coastal regions. Specifically, the larger the GDD Sensitivity Index (GDDSI) index value the more sensitive the climate to warming (in terms of crop growing conditions) is at a particular location. In most cases, sensitivity does not increase significantly as warming rate increases. The higher the base threshold, the higher the sensitivity. Highest sensitivity is for GDD15 at Okhotsk in the far north of the study area. The colder the climate the higher the sensitivity. Where GDD at threshold 15oC is small,

sensitivity to warming is higher. Highest sensitivity is for GDD15 at Okhotsk in the far north of the study area. The mapped results are useful for identifying areas of high sensitivity to climate change as well as the magnitude of the potential.

Application of regional climate model simulations in agricultural assessment – evaluation of bias and bias correction methods

Pang-Ning Tan (Michigan University), Zubin Abraham (Michigan University), Julie A. Winkler (Michigan University), Perdinan Perdinan (Michigan University), Malgorzata Liszewska (Interdisciplinary Centre for Mathematical and Computational Modelling), Sharon Zhong (Michigan University)

Assessments of the potential impacts of climate change on agriculture require climate scenarios at fine spatial and temporal resolution as input to crop phenology and yield models. Simulations from regional climate models (RCMs) are one source of fine resolution climate scenarios. However, phenology and yield models are very sensitive to biases in the RCM simulations. For example, a warm bias in spring and summer temperatures may result in a large overestimation of growing degree units and an underestimation of frost damage. We evaluate the biases present in RCM simulations available from well-known archives (e.g., ENSEMBLES, NARCCAP) against site-specific climate observations for multiple midlatitude locations. The evaluation focuses on climate parameters, including growing degree days, frequency of days with temperatures below freezing, and the frequency of days with precipitation, that are of importance for specialized agriculture such as fruit production. Alternative bias correction methods (e.g., quantile-quantile mapping and local intensity scaling) are applied to RCM simulations driven by reanalysis fields and by global climate models (GCMs). These bias correction procedures are evaluated against model output statistics (MOS) procedures that have been promoted as a means of adjusting for RCM error and for further downscaling the RCM output to a finer spatial scale. The evaluation focuses on the 'added value' of the MOS procedures over simpler, less time consuming bias correction options. The results of these analyses inform stakeholders on necessary steps before employing climate projections obtained from RCM simulations in assessments of the potential impacts of climate change on agriculture.

Impacts of precipitation variability on agricultural vegetation in sub-Saharan Africa

Susanne Rolinski (Potsdam-Institute for Climate Impact Research), Katharina Waha (Potsdam-Institute for Climate Impact Research), Christoph Müller (Potsdam-Institute for Climate Impact Research)

Projections from global circulation models (GCMs) are widely used to assess the impact of climate change on the agricultural sector in sub-Saharan Africa (Jones & Thornton,

2003; Liu et al., 2008; Müller et al., 2011; Schlenker & Lobell, 2010). Although GCM projections agree in the level of median temperature increase of 3 to 4°C in 2090s compared to 1990s in the A1B projections (Christensen et al., 2007) they project very different precipitation patterns in various regions of sub-Saharan Africa due to a large variety in model setting, originating from models resolution and model physics, affecting e.g. the occurrence of convection or the vertical transport of moisture in the tropics (Lin, 2007). There is some consistency between GCMs with respect to projected increase of annual precipitation amount in East Africa and a drying in southern Africa. As farming in many regions of sub-Saharan Africa is closely linked to the occurrence of sufficient rainfall, the length and precipitation of the rainy season very much influence the crop productivity and reachable harvest in a region. Crop failure frequently occurs due to high water stress leading to low grain yield in case of an unusual delayed onset or early break of the rainy season if farmers' cultivation methods are not adapted to these variable conditions. This study focuses on the impact of changing precipitation variability on crop productivity by analysing changes in the wet season length and the precipitation amount in the wet season projected from 14 GCMs for the SRES A1b and transferred to three stylized precipitation experiments. We analyse the stress potential of these changes for growth and productivity of ten food crops grown in sub-Saharan Africa using the global dynamic vegetation model LPJmL (Bondeau et al., 2007; Gerten et al., 2004). The aim is to identify their magnitude and importance for future food production in sub-Saharan Africa. Results show that most parts of sub-Saharan Africa will experience decreases in both, the length of the rainy season and the amount of precipitation in the rainy season of up to 20% (Figure 3). The precipitation sum and the length of the rainy season will decrease most severely in parts of the Sahel, Southern Africa and Central Africa. Overall average crop production in sub-Saharan Africa decreases whereas an increase in the mean annual surface temperature of one Kelvin has a stronger effect on the average crop production than a decrease in the wet season length of 30 days and a decrease in the wet season precipitation of 100mm. The precipitation effect in a precipitation experiment with decreasing wet season precipitation is stronger than in a precipitation experiments with a shorter rainy season and increased rainfall per rain day. In the latter precipitation experiment crop production decrease to a lesser extent and some regions even gain crop production increases like e.g. parts of Nigeria, Uganda or South Africa.

Climate Change Impact Assessments for International Market Systems: An Example for a Specialty Crop

Julie A. Winkler (Michigan University), Jeffrey Andresen (Michigan University), J. Roy Black (Michigan University), Geza Bujdoso (Research Institute for Fruit Growing), Frank-M. Chmielewski (Universität zu Berlin), Peter Hilsendegen (Rheinland-Pfalz, Dienstleistungszentrum Ländlicher Raum), Amy Iezzoni (Michigan University), Dieter Kirschke (Universität zu Berlin), Robert Kurlus (Poznan University), Malgorzata Liszewska (Interdisciplinary Centre for Mathematical and Computational Modelling), Scott Loveridge (Michigan University), Tadeusz Niedzwiedz (University of Silesia), Denys Nizalov (Kyiv Economics Institute), Nikki Rothwell (Northwest Michigan Horticultural Research Center), Pang-Ning Tan (Michigan University), Suzanne Thornsby (USDA Economic Research Service), Zbigniew Ustrnul (University Krakow), Harald von Witzke (University of Berlin), Mollie Woods (Michigan University), Costanza Zavalloni (University of Udine), Jinhua Zhao (Michigan University), Sharon Zhong (Michigan University)

The vast majority of climate change impact assessments evaluate how local or regional systems and processes may be affected by a future climate. Alternative strategies that extend beyond the local or regional scale are needed when assessing the potential impacts of climate change on international market systems, including agricultural commodities. These industries have multiple production regions that are distributed worldwide and are likely to be differentially impacted by climate change. Furthermore, for many industries and market systems, especially those with long-term climate-dependent investments, temporal dynamics need to be incorporated into the assessment process, including changing patterns of international trade, consumption and production, and evolving adaptation strategies by industry stakeholder groups. A framework for conducting climate change assessments for international market systems, developed as part of the CLIMARK (Climate Change and International Markets) project is outlined, and progress toward applying the framework for an impact assessment for the international tart cherry industry is described. The tart cherry industry was selected for analysis in part because tart cherries are a perennial crop requiring long-term investments by the producer. Returns are not realized until 3-6 years after initial investments and capital recovery can take as long as 25 years. The key climate-limiting factor in production is the frequency and magnitude of spring freeze events after the crop has broken its protective winter dormancy. The sequence of unusual early spring warmth followed by freezing temperatures can be particularly damaging. Currently most production is concentrated in central Europe and the Great Lakes region of the United States. The tart cherry industry is at very different stages of development depending on production region, and, although cherry varieties in the growing regions are somewhat similar, they are not perfect substitutes for each other given differences such as taste, color, and size. The CLIMARK research team includes geographers, climatologists, computer scientists, horticulturalists,

and economists from current major production regions and from areas with potential for increased future production. Components of the project include the preparation of fine resolution climate scenarios, evaluation of phenological models for diverse production regions, the development of a yield model for tart cherry production, new methods for incorporating individual decision making and adaptation options into impact assessments, and modification of international trade models for use in impact studies. The transdisciplinary nature and global scale of this effort synergize to provide a more comprehensive and integrated evaluation of climate change impacts and an assessment product of greater utility to industry stakeholders.

C08.04-11 - Potential Impacts of Climate Variability and Change on Agriculture: Changes in Productivity 3

Chair: Julie A. Winkler

Simulation of the Impacts of Climate Variability and Change on Sour Cherry Production

Jeff Andresen (Michigan University), Roy Black (Michigan University), Geza Bujdosó (Research Institute for Fruit Growing), Frank-M. Chmielewski (Universität zu Berlin), Robert Kurlus (Poznan University), Philipp Matzneller (Humboldt University Berlin), Tadeusz Niedzwiedz (University of Silesia), Denys Nizalov (Kyiv Economics Institute), Nikki Rothwell (Northwest Michigan Horticultural Research Center), Greg Soter (Michigan University), Costanza Zavalloni (University of Udine)

While the potential impacts of climatic variability and change on agronomic productivity have been investigated for many major cereal and oilseed crops, the effects on specialty crops have been less well documented. Impact assessment of specialty crops is complicated by the relatively high level of management required in commercial production systems, the necessary consideration of both crop quality and quantity, the localized geographical nature of production areas and, in the case of tree fruit production systems, to the longer term perennial nature of the crop and to the complex topography and terrain typically utilized for production and associated array of diverse microclimates. As a part of the CLIMARK research project investigating the impacts of climate change on the global marketing system of a specialty fruit crop commodity, a system of models was developed to quantify the spatial and temporal impacts of climate variability and change on sour cherry production in major production areas of Europe and the USA. The most important climate-related factor involved in sour cherry production is the loss or damage of bud tissue resulting from cold injury, which can occur in fall, prior to dormancy, in midwinter, during dormancy, or in spring, during and after budbreak of the crop. The yield model developed for this project simulates cold injury as a function of crop phenological stage and accounts for the impacts of weather conditions during the pollination period and during the previous season. The modeling system estimates regional yields based on gridded historical climate data from NLDAS2 and PRISM for the 1979-2010 period at spatial resolutions varying from 4-14 km. This paper will focus on the general development of the regional yield model as well as identification of spatial and temporal trends in productivity associated with climate.

Agricultural productivity in Oltenia Plain, South West Romania.

Investigations for climate change adaptation measures

Monica Dumitrascu (Romanian Academy), Diana Dogaru (Romanian Academy)

Agriculture is one of the most vulnerable sector to climate change and variability, thus requiring in-depth investigations on crop efficiency measures and adaptation support strategies. Impact studies are of increasing relevance for water and food policy and decision making at various levels by providing estimations with the use of robust models, both crop growth and regional climatic models, on yields, water necessity and water - food relationships. In this sense, a systematic tool that analyses the crop productivity in terms of land and plant physical and environmental characteristics, as well as agricultural management practices could be is very useful. GEPIC model, developed by a research team at EAWAG, Switzerland, is a GIS-based EPIC model (Environmental/Policy Integrated Climate Model) that integrates a crop growth model with a Geographic Information System using a series of spatial and ancillary data sets. The objective of the present study is to estimate wheat yield and, subsequently, the water supply for irrigation in the Oltenia Plain, SW Romania, under current and future climatic conditions. The Oltenia Plain, SW Romania (about 8,000 sq km), is an important agriculture region of the country affected by drought and desertification. A productive agriculture in this region is possible through efficient use of the irrigations. The crop yield simulations in this study are realized by applying the GEPIC model at a high spatial resolution (~ 100 m). The input data required by the model are: daily climate data (precipitation and temperatures), geographical data (location data, slope data, DEM), soil data (depth, bulk density, percent of sand, percent of silt, pH, organic carbon content), land use, plant parameters and management data (irrigation and fertilizer application). Regional climate models developed within the framework of the CC-Waters project (www.ccwaters.eu) are used for acquiring the future climatic parameters for 2050 and 2100 time horizons. The simulation results are expected to provide valuable information for the improvement of irrigation and fertilizer management, having in view the emergent need to take into consideration measures for crop efficiency and water use. Acknowledgments. This paper was developed in the framework of FP7 - Building Capacity for Black Sea Catchment Observation and Assessment System supporting Sustainable Development (enviroGRIDS); <http://www.envirogrids.net/>.

The study of drought effect on yield changes of olive product in Roudbar of Gilan, Iran, South Western of Caspian Sea

Bahman Ramezani Gourabi (Azad University)

The aim of this research is appointment of drought connection with amount of olive production in Roudbar Township as a presentable species. To this intention, extracted the dry and wet years with using of standard precipitation index (SPI). Statistical activities were done by Access and Excel software's and needy maps was drawn with using of Arc

GIS. The result shows, this township in 1386-87 and 1372-73 years with drought and wettest tern, has been encountered, in order. Therefore, between amount of product and relationship between two variable, is significant; as the least amount of produce is belong to 1386-87 year with 3294 Ton, 6270 hectare and the greatest is belong 1372-73 year, with 6200 Ton and 2149 hectares. Keywords: SPI index, drought, olive, roudbar.

C08.04-12 - Potential Impacts of Climate Variability and Change on Agriculture: Economic Considerations 4

Chair: Julie A. Winkler

A multi-scale analysis of the impacts of climate variability on Mexican maize crops

Candida Dewes (University of California)

My dissertation research evaluates climate variability in Mexico and its impacts on maize crops. Extreme weather and climate events are the main environmental cause of major crop failures. Throughout the maize growing cycle, each stage presents different tolerance levels for extreme environmental conditions, and farmers have adapted their practices in order to minimize the exposure to climate hazards. Flooding due to extreme precipitation is hazardous in early stages, when new plants require very little water to grow. During mid-season the water requirements are high, and the occurrence of dry spells associated with very warm days create a high risk of crop moisture stress. Towards the harvesting stage, frost events can be hazardous to the point of ruining a year-long investment. Maize is one of the most important crops in Mexico, being cultivated at many scales in both commercial and traditional sectors. Using precipitation and temperature data interpolated from the Mexican meteorological station network, I defined seasonal and annual indices of extreme weather and climate events for the period 1950-2008. The climate indices were averaged over each state in which the warm season rainfed planting regime is dominant. Crop reports of area planted, area harvested, and yields exist at the state level from 1980 to 2008. A canonical correlation analysis will be performed within the overlapping period to distinguish the climate factors that most contribute to the variability in crop yields, and to detect a potential spatial dependence of this influence. Parallel to this interannual variability analysis, a different approach is employed to analyze climate impacts on the maize growth cycle. By focusing on a shorter time period and higher spatial resolution, I evaluate what effects the seasonal climate conditions and the occurrence of extreme events on each crop development stage might have had on the season's final yield. In this section, municipal crop data for years 2005-2008 are used to estimate the timing of development stages. Since planting and harvesting dates can be approximated to the month, the average 4-8 month duration of the planting season can be placed relative to the rainy season. I will test whether the starting date of the rainy season can serve as a proxy for the planting date, and whether the measure of growing degree days (as a function of daily temperature) can serve as a proxy for growing season length. The crop specific moisture requirement curve (Kc) will be used to define the timing of four main development stages. Climate conditions specific to each stage will be assessed and compared to the final crop outcome. The 2005-2008 base-period will be used to validate these assumptions over municipalities with dominant rainfed production. If the model is proved acceptable, I hope to extend the analysis of

intraseasonal climate conditions to the 1980-2008 period, and compare with crop outcomes at the state level.

Who Should Pay for Climate Change Adaptation in Agriculture? Which Crops? How Much?

Scott Loveridge (Michigan University), Ge Eu Lee (Michigan University), Julie A. Winkler (Michigan University)

With public and scientific opinion on climate change diverging, it has become apparent that public opinion will play a major part in determining future scenarios for climate adaptation in the agricultural sector. Public funding may be needed to develop crop varieties adapted to the new climate conditions. While others are measuring overall public attitudes around the issue, we are not aware of any efforts to look specifically at the single sector most likely to be directly impacted by the changes: agriculture. We report on results of a telephone survey administered to adult residents of the State of Michigan (USA) in 2012. Roughly 1,000 households respond to questions about whether national or state government should finance agricultural adaptation. Furthermore, we explore the extent to which the type of crop makes a difference. Michigan is a good test case for this work as it produces many fruits and vegetables that are strongly identified with the growing preference for 'local' foods, as well as basic staple crops that do not typically carry as strong regional association (corn and soybeans). We test whether the public's willingness to support state initiatives varies by crop type. We also explore differences in opinions across six sub-state regions. Finally, we report on measures of willingness to pay.

Concept of a Profitability Model for Ecological-Economical Assessment

Sabrina Plegnière (Universität Trier), Markus Casper (Universität Trier)

The consequences of climate variability and change will concern the ecological and economical components of agriculture. On the ecological side climate change will influence plant growth and yield; on the economical side, it will change cultivation technique as well as profit. There is a close relationship between the ecological and the economical side. Changes in plant growth and yield automatically influence the cultivation method and in consequence the profit. Therefore a concept of a profitability model will be presented which couples economical and ecological aspects of an agriculture system. First, simulations with a plant growth model (simulateur multidisciplinaire pour les cultures standard = STICS) shall give information about the impacts of the ecological side by running the model with different climates for the same crops or crop rotations. In addition, the influences of the soil and cultivation method on yield will be examined in the simulations with STICS. Next step is to obtain details about how sustainable the crop has been cultivated. This can be deduced from the emission of e.g. nitrate which can be calculated by the model. The results of this simulations are the basis for creating a

production and cost function. This function will give information about the effects from the ecological on the economical scope as well as the monetary assessment of every part of the production and the profit. Finally, the integrated assessment enables us to evaluate cultivation methods or adaption options, provide information about the profitability and estimate how sustainable crop can be cultivated in due consideration of climate, soil, cultivation, crop and spatial variability. With this innovative model it will be possible for the first time to assess sustainability or the environmental impact on profitability.

Uncertainty and Hysteresis in Adapting to Global Climate Change

Jinhua Zhao (Michigan University)

Global climate change is one of the greatest environmental challenges facing the civilization, and despite efforts in mitigating emissions of greenhouse gases (GHGs), global temperature is likely to rise, possibly significantly (IPCC 2007 Synthesis Report). Climate change is characterized by several features that distinguish it from other environmental problems, including high degrees of uncertainties in assessing its impacts, the global nature of the public goods problem, and the scale of activities needed in adapting to the change. I argue that the process of adapting to climate change is defined to a large extent by uncertainties, transaction costs, and hysteresis. I then present a framework to evaluate the role of uncertainties and information in adapting to climate change, and apply the framework to farmers' land use decisions such as switching between annual crops and perennial crops (e.g., energy crops) and switching from fruit trees to real estate. In this paper, adaptation is defined as a set of activities that reflect major changes in resource allocation in response to large scale and long-term environmental changes. It includes mitigation activities, technological and institutional innovation and adoption, and environmentally driven mass migration. These adaptation activities share several common features: high degrees of uncertainties in the associated costs and benefits, significant sunk costs that are hard to be recouped if the activities fail to generate the expected benefits, and the opportunities of learning about these uncertainties. Under these conditions, a rational decision maker has incentive to delay the adoption of adaptation activities until more information is gathered, to avoid the expected loss from incurring the sunk costs if the activities turn out to be ineffective. This kind of hysteresis is optimal when individual decisions have no externalities, but when information is shared and there is learning from others, the delay in adaptation is socially suboptimal. I then apply the framework to study farmers' land use decisions. In one study, farmers make decisions to grow dedicated energy crops (e.g., switchgrass) that have lower carbon footprints as a regional mitigation strategy. The expected return from the energy crop has to be significantly higher than that from traditional annual crops (e.g., corn) in order for the farmer to switch to the energy crop. This is the case even when two way conversions are allowed. Policies that are intended to encourage energy crop production might in fact lead to lower acreage in energy crops under this setting. In another study, farmers face both continuous and discrete (large scale) shocks, and we study how these

shocks affect farmer decisions to abandon fruit trees. Finally, I discuss approaches to overcome the hysteresis and to promote the adoption of adaption strategies.

Evolution des îlots de chaleur (ICU) de grandes agglomérations urbaines françaises (1951-2010)

Annick Douguedroit (Université de Provence)

Le nombre de grandes agglomérations urbaines françaises dont il est possible de donner une estimation de l'évolution des îlots de chaleur urbains est réduit par le manque de données de température adéquates. Les principales retenues ici sont les agglomérations parisiennes, toulousaines, bordelaises et strasbourgeoises auxquelles certains résultats d'autres agglomérations, marseillaise, niçoise..., sont comparés. Comme on pouvait s'y attendre l'évolution des températures minimales et maximales de chaque station n'est pas symétrique dans chaque station et agglomération, induisant une variation de leurs écarts dans le temps. Elle diffère également entre stations de référence, de banlieue et de centre-ville. Les premières ont de faibles évolutions marquées par la distinction entre deux périodes successives, avant et après les années 70, plus nette pour les maxima que les minima et que l'on ne retrouve pas, en général, en ville. Les évolutions intra-urbaines diffèrent également dans les banlieues en rapport avec la date de l'intégration par l'urbanisation des environs de la station à l'ICU de la ville voisine. La plupart des stations de banlieue sont situées dans des zones d'urbanisation des années 1970-80. Les centres-villes, de type « centre ancien », les espaces à grattes-ciels de Paris n'étant pas représentés par aucune station, présentent deux types d'évolution de leurs températures minimales dans les premières décennies, soit stagnantes soit en hausse, en relation avec leur localisation géographique, intérieure ou littorale, associée à l'évolution démographique de l'agglomération urbaine. En conclusion l'évolution des températures, en particulier les minimales qui sont les considérées comme les plus représentatives des ICU, n'est pas identique à l'intérieur de toutes les agglomérations. Elle est partout représentée par une augmentation, sans que, ce qui peut paraître paradoxal, cette dernière ne soit pas la plus rapide dans l'agglomération la plus grande, et de beaucoup, la parisienne. Mais les écarts entre station de référence et centre-ville y sont plus élevés que dans les agglomérations inférieures au million d'habitants.

Urban Climate and Environmental Changes in the Brazilian Context: Risk, Vulnerability and Mitigation

Antonio Carlos Oscar Júnior (UFRJ)

This paper proposes to examine the process of construction of the urban environment of the municipality of Duque de Caxias (Rio de Janeiro - Brazil) has contributed to changes in climate parameters, favoring the occurrence of urban problems such as thermal discomfort, heat islands, flooding and pollution. Such problems, mainly due to the

rapid and uncontrolled growth, coupled with social vulnerabilities, configure a perfect setting for the modifications of the physical and natural elements, thus creating serious risks to the population. To ascertain the climatic changes by which the municipality has passed, we will analyze the thermal and rain parameters. The analysis will be based on data from weather stations of São Bento (1949-1970) of Xerém (1920 to 1970). Through SIG's use of LANDSAT satellite imagery will be made "maps of land uses and thermal. It is hoped that this study emphasize the importance of addressing the climate in spatial and urban planning and management as well as in the vulnerability of urban populations in the face of climatic phenomena. It has been an ever-present reality in the life of the city. Some results can be pointed, such as the tendency of temperature increase from 1940, a time of significant urbanization of the study area; Considerable increase in the contribution of atmospheric pollutants, reflecting the health of the population; Finally, the space redefinition rainfall trend in the area of study.

Urban form influencing the surface urban heat island

Nina Schwarz (Helmholtz Centre for Environmental Research)

The urban heat island is the phenomenon of altered temperatures in urban areas compared to their rural hinterlands. The surface urban heat island (SUHI) describes these temperature patterns with remotely sensed land surface temperatures. The SUHI is an indicator for a spatially explicit description of the urban climate and is very important in the light of climate change, likely inducing rising mean temperatures and more frequent heat waves. Measures to adapt cities to climate change also include spatial planning and climate-proof design of cities. Protecting and/or creating more green urban areas or water surfaces are frequently discussed and alter the spatial configuration of cities. Thus, it is essential to analyse the influence of the overall spatial structure of cities onto the SUHI. Therefore, the present study investigates the effect of urban form on the extent of the SUHI for European cities. The dataset used here combines different data sources: (1) SUHIs are quantified with MODIS monthly land surface temperature data products for summer 2001. (2) Urban form is analysed with the help of landscape metrics based upon CORINE land cover data. (3) Urban regions are defined as European Larger Urban Zones, proposed by Eurostat and the Urban Audit initiative. (4) Meteorological and climatological factors (precipitation, thermal climate zone) as well as topography (elevation, distance to coast) are controlled. A statistical analysis is used to quantify the influence of urban form onto the SUHI in European Larger Urban Zones when controlling for overall climate and topography. The results will insights into the relationship of the spatial form of a city and its SUHI. Implications for spatial planning will be discussed.

Seasonal variation in cool island effect of two urban green spaces

Shogo Shimizu (Tokyo University), Hideo Takahashi (Tokyo University)

High temperatures caused by urban heat islands have become an environmental problem in urban areas. Green space within such regions creates a low-temperature area known as a cool island. Previous studies indicate that the temperature in such a green space is lower by several degrees Celsius than that in its surrounding area. In clear calm midnight conditions, cooler air in the green space flows out of the space (Narita et al., 2004). Thus, cool islands are an important element in the mitigation of heat. This study focuses on seasonal variation in the cool island effect of urban green spaces and differences in the effect at different green spaces. Few studies have documented the year-round cool island effect of urban green spaces (Narita, 1997; Sugawara et al., 2006). Since all previous studies were performed in only one green space, differences among green spaces are not known. In this study, year-round temperature variation within and in the vicinity of two urban green spaces of different sizes in the Tokyo metropolitan area were observed. Observations were performed within and in the vicinity of Institute for Nature Study (20 ha) and Koishikawa Korakuen Garden (8 ha). Air temperature was measured at 10-min intervals at eight positions, four of which were located inside the green space and the other four were located outside the space at a distance of hundreds of meters from the green space boundary. The observation period was August 2007 to September 2008. Diurnal variation patterns of cool island intensity, defined by the difference between the average temperature of the green space (T_g) and the average temperature of its surrounding area (T_u), on fine days vary with season. In summer, daytime cool island intensity was larger than nighttime intensity, whereas it was the opposite in winter. In spring and autumn, diurnal variation of cool island intensity was smaller than that in summer and winter. The daytime cool island intensity in summer was larger than that in winter, because of (i) the sunshade effect of tree canopies and high transpiration rate from tree leaves in summer and (ii) leaf abscission in winter. The temperature difference between the green space and its surrounding area was almost 0°C in winter. On the contrary, the nighttime cool island intensity was constant throughout the year. Cool island intensity was greater on fine and calm days, when higher radiation cooling was expected. Among the two green spaces, the cool island intensity was greater in Institute for Nature Study than in Koishikawa Korakuen Garden on almost all days regardless of season. This may be because of the difference in the areas of the green spaces. In addition, the greater cool island intensity in Institute for Nature Study could be due to its higher tree density.

Assessing the standard and perception on visibility degradation of locals and tourists in Hong Kong

Pak Hong Yue (University of Hong Kong)

Studies all around the world had shown an increasing trend of visibility degradation in the recent decades. While the level of visibility has proven to be related to the pollutants level in the atmosphere, visibility degradation would be a signal for deteriorating air quality and potential threat to health of the locals. Hong Kong has long been famous for the fabulous vista viewing from the Peak, in year 2010, 28% out of more than 36 million tourists visited the Peak as one of their tourist spots. The blurring of vista caused by visibility degradation may harm their enjoyment and impact the economic activities as well as the chance of getting a return trip of these tourists. In this study, questionnaire, meteorological measurement will be applied to analyse the impact caused by visibility degradation of Hong Kong. The perception of visibility reduction of tourists and locals will be drawn out and examined to outline the factors affecting their choices of perception and their responses to the problems. Also, the study will try to deduce a perceived standard of visibility violation through photographic investigation. The justifications of air quality from tourists and locals are of paramount importance to Hong Kong. This study will be significant to give some insights for the government planner, tourist board and monitoring organization to develop a better regulation and standard for the visibility of Hong Kong while it will be the first time for Hong Kong to have study result of the perception of visibility impairment of both tourists and locals.

Space-based Technology for Water Security in Urban Area: A Case Study of Jaipur City in India

Kamal Narain Joshi (Institute of Development Studies)

Water security involves protection of vulnerable water systems, protection against water related hazards such as floods and droughts, sustainable development of water resources and safeguarding access to water functions and services. It is primarily concerned with human interventions in water systems. The unplanned growth of urban settlements and infrastructure development act as an obstacle in the path of water flow which ultimately hampers the recharge process of ground as well as surface water bodies in the area. This process has resulted in the conversion of water potential areas into water stress areas. Apart, the extensive damage to ecology and environment due to unplanned and un-managed industrial estate pollution, and un-appropriate use of land can also be seen in the urban areas and its periphery causing deterioration of water resources. As the urban areas spread, the natural hydrological features like rivers, nallah and water bodies

come in the heart of the city and people start encroaching upon them. It results in either completely or partly blocking of the system. Another important issue that many of the cities have experienced its expansion at the cost of flood risk, because they are settled in low-lying areas or along the river/nalla. These lands are often parts of some watersheds or catchments of the water bodies or rivers / nallas flowing in urban environs. Hence this process on one hand breaks the hydrological system and on other hand creates a permanent recurrent flood damage zone in the city area. The present paper provides an overview of some of the effects that land use have on water resource quality as well as quantity. The paper investigate the effects of land use change (from rural land use i.e. forest, agriculture, pastoral and culturable wasteland to urban land use) on water resources in Jaipur urban area. The remote sensing and GIS technique methodology have been adopted to map out the changes brought by human activities particularly in the field of haphazard growth of colonies, unscientific land use and encroachments etc. It also suggests alternative strategy or plan to solve the present problem.

Adapting Australian Cities to Climate Change: Current Urban Research in the Cooperative Research Centre for Water Sensitive Cities

Nigel Tapper (Monash University)

Links between population size, urban density, removal of storm water and the urban heat island (UHI) have been long established in the scientific literature. Typical maximum UHIs for large cities are of the same order of magnitude as projected warming in many regions during the 21st century, so a realistic concern is that urban consolidation with no consideration of the climatic effects of such a process will be problematic, particularly in the face of climate change; the so-called urban climate - climate change nexus. The message from this is that a holistic approach needs to be taken to matters involving urban design. In the case of urban consolidation a range of approaches known to reduce urban temperatures (green infrastructure, maintenance of water in the urban environment, smart building materials, etc) must be applied at the same time as the consolidation process. It must also be recognized that not all heat island mitigation approaches are appropriate in all urban environments. Under the auspices of the Cooperative Research Centre for Water Sensitive Cities at Monash University, Melbourne, multi-disciplinary research efforts are currently being devoted to, amongst other things, identifying what heat reduction strategies, particularly those associated with water in the environment, are best applied in a range of Australian climates. Actively pursuing heat reduction strategies in urban environments, where most of the global population live, and where temperatures are already elevated, might provide some "head room" to manage the increased temperatures associated with future climate change.

Analysis of Individual perception in extreme weather events survey

Yu-gyung Na (Kyung Hee University), Seung-won Han (Kyung Hee University), Won Do Lee (Kyung Hee University), Chang-Hyeon Joh (Kyung Hee University)

Climate change is highly important at the individual level in that it has been affecting individual life style through changing of perception (See Cantrill, 1992). Most of the climate change studies of prediction and management were conducted in Korea on the scientific and technological dimensions. Climatic uncertainty has however continuously increased in practice, and human adaptation to extreme weather events has changed in many directions in the context of perceptual changes. We should also consider perceptual change because climate change could lead to different results depending on the different social and cultural context even if it is concerned with the same risk (See Kim et al., 1995). The current research investigated Korean perceptions which are associated with extreme weather events in Korea. This is a preliminary empirical study that concerns social management under the rapid climate change such as extreme weather. Personality and geographical condition play the central role in our current perception study. Major finding is as in the following. First, this study carries out a survey of human cognitive abilities. Human cognitive process can be delayed, distorted and blocked against the input of new information of environmental changes. The analysis of the Korea National Statistical Office's environmental anxiety surveys in 2008 and 2010 shows that higher education group and younger people perceived the climate change more seriously. The level of details of environmental perception also varies with occupation groups. Human cognitive abilities associated with attitudes about responsibilities and adaptation. Second, responsibility and adaptation about extreme weather events are associated with environmental perception and spatial cognition. We surveyed people in Seoul to ask what people know about their neighborhood regarding environmental conditions, whether they accept environmental changes and how they would evaluate potential extreme weather. The survey was done for 4 weeks in January 2012 with questionnaire. The survey differs from conventional survey in the field in the sense that first we study extreme weather events based on the spatial perception and personal cognitive, and second we understand the adaptation behavior in response to the climate change at the individual level. Climate change risk management should take perception and cognition about the climate change into central account. The current study could provide the agent rules as the adaptation patterns reflected by individual perception. In the future research, the data and the results of the current study will be used for Agent-Based Model and Simulation (ABMS) studies. [*] This work was supported by the National Research Foundation of Korea Grant funded by the Korean Government (NRF-2010-330-B00278).

Climate change impact assessment in Hungarian landscapes

Burghard Meyer (Institute Geography Leipzig), Mezösi Gábor (University of Szeged), Peter Csorba (University of Debrecen)

The assessment of regional climate change (CC) impacts combined with landscape functions sensitivity by predictive modelling of hazardous landscape processes is a fundamental new field of research especially the investigating of the effects of changing weather extremes on meso-regional scale landscape vulnerability. The climatic exposure parameters analysis was made on predicted climate change scenario. On results of the meso-scaled IPCC A1B climate scenario of the models REMO and Aladin of the periods 2021-2050 and 2071-2100 exposure against CC have been analysed on the basis of the original data and regional types of climate change impacts have been calculated by using cluster analysis. The CC information of the climate exposure parameters of REMO and Aladin models are especially analysed for extreme events (days with precipitation higher than 30 mm, heat waves, dry periods, wet periods) and for the daily temperature and precipitation. The exposure of climate change parameters, cluster analysis and an interpretation of main recent and future problematic processes in Hungary by a set of landscape functional indicators are used to explore the regional sensitivity against for soil erosion by water, drought, wind erosion, mass movement and flash floods when analysing the time periods 1961-1990, 2021-2050 and 2071-2100. Basing on sensitivity thresholds risk impact assessments single landscape functional sensitivity indicators are interpreted and an integrative summarizing of the five indicators was made when differentiating the regions in regions facing only few or multiple risks. In central Hungary especially the increasing exposure and sensitivity to droughts risks will be a serious problem when following the REMO scenario. In several regions most of indicators will change the risk from a sensitivity threshold from a tolerable risk to an increased or a very high risk. Policy programmes and/ or the management of adaptive measures to reduce these vulnerability e.g. for the planning of land use systems, agriculture, forestry, water management, soil protection, settlements planning or nature conservation are suitable to develop an early adaptation reaction of society.

The important role of South-Pacific Convergence Zone in the El-Nino – Southern Oscillation Development

Vladimir Platonov (Moscow University)

The South-Pacific Convergence Zone (SPCZ) is the chief part of atmospheric circulation in tropical Pacific, and undergoes unprecedented displacements during the El-Nino - Southern Oscillation (ENSO) cycle. The SPCZ is shifting from the center of Pacific during the warm phase of ENSO to the eastern Australian coast during the cold phase. The areas of active tropical cyclogenesis genetically coupled with this zone undergo respective displacements. At the SPCZ converge two macro-scale currents of an opposite directions: easterly trade winds and equatorial westerly winds. This macro-scale convergence shift strongly to the east and lead to formation at the center of Pacific an extensive band of ascending movements during the warm ENSO phase (El-Nino) in the SPCZ system. Over Indonesia and Northern Australia, on the contrary, emerges the macro-scale divergence zone. Therefore, the water vapor is carrying, on the one hand, to Pacific, towards South America and, on the other hand, to Indian, towards Eastern Africa. This activation of SPCZ in the central Pacific is caused by intensive development of tropical cyclogenesis, involving rich tropical rains in uncharacteristic region. The well-known disastrous fires and droughts in Indonesia and Northern Australia during El-Nino are apparently the consequence of macro-scale divergence zone, mentioned above. During the cold ENSO Phase (La-Nina) the macro-scale atmospheric tropic circulation pattern changes considerably. The water vapor transport in these conditions to Indonesia and Northern Australia region as at trade winds circulation system from Pacific, so and at equatorial westerly winds system from Indian. This situation leads to generation of powerful South-Pacific Convergence Zone. This SPCZ during La-Nina is at most shifted to northeastern Australian coast at the expense of vigorous Pacific trade winds. This displacement of SPCZ to the Australian summer monsoon zone is namely one of reasons of abrupt activity of tropical cyclogenesis in this monsoon region. This activity is corresponding with a rich precipitation, storm winds and frequently dramatic floods. The striking example of these events is the most famous recent La-Nina 2010/11 accompanied with the destructive flood and, particularly, with the most vigorous tropical cyclone in Australian history, "Yasi".

Long-term trend of extreme precipitation in Southeast Asia

Jun Matsumoto (Tokyo University), Nobuhiko Endo (JAMSTEC/RIGC), Hoang Ahn Nguyen-Thi (Tokyo University), Tun Lwin (Myanmar Climate Change Watch)

Trends in precipitation extremes using daily precipitation data at more than 200 stations in the whole Southeast Asian countries are investigated for the period from the 1950s to the 2000s. Number of wet days, defined by a day with at least 1 mm of precipitation, tends to decrease over these countries, while average precipitation intensity of wet days shows an increasing trend. Heavy precipitation indices, which are defined by precipitation amount and percentile, demonstrate that the number of stations with significant upward trend is larger than that with significant downward trend. Heavy precipitation increases in southern Vietnam, northern part of Myanmar, and the Visayas and Luzon Islands in the Philippines, while it decreases in northern Vietnam. In Vietnam, the contribution of heavy precipitation caused by typhoons is examined, and found out that increasing trend of heavy precipitation in Central Vietnam is, at least partially caused by the increase of typhoon related heavy precipitation. Annual maximum number of consecutive dry days decreases in the region where winter monsoon precipitation dominates.

Extreme precipitation patterns in Wisconsin, USA during 1950-2006

Woonsup Choi (University of Wisconsin-Milwaukee)

The objective of the research is to examine temporal and spatial patterns of extreme precipitation in the State of Wisconsin, USA during 1950-2006. Specific research questions are (1) Which extreme precipitation indicators are increasing or decreasing and (2) To what extent are the spatial patterns of extreme precipitation changing. The data used were obtained from researchers at the University of Wisconsin Madison who produced them by interpolating weather stations data across the state to a grid mesh with a spatial resolution of 8 km. For extreme precipitation indicators, I calculated 99th, 95th, 90th, 85th, and 80th percentiles of daily total precipitation in a year, number of days per year with daily precipitation exceeding 10 mm, 20 mm, and 50 mm, and the annual frequency of 1-year duration, 1-year return period events. I conducted the Mann-Kendall test for trend and calculated Sen's slope for the indicators. In addition, I calculated decadal means of the indicators and their Moran's I values for spatial autocorrelation. The results are summarized as follows: (1) Significant trends are generally found in the western and southern parts of the state; (2) The western and southeastern parts of the state tend to show steep slopes of extreme precipitation indicators; (3) Spatial autocorrelation is the lowest during the 1980s, but is significant for all indicators across the time period; and (4) Some indicators are noticeably different between the upwind and downwind sides of the metropolitan Milwaukee area. Overall, the results are in line with national-scale assessments, while revealing more details. Striking differences were found in many indicators between the 1980s and the 1990s. The trend during the 1990s deviates most from the national trend and requires further investigation.

Extreme atmospheric precipitation causing floods in the Polish Carpathians and their synoptic determinants

Agnieszka Wypych (Jagiellonian University), Zbigniew Ustrnul (University Krakow)

Floods and elevated water levels are the most important extreme weather events in Central Europe in terms of frequency and economic losses. The two basic flood types are snowmelt floods and continuous rainfall floods. The largest floods in Poland and across Central Europe are caused by continuous rainfall. The purpose of the paper is to evaluate regional extreme precipitation events in the Polish Carpathian Mountains taking place over the course of the last several decades as well as to determine the circulation basis for these events. Given that most extreme precipitation events cause floods and elevated water levels, one purpose of the paper is to describe the circulation determinants of floods and elevated water levels. The Carpathian region in Poland is the primary source area of dangerous floods in Poland. Extreme precipitation values were identified based on daily atmospheric precipitation totals measured at 14 weather stations in the Polish Carpathians between 1951 and 2010. The analysis looks at mean daily areal precipitation totals in excess of 100 mm per day as well as 50 mm over the course of two or three days of continuous precipitation, which causes flooding in the Carpathians. Both types of data sets were analyzed independently based on a variety of historical materials, some also covering the 1st part of the 21st century. The study analyzes long-term variability in flooding patterns. All extreme precipitation data were analyzed from a synoptic perspective, with special attention being paid to pressure patterns over Central Europe. Several circulation calendars were also consulted. The second part of the paper discussed in detail the meteorological causes of extreme flooding events of July 1997, July 2001, and May 2010.

Coastal Systems

C08.05-01 - Coastal Systems - Beaches and dunes

Chair: Norbert P. Psuty, Edward Anthony

Mid-late Holocene coastal forcing variability as a possible cause of alternating drift- and swash-aligned gravel beach ridges in the Atlantic province of Tierra del Fuego, Argentina

Julian Orford (Queen's University), Gustavo Bujalesky (CONICET), Alejandro Montes (CONICET)

The nature of drift-aligned and swash-aligned coastal accumulation forms have been considered for some decades, as being a product of changing longshore sediment supply: with sediment-rich supply forcing drift-aligned ridges and sediment-poor supply forcing swash-aligned ridges. In recent work on gravel dominated barriers around the mid-latitude North Atlantic (Orford et al, 1996, 2002, and 2007) the paraglacial reworking of limited point sources of glacialic gravel sediments has been shown to account for the significant realisation over time of swash-aligned barriers, compared to decreasing presence of drift-aligned barriers. This is linked to diminishing sediment supply with, as a consequence, increasing cannibalisation of beach ridge sections, linking the transition from drift to swash-alignment. The questions remain as to i) whether this barrier transition is dominated by drift to swash status and ii) whether it is always a function of sediment supply? Is it feasible for forcing conditions (wave climate) to account for this transition, and thereby for a reverse transition to occur? These two questions have been considered in the context of a substantial late Holocene, mixed drift and swash aligned beach ridge series in the macro-tidal San Sebastian Bay, eastern Tierra del Fuego (Isla and Bujalesky, 2000). We consider through a 14C dated ridge sequence the controlling factors by which a prograded, interdigitated drift and swash-aligned gravel beach ridge series (still operating at present) may have been generated. Given the constancy of gravel-rich sediment supply (?), the possibilities of millennium periodic shifts in the interaction between Southern Hemisphere westerly winds (offshore) and incident northeasterly waves is considered as a possible generator of alternation of these characteristic coastal forms.

Short-term evolution of a reflective beach sector in front of a coastal lagoon (Southwest Portuguese coast)

Cristina Gama (Universidade de Évora), Luís Albardeiro (Universidade de Évora), José Jacob (Universidade do Algarve), Isabel Pinheiro (Administração da Região Hidrográfica do Alentejo)

The subaerial beach act as detrital barriers in the opening and closing of lagoons located in sandy coastal areas. The study of beach morphodynamics, considering the

evolution of the beachface and the berm, in these cases is critical to coastal management. The studied area located in an embayed sandy coastline at the Portuguese Southwest Atlantic Coast, is a 308m long subaerial, coarse to very coarse, sandy beach adjacent to the Melides lagoon entrance. In order to characterize the morphodynamics of the study area under the effects of storms (pre and post-storm) and tides (spring and neap tides) during a period of one year (April 2010 to April 2011), 26 field surveys were conducted. A survey grid with an alongshore length of 308m and a width of 14-40m defined between the lower limit of the beachface and the backshore limit (entrance of the coastal lagoon or frontal dune) was used. We performed 12 cross-shore profiles 40m apart from each other. The alongshore profiles describes the main topographic variations (e.g. top of the beachface, berms elevation, beach cusps definition). Horizontal and vertical positioning was provided by Real-Time Kinematics (RTK) GPS. The results obtained allowed to develop high resolution Digital Elevation Models (DEM) using the ArcGIS software. DEM models were used to describe beach morphological changes. The nearshore wave characteristics were described by the SWAN wave model considering as boundary conditions the wave data recorded at the Sines wave rider buoy. The run-up levels were calculated using the wave parameters and the beachface slope (0.12 to 0.18). During the study period were documented two episodes of opening and closing of the Melides lagoon due to storms effect, and one artificial opening episode. A conceptual model for the reconstruction of the sandy beach detrital barrier that controls the opening and closing of the lagoon was performed. This study shows that the evolution of the sandy beach detrital barrier is characterized by a cyclical behaviour of recovery marked by the occurrence of storms. The developed conceptual model is characterized by rapid sediment transport between the submarine beach and the beachface. The incidence of more energetic storms ($H_s=5m$) induces the destruction of the sandy beach detrital barrier leaving open the Melides lagoon to the Atlantic Ocean. Due to storms the beach profile is destroyed and about $1.9 \times 10^3 m^3$ of sand is remobilized above -0.5m (MSL). Beach recovers much of its original morphology and sediment volume 10-12 days after the storm. At the stage of equilibrium, the sandy beach detrital barrier presents a wide berm (35 m), a berm with an elevation close to 5m (MSL) and a reflective beachface. This study was funded by the Administração da Região Hidrográfica do Alentejo (ARH). Bathymetric source was provided by GEBCO_08Grid and the wave data by the Instituto Hidrográfico (Portugal) web site.

Morphodynamics of two microtidal contrasting beaches with intertidal bar morphology: Lido di Dante, Northern Adriatic Sea

Mouncef Sedrati (University of South Brittany), Paolo Ciavola (University of Ferrara), Johan Reyns (UNESCO-IHE Institute for Water Education, Core of Coastal Engineering and Port Development), Clara Armaroli (Università di Ferrara), Vincent Sipka (Université du Littoral Côte d'Opale)

The morphology and hydrodynamics of two contrasting (protected and natural) microtidal beaches of Lido di Dante, Northern Italy, were synchronously surveyed during medium to low-wave energy conditions in order to assess cross-shore and longshore intertidal bar mobility and to examine the influence of Low Crested Structures (LCS) and groin system on wave transmission, and consequently, on the morphodynamics of the protected beach relative to the morphodynamics of the natural beach. Lido di Dante is a small seaside resort in the Northern Adriatic Sea, 7 km from the town of Ravenna. The beach features two different sectors: the Northern one was subjected to erosion and therefore it has been protected by groins, nourishment and a semi-submerged breakwater (LCS); the Southern sector, in a natural state, is also under erosion and is backed by a dune system. A field experiment was undertaken during five days in May 2008 (10 tidal cycles, starting at Spring tide conditions), and involved the monitoring of the morphological changes on both sites during each low tide for the protected beach and each day-light low tide for the natural site (five profiles spaced every 10 m in both beaches). The hydrodynamic measurements for the protected beach were made from two instrument deployments along the central transect using self-recording equipment. A similar deployment was realised at the natural beach and a fifth currentmeter was installed outside the protected area (between the two beaches) with similar deployment characteristics as the first ones. During the first three tides, the offshore wave conditions were relatively more energetic, with $H_s \sim 0.5$ m while low wave conditions with $H_s < 0.3$ m prevailed during the rest of the campaign. The structures' protecting the northern site seems to play a significant role in wave energy dissipation in any wave-energy condition and the waves lost up to 70 % of their energy during the propagation over the LCS. The upper swash bar morphodynamics on both beaches exhibited an important dependency on tide-modulated swash processes and the variation in the rate of morphological response between the both sites can probably be attributed to the role played by the upper beach gradient in controlling bar migration. However, the lower swash bar on the natural beach highlights, on one hand, the landward swash bar migration under slack water conditions in a microtidal barred beach. On other hand, it also showed a longshore migration processes related to the significant alongshore component which was absent in the protected beach. These facts elucidate the difficulty to relate intertidal bar morphologies on the protected and natural beaches with a single hydrodynamic process and/or mechanism, and the complex relationship between tide-wave processes and wave attenuation caused by coastal protection structures. The morphodynamics of an embayed beach-dune system, Essaouira, Morocco: Implications for reasoned management.

Abdel Elmimouni (Université Marrakech), Edward Anthony (Aix-Marseille Univ), Lahcen Daoudi (Université Cadi Ayyad)

Essaouira beach borders a renowned and densely populated bay on the Atlantic coast of Morocco characterised by a complex and fragile dune environment that is presently in a state of geomorphic equilibrium. The processes prevailing in the bay, under the triple command of a constantly active wind regime, waves from the Atlantic, and to a lesser extent, tides, vary considerably in time and space, and could be durably modified in the future under growing human pressures and unreasonable planning. In order to understand the morphodynamics of this beach-dune system and of the nearshore zone, several field experiments, involving topographic, hydrodynamic and grain-size monitoring, were carried out. The experiments were aimed at highlighting seasonal, intra-annual and monthly patterns of evolution of the beach, especially under the influence of a nearby wadi, the Ksob, which is the main sediment purveyor of the beach. An additional objective of the study was also to monitor variations in the beach sediment budget following a major wadi flooding event. The hydrodynamic measurements involved wave and current parameters and were analysed in the light of the marked changes in wind intensity affecting the area. The currents flow dominantly alongshore to the south and southwest north and south of the bay, and exhibit bi-directional flow along the bay beach under both calm and high-energy conditions. The latter bay currents are more pronounced during high-energy conditions. The topographic data highlight longshore and cross-shore variations in beach morphology and their spatio-temporal changes. Essaouira bay comprises a complex beach-dune sediment cell composed of several micro-cells. The Ksob plays an important role in the dynamics of these cells. The dominant winds from the north transport significant quantities of sand to the south in the form of barkhanes that are trapped in the estuary of the Ksob. During river flood events, these sands, as well as fresh inputs brought in by the wadi, are injected in the nearshore zone of Essaouira bay, and are subsequently redistributed onshore, and along the beach by tidal currents and currents generated by refracted swell. A planned resort construction in the Ksob estuary as well as the projected new Zerrar dam 30 km upstream of the bay could result in serious disequilibrium of the fragile sedimentary system of the bay. Keywords: beach-dune morphodynamics, hydrodynamics, erosion, sediment supply, wadi, river flood, coastal resort, coastal management, Essaouira bay, Morocco.

Spatial high resolution methodology for erosion risk assessment in a short coastal stretch

José Pinho (University of Minho), Helena Granja (University of Minho)

Erosion in low-lying sandy beaches acquires a special importance in the context of urban planning once this kind of beaches constitute the first barrier (buffer) against a dynamic ocean with a varying water level that in most cases constitute a threat to people and infrastructures. Different erosion risk assessment methodologies have been applied around the world, in an attempt to classify the coastal areas according to their response patterns to erosion and to evaluate eventual damages to the natural and constructed coastal heritage. In this work, field data and model outputs were integrated, processed and analyzed in a GIS in order to assess the vulnerability to erosion and to produce the associated risk maps using a multi-criteria assessment approach. Followed methodology was developed based on morphological, hydrodynamic, meteorological and other indicators that were quantified using data and results obtained from a short term monitoring program. It was based on previously developed works, but specifically adapted to the local characteristics of a short coastal stretch on the NW coastal zone of Portugal. Comparing this methodology to the previously developed ones, there are four main distinguishing aspects to be considered: (i) a spatial high resolution data base was used to compute vulnerability and impact indicators (ii) the coastal stretch was segmented for quantification of (vulnerability, impact and risk) indexes, accordingly to specific coastal types, obtained by a judicious delimitation based on the beach-dunes-urban front main characteristics, next to human occupation and administrative boundaries; (iii) a new set of vulnerability variables is proposed; and (iv) erosion impact variables resulted from a detailed quantification of the existing building and beach (not building) areas extracted from aerial photos. In a first phase, a base line was defined, delimiting areas that were strongly occupied from those that have capabilities to adapt to the effects of natural phenomena produced mainly by winds and waves. The stretch was divided into elementary segments considering typology, administrative boundaries and human occupation. For each segment a set of vulnerability indicators was quantified: coastal segment average elevation, width and slope, a volume rate computed using two DEMs obtained at different dates, a wave energy related indicator computed according to a wave propagation model, and the percentage of vegetated area. Buildings area in a buffer and the area occupied by sandy beaches in each segment were considered as impact indicators. The erosion risk index was finally computed based on two partial indexes: the vulnerability index and the impact index. Samples of the obtained erosion risk maps will be presented as well as samples of vulnerability and impact indicators maps.

These maps constitute a valuable database for coastal zone management and urban planning policies definition within the studied territory.

Impact of extreme storm events and resilience of gravel barriers: example of Sillon de Talbert (Brittany, France)

Pierre Stéphan (Laboratoire de Géographie Physique - CNRS)

This research concerns morphological impacts caused by extreme storm events on the evolution of Sillon de Talbert, a wash-aligned gravel spit located on the macro-tidal coast of the northern Brittany (France). The role played by overwash dynamic on gravel barrier rollover processes is analysed in two timescales. i) On a decadal timescale, the mobility of the barrier was studied by a set of aerial photographs taken from 1930 to 2002, associated with DGPS topographic surveys from 2002 to 2011. The photographs were numerised with high resolution to obtain a pixel size of 0.5 m. They were then rectified with ArcGIS® software based on the 2002 orthophoto mosaic by selecting a series of well-distributed control points and integrated into a geographic information system (GIS). The seaward limit of crest vegetation and the landward base of the barriers were used as shoreline markers. Errors related to image rectification and shoreline digitizing are always less than ± 1 m. Oceanographic data set was also analysed between 1979 and 2011. Predicted tide data were from SHOM tide model and surge data were obtained from Roscoff tide gauge. Wave data were obtained from Météo-France, CETMEF and LNHE-EDF wave data base on TOMAWAC running model. Calculation of setup and swash runup was undertaken using H.F. Stockdon et al. (2006) formula. Results show high mean migration rates, greater than 1 m between 1930 and 2011. In detail, the retreat of the barrier is characterised by a succession of acceleration and deceleration phases, highly controlled by the frequency and the intensity of a few number of overwash events. ii) On an annual timescale, morphological evolution of Sillon de Talbert was studied by a DGPS survey undertaken annually between 2002 to 2011. Shoreline retreat speed, crest height variations, and sediment volume changes were calculated using Digital Elevation Models. The role played by overwash dynamic was also studied by analysing oceanographic data set. In March 2008, the high spring tide associated to energetic stormy wave conditions (storm Johanna) caused the flooding of the spit which migrated 10 m landward. The volume of sediment transported landward during the storm was estimated at 100,000 m³ (10% of the total volume of the barrier). This sluicing overwash phase occurred after a period of stability related to a low morphogenic activity between 2002 and 2007. After the storm Johanna, a crestal overtopping phase corresponding to the reconstruction of the crest is measured between March 2008 and September 2011. The great resilience of the barrier to an extreme event is illustrated. This results show different pluri-annual phases of morphogenic activity on the Sillon de Talbert, also recognised on other coastal areas along the Brittany coastline. However, the morphological response of sandy barriers and dune systems to March 2008 extreme storm events is slower and gravel barriers appears to be more resilient.

Influence of Sand Bypassing Operations on Coastal Beaches

Charles Lemckert (Griffith University), Steven Brayshaw (Griffith University), Joe Lee (Griffith University)

Sand bypassing operations are engineered solutions for mimicking longshore transport across trained river entrances in coastal environments. To help understand how these operations influence beaches in the up-coast direction, a study was undertaken to investigate how waves, sand pumping and offshore nourishment affected the beach width of five Gold Coast beaches, Queensland, Australia, which are impacted by the Tweed River Entrance Sand Bypassing Project (TRESBP). When first constructed in the early 1960s, the training walls of the Tweed River significantly impeded the natural northerly (up-coast) longshore transport of sand. In 2001, a sand bypassing system was completed that pumped sand across the Tweed River mouth to five different up-coast outlets, to mimic the natural net longshore transport rate of 500 000m³/year. In the 10 years since its inception, the width of the sediment receiving beaches has come under great public scrutiny. Initially, an excess volume of sand was pumped and expected adverse weather patterns (that would have dispersed the sand) did not occur. Beach widths were considered to be 'too' wide, limiting the amenity of southern Gold Coast beaches and causing significant political unrest within local communities, even though increased beach width offered significant protection from possible storm damage. This study used beach width monitoring, offshore wave buoy, sand pumping and offshore nourishment quantity data to investigate whether a simple empirical relationship could be found to improve the management operations of TRESBP and the state of the beaches (i.e. when and how much to pump). Using the Simulating WAVes Nearshore (SWAN) model, wave properties near the shore were predicted and then the Coastal Engineering Manual's 'CERC' formula to estimate approximate longshore sediment transport rates (LST) was used. This calculation, along with sand pumping rates and offshore nourishment from dredging the Tweed River Mouth, were then compared to the changes in beach width from September 2002 to December 2010. Analysis of the data revealed that the changes in beach width appeared to be more influenced by cross shore sediment transport from offshore stores, built up from dredging operations and sand pumping, than by LST. However, without the TRESBP, history shows that the beaches will significantly erode. Overall, it was found that the highly complex nature of the coastal environment made it nearly impossible to model/predict beach widths, but it is clear that the TRESBP is doing its job to maintain a static type nature of the coastal region, albeit of questionable public acceptance. It is evident that greater public education is required to keep them abreast of what coastal processes are and the strategies managers are using to maintain a useful system.

Global Change and storm impacts on anthropogenic coastal features: The case study of the dune of Saint-Trojan (Isle of Oléron, France).

Hervé Regnaud (Université de Rennes), Jonathan Musereau

Most often, studies of coastal morphodynamics assume that environments are 'natural' and that natural equilibriums are modified by human interventions. In this paper, we study a coastal site which has been built by human action during the last centuries and which is, today, exposed to natural forcings. This site, which is called Saint-Trojan, is located along the most exposed coast of Oléron island, in the central part of the French Atlantic façade. During the 19th and a part of the 20th centuries, local inhabitants living close to the coastal dune developed several devices to stop sands invading their houses. They built huge sand fences to stabilize the dunes and planted a pine forest. As the sediment input was large these coastal works lead to a seaward progression of the coastline, of more than 2 kilometers. Nowadays, an opposite behavior is observed. The dune undergoes strong erosion and its retreat reaches unexpected rates of more than 10 meters per year. In some places, the ocean has already invaded the pine forest, for instance during a recent storm named Xynthia (February 2010). The reasons of the reversal of dynamics are many: sand supply has chronically decreased, erosive storms appear to be actually more frequent and side effects of tourism are also mentioned. We reconstruct the history of the coastal dune with a set of local sources (cartographies, archive of climate records, local evidences). The method is inspired by former works dealing with the concept of anthroposystems and anthropogenic landforms. Results incite us to discuss about the feature of such an environment compared with natural ones. We point out that the previous anthropogenic building of the dune of Saint-Trojan makes it retroactively more sensitive to storm and large wave events, and thus more vulnerable to Climate Change than the other parts of the oleronese coastline. We incite coastal managers to integrate such mechanisms in their prospective works about risk due to storms and surges. We also developed a statistical method to sort erosive storms from ordinary ones in order to anticipate the incoming crisis. It is based on a Storm Index mixing wind, wave and tide parameters (data from atmospheric and oceanographic models) which are crossed with field morphological data (DEM).

Sediment characteristics in Barito River Delta, Southern Kalimantan, Indonesia

Deasy Santy (Gadjah Mada University), Junun Sartohadi (FH Cologne), Muh Aris Marfai (Gadjah Mada University), Danang Sri Hadmoko (Gadjah Mada University)

Barito River Delta is a delta in the mouth of Barito River. Barito River Delta has the width of shoreline more than 40 km and the length more than 80 km (Djuwansah, 1985). The boundaries of Barito River Delta are Barito River as the eastern boundary, Kapuas Murung River as the western boundary, Pulau Petak River as the northern boundary and Java Sea as the southern boundary (Bassoullet, et al., 1986). Barito River Delta is characterized by swampy land, mainly for rice cultivation. Two canals (Tamban, Serapat) connect Barito River and Kapuas Murung River. Talaran Canal connects Barito River and Pulau Petak River (Bassoullet, et al., 1986). The canals are used as irrigation channel to agriculture area. Land forest within Barito Watershed decreases every year. During the periods of 2000-2009, the area of forests in Barito watershed decreases approximately 1,047,163.82 hectre or 16.38 % (Ministry of Natural Environment, 2010). Land degradation in Barito Watershed is approximately 0.1 hectre/year (Moehansyah, 2006). Human activities in watershed increase the sediment yield to delta area. The measurement of sediment in subaerial of delta uses hand bore. The location of boring is in the upper of subaerial delta, in the lower of subaerial delta, in the central of delta and a long of river. Characteristic analysis of sediment consists of color of sediment, grain size, type of peat and mottling. To determine color of sediment uses munsell soil book. Analysis of grain size of sediment uses pipette method. To determine the type of peat uses bulk density analysis and color of peat. The research shows that the color of sediment in the eastern indicates the reduction color, whereas soil profiles in the western indicates the oxidation color. Mottling is found in 0-1 meter in the central of delta. Mottling is found in 0-2m in a long of river. Oxidation color is dominant in the surrounding of river because of the high of tide fluctuation. Tide fluctuation has impact to aeration condition in the soil. Reduction condition is found in the central of delta because the water cannot flow quickly. Clay has thickness about 1-2 meters in the central of delta and more than 2 meter in a long of river. Fine sand is found in 1.5-2 meter in the central of delta, and more than 2 meter near of river. Clay is thicker in a long of river than in the central of delta. The type of peat in the central of delta is hemist and saprist. Peat is thicker in a long of river than the central of delta. Agriculture activity decreases the peat thickness in the central of delta. Keyword: sediment characteristic, Barito River Delta

Coastal dune management along a human-altered shoreline, the case of Dunkirk Port, Northern France

Antoine Tresca (Université du Littoral Côte d'Opale), Marie-Hélène Ruz (Université du Littoral Côte d'Opale), Pascal Gregoire (Dunkirk Port)

Dunkirk Port development since the end of the 1950s has resulted in major shoreline changes. Port infrastructures were expanded on land reclaimed from the sea, resulting in the development of a 12 km long shoreline, located between the two main seaport access limited by 2 jetties. This artificial shoreline can be divided in two parts. A western part, where a beach is backed by naturally developing coastal dunes, and an eastern part consisting of a 6 km long asphalt dike overtopped in places by low elevated aeolian dunes. In perspective of its sustainable development and action plan, Dunkirk Port is committed to preserve and manage the diversity of landscapes, habitats and species. In this context, the aim of this study was to promote foredune building in the naturally developing dunes area, and to test windbreaks in order to favour wind blown sand accumulation on the seaward side of the dike, which could help to enhance coastal dune development. Sixteen structures have been installed on the whole site, consisting of sand fences (brushwoods, wooden slats & synthetic fabrics), having a height of 1.2 m and a porosity of 50%. Six of them were first installed in the naturally developing dunes area in July 2010. One of them was placed in a 30 m wide dune breach, while 5 others were erected at the dune foot, perpendicular to dominant longshore winds. Then, in February 2011, ten experimental structures were positioned on the dike at different locations: dike toe, dike windward and leeward slopes. As it was impossible to make holes in the coated surface, chestnut posts inserted in concrete blocks were used to fix them in the ground. In order to evaluate the amount of sand captured in each of the 16 structures, topographic surveys were carried out every month using a differential global positioning system. Digital Elevation Models were generated and volumes have been calculated. First results show that the location of the structures is primordial to trap sand. In the naturally developing dunes area, the sand fences installed in the breach, well above maximum water levels, were rapidly filled, while structures erected at the dune toe were episodically reached by waves during storm surges. The most efficient windbreaks were brushwoods and wooden slats, while synthetic fabrics trapped less sand during the same period. Fetch length seems to play a major rule in sand fences filling. The volume of sand trapped by brushwoods erected in an area with a fetch length of 400 m was four times the volume trapped in brushwoods installed in an area of very limited fetch. On the dike, the most efficient fences were those installed at the dike toe, next to the upper beach. Structures erected higher on the dike trapped little sand, excepted a cross-shaped structure, where a nebkha of more than 1 m high is developing. Monitoring is still ongoing, the next step being to define the best solution to promote dune formation.

Managing sediment budget: recycling sand at the Sandy Hook Unit, Gateway National Recreation Area, NJ, USA

Norbert P. Psuty (Rutgers University), Andrea Spahn (Rutgers University), William Hudacek (Rutgers University), Monica Patel (Rutgers University)

Long-term coastal monitoring in the National Park at Sandy Hook, New Jersey, has established the dimensions of sediment deficits and surpluses along portions of the dynamic Sandy Hook spit. More than two decades of intensive surveying and modeling of change have identified the alongshore variations of sediment budgets and topographical evolution on the ocean shoreline. Sandy Hook is composed of three facets (southern, central, and northern), each with different exposures to the incident wave energy. Early surveys documented annual losses in the range of 120,000 m³ in the southern facet gradually diminishing to a positive budget at the northern facet. Beach nourishment episodes in communities updrift of the Park have altered the sediment budget and have reduced the annual losses to values in the range of 20,000 - 40,000 m³, and occasionally to small sediment surpluses. Construction and comparison of digital elevation models from the RTK-GPS surveys have depicted the geotemporal variations of coastal evolution and have focused on the more recent sediment budget scenarios. Whereas the southern facet has had periods of erosion and near stability, the central facet is either stable or accumulating. Surveys over the past decade have recorded an accumulative trend of 15,000 m³ per year and a shoreline displacement of about 10 m annually. In addition, there are large pulses of sediment passing through in the form of sand waves that migrate alongshore. Each of these nearshore sand masses is estimated to have 40,000 - 80,000 m³ of sediment. In a unique approach to shoreline management, the NPS has installed a buried pipeline and has initiated a program of backpassing from the slightly accumulative central facet to the eroding southern facet. The project involves a specially-constructed eductor apparatus that will fluidize the sediment in the beach and nearshore zone before moving a sand slurry to a mixing vat and then pumping a slurry approximately 6 km to beach disposal sites. This program has been used for the first time in the winter period of 2011-2012. The goal is to backpass, or re-cycle, up to 30,000 m³ and attain a balanced annual sediment budget in the southern facet, thereby working at a scale of change that is similar to the natural system and conducive to the management of the natural and cultural resources in the areas of sediment excavation and sediment placement.

Influence on surface material on coastal erosion in Galle district in the Southern coast of Sri Lanka

Ashvin Wickramasooriya (University of Sri Lanka)

Coastal erosion is one significant issue can be observed in the Southern coast of Sri Lanka. According to the coastline changes calculated by the coast Conservation Department of Sri Lanka, there are places within the study area which are eroded more

than 30 to 50 meters within last two to three decades. Many natural influences as well as human activities are responsible for accelerate such significant coastal erosion in this region. This research focused on clarifying the relationship between available surface materials on coastal erosion trends in the study area. The entire coastal belt considered in this study is about 62 km. Other natural influences such as oceanography conditions, wave energy, coastal accretion and human influences changes for long distance along the coast. Thus, to observe the actual influence of surface materials on coastal erosion, the study area has divided into 5 km segments. A detailed field work has carried out to demarcate available surface materials in each segment. The nature of the surface material varies from place to place. It has been identified that hard rocks, moderately weathered rocks, weathered overburden, Lateritic caps, Beach Rock (Sandstone), Limestone, and coastal deposits are the main surface materials identified along the Southern coast of Sri Lanka from Beruwala to Galle. Physical and chemical characteristics of these materials vary and therefore, surface material has identified as one of the factors that determine the rate of coastal erosion. Few physical and chemical parameters such as strength of materials, fracture intensity, porosity and mineralogy were considered to initiate the coastal erosion sensitivity index (CESI) with respect to surface materials. These four factors do not contribute to coastal erosion in similar manner. Therefore, weightage values (W) for each factor have been introduced based on individual factor's contribution to coastal erosion using Multi Criteria Decision Analysis Method. Also contribution to coastal erosion varies with different conditions within a same factor. Therefore, different ranks (R) have been introduced for each factor using pair wise comparison method. Coastal Erosion Sensitivity Index (CESI) has calculated considering both weightage values assigned for each factor and ranks within factors. Finally, coastal erosion sensitivity map of the study area was prepared using overlay analysis method used in Geographical Information Systems. When compared this map with the coastal erosion trend map introduced by Coast Conservation Department Sri Lanka, it can be conclude that nearly 80% to 85% of two maps show a significant correlation. Highest and lowest coastal erosion sensitive areas marked in the produced map are within the maximum and minimum coastal erosion changes for last thirty years respectively. Therefore, there is a relationship between surface materials along the coastal belt of the study area and trend of the coastal erosion.

Marine Protected Area Policy to Support Local Marine Resources Conservation in Indonesia (A Case Study: Boano Island – Moluccas)

Nandi MSc (University of Leipzig), Jurgen Heinrich (University of Leipzig), Anang Widhi Nirwansyah (Gadjah Mada University)

Background Indonesia is an archipelagic country which more than 17,500 islands and 5.8 million km square ocean territories. Autonomy law in UU No. 32 2004 has given local government autonomous authority including sustainable development of marine policy. The concept was formulated on basis of consideration of the interests involving the utilization of marine resources. Measureable reference in formulating national policy has provide marine protected area (Kawasan Konservasi Laut Daerah) based on PP No. 60 in 2007 (Government Regulations) about Marine Protection Area which accommodate all stakeholders need and conserving spirit for present and future progress. The target of marine conservation areas by 2010 covering 10 million hectares has been exceeded, reaching 13.95 million hectares and also targeting 20 million hectares in 2020. Some of the conservation area is a direct initiative of the ministry, while other region is an initiative of local governments. Boano Island as one of potential marine area in Moluccas has initiated to be conserved based on the indigenous resources of fishes, corals, mangroves, and cultural existences. Observation, measurement, and comprehensive analysis focusing on the natural condition and social economic variables as feasibility study shows the potential marine resources. Result Boano Island, District of West Seram district is one of the divisions based on Law No. 40 of 2003, which originally was part of the territory of Central Maluku District which later became Central Maluku District, District of West Seram and East Seram regency. Geographically, West Seram district is an archipelagic area, consists of 62 islands including 52 uninhabited islands. Most of its marine territory provides ample room for 124 species of fishes, 5,451.25 hectares of mangroves, and healthy condition of corals can provide revenue to the local economy, which also support the program based on local beliefs system. Conclusion: Integrating national and local policy to conserving marine resources area in Indonesia has been conducted in Marine Protected Area. Initiation from local government is accommodate in terms of autonomy issues and sustainable development that covering all stakeholders. Boano Island as one of Marine Protected Area project will be develop for eco-tourism and research center for marine ecology, considering indigenous resources and social economic condition. Strong cooperation between government, academician, and industry is needed to support the natural diversity and future sustainability Keywords: Marine Protected Area, Policy, Boano Island

Sediment Budget at Plumb Beach, New York, USA: Vectors of Change and Impacts

Norbert P. Psuty (Rutgers University), Andrea Spahn (Rutgers University), Tanya Silveira (Rutgers University)

Plumb Beach is at the eastern end of the Coney Island barrier island, part of the ocean shoreline of New York City. Plumb Beach extends for about 1500 m and is bordered to the east by Rockaway Inlet. As the neighboring updrift barrier island migrated westward, Plumb Beach became more and more isolated from the alongshore transport system. In the early twentieth century, a navigation channel separated Plumb Beach from any coastwise sediment transport and resulted in persistent erosion and inland displacement of the diminishing beach-dune topography of the barrier island remnant. In the 1930s, a major highway was constructed on fill over the remnants of Plumb Beach barrier. Continuing erosion is currently mobilizing and re-distributing the emplaced sediment, narrowing the buffer adjacent to the highway, and altering the local aquatic habitats. Studies are currently underway to quantify the vectors of change and to evaluate opportunities to augment and manage sediment supplies to reduce the impacts of sediment loss as well as limit the negative impacts of sediment accumulations in threatened habitats. Early attempts at shoreline stabilization consisted of a variety of riprap barriers, dumping of available sediment, and installation of some rudimentary offshore and shore parallel structures. In 1992, approximately 72,000 m³ of sediment were placed along 520 m of the central Plumb Beach shoreline, displacing the water line about 55 m seaward. By 2008, most of that emplaced sediment was eroded from its original emplacement. Two major storms, November 2009 and March 2010, continued to alter the Plumb Beach morphology. Maximum inland displacement of the erosional scarp in the foredune was 5.6 m in the earlier storm and 6.4 m in the latter storm. Whereas previous estimates indicated losses in the range of 1500 to 2000 m³ per year, the Nov 09 storm eroded 4800 m³ from the central area of Plumb Beach and the Mar 10 storm eroded over 5,000 m³, leaving a very narrow, sand-bagged strip between the beach and the infrastructure. In each case, the downdrift beach-dune system had losses in the upper beach and the seaward face of the foredune. However, the downdrift system actually accumulated almost 5000 m³ through a combination of seaward expansion of the low-tide portion of the beach profile and sediment transfer inland of the dune crest, further reducing the adjacent wetland habitat. Since 1974, more than 50% of the wetland habitat has been lost to the accreting beach-dune system, both by alongshore extension and inland displacement. Current plans for shoreline stabilization include use of sediment dredged from a nearby navigation channel to buffer the effects of erosion and sediment traps to either end of the central portion to catch and recycle alongshore transport.

The impact of the storm Xynthia on PPR-L

Céline Chadenas (CNRS), Denis Mercier (CNRS), Axel Creach (CNRS)

The storm Xynthia, occurred on February 28th, 2010, was one of the most murderous that knew the metropolitan French territory for several decades, making 47 victims, among whom more than half on the department of Vendée. Indeed, the conjunction of various natural phenomena (atmospheric pressure, strength and orientation of the wind, the tidal range) carried an important flood of marine origin, recovering of water certain sectors urbanized on several municipalities from Vendee and Charente-Maritime (west central atlantic région of France). The balance sheet after disaster revealed certain number of problems: delays in the approval of the PPR-L in particular, at the origin of an urbanization exposing the populations to major natural risks, as the flood marine. Since February 28th, 2010, the French State seized these files by trying to define in a more precise way the criteria ending in the zonings of the PPR-L and the contents of these files. The number of circulars, recommendations, was multiplied, specifying every time the rules of protection of the housing environment towards the risk of flood and the necessary adaptations (height of the 1st floor, stage refuge) of built, current and future, according to the level of risk. The objective of the communication is double: bring to the fore the impact of the disaster Xynthia on the realization of the PPR-L with court / medium terms, by leaning on the example of the municipality of Faute-sur-Mer; analyze the evolution of the official texts since February 28th, 2010, with special attention to the proposed criteria for consideration of the hazard.

A study of shoreline rotation and response to nourishment of a gravel pocket beach using low-cost videomonitoring techniques

Umberto Andriolo (Università di Ferrara), Clara Armaroli (Università di Ferrara), Paolo Ciavola (Università di Ferrara), Mitchell Harley (Università di Ferrara)

The study analyses a dataset of a coastal video station that has been operating at the gravel pocket beach Spiaggia San Michele-Sassi Neri on the Conero's coast (Marche, Italy) for one year. The system consists of two high resolution security IP cameras (both containing 2 optics for a total), monitoring a difficult to reach site, with high naturalistic and touristic value. Shoreline movements following and artificial nourishment are discussed for the period of April 2009-June 2010. The images obtained by the system were processed with shareware and freeware software in order to obtain Timex Exposure and Sigma-Variance images; afterwards, those were corrected, geo-rectified, and properly selected to have a dataset of images taken under the same wave and tide conditions. The shorelines were manually mapped on selected geo-rectified images in a GIS environment. A shoreline database was built and the Net Shoreline Movement was automatically computed using the Digital Analysis Shoreline System (software developed by the U.S. Geological Survey) comparing two shorelines for a selected time period, selecting a total of 49 shorelines. The daily calendar of nourishment works was compiled

detecting the presence of the dredges along the coast, and locating on the image the beachface zones where the gravel was discharged by the dredger. In this case nourishment was done by berm building on the shoreface, thus the position of discharge and the building up of the beach wedge was clearly visible. A shorter period analysis was carried out relating shoreline movements to the material deposition zones. Moreover, a comparison of coastlines mapped pre- and post- 6 storm events was undertaken in order to relate the shoreline change to the wave energy and wave direction. In agreement with the literature, a net rotation of the embayed shoreline was observed over the long period, resulting in shoreline recession in the northern part of the beach and accretion in the southern part.

Coastal Development and Management: A Case Study of Karnataka State, India

Rathy Ganapathy (Mangalore University College), Dasharatha P. Angadi (Mangalore University College)

Coastal zones are areas of Intensive activity of interchange within and between Physical, biological, social, Cultural and economic processes changes at any Stage and in any part of the System, can generate chain reactions for beyond their starting point and possibly in a totally different System whose environment conditions will be Subsequently altered. It has now been recognized that effective management of Coastal area should be based not only on an analysis of Individual activities and their impacts, but also on the combined effects of various activities on each other as well as on Coastal resources as a Whole. There is a need to bring the Various activities together in order to achieve a commonly acceptable Coastal Management frame work; the Integrated Coastal Area Management (ICAM) represent a continuous Proactive and adaptive process of resources management for Sustainable development and Management in Coastal areas of Karnataka in India. The paper observes that the coastal development and Management is depends on the Socio-Economic Sectors. The Following objectives have been formulated and they are: a) to identify the potentialities and prospects of development of Coastal Karnataka (Study area).b) to know the Banking, Education and Economic Sectors development of the Study area. c) to know the policies relating to Management of coastal Resources and activities play out in the study area. d) to find out tools and approaches are need to improve Coastal Management and decision making. The Study area is located West Coast of India in Karnataka State; the total length of the Coast is 320Kms. The Study is based on Primary and Secondary data.

Sustainable Development of Coastal Zone and Marine Ecosystem: A Case Study of Karnataka, India

Dasharatha P. Angadi (Mangalore University College)

Coastal environments occupy one of the most dynamic interface on earth, at the boundary between land and Sea, and they Support some of the most diverse and productive habitats. These habitats include natural ecosystems, in addition to important managed ecosystems economic sectors and major Urban Centers. The existence of many Coastal ecosystems is dependent on the land-sea connection or arises directly from it (e.g. deltas and estuaries). Coastal environments, Settlements, and infrastructure

are exposed to land sourced and marine hazards such as storms (including tropical cyclones), associated waves and storms surges, tsunamis, river flooding shoreline erosion and influx of biohazards such as algal blooms and pollutants. All of the factors need to be recognized in assessing Coastal zone in India in particularly in Karnataka State. In this paper an attempt has been made to Sustainable development of Coastal Zone and marine Ecosystem. The Coastal Karnataka is selected as Study area it includes three districts. The total length of Coast is 320kms. This region lies between 12°27' to 15°49' North latitude and 75°49' to 75° 10' East longitude. The study is based on Primary and Secondary data.

Nature compensation and coastal defence: building with nature in the Dutch Delta

Frank Van der Meulen (Deltares), Bert van der Valk (Deltares)

Keywords: barrier coast, sand nourishment, building with nature, Natura 2000 During 2008-2009, a special and unique case of nourishment has been completed along the Dutch delta coast. A new dune area was constructed to compensate for the predicted losses in ecological values in existing dunes in the delta, due to the use of the new harbor extension of Rotterdam, Maasvlakte 2 from 2013. The nourishment combines coastal defence and the development of high quality ecological values. The new area also adds to recreational facilities in the densely populated Dutch delta. Will the new dune area develop in the desired compensation direction? Design, construction and first development of the new area are presented and discussed. The Delfland Coast between Hook of Holland and The Hague was designated as one of the "weak links" along the coast. A large nourishment was carried out between 2008-2011 and as part of the protection works, the compensation dune area was constructed. This means that the coast is safe now (but not when a future climate change is taken into account). The use of Maasvlakte 2 (after 2013) is expected to cause damage to certain important dune habitats and plant populations in the immediate surroundings that are under protection of Natura 2000. The damage would be caused by NOx emissions from the traffic (boats, cars, etc) that uses the new harbor. Airborne N-deposition in fact acts as an extra nutrient load to the rare dune ecosystems, which are (extremely) nutrient poor under natural conditions. According to Natura 2000 regulations, the damage has to be compensated. Using some multiplying factors, it was calculated that ca 35 ha of new dune critical habitat area was needed. This was created by adding an extra 6,5 *10⁶ m³ of sand to nourishments already foreseen along this coastal stretch. However, sand for this special extra area had to be of specific grain-size composition, because, after nourishment was completed, aeolian transport and deposition of the sand was foreseen, to create the optimal ecological soil start situation for rare dry and moist dune vegetations to develop. Besides the geomorphology of the new terrain, also the groundwater conditions have to develop in the desired direction. Monitoring of geomorphology, vegetation

development and groundwater is carried out to support the management of the area with the compensation requirement as an ultimate management goal.

Ostracoda and Foraminifera in Coastal Research

Anna Pint (Universität zu Köln), Peter Frenzel (Universität Jena), Helmut Brückner (Universität zu Köln), Thomas Daniel (Geowissenschaftliche Sammlungen), Max Engel (Universität zu Köln), Sascha Fürstenberg (Universität Jena), Daniel Kelterbaum (Universität zu Köln), Heike Schneider (Universität Jena), Carmen Trog (Naturkundemuseum Görlitz)

Ostracods and foraminifers are classical groups of micropalaeontology. Both groups can be found globally in high diversity in the sand size fraction of aquatic and sometimes semiterrestrial sediments. It is possible to identify the taxa down to the species level by using their easily fossilizable hard parts, mainly archived in fine grained sediments. Even samples of only a few grams of sediment may contain hundreds or thousands of these kinds of microfossils. Thus, they have a great application potential in coastal research for geosciences, environmental micropalaeontology, and geoarchaeology. Ostracods are minute Crustacea with their body enclosed by a bivalved carapace made of calcite. They occur in salinities from freshwater to fully marine and even under hypersaline conditions. Brackish waters often show mass occurrences of this group. Foraminifers are Rhizopoda normally protected by a test. This test mainly consists of calcite or is agglutinated from sediment particles in marginal marine environments. The group is most diverse in marine habitats and strongly diminishes in diversity and abundance in brackish waters. Some marine taxa live planktonic, but most species are benthic like the ostracods. The association structure and shell chemistry of Ostracoda and Foraminifera can be used to reconstruct salinity, water temperature, oxygen and food availability, extreme events such as storms and tsunamis, precipitation/evaporation ratios, estimated water depth and turbulence, erosional and depositional processes, as well as habitat structure of palaeoenvironments. This shall be exemplified in four case studies from the City of Stralsund (southern Baltic Sea), the Island of Bonaire (southern Caribbean Sea), Kerch Peninsula (northern Black Sea), and the Alvor Estuary (southern Portuguese coast, Eastern Atlantic coast).

Coastal morphodynamics determine intertidal wetland development: A case study on mangroves

Thorsten Balke (Deltares), Edward L. Webb (University of Singapore), Erik M Horstman (University of Twente), Claire Jeuken (Deltares), Peter M.J. Herman (NIOO-CEME), Tjeerd J Bouma (NIOO-CEME)

Coastal wetlands such as mangroves and salt marshes are declining worldwide (e.g. Duke et al. 2007). Due to their numerous ecosystem services, e.g. nursery grounds, carbon storage and coastal protection, they are now in the focus of many coastal managers and scientists. However we only begin to understand the mechanisms behind the dependency of coastal vegetation on local and large scale geomorphic processes (Friess et al. 2011). Minerogenic, tidal wetlands are closely linked to the morphodynamic development of the coastal zone, especially during their establishment. After successful establishment these wetlands are able to influence sedimentary processes, thereby creating positive bio-geomorphic feedbacks to maintain the ecosystem and therefore the shoreline. Hence, the most critical phase for coastal wetlands is the seedling stage where plants are extremely vulnerable to physical disturbance. For mangrove seedlings we show experimentally how physical disturbance created by morphodynamic processes (accretion and erosion) can limit or enable their establishment. Erosion around the individual seedling can excavate the roots and cause toppling, whereas rapid accretion can bury parts of the shoot and cause smothering. In the field, physical disturbance by morphodynamic processes (i.e. sediment mixing) was measured along transects from the mudflat into the mangrove forest. The mixing depth decreases towards the forest hence posing spatially variable establishment limitations to seedlings. Finally, we explain establishment of intertidal vegetation by modeling the spatial and temporal variability of the disturbance regime. Periods with calm conditions may offer 'windows of opportunity' (cf. Balke et al. 2011) during which mangrove seedlings can anchor and gain stability against future disturbance. However, if during this initial period thresholds are exceeded, seedling establishment will be prevented. Overall, our study provides a first mechanistic understanding of limitations to establishment of coastal vegetation by morphodynamics. Such understanding is urgently needed to develop alternative management and restoration strategies to protect the valuable coastal wetlands. Literature Cited: Duke et al (2007) A World Without Mangroves? Science 317: 41-42 Balke et al (2011) Windows of opportunity: thresholds to mangrove seedling establishment on tidal flats. Determination of sediment budget and assessment of areas at risk from coastal hazards on the shore of northern France using airborne LiDAR

Adrien Crapoulet (Laboratoire d'Océanologie et de Géosciences), Arnaud Héquette (Laboratoire d'Océanologie et de Géosciences), Antoine Gardel (Laboratoire d'Océanologie et de Géosciences)

Despite strong urbanization and development of major harbors during the 20th century, the coast of northern France still largely consists of coastal dunes of variable width associated with 500 to 800 m wide, gently sloping, macrotidal sand beaches characterized by series of shore-parallel intertidal bars. These coastal accumulation landforms, which often represent the only barrier protecting low elevation backshore areas from marine flooding, are particularly vulnerable to coastal hazards that may increase during the next decades due to sea level rise associated with climate change. Climate change may have dramatic impacts along the low unconsolidated coastlines of northern France, especially where sediment supply is limited, which may result in negative sediment budget and recurring coastal erosion. Although several studies have shown that the stability of the shoreline strongly depends on the local sediment budget, no studies have been conducted so far to evaluate the changes in the coastal sediment stock at the scale of the northern France region during recent years. The main objectives of this study are to determine shoreline changes and variations in sediment budget at the regional scale, to assess the role of changes in sediment volume on the stability of the shoreline, and to identify the areas that are the most vulnerable to coastal hazards in the near future. This work is largely based on the acquisition and analysis of high-resolution topographic data of the entire littoral zone of northern France using a LiDAR (Light Detection and Ranging) airborne laser system for high precision which gives a fine rendition of the topography over large areas. LiDAR complete coverage of the coastal fringe of the northern France was conducted in 2008-2009 and another full LiDAR survey of the coastal zone was completed in March 2011. Additional LiDAR data have also been obtained in September 2011 at two specific sites (East Dunkirk and Wissant Bay) where detailed in situ topographic measurements are regularly carried out. These spatially dense elevation data sets were used for determining topographic variations between 2008 and 2011 and for carrying out high-resolution 3D mapping of the coastal zone. The analysis of these evolutions allowed us to quantify sediment volume changes in coastal dunes and intertidal areas, including estuaries that represent major sediment sinks in the coastal zone of the region. This work was complemented by an analysis of storm surge frequency based on theoretical tidal elevations and tide gauge data recorded at the harbors of Dunkirk, Calais and Boulogne-sur-Mer during the last decades. Analysis of these time series of water levels enabled to estimate the return periods of high water levels. The combination of digital elevation data with these water level statistics allowed us to determine potentially sensitive areas that may be exposed to marine flooding, but also to other natural hazards such as coastal erosion.

Morphological changes and developments between Silivri and Tuzla coasts, Istanbul, Marmara Sea, during the last century (1900-2012)

T. Ahmet Ertek (Istanbul University)

The southern coastal parts of the Çatalca and Kocaeli peninsulas terminate at Silivri, Cape Moda, Cape Tuz and Pendik with high cliffs, whilst almost the rest of Istanbul's coastal areas are severely modified due largely to human interferences, cutting the land off from the sea. In that part, Haydarpasa and Karaköy ports serve as shipping and passenger transport, respectively. There are, on the other hand, a number of moorages for boats, fastcrafts, passenger ferries, ferryboats that meet daily needs. The marina sector developed at the coasts of Ataköy and Fenerbahçe. Shipbuilding yards between Pendik and Tuzla coast and natural gas filling factories in Ambarlı Port are other worth mentioning coastal structures. The coastal areas between Bakırköy and Eminönü and Moda and Tuzla were filled at 1960's and 1980's, causing expand of 200-500 m in coastal band. Stuffing beaches in various parts such as Silivri, Selimpaşa, Celaliye, Kumburgaz, B.Çekmece, Avcılar, Menekşe, Florya, Yeşilköy, Ataköy, Moda, Caddebostan and Süreyyapaşa led to disappearing of natural coastal landscape. Increased pollution in Marmara Sea waters dwindled the attention down to natural beaches during tourism season in the summers. Parks, fishing ports, seaports, boat yards and activity areas of sailing and water sports constructed on newly filled coastal areas took the place of sea towns. Thus, coastal areas which were once receded to personal use of the summer house and seaside residence owners kept 200-300 m inside due to coastal fills built for recreative purposes. These areas were then turned into common weal, including green fields, parks and a double flow three-lane road. The heavy traffic load on the E5 highway and O1 motorways have then been disburdened by that new alternative coastal road. The superintendence of structuring on river valleys and filling lands which have low resistance to natural disasters is of top priority in this tectonically active region. Nevertheless, skyscrapers and office towers in the coastal areas of Beylikdüzü, Ataköy, Yeşilköy, Gültepe, Maslak, Ümraniye and Kartal, settling on load-bearing grounds, seem to increase the population (ca. 12 million) of Istanbul in the future. Nowadays their numbers are around 30, but more 24 skyscrapers are being under construction. These tower blocks caused vertical urban development in contradistinction to horizontal expand formed of garden houses. As result, the Marmara Sea coast of Istanbul between Gümüşyaka and Tuzla had been of seawater intake in early 1900's. At present, these coastal areas are adversely affected by urbanization and excessive migration and lost almost completely its primary coastal characteristics.

Depth of disturbance measurements on macrotidal mixed beaches: insights from the eastern Channel coast.

Jerome Curoy (University of Sussex), Cherith Moses (University of Sussex), David Robinson (University of Sussex)

Mixed beaches, with sediment sizes ranging over three orders of magnitude, are an increasingly important coastal defence. In Great Britain, beaches with an important gravel fraction are estimated to occur along approximately 19,000 km of shoreline and in France, at least 2270 km. On both sides of the Channel these beaches are heavily managed via a range of methods: sediment recycling, sediment recharging and/or beach groyning. Accurate measurement of the depth of disturbance is critical to quantifying cross-shore and alongshore sediment transport for management purposes. Because it is difficult to measure, the depth of disturbance is often estimated and considered homogenous across and alongshore. Using the method described in Curoy et al.(2009) the depth of disturbance has been measured on two mixed beaches in the eastern Channel: over 21 tides from March - December 2006 at Birling Gap, East Sussex, England; and, 28 tides in December 2005 at Cayeux-sur-Mer, Normandy, France. At Birling Gap, incident wave approach varied from 20-152° to the beach, significant wave heights ranged from 0.3 to 2.61 m and significant wave period varied from 2.1 to 8.6 s. At Cayeux-sur-Mer, incident wave approach varied from 7° to 60° to the beach, significant wave heights ranged from 0.4 m to 2.7 m and significant wave period varied between 4 and 9 s. The beach sand content for both beaches varied over time and was up to 30%. A sand content of >25% is thought to reduce the hydraulic conductivity of a mixed beach to approximately that of sand, influencing the profile response of the beach. This study contributes new baseline data to help refine presently limited understanding of the relationship between depth of disturbance (Z_m) and tidal maximum significant wave height ($H_{st. max.}$) on mixed beaches and allows a comparison of the results obtained on two different mixed beaches: · At Birling Gap: Upper beach: $Z_m = 0.05H_{st. max.} + 0.02$ ($R^2=0.58$); Upper middle beach: $Z_m = 0.08H_{st. max.} + 0.03$ ($R^2=0.75$); Lower middle beach: $Z_m = 0.04H_{st. max.} + 0.07$ ($R^2=0.26$); Lower beach: $Z_m = 0.06H_{st. max.} + 0.03$ ($R^2=0.3$). · At Cayeux-sur-Mer: Upper beach: $Z_m = 0.11H_{st. max.}$ ($R^2=0.25$); Middle beach: $Z_m = 0.2H_{st. max.}$ ($R^2=0.34$); Lower beach: $Z_m = 0.17H_{st. max.}$ ($R^2=0.64$). Results show that, despite a sand content of up to 30%, the depth of disturbance is significantly lower on these mixed beaches than on steep sandy beaches. The correlations determined from the measurements located at the middle sections of the beach are 26% lower at Cayeux-sur-Mer and 70 to 85% lower at Birling Gap compared with Ciavola et al. (1997) empirical formula for steep sandy beaches. Curoy, et al.(2009). Zeitschrift für Geomorphologie 53, 387-409. Ciavola et al. (1997). Marine Geology 141, 147-156.

Morphodynamic evolution of the submerged beach at Lido di Dante (Ravenna, Italy) through videomonitoring and modeling

Paolo Ciavola (University of Ferrara), Elisa Piazzalunga (University of Ferrara), Clara Armaroli (University of Ferrara)

The understanding of morphological coastal changes has made great advancements in the last twenty years, thanks to the development of high frequency videomonitoring techniques. The temporal coverage of data acquisition is incomparable with traditional methods and can provide numerical modeling with unique datasets for calibration. The aim of this study is the analysis of the morphodynamic evolution of the submerged part of the beach of Lido di Dante (Ravenna, northern Italy) and the evaluation of the performance of an algorithm (Beach Wizard), which automatically integrates the results of a morphological model (XBeach), that was calibrated for the study site, with video-derived data (Argus images). The study site, located in the Emilia-Romagna Region, facing the Adriatic Sea, is a two-kilometre long natural beach, backed by a pine forest and bounded by coastal defences to the north and by the Bevano river mouth to the south. The area is exposed to microtidal conditions and the wave climate is usually of low energy. An Argus station is installed at Lido di Dante since February 2003 and it represents the instrument which allows the observation of the morphodynamic evolution of the coastal area with good resolution in space and time. Based on wave dissipation patterns, the bar crest position and its plan shape, along cross-shore transects 25 meters spaced, were studied for the period between September 2007 and October 2009. After a careful selection of the available time exposure images, aimed to remove those characterized by low quality information, the sand bar crest position was detected through the analysis of the pixel luminosity intensity. The sandbar system behaviour in response to changing wave forcing, according to its plan shape, amplitude and length of rhythmic forms, when present, and cross-shore bar crest location, was studied in order to extend the analysis already done for the four-years period between February 2003 and June 2007. A beach nourishment was carried out in April/May 2007. Therefore one of the main objectives of the study was to understand the short and long time effects of the sand replenishment to the submerged part of the beach. The results were also compared to the outcomes of Beach Wizard that was previously validated against two in situ measurements. The model performance was hence investigated for a significant (more than 180 images) dataset in order to estimate the model skill related to the number of high quality images, used for the bathymetry update, and to the length of the investigated period of time.

A Bay of Fundy Salt Marsh Restoration in New Brunswick, Canada

Jeff Ollerhead (Mount Allison University)

The purpose of this presentation is to report on the progress of a salt marsh restoration at a site near Aulac, NB in the Cumberland Basin of the Bay of Fundy. Cumberland Basin is a 118 km² turbid estuary with a semi-diurnal tidal range of 10 to 13 m. The fetch ranges from 5 to 20 km and the water has a high suspended sediment concentration (mean > 300 mg/L). The project was designed in 2009-2010 and implemented in 2010. Three openings were cut in an existing dyke at the site in October 2010. As a result of this action, two different agricultural fields are now being regularly flooded with salt water from the Bay of Fundy. Field data were collected prior to construction for a number of environmental variables (e.g., existing vegetation) and marker horizons were installed. Since the openings were constructed, they have been mapped twice (2010 and 2011) using ground-based laser scanning (LiDAR), flows through one of the openings were measured using an acoustic Doppler current profiler (ADCP), and water levels both inside and outside of the restoration cells have been measured for several months. Erosion of the openings has been largely as expected. In addition, sediment deposition over the marker horizons has been measured using cryogenic coring and DGPS. In the first year, up to 50 cm of sediment deposition per m² was measured, with mean deposition ranging from 9 cm per m² at the west end of the site to 22 cm per m² at the east end of the site. The presentation concludes with an assessment of the initial success of the project.

Creating national inventories for habitats which are challenging to map- the case of the English and Scottish coastal vegetated shingle inventories

Andy Murdock (University of Southampton), Roland Randall (University of Cambridge), Chris Hill (University of Southampton), Jonathan Cox (Jonathan Cox Associates), Ian Strachan, Susan Watt (Scottish Natural Heritage), Stewart Angus (Scottish Natural Heritage), Sue Rees (Natural England), Alan Booth (Central Environmental Surveys)

The UK Terrestrial Biodiversity Strategy and EU Habitats Directive require monitoring of habitat extent and condition for Annex 1 habitats. However, in many cases habitat inventories are either out of date, inconsistent or simply do not exist. In the UK, the government conservation agencies have been working to establish habitat baselines through the creation of GIS-based inventories depicting the area of priority habitats against the principle of being 'evidence-based' organisations. Typically, these datasets are created from multiple existing data sources (which may be inconsistent and outdated) and / or from aerial photographic interpretation (API) with variable levels of field validation. This is a time consuming process. In recent years, remote sensing techniques have been proposed as a more consistent and efficient mechanism for gathering this habitat extent information for surveillance. However, challenging habitats such as coastal vegetated shingle are hard to map using remote sensing because they are often form narrow, linear

sites, have vegetation cover at very low densities and have blurred transitions into other habitats, many of which are impossible to detect from remote sensing with the current resolution of widely available imagery. Similarly, inventories are based on habitat definitions which include consideration of boundary relationships with other habitats (e.g. allowable overlaps). Image classification approaches are of land cover which often assume overlaps do not exist. In addition, seasonal changes pose an added difficulty, especially to the spatial extents of the driftline vegetation. Finally, the detail required to identify habitats to Annex 1 level (species information) and for condition assessment is not possible to obtain from remote sensing methods alone. This paper describes some of the challenges in mapping coastal vegetated shingle habitats and an approach to generating national inventories which has been developed in England and extended in Scotland. This pragmatic approach uses expert ecological input and traditional habitat mapping techniques informed by remote sensing products (aerial photography, LiDAR, false colour infrared). The output is an inventory which meets multiple reporting and monitoring objectives and one which has been extensively validated through focussed ecological field surveys. We also discuss the potential to utilise digital field mapping techniques for the generation of inventories and the long term data management requirements for on-going monitoring.

A GIS-based shore monitoring and surveillance observatory on tropical islands exposed to climate change and extreme events: The example of Mayotte Island, Indian Ocean

Matthieu Jeanson (Laboratoire d'Océanologie et de Géoscience, UMR CNRS 8187 LOG), Edward Anthony (Aix-Marseille Univ), Franck Dolique (Université des Antilles et de la Guyane)

The global change currently observed generates accelerated coastal erosion and an increase in the frequency and intensity of extreme weather events. Populated tropical island coasts are particularly vulnerable. Awareness of this vulnerability has prompted the construction of an operational observatory aimed at monitoring the coastal dynamics of several French tropical islands, including Mayotte. The aims of the project are to monitor the rhythms and mechanisms of evolution, adaptation and resilience of tropical island shores in the face of extreme climate and wave events (cyclones, storms, surges, strong swells) in order to develop and implement appropriate defence strategies and/or adaptation. Mayotte Island, in the northern Indian Ocean, is characterised by a highly diversified reef-lagoon complex comprising pocket beaches and mangroves. Field experiments involving hydrodynamic measurements, topographic surveys, and observations were coupled with the analysis of aerial photographs and regional meteorological data in order to gain a better understanding of the evolution of the reef-lagoon complex. The results highlight a remarkably variable mangrove system subject to progression or stability in the north and east of the island, but exhibiting a clearly regressive pattern along the southern and western shores. The hydrodynamic data also

throw light on the short-term morphodynamics of the small pocket beaches associated with some of these mangroves. The degree of exposure to waves, and reef structure, notably in terms of width and elevation relative to the tidal frame, have a determining influence on the afore-mentioned variations in mangrove dynamics along the shores of the island, and in the greater vulnerability of the mangrove shores of the south and west of the island, especially in the face of strong impinging development pressures. The operational observatory set up on Mayotte Island is a GIS tool based on a network sourced by these measurements and field observations. Within a local framework of strong socio-economic and demographic pressures, and a more global context of environmental change, this observatory should lead to a better understanding and prediction of the morphodynamics of the shores of Mayotte, while providing data indispensable to stakeholders involved in decision-making in the face of the major and rapid environmental and socio-economic changes liable to affect the fragile reef-mangrove coastal systems. Keywords: tropical islands, mangroves, coral reefs, beach morphodynamics, monitoring, observatory, GIS, coastal management, Mayotte Island, Indian Ocean.

Monitoring annual coastal changes of different coast types in Western Greece by terrestrial laser scanning

Dirk Hoffmeister (University of Cologne), Konstantin Ntageretzi (University Mainz), Nora Tilly (University of Cologne), Constanze Curdt (University of Cologne), Hanna Hadler (University Mainz), Timo Willershäuser (University Mainz), Georg Bareth (University of Cologne), Helmut Brückner (University of Cologne), Andreas Vött (Universität Mainz)

Coasts are areas of permanent change, influenced by gradual changes and sudden impacts. In particular, western Greece is a tectonically active region, due to the nearby plate boundary of the Hellenic Arc. The region has suffered from numerous earthquakes and tsunamis during prehistoric and historic times and is thus characterized by a high seismic and tsunami hazard risk. Additionally, strong winter storms may reach considerable dimensions. In this study, terrestrial laser scanning is applied for annual change detection at six coastal areas of western Greece for three years (2009-2011). These areas show essential differences in size and coast type. The aim is to determine their annual changes. Thus, the Riegl LMS-Z420i laser scanner was used in combination with a precise DGPS system (Topcon HiPer Pro). Each scan position and a further target were recorded for georeferencing and merging of the point clouds. For the annual detection of changes, reference points for the base station of the DGPS system were marked. High-resolution digital elevation models are generated from each dataset of the different years and are compared to each other, resulting in mass balances of elevation changes. These results are checked by according photographs. Our results show that annual changes are detectable by multitemporal terrestrial laser scanning. On exposed areas, gravel with 30-50 cm diameter is displaced annually, as well as sand covers and sea weed. Minor changes are detectable for other areas, which are not directly exposed or consist of bigger gravel. However, for these coastal areas post-processing of point clouds turned out to be more difficult, due to noise effects by water and shadowing effects

Improved remote sensing-based digital modelling of a macrotidal foreshore on the North Sea coast of France: the Shoreline Detection Method

Aline Aubry (Laboratoire d'Océanologie et Géosciences), Antoine Gardel (Laboratoire d'Océanologie et de Géosciences), Sandric Lesourd (Laboratoire d'Océanologie et Géosciences)

Topographic measurements of beach and intertidal zones have various uses, including coastal management and defence, economic exploitation of the intertidal zone, and flood forecasting. This study has evaluated the ability of SPOT5 and Formosat-2 satellite based-sensors, which have different band wavelengths and different spatial resolutions (10 m, 8m), to extract waterlines of a macrotidal beach in northern France as a complement to topographic mapping. The study area (12 km²) is characterized by various sedimentary facies and morphological features (multiple intertidal bar-trough beach, sandflat, coastal foredune) and is affected by semi-diurnal tides with a mean spring tide range of about 6.4 m. Spot 5 and Formosat-2 satellites were programmed (in April 2007, May 2008 and September 2008) to acquire images simultaneously with field topographic measurements. Extracting waterlines under various water-level conditions can provide topographic information on the intertidal zone because such lines can be regarded as contours. Satellite sensors can extract waterlines across a wide area, and this waterline detection method can serve as an alternative to digital elevation models created from aircraft-based LIDAR and photogrammetric methods. By regarding beach waterlines as shorelines, data from satellite sensors can be used to detect shorelines and complement conventional aerial photographic methods of shoreline change analyses or in situ measurements. Ability to extract waterlines was quantified by calculating errors of extracted waterline positions relative to the true positions, which were determined by field topographic measurements along some transects using a differential GPS and a total station. This work also enabled a comparison of topographic data from SPOT and Formosat-2 images with the in situ topographic data. Analysis of estimation errors and image costs shows that recourse to SPOT5 or Formosat-2 data is very cost-effective for extracting waterlines with reasonable accuracy. The results serve as general guidelines for using satellite-derived data to estimate intertidal topography, detect and monitor shoreline change. Furthermore, combining satellite-derived and ground-based data should enhance the accuracy of waterlines extracted by satellite sensors, which cannot provide topographic profiles of the beach. Waterline extraction based on satellite sensor data is applicable to shorelines in all tide-ranging settings but should prove particularly useful in estimating the intertidal topography on remote shores difficult of access, as well as on shores with large tidal ranges. Keywords: Shoreline, waterlines, macrotidal, topography, SPOT5, Formosat-2.

Monitoring and Modelling Salt Marsh Margin Dynamics: Lessons from the Dengie Peninsula, Eastern England

Thomas Spencer (University of Cambridge), Susan Brooks (University of London), Iris Moller (University of Cambridge), Denise Reed (University of New Orleans), Rosalind Turner (Mott MacDonald)

Loss of intertidal salt marsh, which is of high biodiversity value and which provides a number of important ecological services, including the buffering of incident storm waves, is an important global environmental issue. However, the 'when', 'where' and 'how' of changes in salt marsh extent resulting from salt marsh edge erosion remain poorly understood, not least in the nature of the linkages between salt marsh surface and fronting mudflat elevations. In particular, it is not clear to what extent marsh edge dynamics are controlled by intrinsic thresholds to salt marsh and mudflat change, which can lead to cyclical patterns of marsh edge retreat and advance, and extrinsically-derived forcing, including the role of estuarine channel migration, changes in the configuration of offshore banks and accelerating sea level rise. These questions are examined for the data-rich setting of the fringing saltmarshes of the Dengie Peninsula, Essex coast, eastern England, across a range of time periods and spatial scales and incorporating both GIS methodologies and field observations. The paper considers i) centennial scale map evidence since the 1870s; ii) decadal scale change as revealed by aerial photography since the 1960s, and particularly annual imagery since the 1990s; iii) bi-annual cross-shore profile records of mudflat / salt marsh position at 1 km intervals along the Peninsula; and iii) short-term process studies of marsh creek and surface sediment budgets, wave energy modification across cliffed and ramped mudflat-saltmarsh transitions and studies of rates and styles of saltmarsh cliff failure. In addition, the paper assesses different forms of erosion control - from the placement of sunken barges as breakwaters to the emplacement of artificial polders - and their impact on the migration dynamics of the salt marsh edge. These different datasets are synthesised into a conceptual model which informs, in particular, the likely near-future trajectory of this southern North Sea coastal margin and, in general, the potential evolutionary pathway to be experienced by NW European salt marsh shorelines, in both the presence and absence of management interventions.

Design and development of a large and high-resolution beach-monitoring program at Balearic Islands Coastal Observing and Forecasting System

Lluís Gómez-Pujol (Balearic Islands Coastal Observing and Forecasting System), Alejandro Orfila (Mediterranean Institute for Advanced Studies), Amaya Álvarez-Ellacuría (Balearic Islands Coastal Observing and Forecasting System), Joaquim Tintoré (Balearic Islands Coastal Observing and Forecasting System)

New monitoring technologies are being progressively implemented in coastal ocean observatories. These new observing systems, such as IMOS, OOI, IOOS, among others,

are delivering new insight into coastal ocean variability. SOCIB is one of such systems, a Coastal Ocean Observing and Forecasting System located in the Balearic Islands, a new facility of facilities open to international access. SOCIB is a multi-platform distributed and integrated system that will provide streams of oceanographic data and modelling services to support operational oceanography in a European and international framework. Among different facilities, SOCIB holds the Beach Monitoring Facility, which provides data on shoreline evolution, wave climate and sediment budgets. Beach Monitoring Facility is one of the more relevant facilities for the Balearic Islands society given the importance of beaches on the environmental and socio-economical context of the islands. The goal of this paper is to introduce SOCIB's Beach Monitoring Facility. Because a continuous, large and high-resolution dataset on coastline evolution, nearshore waves and currents, sediments and beach bathymetry is a key issue in order to characterize and manage coastal systems properly, the aim of the Marine and Terrestrial Beach Monitoring Facility is to contribute to this issue by means of the Modular Beach Integral Monitoring System (MOBIMS). MOBIMS enable the autonomous and sustained collection of physical data on coastline evolution, hydrodynamics, sediment budgets and sediment transport. Each one of the MOBIMS consists of a coastal video monitoring system (SIRENA developed at the Mediterranean Institute for Advanced Studies, IMEDEA ; Nieto et al. 2010), an Acoustic Doppler Current Profiler (ADCP) and a programme of bathymetric surveys and sediment sampling. This system is modular in order to gradually expand the number of beaches under observation to cover different types of energetic input.

Decadal beach profiles and wave conditions, and sediment redistribution in an embayed storm- and tide-dominated macrotidal setting: Wissant Bay, northern France

Edward Anthony (Aix-Marseille Université), Mouncef Sedrati (University of South Brittany)

Wissant Bay, on the extreme northern coast of France, comprising a picturesque beach-dune shoreline, coastal marshes, and bold capes facing the Dover Strait, also incorporates some of the most rapidly eroding sectors of coast in France. Shoreline retreat has exceeded 250 m in the last fifty years in the central and western parts of the bay, while the eastern sector of the bay is now a zone of accretion, after being a sand-starved zone in the past, when the western sector was either stable or in accretion. The reasons for these changes are still not clear. They seem to involve interactions between a nearshore sand bank and the activity of current gyres related to the projecting headland of Cape Gris Nez, beach rotation processes and human activities, notably past aggregate extraction from the nearshore sand bank which acted hitherto as both a dissipater of incident storm wave energy and as a coastal sand source. The aim of this work is to contribute to the understanding of these long-term changes. To this end, 10-years of topographic profile data throughout the bay were analysed and confronted with offshore wave data. This analysis complements a previous analytical effort that determined gross rates of annual shoreline retreat by time slices of several decades from the careful interpretation of long series of ortho-rectified aerial photographs. The overall data suggest chronic sand bleeding from the western sector of the beach and longshore transport to the east, within a framework of what appears to be an ongoing beach rotation process within a dominant longshore sediment transport cell between the headland of Cape Gris Nez and the bold chalk cliffs of Cape Blanc Nez. The overall context appears to be one of a balanced overall embayment sediment budget. Potential sediment losses from the offshore sand bank, the lowering of which has also been invoked as a partial explanation for the chronic erosion of the western part of the bay through lessened storm wave dissipation, may be due to longshore transport within the dominant large-scale macro-scale sand circulation cell operating between the English Channel and the southern North Sea via the Dover Strait. Retreat of the beach-dune barrier in the western sector of Wissant Bay poses a threat in the coming years, as there is a likelihood of storm breaching of this narrowing barrier.

Monitoring of the morfolitodynamic processes on the White Sea inter-tidal zone (Kandalaksha Bay)

Natalia Kosevich (Moscow University), Tatyana Yu. Repkina (Moscow University), Natalia V. Shevchenko (Michigan University)

Ice spreading is one of the significant morfolitodynamic processes in the coastal area of northern seas. However the mechanism, extent and rhythm of this process are not well studied. The quantitative data on the ice component of the lithodynamic flows can help solving the problems such as the origin of boulder clay loams of the Northern arctic, definition of deposits balance of the coastal zone, monitoring of the coastal environment of the Northern seas. In order to investigate one of the poorly studied aspects of the ice spreading in the White Sea Biological Station vicinity, the monitoring of the boulders movement within the intertidal zone due to the ice effect is conducted. Starting in 1960s prof. NN Marfenin, and later FA Romanenko (since 1999) studied this process by means of photo-registration. Their data showed boulders mobility within the intertidal zone. The ice shifted them to a distance of 20 m in one winter season. The mechanism of boulders capture and further shifting by the ice remains unknown. Three arctic for boulder shift recording with different morphological and/or hydrodynamic conditions were organized in 2009. The first is located at Cape 'Cross', where due to immediate proximity to the axial channel flow the tidal currents are the strongest. The other two sites are located in areas with lower current velocities: within the small open bay, and within a straight coastal line. In all areas, the monitoring included:

Landscape Change Monitoring in the Black Sea Coastal Zone in Bulgaria for 1990-2006 Using Remote Sensing Data

Rumiana Vatsева (Bulgarian Academy of Sciences)

Coastal zones are areas of substantial importance due to their significant natural and economic resources, as well as to their sensitivity with respect to unfavorable ecological impacts. Landscape change monitoring in the Bulgarian Black Sea coastal zone appears to be an essential factor to the integrated coastal zone management. The present study aims to analyze landscape dynamics in coastal zone of Bulgaria based on satellite imagery. The survey covers 16th-years period during the transition from planned economy to market economy in Bulgaria (1990 - 2006). The remotely sensed data used include multispectral images from Landsat TM of 1991 and 1992, Landsat ETM+ of 2000 and 2001, IRS-P6, SPOT 4 and SPOT 5 of 2006 and 2007. Visual interpretation of multispectral satellite imagery was applied for landscape change detection. The landscape change total area was 6682.9 ha in 1990 - 2000 and 3754.7 ha for the period 2000 - 2006. The results indicate that the urban area expanded substantially along the Black Sea coast in Bulgaria during the period 1990-2006, mostly to the detriment of arable land and woodland.

DSM generation from stereo aerial images for the reconstruction of the sea-cliff retreat pattern controlled by gullying process, Costa da Galé and Melides sectors (Southwest of Portugal)

*Cristina Gama (University of Evora), André Jalobeanu (University of Evora),
Hélder Almeida (University of Évora)*

The seacliffs evolution is an important aspect to be taken in account in the evolution of the world coastline. The seacliffs can suffer erosion induced by the storm wave incidence or subaerial erosion leading to the retreat of the coastline. However the amount of sediments that come from the cliff retreat represent an important sediment source to the coastal system. In some cases it is essential to include this volume in the sediment budget balance of the studied coastal area. Many methods have been developed to monitor the evolution of seacliffs, most of them are supported by field measurements. In these work you propose the application of a new stereo photogrammetric method to reconstruct the cliff topography producing digital surface model (DSM) revealing the spatial distribution of the elevation errors. The model results are complemented by the acquisition of field data (GCP-ground control points) obtained using the DGPS (Differential Global Positioning System). This method also allows the generation of a coarse Digital elevation model (DEM) of the bottom of the seacliffs. The field study was conducted considering two small stretches of the sandy embayed coastline between Tróia and Sines (Southwest of Portugal). In these sectors the backshore of the subaerial beach is limited landward by the presence of seacliffs that suffer subaerial erosion (gullying process). The seacliffs presents poorly consolidated sediments (sand, clay, granule and fine pebbles) that suffer subaerial erosion showing complex gully morphology between the top and the bottom of the cliff. The sediments eroded by this process are stored at the base of cliffs in the form of debris fans. During storm periods the subaerial beach significantly decreases its width and the sediments contained in debris fans suffers cut-off. The sediments are transported by the waves thereby entering in the coastal system. Two data series of digital aerial images at 20 cm resolution, acquired in 2008 and 2009, were used to reconstruct cliffs digital surface models (DSM) and monitor the evolution of the complex gully system. A data set of 50 GCP was used to constrain the sensor location and orientation. The method was able to detect the presence of main areas of cliff displacement although the sensitivity of camera calibration prevented the absolute estimation of the displacement rate. New field surveys should help improve the results. This work was partially funded by the French Research Funding Agency (ANR) (SpaceFusion project, Jeunes Chercheurs 2005 JC05 41500) and by the Portuguese Funding Agency (FCT) (AutoProbaDTM project PTDC/EIA-CCO/102669/2008, FCOMP-01-0124-FEDER-010039).

Chair: Wayne Stephenson, Edward Anthony

Wave transformations across a macro-tidal shore platform

Wayne Stephenson (University of Otago), Larissa Naylor (University of Exeter), Bin Chen (University of Otago)

Wave transformations across a macro-tidal shore platform Wayne Stephenson¹ Larissa Naylor² Bin Chen¹ ¹ Department of Geography, University of Otago, PO Box 56 Dunedin, New Zealand. ² College of Life and Environmental Sciences, Geography, University of Exeter Cornwall Campus, Penryn, Cornwall, TR10 9EZ How swell and wind waves are transformed across shore platforms has become a central question in rock coast studies with only a limited number of field studies recently reported in the literature. Critical questions include; how much energy relative to deep water is delivered to the platform cliff junction (where platform extension occurs), how much energy is transformed to infragravity frequencies and does energy in the infragravity band have any geomorphic consequence for rock coasts? Previous investigations of wave transformations across shore platforms have mostly occurred in micro-tidal environments where water depth and platform width are limiting factors on wave energy arriving at the cliff platform junction. Only one previous study has occurred in a macro-tidal setting, where the erosive potential of waves was assessed. Here we report on the results of the deployment of three wave recorders across a shore platform in a macro-tidal setting, on the Glamorgan coast of South Wales, United Kingdom. The pressure transducers were deployed across a platform for four days recording 2048 samples at 4 Hz, in burst at 10 minute intervals over eight high tides (489 bursts). At the outer edge of the platform water depths at high tide were 8 m meaning that waves crossed the platform without breaking. Maximum wave height at the top of the platform was 2.4 m and H_{sig} never exceeded 1.34 m. Water depth at the cliff platform junction at high tide were 1.4 m and limited wave heights by forcing breaking. Only a small amount of energy were observed at infragravity frequencies at the top of the platform. Analysis shows that less than 8% of the total energy is contained within infragravity frequencies; swell, wind and capillary waves dominate containing 92% of the total energy. On this platform it is unlikely that infragravity energy has any geomorphic function other than to remove a small amount of energy from the gravity wave frequencies.

Limitations to modeling tidal notch development: insights from erosion rates on Mediterranean and tropical coasts

Cherith Moses (University of Sussex), Stefano Furlani (University of Trieste)

Tidal notches, recesses extending along marine cliffs, develop because of higher erosion rates in the intertidal zone compared to the supratidal or subtidal zone. They are widely

distributed on Mediterranean and tropical rock coasts and are commonly used as geomorphological indicators of sea level change and tectonic movement. In such cases their formation is usually associated with wave erosion, although the role of bioerosion and secondarily weathering, e.g. solution, is sometimes given more importance. On certain rock types, e.g. granite and sandstone, wave erosion is mainly related to the removal of weathered materials rather than to direct erosion of the rock. Rock type is also thought to be important in this context, with limestone coasts said to provide more reliable indicators than other rock types. As well as indicating the vertical position of former sea levels, tidal notches have also been used to estimate the duration of stillstands (e.g. on harder limestones) and to calculate the periodicity of cliff-falls (e.g. on softer limestones). Despite their global importance, their genesis is still not fully understood and there are relatively few studies that directly measure rates of notch development. We review studies that measure, using a range of methods, rates of tidal notch development in Mediterranean and tropical coasts. We also present notch erosion rates directly measured using the Micro Erosion Meter (MEM) and Traversing MEM (TMEM) on limestone on the Northern Adriatic and Andaman coasts: the former collected over > 10 years on the Trieste and Istrian coasts and > 3 years on an experimental vertical slab in the Gulf of Trieste; the latter over a 9 year period at Krabi in Southern Thailand. We discuss these rates of erosion in the context of Pirazzoli's (1986) model of intertidal notch development. The model stresses the influence of cliff slope on the development of tidal notches in sheltered areas with a tidal range of 1.0 m and erosion rate at mean sea level 1.0 mm/yr. Moreover, we highlight some of the interactions over time and space between process and measurement that continue to limit our understanding of, and ability to model, tidal notch development. Our results suggest that intertidal notches may develop more rapidly than has previously been suggested, dependent on the dominant process and environmental conditions. We conclude by identifying fruitful areas for future research. Key words: Rock coasts, models, tidal notch, limestone, erosion, weathering, tropical, Mediterranean, relative sea level.

Shore platforms as inherited landforms along the coast of Eastern Liguria (NW Italy)

Alessandro Chelli (University of Parma), Marta Pappalardo (Dipartimento di Scienze della Terra), Mattia Barsanti (ENEA), Federica G Pannacciulli (ENEA), Ernesto Rosa

Shore platforms are landforms shaped in the rocky coasts; they are widespread and studied especially along ocean's coastlines, characterized by wide tidal ranges, where they can be found in the intertidal and lower supratidal zone. Among rock coasts geomorphologists there is not agreement about the role that wave erosion and weathering exert in the genesis of these landforms. Studies carried out in different contexts stated the prevalence of either one process or the other or, in some cases, claim the occurrence of both. In the Mediterranean Sea shore platforms are not the main

landform. When present, they are constrained in the supralittoral, up to the elevation directly affected by marine processes. This is variable from place to place. The study of shore platforms along the Liguria eastern coast, was approached classifying them according to the classical scheme of Sunamura, which differentiates rocky coasts types in cliffs and type A and type B shore platforms. For the supralittoral zoning those criteria proposed first by Schneider were adopted. Geomorphological analysis and age constraints (for instance at Palmaria island, in the La Spezia Gulf, dated slope deposits overlapped to the platforms exist), enabled to assess that investigated shore platforms could be sometimes forms inherited from past climate-marine condition. Schmidt hammer test, traditionally employed to compare the degree of weathering of exposed rock surfaces through rock hardness value, provided some insight on processes operating on these shore platforms. Comparative tests were performed along each platform and between shore platforms at different height above mean sea level. Besides, comparative test were also performed among shore platforms and rock surfaces artificially exposed since the 19th century or new artificial rock cuts. The evidence provided by Schmidt hammer test display a seaward trend of increasing weathering. Rock hardness decreases in the intertidal and lowermost supratidal where repeated wetting and drying and biological weathering prove to be active. The comparison with old and new artificial rock outcrops demonstrated that weathering loosens the rock in a very short time span. The reduction in hardness of the rock is on the order of 15% to 50% compared to unweathered rock. This work demonstrates that shore platforms of Eastern Liguria are currently being dismantled due to different types of weathering processes, and are thus inherited landforms.

Sediments and inheritance in rock coast evolution. Linking Holocene sedimentary cliff retreat with a process of beach crest construction in a rock coast sector (NW Spain).

Alejandra Feal Pérez (University of Santiago de Compostela), Ramón Blanco Chao

The use of pedological and sedimentological techniques to study of a complex sedimentary sequence have show new evidences of the importance of considered the time vector for understanding the present dynamic of rock coasts. This study was conducted in a rock platform-sedimentary cliff system located at the NW coast of the Iberian Peninsula. The area under investigation was subjected to periglacial conditions during Quaternary cold stages with active solifluction producing extensive spreads of unconsolidated both coarse and fine sediments. The occurrence of sea-shells (*Nassarius pygmaeus*, *Littorina saxatilis*, *Littorina neritoides*) in a silty sandy level dated in 5580-5530 cal BP suggest a marine influence in the sedimentation during the Holocene Climate Optimum. After this relative high-stand, a radiocarbon date of 4015±3685 cal. yr. BP obtained in a continental- alluvial facies indicates a fall in the relative sea-level. During the Holocene Transgression the very high cohesiveness of the Weichselian sediments

conducted to the formation of a sedimentary ramp at the back of the shore platform that today's determine the slope of the boulder beach. During the Upper Holocene, after the sea level stabilization, the presence of this cohesive sediment ramp helped starting a different sedimentary dynamic at the back of the shore platform: a process of beach crest construction related to storm activity. The studied sequence has two coarse beach layers at an elevation of 2.8'3.5 m above the present astronomical highest high tide. AMS Radiocarbon-datings revealed that this deposition started at 1735-1590 cal yr BP and expands to the present. Lorang's (2002) equations applied to the studied sedimentary levels allowed to identify the type of wave (in terms of H_s and T_p) needed to deposit the clasts at the top of the sedimentary cliff. The presence of a boulder beach and a cohesive clay ramp (formed by the erosion during the Holocene Transgression of late Pleistocene alluvial sedimentary levels) below it have been showed as necessary features to drive wave energy to the top of the sedimentary cliff allowing the deposition of clasts eroded from the Pleistocene deposits in the upper sedimentary level. The beach crest formation model described is a new example of the response of a para-periglacial coastal system to the Holocene transgression. By other hand, the reconstruction of the processes of beach construction points to a very important role of deep storms, which frequency and intensity modulates the wave energy arriving to the north coast of Spain. This research implies a new interpretation of coarse levels in a sedimentary sequence, underlining the imprint of high energy events and the synergies between past and present processes in the recent evolution and present morphodynamic of rock coasts environments. Lorang, M. S. 2002. Predicting the height of a gravel beach. *Geomorphology*, 48, pp. 87-101.

Chair: Wayne Stephenson, Edward Anthony

Determinants on the presence and character of Calas: a limestone rock coast macroform

Lluís Gómez-Pujol (Balearic Islands Coastal Observing and Forecasting System), Bernadi Gelabert (Universitat de les Illes Balears), Joan J. Fornós (Universitat de les Illes Balears), Josep Eliseu Pardo (Universitat Politècnica de València), Vicenç M. Rosselló (Universitat de València), Francesca Segura (Universitat de València)

Calas are characteristic embayed coastline landforms related with steep sided drowned valleys that were deeply incised during low sea-levels stages into carbonate plateaus. Therefore coastal, fluvial and karst processes and structural control are the main factors in cala's morphology. Calas or calanques, are a conspicuous rock coast macroforms quite frequent in Mediterranean, but also in many other locations as southwestern Australia or Caribbean islands among others. This paper studies the determinants on the presence and character of calas in three different islands of the Balearic Archipelago (Mallorca, Menorca and Formentera Islands), Western Mediterranean, by means of DEM exploitation, embayment and catchment morphometric analysis and through the compilation of fault and joint orientations. All islands exhibit emerged carbonate platforms (Upper Miocene in age) outcropping with horizontal or very gentle dipping bedding. Two patterns discernible at all the study sites are the absence or poor development of calas when carbonate plateaus exhibit strong coast-parallel structures; and a greater variability of cala embayment size according to stream catchment size, lithology and karst processes, or to the catchment distance from the coastline. Also, the amount of incision of the streams, and then the character of a cala at its mouth, depends on the proportion of impermeable rocks exposed in each drainage basin. Major incisions correlate with greater proportion of impermeable rocks at basin surface. This work was supported by the research fund of MICINN Project CGL2010-18616/BTE of the Spanish Government.

Evaluating the complex response of rapidly-retreating soft rock cliffs to global warming: decadal scale variability in the cliffs of the East Anglian coast

Susan Brooks (University of London), Thomas Spencer (University of Cambridge)

Rapidly eroding soft rock cliffs typically retreat at rates in excess of several metres per year, thus allowing the resolution of linkages between cliff dynamics and a range of climatic and marine forcing factors. This paper firstly presents averaged decadal-scale rates of retreat in the unprotected cliffline between Benacre and Southwold, Suffolk Coast, eastern England. The application of the DSAS GIS package (Thieler et al., 2005) to

historic map and aerial photograph sources show these cliffs have experienced considerable decadal-scale variability in retreat rates. For the 1990s, rates were close to 5 m/a, while for the 2000s they fell to 2 m/a, against the long-term average of 2 - 4 m/a between 1883 and 2008 (Brooks and Spencer, 2010). Secondly, we present new evidence from the wider coastline of East Anglia, also gathered from application of DSAS, that suggests that this decadal-scale variability in cliff retreat is a more widespread phenomenon. Unprotected soft rock cliffs from dispersed locations around the east Anglian coast all show similar variability in retreat behavior on decadal timescales, which we attribute to changing patterns of storminess in these decades. The 1990s were characterized by frequent months in which the North Atlantic Oscillation (NAO; a well-established measure of inter-annual climatic variability in North-West Europe) was extremely positive ($> +3$) or extremely negative (> -3), while the 2000s showed few occurrences in such extreme values. Depression tracks in positive NAO phases make the East Anglian coast prone to storm surges in which raised water levels result from deeply developed low pressure systems, generally associated with westerly air streams. In negative NAO phases the region is prone to easterly airflow which results in periods of strong onshore wind. Both phases are associated with high energetics in the forcing factors. In this paper we evaluate the complex effects of both westerly and easterly dominant weather types (Lamb, 1972) on cliff retreat and suggest that the response to global warming in these cliff systems needs to consider a complex suite of climatic and associated marine phenomena and should not be regarded as a simple response to secular sea level rise over the twentieth century.

Erosion processes on the rocky coasts of Ponza Island (Italy)

Alessio Valente (University of Sannio), Sergio Ginesu (University of Sassari)

The Island of Ponza is part of the Pontine Archipelago located at an average distance of about 50 km from the coast of southern Lazio in Italy. From the geographical point of view, this archipelago is situated between the outer edge of the continental shelf and slope, which connects with the abyssal plain of the Tyrrhenian Sea. Its origin is linked to volcanism that has characterized this margin of the Apennines during the Plio-Pleistocene extensional phases. At present tectonic and volcanic events (the latest emission date back about 200,000 years) can be considered concluded even if the area is still affected by a weak earthquake activity. The coast of the island is characterized by cliffs cut off in volcanic rocks, mostly sub-vertical, with heights ranging from about 10 m to over than 130 m. Not lacking at the base of them, as well as inside inlets and bays, often coinciding with secondary craters, sandy-pebbly beaches. The concentration of energy on headlands has also formed arches and sea stacks. Evidences of marine abrasion, active since the Early Pleistocene, are present in some relics of surfaces at altitudes of 200-270 m, 100-120 m and 45-50 m. To these raised surfaces are respectively associated gravelly beach deposits, a strongly altered paleosol and weakly cemented eolian deposits. Marine erosion takes place at the foot of the cliffs, whereas on the face of

them works the abrasion of the wind, the run off of the water and its infiltration in the lines of weakness, the weathering of the rocks by meteoric agents and, even, the seismic action. The lithological nature of the volcanic formations, characterized by high fracturing as well as fault plane and fractures, which also isolate blocks of considerable size, determines conditions of great danger with frequent falls involving rock masses from small to extremely large sizes. The danger is usually heightened, when the top of the cliff is mantled by epiclastic deposits from loose to weakly cemented. These deposits, due to the flow of water and the physical action of plant roots, can become unstable, resulting in slidings and rapid flows. In these mass movements are also involved other volcanic material detached from the cliffs. The continuous retreat of the cliff is proved by: the constant presence of significant accumulation of debris at their foot, despite the wave action; absence or lack of evidence, on the exposed face of the cliff, of notches or sea terraces immediately above to the present sea level, related to eustatic sea level changes occurred in the latest Pleistocene (this phenomenon shows a low coefficient of morphological preservation and thus a "high speed of erosion"; the presence of truncated valleys; the uncovering of the underground ducts of the Roman age.

Structural evidence of recent uplift at a small coastal area (S. Paio , Vila do Conde, NW Portugal)

Maria Araújo (Universidade do Porto), Manuel João Abrunhosa (CEAUCP)

Variscan granite and undeformed pegmatite veins intrude a metamorphic complex probably derived from a Precambrian-Lower Proterozoic crustal terrane (ZOM) accreted to the east to the core of the variscan orogen (ZCI) along a large deep crustal suture zone (ZCPT) that is recognized as a major neotectonic feature. Granite was affected by tectonic events from ductile-brittle mid-crustal to pure brittle stages in high-crustal settings. High-crustal faults and joints postdate lamprophyre dikes. 5 kilometres to the NE a low angle reverse fault cuts through a probable Pliocene-Pleistocene deposit. The fault has a granite footwall overlaying sediments demonstrating a horizontal compressive regime. It is concordant with present regional tectonic stress. If similar faults were able to reach the nearby coast we would expect previous geoforms to be vertically dislocated from their original or normal position to a higher one in a short distance. We could also anticipate that a leveled geoform could maintain its normal position a short distance from the fault trace. Because faulting as usual is polycyclic it is possible to accept, giving the right local conditions, that geoforms built by coastal processes can also be dislocated in altimetric steps, the older in the top. This conceptual model is being confronted with detailed geomorphologic and geologic observations. This area is the highest point on this coastal stretch, culminating at 20m amsl with rectilinear rocky cliffs. It supports several small remains of marine deposits at different elevations. The lower one consists of a complex outcrop where an aeolian deposit dated of ca 84.ka BP is covering a solifluidal and a marine deposit, lying at 5m. As it is superposed by a 84k deposit, the underlying marine deposit must be from last interglacial (probably MIS 5e). 90 m to the south,

fossilizing an almost fresh granite notch there is another marine deposit at 10m. At 19m, the same granite outcrop, almost unaltered, supports the remains of another marine deposit. 18 km to the South (Lavadores, Vila Nova de Gaia) we find a staircase of 3 distinct marine levels, ca 26, 18 and 5m high. However, at Lavadores the bedrock alteration is much stronger in the higher levels than in the highest level at S. Paio, indicating that the southern staircase probably represents marine levels from MIS 5e till at least MIS 9. At S. Paio the several benches organized in a staircase fashion seem to correspond to a younger age, possibly to different relative positions of the sea level included into last interglacial. This could mean that this area had suffered a localized uplift, producing a clear relationship between topography and tectonics. We are focusing on the study of rock structures, trying to identify fragile neotectonic movements responsible for the topographic development of the area.

Community Adaptation to Sea-level Rise

Riswan Septriyadi Sianturi (Gadjah Mada University)

Late Holocene submerged beachrock, Hasir Island, Marmara Sea, Turkey: cement fabrics, stable isotope measurements and AMS 14C ages

T. Ahmet Ertek (Istanbul University), Elcin Kilic (Istanbul University), A. Evren Erginal (Ardaahan University)

The Marmara Sea, located between the Mediterranean and Black Sea, Turkey, keeps invaluable records regarding both Late Pleistocene water exchanges between these two seas and Holocene sea-level changes, which made this deep inland sea focus of interest since the second half of 19th century. In this study, we, for the first time, attempt to discuss implications of a totally submerged beachrock on the coast of the Hasir Island, Marmara Archipelago, based on micro-morphological features, stable isotope determinations and AMS 14C ages. Our results reveal that 1-m thick beachrock which slightly exceeds contemporary tidal range is indicative of a former sea-level at Late Holocene. Various types of sequential cements were determined, such as micrite envelopes, void fills, rhombohedral blades and aragonite needles. The coccolithophore *Emiliania huxleyi* and some species of ostracod also exist. Stable average isotope values for ¹⁸O and ¹³C from beachrock carbonates yielded average values of -0.4 and 2 PDB, respectively. These data show that beachrock is characterized by marine phreatic cements with slightly negative ¹⁸O and positive ¹³C values and occurred when level of the Marmara Sea was 1.5-2 meters lower than today based on calibrated AMS 14C ages of 2.9 - 2.5 ka BP.

The future of coastal zones – global analysis of present and future population exposed to coastal hazards

Barbara Neumann (University Kiel), Athanasios T. Vafeidis (University Kiel), Juliane Zimmermann (University Kiel), Robert J. Nicholls (University of Southampton)

While there is broad scientific consensus that global mean sea-levels are rising at an accelerating rate, the factual rise in the 21st century is unsure. Recent studies raise that future sea-level rise (SLR) could exceed the dimensions suggested by the IPCC in its Fourth Assessment Report (AR4) by far. The impacts of SLR will primarily be felt in low-

lying coastal regions with increased coastal flooding, submergence and erosion, besides other biophysical effects and associated socio-economic impacts. At the same time, the coastal population is growing at a much larger rate than the inland population, a trend that is going along with a rapid change in land use and urban development in the coastal zone. To assess the future socio-economic impacts of SLR, data on the people exposed to SLR and storm surges are essential but difficult to retrieve at global scales, in particular with regard to the demographic development. In our study, which was conducted in the context of the UK Foresight project on migration and global environmental change, we have taken a global look at the urban and rural population in the low-elevation coastal zone (LECZ) at present and in the years 2030 and 2060. The assessments have been carried out through geospatial analysis of publicly available global-scale spatial datasets and national-scale projections of the United Nations on future population growth and urbanization. Scenario-based assumptions on coastal versus inland population development have been developed and implemented on the basis of these data in order to estimate the future coastal urban and rural population at national scales. According to our assessment, the coastal population will be growing from 625 Mio (year 2000) to 949 Mio in 2030 and exceed 1.388 Mio by 2060 under highest-end growth assumption (Scenario C) - which would amount to almost one fifth of today's world population. But even under lowest-end estimates (Scenario B), there will be more than a billion people living in the LECZ globally by 2060. The results show that Africa will be experiencing the highest growth of coastal population and urbanization, especially Sub-Saharan Africa. The dramatic development of Africa's coastal zones will add to the general high vulnerability of many African coastal countries, while Asia will be struggling with the overall large number of people exposed to coastal hazards. Asia's coastal population, which amounted to 461 Mio in the year 2000, will be growing at only half to two-thirds of the rate of Africa and still reach 983 Mio people by 2060 (Scenario C), making up more than 70 % of the global coastal population. The study sheds new light on the present and future coastal population potentially exposed to coastal hazards and provides a good basis for further impact assessment modelling. Nevertheless, global studies always come along with data issues and limitations that need to be taken into account.

Using the past, to understand the present, to predict for the future

Sarah McGowan (University of New England), Robert Baker (University of New England)

Climate change and associated sea-level rise are an increasing concern for coastal communities. One of the greatest challenges lies in predicting future rates of sea-level rise and climate change. This study outlines the need to understand past episodes of sea-level variation, in order to better understand present sea-level rise, enabling a better prediction of future sea-levels. This study undertakes a somewhat controversial approach to predicting future sea-levels. Evidence from past episodes of higher sea-levels during the Holocene and Pleistocene from the south-eastern Australian coast is used to develop

estimates of future rates of sea-level rise. A rule of thumb calculated from ice cores and other palaeo-proxies is that for every 1°C increase in temperature, on average, there would be a 0.8m positive response in mean sea-levels in south-eastern Australia. Although this approach is controversial it is relevant as correlations between past sea-level heights and temperatures have been reported. Palaeo data can therefore be used to test the validity of models predicting the response of coastlines to sea-level rise. These estimates were then applied to a case study of an area surrounding the Hexham Swamp, Newcastle, New South Wales, Australia. The outlined approach provides an alternative to the computer generated simulations with ad hoc assumptions. When assessing the vulnerability of coastal and estuarine areas to future sea-level rise, there is a need to consider multiple sea-level rise scenarios to account for the uncertainty of predictions. Whilst developing sea-level rise policies for future coastal adaptation it is necessary to ensure that these policies are informed by accurate scientific knowledge to enable the development of adequate coastal management plans. The variations in predictions of future sea-level heights is particularly concerning as decisions are being made now regarding future coastal development on land that may be subject to inundation within the lifetime of the development. Within estuaries a small increase in sea-level rise can result in a significant increase in the area of land inundated due to the low gradient of the shoreline. This study has also illustrated the need for planning policies to be developed at a local scale as rates of sea-level rise will not be synchronous globally and impacts will vary due to regional and local coastal conditions.

First record of Late Holocene coquina on Thrace (Western Black Sea) coast of Turkey

A. Evren Erginal (Ardahan University), Elmas K'rc' Elmas (Istanbul University)

First record of carbonate-cemented coquina on Thrace coast of Turkey is presented based on field observations, microanalytical examinations, fossil contents and radiocarbon dating data from fossil shells. The moderately to hardly cemented coquina crops out along the Karaburun coast to the northeast of Lake Terkos, western Istanbul, and exhibit a well-developed cross-beds with abundant broken shells. Having an average thickness of 80 cm, the cemented beds extend along a low-angle sandy beach with small fragments of shell debris. They are mostly composed of discontinuously exposed large blocks exposed between rip-rap breakwaters. XRD and EDX data show the existence of calcite, aragonite, quartz and magnesite minerals and various elements in decreasing order of O, Ca, C, Si, Al, Fe, Mg, K and Na, respectively. Its shell components are composed of *Donacilla* sp., *Venus gallina*, *Pecten glaucum*, *Ostrea edulis*, *Cardium* sp., and *Donax* sp. The rock also contains various foraminifera, such as *Spiroplectinella wrighti* (Silvestri), *Spiroloculina excavata* d'Orbigny, *Quinqueloculina* sp., *Triloculina* sp., *Polymorphina* sp., *Brizalina spathulata* (Williamson), *Cassidulina crassa* d'Orbigny, *Valvulineria minuta* Parker, *Neoeponides bradyi* (Le Calvez), *Rosalina floridensis* (Cushman), *Cibicides* sp., *Lobatula lobatula* (Walker & Jacob), *Asterigerinata mamilla* (Williamson), *Ammonia compacta* (Hofker), *A. tepida* (Cushman), *Elphidium macellum* (Fichtel & Moll), *Elphidium* sp., and the coccolithophore *Emiliania huxleyi*. From bottom to top, radiometric dating results from those shelly coquina beds typical of high-energy marine environment yielded calibrated ages ranging from 3.70 ka to 2.85 ka BP, matching the subboreal stage of Holocene. Much of these benthic foraminifera, *E. huxleyi* and shells were, on the other hand, founded in samples collected from uppermost level dated at 3140-2850 ka cal. BP.

Impacts of the last rapid sea-level rise on the Caspian barrier coasts

Mikhail Lychagin (Moscow University), Maria Kasatenkova (Moscow University)

Global warming causes world-wide concern on the impact of sea-level rise on oceanic coasts. Predicting this impact is hampered by the slow pace of sea-level rise in the past, and the complexity of coastal processes. The Caspian Sea, having experienced phases of sea-level rise of up to a hundred times the eustatic rate, offers accelerated real-world models of how coastal zone behave under such conditions. These data can be used to predict possible changes within coastal areas of other seas. Of a special concern is a

problem of contamination of coastal zone by heavy metals and other pollutants. The study of the Caspian shores during the last period of the rapid sea-level rise in 1978-1995 showed that impacts of this dangerous event on the coastal landscapes are highly determined by their morphology. The mostly possible dangerous processes for the abrasive shores are their erosion and destruction. For the accumulative shores a set of dangerous processes is definitely higher. It includes flooding and water-logging of the coastal landscapes, salinization of soils and groundwater, disturbance of biogeochemical cycles, and also accumulation of heavy metals in coastal soils and sediments. Barrier coasts are typical for the western and southern Caspian. The coasts with intermediate shore-face slopes experienced mainly passive drowning during the continuous sea retreat. Sea-level rise caused formation of larger barriers and adjacent lagoons, which encroached landwards dozens of meters each year. From the geochemical viewpoint the sea-level rise caused a sharp alteration of geochemical conditions in soils and sediments with a consequent changes in migration of heavy metals and other chemical substances. The most complicate geochemical pattern became characteristic for lagoons and adjacent marsh zones. The Caspian barrier coasts are located in different mineralogical and geochemical provinces and climatic belts. Therefore natural heavy metal levels of coastal soils and sediments differ up to ten times. Essential climatic differences along the seashores caused a significant variability in the intensity of the modern geochemical processes. Salinization and sulfidization are the mostly pronounced in semi-desert conditions, while organic matter accumulation is the highest in humid subtropics. The study showed that the risk of HM accumulation is the highest within coastal areas built by clayey deposits, water-logged by brackish waters, with soils enriched by organic matter. Along the sea coasts of a special concern are lagoon shores, salt marshes and river deltas. Additional technogenic input of heavy metals in such areas located in highly populated or industrial regions can determine excess of HM permissible levels in components of coastal ecosystems.

The Implications of New Sea Level Rise Estimates for US Pacific Coast Wetlands

Denise Reed (University of New Orleans)

The response of flats and marshes to sea-level rise depends on the balance between submergence, erosive forces, and sediment supply, and is mediated by climatic influences on biotic processes. This paper will describe interactions among these processes as influenced by new predictions of sea-level change for the US Pacific Coast to be released to spring 2012. Along this complex shoreline, tidal marshes are found within major estuarine embayments such as San Francisco Bay, but also within bar-built estuaries and along the margins of rivers that flow directly into the ocean, e.g., the Salmon River, OR. Extensive tidal marshes also existed historically within the deltas of the major rivers flowing into Puget Sound. The National Research Council Committee on SEA LEVEL RISE IN CALIFORNIA, OREGON, AND WASHINGTON has been charged with

evaluation of sea level rise for California, Oregon, and Washington for the years 2030, 2050 and 2100 which will be published in spring 2012. The Committee also examines the response of coastal wetland systems to these predictions. Their estimates of sea-level rise along the coast also consider regional variation in tectonics and other influences on vertical land motion. Within estuaries, transitions between subtidal (permanently flooded) areas, intertidal flats (unvegetated area regularly exposed by falling tides), and vegetated marshes occur as tides interact with local topography on time scales ranging from weeks to millennia. As local sea-level changes, the tidal dynamics within the estuary may change. Changes in tidal dynamics, including the tidal range, affect saltwater penetration, the duration of flooding or exposure of intertidal flats and marshes, and the depth of flooding, which in turn influences wave activity, the potential for erosion, and a host of biological processes. Compounding these changes is the variety of vegetation types found in coastal marshes on the US Pacific Coast. These, for the most part, are different from those of the more studied coastal wetlands of the SE US for which many studies of the response to sea-level rise have been conducted. The situation is further complicated by extensive management of rivers feeding sediments and freshwater to the coastal zone. The paper will consider the fate of coastal wetlands under the new predictions both assuming the current coastal context and in terms of what other actions, both on the coast and within watersheds, could be undertaken to enhance coastal wetland adaptation and survival.

Palaeo-environmental evolution and coastal risks on the Kathari coastline (Kition, Larnaca, Cyprus)

Guénaëlle Bony (CNRS Cerege), Daniel Borschneck (Université de Provence), Nicolas Carayon (Université de Provence), Clément Flaux (Université de Provence), Nick Marriner (Université de Provence), Christophe Morhange (Université de Provence), Jean-Marie Rouchy (Université de Provence)

At the request of HISOMA Laboratory, attached to MOM Laboratory (Lyon), a coring campaign was conducted along the coastline of the archaeological site of Kathari (Kition, Larnaca). The two main objectives of this study are: to characterize the palaeo-environmental evolution of the shoreline from the Bronze Age; to understand the evolution of the settlement with regards to relative sea-level variations (e.g. tectonic movements) and sediment supply. Kition was a harbor city founded by the Mycenaeans. It is located in southeast Cyprus, on the shores of the current Larnaca Bay. This city has experienced continuous human settlement from the end of the Late Bronze Age until today. Archaeological remains, attesting to the urban organization of the city, are few. Only two areas of the city have been identified: the district of Bamboula and its military harbor renowned for the Phoenician Slipway (Yon, 2006) and the district of Kathari used as a place worship. Between Kathari and the promontory of Prodomos, located further east, many tombs dated from different periods were found. Several studies on the palaeo-environmental evolution of this area have been conducted (Niccolaou, 1976; Gifford,

1978; Morhange et al., 2000). These studies demonstrate a logical evolution of the coastline. Only Morhange et al. (2000) clearly indicate, in their study of the military harbor of Bamboula, that the harbor basin was transformed into a salt lake around 1600 BP. Following these studies, several hypotheses concerning the environmental changes were raised: modifications in the sediment budget of Thremitos (the main sediment source in the Bay of Larnaca) and/or tectonic uplift. Our study focuses on several issues. Does the Bay of Kathari follow the same palaeo-environmental evolution as Bamboula? What is the chronology of this coastal evolution? Are the Tremithos sediment supplies only responsible for these environmental changes? To resolve these issues, two cores were undertaken and analyzed at high resolution. Results show a more complex evolution than previously attested. Indeed, it appears that the salt lake transformation took place evenly along the coast of Larnaca, especially east of Prodomos where this promontory was an island at this period. This first environmental change was linked to the accretion of a pebble spit (Morhange et al., 2000) which closed the lagoon. During the same period, only the small bay of Kathari was transformed into a fresh water lake. This environmental change, in contradiction with the rest of the bay, is probably due to the water table. In fact this area, without any river, is characterized by a water deficit. The second environmental transformation of the Bay of Larnaca comprised a reconnection to the sea. These environmental changes were probably due to the opening of the pebble spit. Because these environmental changes were sudden, we hypothesize that they were driven by a vertical tectonic movement.

Barrier rollover and barrier spit accretion due to the combined action of storm surge induced washover events and progradation: Insights from ground-penetrating radar surveys and sedimentological data

Tanja Tillmann (Goethe University), Jürgen Wunderlich (Goethe University)

Barriers comprise approximately 15 % of the world's coastlines and are formed due to the combined action of wind, waves, and longshore currents. Barrier islands and barrier spits are geological young, highly dynamic and represent a complex coastal system that includes a number of different but closely related sedimentary depositional environments and geomorphologic elements of varying origin, genesis and evolution. The stratification of barrier islands is often exclusively investigated by using borehole data. Therefore, the processes of evolution and the internal structure of barrier islands are often unknown. In recent years the ground-penetrating radar (GPR) method has been widely used to examine the internal structures of Holocene sediments. In this study ground-penetrating radar data of different antenna frequencies, sedimentological data and amino acid racemisation datings (AAR) were combined to reveal the sedimentary structure and architecture of the southern barrier island spit of Sylt and to define different coastal environments and to set up a barrier island stratigraphy. Based on these data, two sedimentological models of barrier spit development have been generated for Southern Sylt which describes the inter-action between extreme events, coastal processes and sedimentary development and contains the major episodes of barrier island evolution. The first model is concerned with the spit add-on zone where the barrier spit is attached to the central island moraine core and shows a landward migration through barrier rollover affected by an interplay of barrier retreat and washover flooding associated with accumulation of sediment in a backbarrier environment as a result of several storm surges. With the exception of the uppermost dune facies the spit add-on zone reveals a transgressive coarsening upward sequence starting with sandy mud flat deposits at the bottom which turn into coarser sandy tidal flat deposits toward the top. Sandy tidal flat deposits are overlain by washover sheet and washover fan deposits. The second model demonstrates a barrier spit accretion through southerly directed progradation. Eroded sediment was transported along the west coast of Sylt by longshore drift and was added to the southern spit-end. Growth and progradation of the southern spit-end has forced a southward directed tidal-inlet migration of the Hörnum tidal inlet. Progradation and barrier spit accretion were also interrupted by severe storm surges. Storm surge generated erosion unconformities in a foreshore to shoreface environment redraw old spit-end positions that represent stages of barrier spit progradation. Spit enlargement increased when the time interval between storm surges was long and the delivery rate of sand from

longshore drift was high. Annual winter storms also caused inundation of the barrier spit-end and produced elongate washover channels formed during numerous erosional overwash processes.

Geographical Model (Phase 1) for Tsunami Risk Reduction

Laura Cano (Texas University), Osvaldo Muñiz (Texas University)

Local and regional tsunami events cause considerable property damage and high casualties when preventive measures to reduce risks are scarce or they have not been designed at all. Hazard mitigation and preventive measures are focused on the creation of physical structures to reduce the effect of high waves (Koutitas and Karambas, 2005), geospatial information to model wave trains on coastal areas and emergency relief (ESRI, 2006), warning system procedures for effective and efficient evacuation (Bernard, 2005), and educational programs for public awareness (Samant, Tobin, and Tucker, 2007; Damiano and Pacheco, 2011). The aim of this study is twofold. The first phase of this study develops a geographical model for population evacuation based on geospatial analysis. The second phase is devoted to design evacuation strategy procedures based on specific geographical education objectives. During the first phase the researchers work with three specific locations in Chile, Costa Rica, and Mexico in order to obtain a geographical model. The study of specific locations in the selected countries of the Pacific allows a comparison of coastal characteristics and geomorphology of local and contiguous region, population growth, population distribution, and population density. This paper reports the result of Phase 1 which shows digital elevation maps, population maps of rural and urban communities and preliminary evacuation route maps. This analysis is initially performed with GIS applications and high resolution remote sensing imagery which are complemented with population data from census information and surveys. Vegetation dynamics and its response to freshwater input and climate variability in Yellow River Delta

Dejuan Jiang (Chinese Academy of Sciences)

Vegetation coverage can deliver important information of wetland landscape and its ecological regimes. In Yellow River Delta wetland, vegetation cover is greatly sensitive to

local climate conditions (precipitation and temperature) and freshwater input of Yellow river. Particularly, freshwater inflow has a significant restrictive effect on wetland vegetation. Therefore, the study on vegetation dynamics and its response to freshwater input and climate variability in Yellow River Delta has theoretical and practical significance. First, based on the data of MODIS images and under the support of GIS technique, the normalized difference vegetation index (NDVI) was calculated. Then, using NDVI as a key quantitative index, the spatial and temporal characteristics of vegetation cover were detected by the spatial autocorrelation analysis method. Finally, the Person correlation coefficients between NDVI and freshwater inflow, precipitation and temperature was calculated and further, the effects of freshwater input and climate variables on vegetation cover were evaluated. The results of this study would be helpful for the assessment of wetland ecological conditions and to develop appropriate adaptation and mitigation strategies for vegetation protection and restoration in the estuary wetland of Yellow River Delta.

The potential of different overwash deposits for palaeotempestological research – preliminary findings from Western Australia

Simon Matthias May (University of Cologne), Helmut Brückner (University of Cologne), Max Engel (University of Cologne), Dieter Kelletat (University of Duisburg-Essen), Anja Scheffers (Southern Cross University), Peter Squire (Southern Cross University), Anna Pint (University of Cologne)

Palaeotempestology, the study of prehistoric storms, uses sedimentary evidence to enlarge the temporal frame given by historical records and provides important information about past storm frequencies and magnitudes, and thus a basis for coastal hazard assessment. Along the Pilbara coast, Western Australia, different sedimentary archives (washover fans, beach ridge sequences, mud flats) were investigated in 2011 in order to identify and date sedimentary traces of storm overwash. The stratigraphy of washover fans at Onslow shows several depositional units of mainly well stratified sand with distinct heavy mineral laminae of varying concentrations, similar to storm deposits from the Florida (Sedgwick and Davis, 2003) but also to tsunami deposits from India (Switzer et al., 2012). These units are intercalated by massive coarse sand deposits with channel structures, implying different flow regimes and flow conditions during deposition. According to bioturbation horizons, several different depositional events (cyclone and/or tsunami) can be inferred. At Point Lefroy headland, southwestern Exmouth Gulf, distinct lobate washover fans were detected in the mud flat behind the dune belt. They exhibit washover terraces and incised channels. Its stratigraphy shows distinct layers of shell debris, sand and coarser components such as coral and larger shells, intersected by a minimum of three palaeosols, unambiguously documenting multiple depositional events and periods of geomorphologic stability, when soil formation took place. Multitemporal satellite images and aerial photos indicate that these overwash fans were stable at least during the last 45 years. Reactivation is likely since the dune gaps at the apex of the fans

provide pathways for inundation during extreme wave events. Our preliminary findings suggest that the investigated sedimentary archives have a high potential for improving extreme wave histories (tsunamis and cyclone landfalls) of Western Australia. Main challenges for the future include dating (^{14}C , OSL, U/Th, ^{210}Pb) and distinguishing between event types based on sedimentology, microfauna, and shell taphonomy. Cold Region Environments

C08.06-01 - Contextualising climate change: methodological, institutional and regional responses

Chair: Tatiana Vlasova, Nancy Doubleday

Strengthening Arctic Cooperation to meet the climate, energy and resource depletion changes and challenges

Tatiana Vlasova (RAS)

More and more government, non-government institutes, organizations and programs both international and national are becoming involved in the investigation and monitoring of changes happening in the Arctic (Arctic Council groups and projects, indigenous people's organizations, IASSA, IASC, UNEP, Polar foundation, WWF, and many other). The goal of this paper is to figure out ways for strengthening multi-disciplinary, multi-scale and inter-institutional cooperation in investigation and monitoring of the Arctic change. The Arctic nowadays has gained increased attention due to many opportunities, challenges and rapid changes. Among them there are: the Arctic is expected to warm at twice the global average rate and climate changes impacts (both positive and negative) are more pronounced in the Arctic, opening new perspectives and thresholds and having far-reaching consequences for ecosystems and for the people dependent on ecosystem services; the Arctic may serve as an indicator of environmental change and an "early warning system" for other parts of the world; the increasing interest to the Arctic for new sources of depleting fossil fuel resources; the spread and the improvements in Internet and mobile communication as well as sea ice melting opening new routs, make the remote regions of the Arctic more accessible for settlement and development; the need for experience exchange in elaborating strategies for sustainable development in the Arctic and adaptation to climate changes at different scales. In the era of global climate changes and globalization many new and poorly predicted issues are emerging as well as new perspectives and opportunities are opening in the Arctic. That is why there is a strong need nowadays to increase not only multi-disciplinary research (social and natural sciences synthesis with local and traditional knowledge integration), but to enhance multi-scale geographical approaches (from global to national and local), as well as to strengthen inter-institutional cooperation in observing, investigation and managing Arctic changes in order to increase robustness and resilience of entire human-nature systems at different territorial scales. The experience of the Integrated Arctic Socially-oriented observation System (IASOS) network elaborated within the International Polar Year 2007/2008 in understanding and finding ways of responding to changes happening in the Russian Arctic will be demonstrated and it will be shown the need for broad Arctic cooperation in monitoring challenges, changes and best ways for building resilience and sustainability in the Arctic.

The features of the Central Siberia local tribes (on the example of the Kethes) and their problems in the period of globalization and climate change

Alexei (Aleksey) Medvedkov (Moscow University)

The features of the Central Siberia local tribes (on the example of the Kethes) and their problems in the period of globalization and climate change There is one tribe among the wide variety of local ones in the North of Enisey river area which incite a lot of scientific questions. It is the tribe of the Kethes. The dispersed groups of the Kethes live in the middle and the lower parts of the Enisey river basin and the lower part of the Podkamennaya Tunguska river basin. According to an approximate estimation, the total population of the Kethes is about 1200 inhabitants. The Kethes is a unique phenomenon because of the language that doesn't have any analog. The main activities of the Kethes are fishing, hunting after elks and reindeer, mushrooms harvesting, berrying and furring (sable and squirrel). Some groups grow potato and other vegetables. The unemployment is a serious problem for the Kethes' community. During the postsoviet period the Kethes' social behavior became more profit-oriented. Currently the land where the Kethes live is used for poaching. In addition, legal entrepreneurs often ignore the interests of the Kethes. The problem of the Kethes isolation from their traditional source of living is getting more and more important. Along with a gradual disappearance of traditions, there is also a disappearance of the Kethes' language. Less than 15% of the Kethes can speak the native language. It reflects the problem of communication between generations. Some members of local communities don't see the necessity of the native language usage. The Siberian Kethes follow the lifestyle which has strong relations with natural resources and subsistence production. Climate changes lead to some negative consequences for local tribes: the decrease in productivity of natural system, the decrease in berries, pine nut and mushrooms harvest (the outcome of short and strong spring frosts in the period of flowering and dry heat), the decrease in sable population and other fur-bearing animals' populations as a result of nutritive base reduction, the increase in the number of forest fires and their area as a result of watering lack in landscapes and the expansion of the swamped permafrost area (the level of frozen subsoil in some regions lowered at 1-2 meters deep). So, the question of special measures and strategy projecting for local tribes' adaptation to climate changes is becoming more important. The decrease in natural abilities of a 'feeding landscape' leads to the necessity for local natural economy diversification. Under the conditions of global warming and the increase of climate instability we can more clearly fix the close interrelation between the development of local traditional economies and geographical and ecological factors of nature.

Polar glacier, the eyewitness of the climate change

David Chinarro (Universidad San Jorge), Carmen Dominguez (University of Salamanca), José L. Villarroel (University of Zaragoza), José A. Cuchi (University of Zaragoza), Adolfo Eraso (University of Madrid)

This work is intended to analyze the results on Antarctic glaciers as indicators or gauges of climate change. The available stuff are the different research studies, that analyzes time-series of the discharge, precipitation, air temperature, solar radiation, weather pressure, and humidity, measured over some glaciers and ice caps situated on South Shetland Islands. Since glaciers are close to the melting point, they can reveal noticeably some aspects of climate change, and thereby, provide some of the clearest evidence of this change. The data are used to investigate the influence of model coherent structures where the essential factors are the air temperature and the discharge time series. Some techniques, as artificial neural network, wavelets or Singular Spectral Analysis, will be exposed comparatively in order to valid the model closer to the natural system dynamics. The system identification methods are applied to find out coherent structure models that are significant of system dynamics. Nevertheless only an efficient core of the certain seasonal period should be considered to build the model, due to anomalous discharge at the beginning and end of the season, manifested in the intermittent glacier ablations and irregular outbursts. The analytical process to determine the effective core of the discharge time series is performed by methodical calculations based on wavelet coherence. Some models have been attempted from the identification of block structured systems, getting a comparative study by the adjustment coefficients, that reveals the efficient of some nonlinear methods over others. The conclusions are tackled from the causal analysis to highlight the major changes that are occurring in a certain glacier. Final reflections try to avoid inaccurate statistical generalizations or incompletely tested assumptions, that might bring up hackneyed controversy and slow down the scientific progress on global warming. Only a few assertions turned out on quantitative analysis carried out on an Antarctic glacier. Even though mathematic results allow a free interpretation, undoubtedly, the glacier is the key indicator that can shed light about the climate change.

Social-Cultural-Ecological Systems Perspectives on Cold Region Environments and the Changes Affecting These Regions and the Peoples Who Inhabit the Cold Regions

Nancy Doubleday (McMaster University)

Interactive Session Hosted by Cold Region Environments Commission The following session will be held as a round table in part, open to interested participants, who will be asked to respond to the challenge of framing current knowledge in the context of complex systems models drawn from interdisciplinary sciences, social sciences and humanities. A discussion draft will be circulated by the session chairs addressing problems of complex social-cultural-ecological systems in selected cold regions,

exploring the proposed session theme, including the following key elements: · Connecting Changes in Peri-glacial Regions, Permafrost and People is essential to understanding environmental change and health and well-being in cold regions using integrated frameworks for understanding environmental and social change. · Creating change-oriented approaches to health and well-being is of necessity a complex task well-situated within traditions of geographic thought and emergent resilience frameworks. The attendees will be invited to discuss the problems of integration of knowledge of the interactions of people and cold region environments across scales at a range of system scales. Ideally the discussion of the interactive session and of the session as a whole, will 'provide outlines for a set of papers illustrating best practices for cold region knowledge integration, as well as locating a self-identified group of people willing to collaborate to contribute future synthesis papers.'

Cultural Approach in Geography

C08.07-01 - Cultural Approaches in Social and Geographical Theory 1

Chair: Benno Werlen

The spacing capital of individuals. Elements of a geographical approach of practice.

Mathis Stock (Institut Universitaire Kurt Bösch), Michel Lussault (Université de Lyon)

The question of the differential capacities of individuals has been theoretically explored by numerous authors. Bourdieu (1984) proposes, as element of his theory of practice, a model of agency where agents engage their social, economic, cultural, technological capital in order to achieve objectives within a specific social field. Within geography, Lévy (1999; 2003) proposed a "spatial capital", defined as disposition of individuals of engaging with spatial problems, especially distance. He defines the "maitrise des métriques" as a fundamental element, but also location of residence or past, memorised experiences of cities. In this paper, we would like to go a step further in the working out of the differential capacities of individuals' coping with space (Lussault, Stock, 2010). In order to make clear the practice-centred spatialities, we propose here the notion of "spacing capital" of individuals. Spacing - in French we would say "capital de spatialité" - is defined as relationship to (material or immaterial) spatial realities, which arise through action and deal with action. In the urban, digital and globalised societies, spatial cultures develop not any longer alongside regional differentiations (i.e. France, America, Maghreb, China, etc.) despite persistent national habitus and national regulations. It needs further elaboration. That means the individual systems of placement/dis-placement are under scrutiny because they contribute to generate spatial cultures. We need therefore not to study the spatial dimensions of social classes or of cultures defined a priori, but to consider the very spatial cultures of individuals as a main problem. The aim of explaining the highly differentiated spatial cultures is attempted through the development of a geographical theory where elementary spatial competences are seen as expressions of different modalities of spacing capital. We form the hypothesis that those competences depend not only upon the cultural, economic or social capital, but also upon the spacing capital of individuals. There is therefore a reworking of the "theory of capital" to engage where the spatial, cultural, social, economical dimensions of the dispositions and accumulation of advantages are to be reordered in order to achieve a more adequate theoretical framework. The identification of the spacing capitals permits then to work on the relationships to identity and alterity in a globalised world, where the negotiations between I- and We-Identities in relationship to the Other appear to be more complex."

The place of culture in social theory and in social geography. A new approach towards linking agency, structure and culture

Tabea Bork-Hüffer (University of Cologne)

Social theory approaches as developed e.g. by Anthony Giddens have received substantial appraisal within human geography and especially social geography. Yet, one approach that hardly received attention in geography up-to-date is Margaret S. Archer's (1982; 1988; 1995) morphogenetic approach that she developed parallel and for the most part as a criticism on Giddens' theory of structuration. Archer is a proponent of realist social theory and the theory of relational emergentism. In comparison to Giddens' theory, one strength of Archer's approach is that she pays special tribute to the role of culture in the structure-agency interlinkage - especially in her work on "Culture and Agency. The Place of Culture in Social Theory" (Archer 1988). Furthermore, she delivers a conceptualization of the social dimension through integrating the different kinds of influences of other agents (individual, corporate and primary agents) in the creation of structure (and culture) but also in their influence on an individual's actions and vice versa. In opposition, Giddens puts special emphasis on the role of the individual actor within his theory of structuration. In this paper a theoretical approach is presented that is based on a combination and further development of mainly Archer's and Giddens' approaches. It is argued that both approaches elaborate in-depth on different aspects of the nature of structure and agency as well as their interlinkage and when combining strong parts of both approaches it is possible to overcome some of their individual shortcomings and one-sided emphasis. Special attention is paid to the various interlinkages and interdependencies between structure, agency and individual action as well as to their development in time and space in order to understand the broader context of individual actions. The approach was applied to the example of rural-to-urban migrants' health seeking actions in Guangzhou, China. The primary data that is used consists of 39 qualitative interviews with migrants and a quantitative survey with 450 migrants as well as 29 qualitative interviews with representatives of administrative units of different levels, health services providers, representatives of NGOs and social organizations. Selected results that show the relevance of culture in migrants' actions are presented. Among these are the influence of culturally shaped health beliefs, principles, instructions, precepts and established systems of rules (e.g. guanxi system, the Confucian belief system, the system of face and the systems of Traditional Chinese Medicine and Western Medicine). The results exemplify the potential of the approach in integrating the cultural dimension in (geographical) research.

Social practices in metropolitan regions. Experiences from the fringe.

Antje Matern (Universität Hamburg)

This paper contributes to social theories about region-building and social practices on macro-regional level. It focuses on metropolitan regions, a spatial planners concept and contribution to discourses about competition of places in the globalized space of flows.

Patterns of regional governance - that combine hierarchical, market oriented and cooperative forms of governing - already became a main concept in spatial planning and regional development (Benz 2005, Herrschel, Newman 2002). But with the discourses about the competition of places in globalization a new debate about region-building and regional governance on a macro-regional scale (Brenner 2003, Salet 2007) as strategy to bunch regional resources and strengths and to foster competitive regions by networking started. Additionally, by urban-rural partnerships (another concept announced) positive development trends should spill over from metropolitan to peripheral areas. Debates in political and spatial research about metropolitan regions and governance often ignore ongoing discourses about relational spaces e.g. in social geography (Werlen 2010) or sociology (Giddens 1999) and use container space concepts. While the governance debate focuses on different patterns of governance, structures and cases of conflicts (Christmann 2010), research about metropolitan regions concentrate on infrastructures assets and facility factors (Blotevogel 2009). Consequently, practices of (collective) construction of spaces are neglected while normative models of an ideal metropolitan region were overemphasized. This paper contributes to these gaps in spatial planning and governance research by analyzing the region-building and social practices of urban-rural partnerships in the metropolitan region of Hamburg. In a case study analysis (undertaking as PhD project finished 2011) the project focuses on construction of spaces as social practices, motivations, techniques and the materiality of practices. In this actors-oriented analysis the concept of 'Matrix-space' (Läpple 1991) was adopted for identification of on-going spacing processes in different spatial dimensions with special regards to practices of actors from the periphery. In the interrelation of path dependencies regarding actors constellations, distribution of power and institutionalizations of collective spacing on one side and orientations on global trends and international discourses on the other side, the construction processes in the metropolitan region illustrates dependencies of social practices and influences of power, localization of actors and involvement in collective spacing as well as impacts of spacing on spatial pattern with regard to territorial cohesion. Thereby, the analysis identified e.g. shortcomings of urban-rural partnerships for territorial cohesion caused by imbalances of power and the reproduction of dependencies on social practices.

Between place and chance: regimes of producing public transport stops

Andrey Vozyanov (University at St. Petersburg)

Public transport stop (hereinafter PTS) represents kind of urban location with specific features such as transitivity, anonymity, local centrality and orientating role. These are constituted on the intersection of physical space properties (which are localization, naming, terminal architecture or road and service signs) and social interactions (of one people getting on and off the vehicles while others are waiting and thirds are driving, with all of them being somehow aware of PTSs urban map). PTS is included in relationships with adjacent space. In some cases it services certain objects, be that trade center,

university or factory. Otherwise it turns out to be the center of previously homogeneous space (e.g. street with monotonous development). PTS may also be a toponymic marker, see common urban question 'On which stop do you live'? One part of my report is about how PTSs are localized, equipped, developed and which changes in nearby landscape it may involve. I will try to define and characterize the common relations between 'micro-histories' of PTS and nearby area. My interest is particularly focused on scenarios of either building the PTS into the local map or influencing such a map via PTS establishing. PTS is usually stable locus regularly providing passengers' access to transport. It may also specify routes and schedules, 'tuning up' urban dwellers' city knowledge and forming their geographical habits and rhythms. Nevertheless, PTSs' topography is changeable. On planning level this is implemented through placing, moving or removing PTS. Corrections may also be made via tactics and practices of passengering stakeholders. Such process occurs in various forms - from routinized practices to claims for official PTS recognition. My paper will describe an example of tactic intervention in fixed PTSs map which I would call 'placeless stops'. By this I mean stopping public vehicle by passenger's request and on driver's 'mercy' in place not designed as PTS. To my view it is important to problematize this practice. When 'placeless stop' happens (rather than takes place!) it misses both certainty and spatial stability. As far as such stop is voluntary and dependent on driver's decision, it may evoke conflicts, inequalities and risks. Via mentioned practice passenger's getting to place drifts from the provided right towards the accidental chance. To illustrate this thesis with help of my field research data I'll try to find out where and when placeless stops are most frequent and who is authorized for them. Besides that, placeless stop practices questionably effect on passenger's opportunities. This is because namely the PTS places and organizes info about passenger's navigation and service, which play significant role in sustainable urban mobility.

Multiculturalism: the new European cosmopolitanism under fire

Louis Dupont (Université Paris-Sorbonne)

Multiculturalism: the new European cosmopolitanism under fire. And now Great Britain ! As did his peers in the Netherlands and Germany, the British Prime Minister, David Cameron, recently called multiculturalism a 'failure'. Those countries have been leaders in Europe in claiming that multiculturalism is at once : 'telling the truth about the realities of Europe' and 'setting its horizon'. Multiculturalism has indeed become over the years the new European cosmopolitanism in most well-intentioned political and intellectual European circles, where it is seen as a heuristic device and focus of comparison between cities and countries. Multicultural environment is said to provide personal enrichment, a source of creativity, social and economic assets, a way of seeing and being in the World. By mimetic as well as by conviction, this discourse has spread throughout the World. In focusing on multiculturalism, this paper questions the construction of a global discourse in the social sciences. Indeed, multiculturalism's recent reversal of fortune in Europe gives us an opportunity to examine its contradictions as a cosmopolitan and globalized concept or term (along with, say, sustainability and risk in physical geography): between the discourse and the realities, between the multicultural thought (liberal and critical) and its links to the various discourses, as well as between North American and European visions of culture, and their combined influences on how people and places see and call themselves.

Spaces, places, messages. Aspects of a theory on architecture and space as acts of communication and power.

Werner Hennings (Universität Bielefeld)

After a long period of indifference social sciences have rediscovered space (spatial turn). Despite this interest even recent theories of space often lack an appropriate attention as for implications concerning communication theory, i.e. those aspects of a theory of space which could explain how architecture, places and spatial structures can narrate stories and history. Architecture, places and spatial structures in this respect can be seen as texts (narrative places) which develop as parts of a system of signs continuously exchanged in the act of communication between senders and receivers, signs which materialize in a specific form and load with a specific meaning and message. Spatial structures thus constitute an archive of the society mirroring its social experience and culture. Based on the theoretical findings of Eco, Chomsky and Giddens, the lecture first would like to present in a theoretical part some elementary aspects of a theory of

narrative places which sees architecture and spatial arrangements embedded in the wider framework of communication and language theories. Subsequently in an empirical part, the lecture would like to observe the spatial structures of the small town of Jicin east of Prague which in the beginning of the 17th century has been the capital of the Duke of Friedland, Albrecht von Wallenstein, commanding general of the armies of the emperor of the Holy Roman Empire of German Nation. Architecture and spatial structure of the buildings constructed by Wallenstein's architects relate to three messages materialized in narrative places: - Politically Wallenstein being a man convinced of the ideas of absolutism; the spatial structure and the architecture clearly reflect the social order of the time - Philosophically Wallenstein being a man convinced of the Ancient Greece; the spatial structure of the landscaping reflects obviously the principal elements of pre-socratic dialectics and - Personally Wallenstein being a man of Macchiavellian power; architecture and spatial structure of his palace in Prague (Palais Valdstejn) standing in relation to his buildings in Jicin and Hradschin, seat of the Emperor in Prague thereby reflecting the duke's manorial ambitions.

Atmospheres - the stepchildren in social research

Thomas Doerfler (University of Göttingen)

Atmospheres had always been stepchildren in social research: too metaphoric to be operationalized adequately, too metaphysical to be in the focus of anti-essentialist social studies. But in contrast there exists no social setting without an atmospheric context like emotions, a sense of place, normative orders etc., as one can see regarding social scenes like tribal feasts, matrimonial bedrooms or prison cells; literature has found uncountable stories in this. Hence, social research had hardly come across the potential of such analysis as its tools haven't been designed for 'atmospheric' approaches. Interactivism, behaviorism, functionalism or recent 'turns' like the 'linguistic turn', the 'pictorial turn' or the 'discursive turn' (if they are at all) fail to grasp atmospheric contexts as they are focused on language, imaginations and/or political determinations that shall surround human actions. To analyze atmospheres signifies for their protagonists to act 'metaphysical', to be interested in 'irrational' context that stick 'essentialistically' to the place and space to be analyzed. Especially recent 'postmodern', German-speaking social geography propagates such declines as it propagates the (formerly critical) Derridean/Foucaultian argument that there exists nothing outside the text/discourse, now having become a dogma to block any research on the material requisites for social settings. Beside the fact that there has to be undertaken further research on the epistemological grounds of atmospheres, thereby not falling behind the legitimate criticism on essentialist terminologies, it is necessary to emphasize the practical and cultural aspects of atmospheric contexts: There is no atmosphere without the subject, no social setting without cultural praxis incorporated in habitus, doxa and similar concepts. On the one hand it is necessary to provide a profound social theory on atmospheres, how they could be analyzed, established, perceived and therefore built, avoiding

postmodern/poststructural shortcuts or dead ends and providing empirical insights which show the potentials for explaining certain (built) environments via their atmospheres: the clashes of divergent interests between city inhabitants and urban planners, the pleasurable enjoyment of specific environments (suburbia, creative city districts) etc. Insights from my recent research project in Hamburg are given to concretize the points made: a comparison between the urban, but neglected districts of Wilhelmsburg and the suburban 'Mustergemeinde' Neu Wulmstorf can bring up the decisive distinctions between suburban and urban atmospheres as lived spaces. The paper would like to contribute to the current initiatives on researching urban ambiances by investigating the social and cultural practices and unconscious imaginaries of place settings as necessary, but neglected concepts in contemporary social/cultural geography.

Kidding ourselves? The Highs and Lows of Liverpool Young Researchers Network (LYRN).

Tracy Ramsey (University Liverpool), Ceri Anwen Jones-Ellis (University Liverpool), Yvonne McNamara (University Liverpool)

Davies (1999:14) contends that, during periods of heightened uncertainty, young people become the 'societal litmus test' or Amin's (2003) 'lightening rod' for wider public fears concerning social stability, an issue brought into sharp relief in the UK during the 2011 summer riots. In the UK responses to concerns regarding social stability have been manifest in a range of repressive measures specifically targeting young people, including Anti-Social Behaviour Orders (Crime and Disorder Act, 1998) and Dispersal Orders (Anti-Social Behaviour Act, 2003). Repressive measures, which would be unacceptable if directed towards other identified sections of the community, have been ameliorated by an ostensibly inclusive policy agenda, which has emphasised young people's participation in matters that affect them (UNCRC, Article 12 Right to Participation, ratified in 1991 by UK government). However, the meaningfulness of young people's participation is frequently questioned (Cruikshank, 1999) as their discursive constructions have remained resistant to change, as the economic and political environment has led many UK youth services to target their services to those deemed 'at risk', thus compounding the construction of young people as either 'in trouble' or 'as trouble' (Griffin, 2001). This changes the parameters within which workers engage with young people and the nature of the relationship between them. This tokenism may be extended to 'participation practice', as young people are asked to confirm decisions made by adults, or work without designated budgets to support any changes they advocate, thus undermining their participation and empowerment. In contrast, research with young people has a developing and honourable history (for example Aldred, 2002). However, researchers are frequently aware that their determination to develop young people-led research may fall short of their ambition. A number of explanations are offered for this as 'we all take part, in different ways, in shaping narratives of youth' (Griffin, 2001:162). Critical to notions of genuine participation is power sharing, specifically power to construct the research agenda (Lukes, 2005). The

following is a description and partial analysis of a participatory research project which, despite the reflexivity, experience and determination of the research team, was in danger of becoming another tokenistic 'young people's' research project, until the young people took power.

Place to roads: Bio-Bio's case (Chile)

Hugo Capella Miterique (Universidad de Chile)

Roads have been studied in geography in its functional dimension but with less regard to its cultural one. Nevertheless, roads are one of the main elements to understand territorial building and inheritance. In this article, we focus, on a theoretical revision around the geographical complexity of the road concept, understood not only in its spatial dimension, but also as a temporal marker. In that sense, roads supply not only a Kantian dimension, but also live functions and lived experiences, as places. After that, we'll base the article on the study case of Bio-Bio's Road in Chile, to show how the study of a forgotten road can be useful to understand a whole cosmology. Bio-Bio's road represents an old river path that has been completely forgotten behind the idea of boundary but that has left a deep print into the territory. Thanks to the study of this landmark we are able to understand different pattern settlements, to rebuild the Mapuche's cosmology and to finally find a regional identity, from merge to a mixed diversity.

The way of Saint-James: architectural transformation of a cultural landscape

Belen Castro Fernandez (University College Dublin)

The Way of Saint-James: architectural transformation of a cultural landscape The architectural restoration developed in Galicia between the 40's and the 80's of the twentieth century boosted the monumental revitalization of the Way of Saint-James. The interventions made for the defense of its artistic heritage lead to a stage that reaches the present, where the Way of Saint-James is considered as World Heritage since 1993. The Galician medieval heritage deserved a priority attention because it was the keypoint of a historical and unrepeatable personality: that of a country located in the peripheral of the Western Europe whose privilege was settled on the medieval pilgrimage to the jacobean sanctuary. This medieval pilgrimage gave an european culture to Galicia, with main artistic and literary hits, such as the compostelan romanico or the galician-portuguese poetry. Maybe, the most amazing fact from the analisis of these interventions is the progressive creation of an open-air museum on route (on the route of the Way of Saint-James), that goes beyond previous experiences with medieval art. The cathedrals, the monasteries and the romanico churches are still the keepers of the historical memory in Galicia. So it explains why the 40's, 50's, 60's and 70's interventions were so important for our collective awareness of the Way of Saint-James. These interventions were conditioned by

both the Spanish and European postwar. This led to the withdrawal of many criteria from the modern restoration as stated in 1931 Athens Charter. And so, in an Europe marked by the reconstruction it was very difficult to apply strictly the criteria of the Camilo Boito's philological restoration or the Gustavo Giovannoni's scientific restoration. As a consequence, the restoration interventions that were made that time on the artistic heritage from the Way of Saint-James, were projected from a reductionist point of view vision. A tour for actions than have simplified the way and the evolution of monuments is shown here, selecting from all its history a single moment that usually coincides with the medieval settlement stage. And this, implies the elimination of all the subsequent interventions.

The New Tendencies in the Geography of Pilgrimage. Changes, Patterns and New Dynamics in the Sacred Space of Santiago de Compostela.

*Rubén Camilo Lois-González (Universidade de Santiago de Compostela),
Lucrezia Lopez (Universidade de Santiago de Compostela)*

Religion has 'territorially organized' the sacred space, thus creating sacred places and peregrination routes; the first ones mark the routes, while these allow reaching the places. Nowadays, new cultural and secular tendencies are changing the religious essence of the sacred places; consequently, the geography of pilgrimage focuses its attention on both sacred and secular places (COLLINS-KREINER, 2010). This change requires a reconsideration of the meaning of 'pilgrim' and his contextualization in a scenery where mobile individuals are continuously proliferating: pilgrims (religious and secular ones) and tourists (religious and cultural ones etc.). All of them share the same desire to live an authentic experience; therefore our question is what the difference among them is? One of the most consolidated European holy places and, at the same time, tourist destinations is the city of Santiago de Compostela and, of course, the Way of Santiago; here, the original religious essence lives together with new cultural changes. With a careful look to the global era, we pretend to analyze how these new cultural patterns affect the holy space. From the point of view of a phenomenological methodology, which has been recently re-discovered by the geography of pilgrimage, we can consider some transformations regarding experiences and human practices linked to pilgrimage. Considering that pilgrimage is a performative act, which exists when we make it and respect its rituals (COLEMAN, EADE, 2004), it can be interpreted as a theatrical representation of the daily life. The value of the pilgrimage becomes complete thanks to an adequate location: pilgrimage landscape (ALDERMAN, 2002). As far as landscape is concerned, we consider that the sacred space organization and the scenery observe behavioral and movement patterns; for these reasons, we investigate the pilgrimage landscape as social product. Considering that, the physic and symbolic territorial organization is determined by a cultural meaning, the sacred conception of the medieval and religious world has been replaced by a new setting endowed with services and improved accommodation and hospitality offer, etc? This implies a social change, as

inhabitants have to 'change their role'. In other words, the sacred space is undergoing a process of commercialization moment, which requires new tourism equipments (SCHRAMM, 2004). Finally, we analyze how the cultural products of the globalization are transforming the sacred space: while in the past the 'essence' of the pilgrimage lied in the sense of adventure and the unknown world, nowadays the new technologies are turning the unknown place into 'something' easy to reach by means of web-pages that enable to make virtual route or to read blogs.

Pilgrim experience of a sacred place in the shadow of a myth

Mats Nilsson (Department of Geography/Tourism)

Tourism, among them tourism around myth, rapid increase in the world is often considered a result of our constant desire for new experiences to places that we perceive to be different. The sites will give us experiences that contribute to satisfaction and variety and a break from our daily lives: something new, exciting and create a curiosity of us at varying ways. Places where myths are part of the identity are in tremendous quantities. They have in most cases created a long time and around those circuits at various levels stories and events that will enhance the importance and hence the attraction of the myth. This Article intends to contribute to our understanding of place and myth based on concepts such as identity, symbol and sacred tourism. Articles are an understanding of how places of course in tourism contexts in which myths are at the center. How these sites with focus on myths understood from today's tourism agenda. Identity relevant to the site and the site's identity in shaping the individual's experience of place have long been a focus and a starting point for cultural geographical research. What is considered sacred, however, differ from individual to individual but in this study are related which the individual is regarded as sacred. Sacred place, of course, often, perhaps idealized, as something that is contrary to everyday life and can such an understanding from the outset appear to be a "center" for tourism. The article characterized the relationship between the concepts of place, identity, symbol, myth and the sacred in a touristic context. This means in this context that the Central is a place that has an identity built around and around a myth in a touristic context, as the center of experiences in which people interpret, perceive and make sense. Location is defined to be the center for mediation and meaning or focus on human feelings rather than just a physical location in the room. Purpose of seeking deeper insights into the (myth) identity that is marketed for a place and individuals who experience and are part of the site, and what it means for them based on their conditions, world and ambient. The starting point is a place-related identity and highlights section which together creates an attraction for the site and, by extension, a commercialized part of the sacred. Two overarching questions about the site design are: the role of myths for a place? It can also be slightly different: What impacts will the myth have of a place? The questions are deliberately open, covered and do not lead to the same answer but the intention is that the answer can have several shades. The article wants to contribute to the understanding of how places identity related to a

myth, used and fills the functions of individual travelers and how to spot and myth interact on an individual's experience. The study intends to relate both generally and also show on the site-specific.

Geographical Studies of Pilgrimage in Ukraine

Olga Lyubitseva (Kyiv University)

Pilgrimage is an exceptional cultural phenomenon which comprises the subject-object field of Cultural Geography and Geography of Religion. Geographical studies of Catholic sacred centers (Poland, France) are better known than Orthodox ones. Ukraine has different religions and historically shaped traditions of pilgrimage. These traditions been suppressed during Soviet times revived after the independence gained by the country. The Geography of Religion began to take shape in Ukraine as the separate direction of scientific research in the early 1990s with the direct participation of the author, and, given the number of scientific publications on this subject, one can state the formation of this scientific discipline. The main problems of the Geography of Religion are as follows: 1) the religious situation and the dynamics of its spatial changes evaluation; 2) the spatial patters of the sacred centers of the country identification; 3) spatial and temporal characteristics of the pilgrimage determination; 4) assessment to the ability of sacred centers of the country to meet the needs of the believers and operate in accordance with the principles of balanced development. Territorial organization of the religious sphere in Ukraine is determined by the proportion of Orthodoxy, Catholicism and Protestantism in Christianity, Islam, Judaism and other small religious communities. Each religion has its own hierarchy of pilgrimage centers, which has been formed historically and entrenched in the minds of believers. There are three orthodox large monasteries in Ukraine, which plays the most significant role: Svyato-Uspens'ka Kievo-Pechers'ka (got this status in 1598), Svyato-Uspens'ka Pochaivska (1833), Svyato-Uspens'ka Svyatogors'ka (2004). Rocky Orthodox monasteries of Crimea and Pod'ilya are known since the Middle Ages. Sacred places of Old Believers are preserved in Chernivtsi and Chernigiv regions. Geography of Catholic sacred centers in Ukraine is presented by the hierarchical structure, in which Lviv and Zarvanitsa are the most known. Reformed Faiths (Protestantism, Lutheranism, Calvinism) centers are located mostly in Volyn and Trans-Carpathian region are mostly represented now by Baptizm, legovizm and modern sectarian forms. The Judaism centers of pilgrimage in Ukraine are related to Khasidizm: Medzhibozh, Uman', Berdychev, Belz, etc. The followers of Islam are concentrated mainly in Crimea. There are also the sainted places of Armenian and Karaim religions in Crimea. Issues of the logistic provision of centers of pilgrimage, improvement of their infrastructure, including hospitality, aimed to the balanced development are of the greatest importance. These problems become yet more topical in connection with the

increasing number of the both Ukrainian and foreign pilgrims, development of centers of pilgrimage, and clergymen's neglect towards the problems of the balanced development.

Religious landscapes in borderlands: an example of Czechia

Tomas Havlicek (University Prague)

With the growing significance of the new cultural geography since the 1980s and the return of religious topics to social and geographical sciences, more attention has been given to research on sacred structures. A culture cannot understand itself without first understanding its implicit connection and development within the constructs of religious belief and practice (Carrette 1999, Brace, Bailey, Harvey 2006). The paper that follows aims to contribute to discussions surrounding the study of Czechia's religious landscape, by exploring the condition, development and role of sacred structures in the country's borderlands. The results of field monitoring (monitoring of sacral objects and interviews with key actors in micro-regions) show that the religious landscape (religious identity) in Czechia develops only partly after general presumptions. The character of the religious landscape does as well as the role of religion in a given territory but also the human and the social factor. By the synthesis of the ascertained information it is possible to distinguish three key posts are: a) religious representative (e.g. priest), b) involved subjects (e.g. municipal and regional authorities, councillors), c) local population (believers, patron or sponsor). Local people can also contribute to the flowering of religion and sacral objects in their home place. Sacred structures represent also a significant pillar in the formation of regional identity. Nearly every municipality presents itself visually on the Internet or in postcards predominantly with images of its sacred structures (churches, chapels, etc.). Most residents of Czechia's rural areas also identify with sacred structures, in spite of the fact that representatives of local government often perceive such items more as cultural-historical symbols in the landscape than as religious structures. Sacred structures helps to build more cross-border interaction in the "new" Europe.

Valorisation locale d'un itinéraire de pèlerinage et développement durable en moyenne montagne : le chemin de Saint Jacques du Puy-en-Velay à Conques (GR 65)

Mauricette Fournier (Université Blaise Pascal)

Cette communication se propose de montrer l'impact de la valorisation d'un itinéraire culturel sur les territoires qu'il traverse dans les moyennes montagnes du Massif Central (Velay, Margeride, Aubrac), espaces de faibles densités à l'économie très fragile, et précisément de montrer comment le GR 65 participe à un développement à la fois endogène et durable. Sur les premiers 200 km de la via Podiensis (Le Puy-en-Velay / Conques), rebaptisée localement « l'autoroute de Saint-Jacques » en raison de l'importance de sa fréquentation (18000 marcheurs comptabilisés à Saugues en 2011 ; 25% d'étrangers) 3 hypothèses ont été testées à partir d'enquêtes de terrain (auprès des

responsables de structures d'hébergements, commerçants, élus locaux et pèlerins) : 1- la capacité d'initiatives des sociétés locales ; c'est en effet au rôle précurseur de certaines associations attiligériennes que l'on doit la renaissance de cet itinéraire jacquaire à partir des années 70 (redécouverte des sentiers historiques, balisage, topo-guides) ; c'est encore grâce à la dynamique des acteurs endogènes (municipalités et acteurs privés) qu'a été mis en place le dense réseau (1 gîte d'étapes /5 km) des structures avant que le caractère massif de la fréquentation n'incite maintenant de nouveaux arrivants à en ouvrir d'autres. 2- le GR 65 comme levier de développement durable ; - au plan économique le GR 65 est devenu une source de revenus pour les populations et les collectivités riveraines ; les structures d'accueil bénéficient d'une saison touristique élargie (6 mois d'avril à octobre) ; les commerçants locaux se sont aussi adaptés à la demande des pèlerins (restauration, chaussures, pharmacies, librairies, pressing...), ce qui permet leur maintien dans ces territoires démographiquement anémiée ; de nouveaux services sont proposés (port des bagages) ; - au plan environnemental, la voie jacquaire a permis la mise en valeur des patrimoines naturels et bâtis des régions traversées ; les paysages sont entretenus, les édifices réhabilités. 3- le GR 65 comme créateur d'identité ; les riverains sont maintenant fiers d'avancer qu'ils habitent sur le chemin ; les prestataires d'hébergement se connaissent le long du linéaire ; s'est ainsi développée une forme d'attachement à l'itinéraire de Saint-Jacques. Ainsi la via Podiensis constitue-elle un élément majeur de la recomposition en cours de ces espaces montagnards. Elle permet l'affirmation de territoires singuliers sur ce linéaire.

The Changing World Religion Map

Stan Brunn (University of Lexington)

Global religions are being challenged by three underlying factors: the worlds of speed, fluidity, and cyberspace. Each of these is discussed within the context of transformations in traditional cultural hearths and homelands, new global diasporas, transboundary interactions, and the role of social media at personal, local, regional and global scales. Place based institutions are being challenged by new social media, secularization, de-institutionalization of formal institutions and the multiple new religions faces. Virtual religion is now a recognized ingredient of many faith based communities. The cyberspaced knowledge-information sector is even questioning the place-based nature of traditional religious places, landscapes and pilgrimages. States themselves are facing the changing faces and mixes of religious or faith-based issues, groups and parties. Adjusting to religious worlds where speed, dynamics, and local equals global and vice-versa are challenges faced by traditional permanent religious institutions and their adherents as well as temporary and even ad hoc institutions. The result of these changes are evident in both the cultural wars, conflicts and faces of communities and megacities in the Global North and also the Global South. Maps of religious networks, adherents, and institutions are both devolving and evolving. Cartographic examples of these shifts on regional and global scales are presented for discussion.

C08.07-04 - Cultures and sustainability

Chair: Benno Werlen

Relevance of cultural knowledge and skills to guide individual and social practices towards sustainability

Bhaskar Poldas (Nexus Institut für Kooperationsmanagement)

Dr. Bhaskar Poldas, post doctoral research fellow of German Academic Exchange Service, affiliated to Sustainable Hyderabad project & nexus Institute for cooperation management and interdisciplinary research, Berlin (www.nexusinstitut.de) In India culture strongly influences lifestyles of people and social practices. Some of these are quite detrimental to environment and climate. For instance, people compete with each other in celebrating marriages of children in a pompous way. They boast to have organized wedding buffet for guests in such a grand way, with so many no. of dishes. Large amounts of food are wasted on such occasions. Spending huge money on food is just one negative aspect in lavish wedding parties. According to food minister, around 100,000 weddings and social events are held in India daily. With food wasted each day in Mumbai the city's vast slum population can be fed, he added. Similar is the case when people of a religion compete with each other in burning fire crackers to celebrate a religious festival. On the occasion tons of fire crackers are burnt, extremely polluting the air, generating tons of waste on the roads, causing severe sound pollution, badly disrupting the traffic flow on the streets and jeopardising the passersby. These are only two examples of cultural aspects adversely affecting the climate, which can be tackled with knowledge and skills embedded in the very same culture, following the homoeopathic principle 'Like cures like'. The author as part of his research on 'Religious explanations for the impacts of climate change and their influence on the climate related behaviour of citizens' has been studying cultural and religious aspects influencing the climate related behaviour of citizens in the emerging Megacity Hyderabad, India to find culture-based strategies to motivate citizens to adapt their lifestyles to be climate friendly. This paper presents results of expert interviews with religious scholars of three major religions in Hyderabad, Hinduism, Islam and Christianity. In the survey when asked, inter alia, about the ways and means to guide citizens to lead a climate friendly lifestyle, the scholars have made promising suggestions. The survey is part of German research project 'Sustainable Hyderabad' (www.sustainable-hyderabad.in). It is funded by the German Federal Ministry for Education and Research (BMBF) within the program 'Research for the Sustainable Development of the Megacities of Tomorrow - Climate and Energy Efficient Structures in Urban Growth Centres.'

Learning, Faith, and Sustainability: Considering the Work of Faith-Based Organizations in Kenya

Joanne Moyer (University of Manitoba)

Sustainability, global society's response to the interconnected reality of widespread poverty and environmental degradation, is essentially a learning process. To move more effectively toward this goal, a deeper understanding of learning is necessary. Non-governmental organizations (NGOs) have become a vital force within the sustainability project in recent decades, and as such, form the context for much of this learning. This research investigated learning within faith-based organizations (FBOs), a prominent, though often ignored, segment of the NGO family. Using the framework of Mezirow's transformative learning theory, the research examined learning among individuals within FBOs doing environmental and development work in Kenya, East Africa. Research findings focus on the cultural and social context of the learning, learning content and process, and the relationship between individual transformation and social action and change. The research highlights, for instance, the importance of instrumental learning and related learning processes, an undervalued component of the theory. Learning by doing, through practical application and experimentation is not included as a primary learning mechanism in transformative learning theory, but is highly relevant in the Kenyan context, and may even play a significant role in facilitating transformation of higher level meaning structures. For example, learning the skills required to band or ring birds helped staff and volunteers at a Christian conservation organization to increase their broader awareness, appreciation and commitment to environmental issues, while staff at a rural development organization were personally empowered while learning and teaching practical health, agriculture and appropriate technology skills in communities. Personal and social actions were understood by the participants as important expressions of their learning, both as a means of deepening their learning, and as an extension of their learning to others in their communities. The study concludes by considering the implications of these learning insights for the sustainability project.

Mediation Agreement to Resolve an Environmental Conflict and its Social Implications – The Case of Wadi Zalmon (Israel National Park)

Irit Amit-Cohen (Bar Ilan University), Riki Halamish-Leshem (Tel Hai College)

Mediation refers to an informal process in which a neutral third party helps parties in conflict attain an agreement which they were unable to reach on their own. It is mainly used to solve social, economic and political problems, but its characteristics allow using it to resolve also environmental disputes. The purpose of this article is to examine over a period of time the different attitudes of some groups of populations (communities, municipalities and governmental authorities) toward mediation agreement and its implications. The agreement was signed for an area which was declared a National Park due to its unique landscape - characterized as a cultural landscape (a landscape which

represents a combined works of nature and of man). Examination over time is intended to expose whether changes have taken place in the populations in respect to the agreement and its social and cultural influences on them. The paper is dealing with Wadi Zalmon, a stream flowing from east to west in Western Galilee, in the north part of Israel and its environs. In this declaration are involved many populations, which represent the multicultural distinctiveness of Israeli society: Christians, Moslems, Bedouins and Jews.

Putting sustainability into teaching practice – Experiences from an international network on global environmental sustainability

Holger Jahnke (University of Flensburg)

In the past two years, the universities of Flensburg, Javeriana in Bogotá and the University of the West Indies are developing a joint course on 'Environmental and global studies' which focuses on questions of sustainability and sustainable development in an interdisciplinary perspective. In a regular basis, theoretical foundations, empirical case studies from the field of renewable energies as well as teaching concepts are tested and evaluated at all sites. In this presentation I will focus on some key issues of the regular exchanges, which offer insights in the cultural and epistemological foundations of teaching sustainability and sustainable development in the respective geographical context where the course is taking place. These issues touch upon very fundamental distinctions of theory and practice, local and global, as well as reality and imagination.

The Reconfiguration of Urban Identity after Globalization in Incheon City, Korea

Je-Hun Ryu (Korea University)

In the 1990s, however, Republic of Korea began to participate in the globalization that followed the demise of Cold War, being accompanied by neo-liberalism. Consequently, a new trend of reevaluating the geopolitical conditions surrounding the Korean Peninsula emerged among people. In Incheon City, also appeared a group of citizens who began to think alternately of the geopolitical position of Incheon City, which had been intimately associated with that of Seoul. Due to the revival of diplomatic tie with China in 1992, the trade barrier against China was eliminated on the west coast where Incheon Port had occupied the leading position among many ports. Incheon Port has been expected to grow in the future as a main trading port that would be open to China as well as North Korea. Moreover, the opening of Incheon International Airport (2001) newly provided the geopolitical conditions under which the importance of Incheon City had to be reevaluated in terms of economic strategy rather than military strategy. A group of citizens are now even dreaming of the future of Incheon City as a global city, which is economically independent from Seoul, with its hinterland of Northeast Asia. In addition, the planning of Songdo New City, following the reclamation on the tidal flat, has encouraged citizens to reconfigure the urban identity in that direction. The reconfiguration of urban identity, of course, involves the acceptance of the postmodern concept of identity that premises its complexity and multiplicity.

Racialising nation through a sensibilities of hate in Japan

Masato Mori (Mie University)

This paper discusses the relationship between national identity and ecology of alien species (fauna and flora), focusing on the symbolic construction of the myth of purity of Japaneseness. In this paper I argue that it is the organization of emotion toward the alien species which have racialised the nation. I look at attempts to foster civic inclusion and argue that they need to work through felt exclusion and fears. I trace history of discursive construction of the sense of fear towards 'alien' in general, particularly after the late 1980s, when Japan witnessed herself being in a process of 'internationalization' and globalisation. The reformation of immigration act for children of Japanese immigrants in the early fostered a process of civic inclusion and exclusion through a definition of non-native. A representation of non-natives as offenders to Japanese nation included 'alien' people, such as Japanese-south American and Korean residents in Japan, and 'alien'

fauna and flora, such as black bass and bluegill through the 1990s. I choose the imperial palace in Tokyo, a canonical site for Japanese nationhood, to exemplify this issue. The ministry of environment launched a cleansing campaign of alien species living in a pond surrounding the palace in the early 2000s.

Representing the imagined city: place and the politics of difference during Guangzhou's 2010 language conflict

Hong Zhu (South China University)

In this article we investigate local citizens' place politics and discourses of place identity during the 2010 language conflict in Guangzhou, China. Drawing on geographical scholarships on the relational construction of place and the progressive politics of difference, we conceptualize place as an assemblage of trans-local connections and disparate trajectories which constitute the radical hybridity of any particular place. In concretizing a relational rethinking of place into a local politics of difference, we suggest that Doreen Massey's thesis of a global sense of place provide an important epistemological basis for destabilizing the normative local-non-local boundary in order to realize a relational constitution of place-based cultural identity and subjectivity. Based on a social and political campaign against the state-led hegemonic language standardization, the 2010 language conflict in Guangzhou is a socially and culturally constructed process in which the Guangzhou locals' imagination and representation of place and identity are reproduced within a local geometry of social relations involving the state language policy, the local community and the city's migrant population. Both exclusionary and progressive discourses of place identities have been articulated in this process of re-negotiation and re-imagination of place-based identities. This paper acknowledges that some place-bounded politics may demonstrate a counter-hegemonic dimension and therefore not inherently regressive. But we also contend that any place politics needs to ask which elements are to be welcomed and which can be excluded in a fluid regime of politics within specific networks of social relations. The cultural boundary of insider/outside must be constantly re-negotiated and rendered relational with an inescapable dimension of responsibility.

Spatial Formation of Advertising Industry in East Asia

Zhengyuan Zhao (University of Tokyo)

This study involved 1) a quantitative analysis to clarify the spatial distribution of the advertising industry in East Asian metropolitan; 2) a qualitative analysis of interviews of respondents from local advertising agencies in Shanghai and Tokyo to examine the motivation of CBD concentration, and its impact on creativity and income. Some researchers have suggested that creative actives, such as production and circulation, are more concentrated in global cities. The study first analyzed the Economic Census data of China and Japan of the past two decades and verified the tendency towards

concentration using ArcGIS. The second finding of this study is that in both China and Japan, the advertising agencies, similar to other professional service industries (e.g., law firms, accounting firms and consultant firms), are more likely to be located in downtown area near headquarters of big corporations or major media groups. This is different from North American and Europe where advertising industries are sometimes concentrated in a specific zone, like Soho area or Madison Avenue. Our interviews revealed a possible explanation of this unique concentration: in East Asia, the personal connection between advertising creators is extremely weak. In China, local advertising agencies benefit from the vicinity to global network agencies by learning idea and information from their foreign competitors, especially big four advertising and communication service groups (e.g., Omnicom, WPP, Interpublic and Publicis). In Japan, the role of transnational advertising groups always accomplished by Dentsu and Hakuhodo, the Japanese monopoly agencies.

C08.07-06 - Cultural identities 2: Historical places in East Asia

Chair: Je-Hun Ryu, Shangyi Zhou

From Monarchical Space to Ritual Space

Xiaofeng Tang (Peking University)

The paper documents four phases of the imperial capitals: (1) the pre-imperial and Qin (221-206 BC) dynastic capital of Xianyang; (2) the early Western Han dynasty before and during the reign of Han Wudi (r. 141-87); (3) the late Western Han (after Han Wudi, and especially during Han Chengdi, r. 33-7 BC); and (4) the Wang Mang interregnum. In the first period, he shows that some aspects of the Qin capital of Xianyang anticipated later developments in Chang'an, insofar as the capital increased in size and came to dominate the landscape of the region "within the passes" (Guanzhong). After the establishment of the short-lived Qin capital at Xianyang, we see other architectural developments that prefigure the logic of the later capital at Chang'an. The First Qin Emperor essentially remade the capital, which was built on an axis. During the second phase in the early Western Han, Chang'an (built on the site of a Qin "traveling palace") went through a process of transformation, from the actual residence of the emperor to a ritual space; this process marked the consolidation of imperial power and the increasing ritualization of the empire. City planning undertaken during the first five reigns nevertheless can be thought of as variations on the older palace system, a system predicated on very personalized notions of imperial power. Before the reign of Wudi, the Martial emperor, the capital of Chang'an only had three palaces. Wudi, however, busied himself with the construction of several new palaces. The new palaces connected by covered walkways also came to encroach upon the clear boundaries once established by the walls of the palace and of Chang'an city itself. The emperor, keenly sensitive to the ritual and ideological implications of space, still did not make the capital his ritual or sacrificial center. In the third period, that of Emperor Cheng, we move a step closer to a true articulation of the capital system. At the same time, the palace complexes ceased to be the most central feature of the capital, because the ritual centers assumed a new prominence. The largest change, however, occurred during the fourth phase, that during Wang Mang reign. In this period, the person of the emperor and the imperial capital for the first time acquired a transcendental character.

The representation of Beijing's historic districts and their identity groups

Shangyi Zhou (Beijing University)

The culture of a city is diverse. The typical areas that were represented in historic record are mostly chosen as the city's cultural heritage or historic area. This is a process of place construction. But the city's new residents can't understand the meaning of city's cultural

heritage, neither the residents living out of historic area. It causes the significance or meaning of a historic area could not be identified by most residents. The city will lose the dynamic of cultural heritage protection and the meaning of a cultural heritage will die, if the city's heritage is neglected by new generation of its residents and immigrants. The identification process of a historic area is the identity process a local culture by the local people and other people, is also a process that a small-scale culture becomes into a large-scale culture. The process is different from that of cultural diffusion. This article takes Beijing as its research area. It analyses the difference of some groups' identification for the cultural heritages, which were represented in text. Beijing's old city has 25 historic areas, including residential, commercial, royal palace, and religious areas. This study investigated the protection willing of local residents, old Pekingness outside of historic areas, the city's new immigrants and people from other cities or provinces. This article concludes that the identification for a historic area's meaning of four groups are vague. Four groups identify the Beijing's culture represented by mass media. The new immigrants and people from other provinces and countries are difficult to identify the local culture that is not represented in formal text.

Production of Place Identity with World Heritage Registration movement -A Case of Nagasaki, Japan

Keisuke Matsui (Univ. of Tsukuba)

A significant phenomenon, which could be called a World Heritage site boom, has occurred in recent years in Japan. There are great expectations for positive impacts on the regional economy to occur from World Heritage site registration, with some people regarding it as a trump card in their regional rehabilitation via the promotion of tourism. Registration as a World Heritage site significantly increases the information available globally on a site from a variety of media, including tourist magazines and guidebooks, TV, the Internet, etc.; thus, the expectation that an increase in tourists will occur in association with the registration. The expectations of the tourist industry for an increase in tourists, and of local municipalities and economic organizations wishing to use it to trigger promotion of their region has led to a movement of more and more World Heritage site registrations. Commodification of places considered sacred is not a contingent phenomenon. In modern Japan, attempts have been made to commodify sacred places with ulterior motives through the activities of actors that include administrations and other related organizations, mainly with a political, economic, or social context, and in connection with regional revitalization, tourism promotion, etc. How then are such attempts conducted, and are there any problems that arise in the sacred places which are consumed? In this paper, the focus will be on the World Heritage movement involved in attempts to register sacred places and the tasks involved in the cultural heritagization of sacred places, which is closely related to the World Heritage movement and tourism commodification. This paper takes these approaches from the two points of view stated below. The focus will first be on the actors that are promoting the heritagization of cultural

landscapes, including sacred places. The problem of the politics involved in the promotion of heritagization is considered from the point of view of the ulterior motives of the actors concerned and the movement for the realization. The creation of a 'locality' is an important technique frequently used in World Heritage movements related to sacred places. The heritagization of sacred places can be seen as a move to place value on the uniqueness of the place, the lives of the people that live there, and the climate and history behind them, and not the actual religious facilities or subject of worship themselves; hence, these movements will be considered using specific examples. Secondly, in the link between the heritagization of sacred places where their value is 'discovered' or sometimes 'created' and tourism is considered, along with ways in which the commodification of sacred places can affect the lives of the people who look after them.

The presence of Catholic churches of 19th century in contemporary urban center as symbols of globalization and evolution of urban identity

Kyu Won Kim (Korea Culture and Tourism Institute)

From the end of 19th to the beginning of 20th century, two catholic churches (one is cathedral) built outside of city wall. Until recently they were symbols of western globalization and, now they became urban landmarks. One lies at the preserved traditional urban district where symbol of religious globalization and traditional identity overlaps, at the center of city, Jeonju of 240,000ha. The other church also situate where the international CBD area and vernacular urban landscape meet in Seoul, city of 10 million habitants. The cases of two symbols of late globalization of nearly 100 years ago show different evolution of urban landscapes and situations. In this paper I would like to identify the harmony and competition between changing identity and globalization in urban centers. One of the representative types of traditional means of globalization in human history is the Religion and missionary works. The Christianization of European continent in early days and islamization in African continent shows a powerful globalization in culture, economy and administration. In Korea from 19th centuries, the missionary works of Catholic were concentrated then 20th century follows Protestant missionary works. The influences of missionary, are not only spreading the Religion but also introducing the same values and cultures as western world as a true globalization. In 1866 four French priests from 'Mission étagère de Paris' were martyred. After then it was mostly French missionaries from 'MEP' who worked as missionary. From the 1890s catholic missionaries (mainly MEP) were absorbed in building churches in major cities of Korea. At that period, it was hardly possible to build churches inside city walls (intra-muros). Consequently, many early churches in major cities were built in adjacent to exterior of city walls, as in Seoul, Daegu and in Jeonju. The Ayakhyun catholic church in Seoul is the first western style edifice built in Korea with its gothic style and brick structure. The Jun dong Cathedral in Jeonju is the first western style edifice in south-western region of Korea with its renaissance style of brick structure. They were all built on the execution ground outside of city wall. The village near Jundong Cathedral became

actually Jeonju city's traditional urban heritage district with traditional housings and urban form. On the other hand in Seoul, the ex-execution ground became a memorial park for martyrs near Yakhyun Church. And from the park the major rail road station of Seoul Station, the most concentrated CBD of Seoul and vernacular urban districts locate in neighbor. The situation in urban landscape and the symbolic values are different. And it is these differences in urban identity that I would observe and explain in geographical ideas.

C08.07-07 - Cultural Identities 3: The urban and rural places of East Asia

Chair: Je-Hun Ryu, Shangyi Zhou

The Landscape Presentation of the Sense of Place in Different Authoritative Dai Villages

Chen Yapin (Yunnan University)

Applying community mapping and GIS, the research takes a cultural space perspective to look at correlation between the landscape implication and authority structure of the sense of place. The research conducts a case study of Dai villages in Xisuhangbanna to demonstrate development of the sense of place among the Dai villages of different authority sharing, as well as the spatial structure and place identification among different places. The research also discusses the landscape presentation of the sense of place, reveals the factual demonstration of local emotions, and associates social authority and power with contextual landscape, spatial loading and spatial reconstructing. The research has the following findings: 1. As a means of showing people's sense of belonging, the sense of place can highlight the spatial characteristics of regional emotion when it is spatially contextualized to some degree. 2. The landscape with local emotions serves as a medium through which the regional authority and power is demonstrated and spatialized. 3. The landscape perpetuates the sense of place, and the sense of place diversifies the landscape. 4. In order to build up harmonious villages, it is constructive to honor and harmonize the senses of place of all holders of rights among different minority nationality villages in Yunnan.

Tourism developing and preservation of traditional culture of ancient village in Huizhou – A perspective from cultural identity

Xiang Kong (East China University)

The traditional culture of ancient village in Huizhou Area, which has been preserved and lasting from the period of Ming Dynasty in China history, contains a lot of positive things as achievements of farming culture in the period of which the human-environment relationship is balanced. A relatively closed geographical environment contributes a lot to the preservation of traditional culture of ancient village in Huizhou. However, with the tourism development of these ancient villages, traditional culture will face the impact of culture diffusion and may lost its authenticity since it has to adapt the need of the 'other'. In this context, the cultural identity of the inheritors of the local culture will have great value to the culture preservation. This study, based on relevant researches on identity of local culture, takes Xidi, Chengkan and Xucun three ancient villages with different levels of tourism development as working objects and is mainly intended to get to know the local

residents' culture identity and to find out its influencing factors and then to analyze the relationship between tourism developing and preservation of traditional culture of ancient village in Huizhou. It is showed that tourism developing will not only provide financial support to ancient villages' preservation, but more important, it will profoundly affect the cognition and emotion on traditional culture. Therefore, promoting depth cultural exchange between tourists and local residents will be conducive to the formation of positive interactions between tourism developing and traditional culture preservation which will have important value to cultural tourism.

The Production and Consumption of Urban Space: Making of Jing'an District, Shanghai

Xiaohong Zhang (Fudan University)

The relationship between production of urban space and consumption of space image is an important issue in urban geography. Based on historical data, this paper discusses the role of production and consumption of urban space in the making of the Jing'an district, western part of Shanghai City. Since opening in 1843, the traditional rural society began to change to modern urban one in Shanghai. The authors find that the production of urban space of Jing'an district was based on the logic of capital accumulation which was strictly limited by the Land Regulation and was deeply influenced by the development policies of the Municipal Council. Before 1899, the threshold for living outside the Foreign Settlement was so high, as there were much more wars and disasters in China that time, that only top-class had ability to live the area around Jing'an Temple. Meanwhile, the quiet Chinese rural landscape attracted many rich people to build their mansions there. After 1899, Jing'an district became the western side of the Foreign Settlement. Because the threshold for living there lowered, the district started on converting suburb where the middle class could and would live in. Targeting this social group, consumption of the space image of the area, formerly used as exclusive residential district, became an important strategy the businessmen implemented to develop the area. Some western-style modern entertainment facilities, such as cinemas, theaters and cafes were built up there. Until middle of 1930s, Jing'an district had been successfully transformed from rural landscape to modern urban space. This case study exemplifies the important role the space image played in production of urban space in colonial Shanghai. It means that the consumption of space image not only enhanced the formation of urban landscape but also characterized the reproduction of its urban space.

D'un territoire agricole au territoire de loisirs: changement de l'identité territoriale vue à travers l'évolution de la pratique musicale au Jeolla-do en Corée.

Sujin Lee (Université Paris)

Depuis la fin du XXe siècle, on assiste à un renouveau de la pratique musicale régionale en Corée. Ce renouveau est apparu pour promouvoir la musique locale dans la province de Jeolla, qui essaie de valoriser son identité territoriale à travers la musique traditionnelle depuis 1997, date marquée par l'octroi de l'autonomie municipale. Situées à l'extrémité du pays, cette région a été longtemps rurale et profondément religieuse, ce qui fait qu'elle garde encore aujourd'hui des traditions bien souvent disparues ailleurs dans le pays. Les modes de vie dans la communauté agricole se sont formés à travers la pratique musicale ; la musique jouait un rôle intermédiaire entre l'homme et la divinité : les travaux agricoles se déroulaient suivant les rythmes donnés par les musiciens : les événements de vie étaient rythmés suivant la musique et la musique était un moyen de faire connaître les tragédies et les injustices de la société. Cependant, depuis l'industrialisation au niveau national en Corée dans les années 1960, l'Etat mène une politique culturelle qui vise à désigner les genres artistiques comme patrimoine immatériel. La mise en place de cette politique s'explique par une disparition rapide des cultures régionales face à la modernité : l'urbanisation, la mécanisation de l'agriculture et l'exode rural massif durant plus d'une trentaine d'année au niveau national. Enfin, à travers la mondialisation, la culture musicale régionale se transforme en un vecteur important pour le tourisme et les loisirs. En effet, les acteurs locaux ont choisi la musique comme un atout régional pour fonder un patrimoine culturel commun pour la préservation et le renforcement de l'identité territoriale. Les communautés agricoles se transforment en communautés de loisirs. De nombreuses manifestations musicales, festivals et concours en témoignent. Ces pratiques musicales s'exportent dans le monde en représentant le territoire dont elle est issue dans des échanges internationaux. La désignation par l'Unesco comme Patrimoine Culturel Immatériel aide à promouvoir ces cultures territoriales. Le marché du disque propose davantage, par ailleurs, des musiques représentant une identité territoriale, véritable emblème de la promotion des territoires dans la civilisation de loisirs.

C08.07-08 - Multilocality: symbolic and material constructions of space in societies of mobile individuals 2

Chair: Mathis Stock, Michaela Schier

Transnational professionals and their socio-behavioral and spatial-behavioral patterns in a multilocal and mobile environment

Sakura Yamamura (University of Hamburg)

Research on transmigrants has been so far more focused on the 'migration from below', which takes the mobile lives and living spaces of the less privileged under closer scrutiny. The migration of highly skilled and highly mobile transnational migrants, on the other hand, who can be regarded as being representatives of the globalizing movement 'from above', is still a rather under-researched field. This study presents research done on transnational financial professionals who were once or still are based in Tokyo and have work experiences in multiple locations in the world. Semi-structured interviews were carried out with over thirty professionals of the managerial level in trans- and multinationally operating corporations of the financial industry. The individuals of this kind of mobility group have gathered experiences of geographical mobility and multi-local lifestyles both in their occupational as well as private lives. They, thus, tend not only to share the working practice in a transnational and highly mobile environment, but - over time - they also tend to share social practices, values and behaviors as they have adapted to such mobility and multilocality in private, too. Their identities are increasingly shaped by the experience of being mobile in multiple locations, - irrespective of the differences of the actual locations they have experienced -, and an according formation of a specific social grouping of such transmigrants can be observed. Furthermore, the results show that they have not only adapted certain socio-behavioral patterns throughout their multilocal work and living experiences; they also show specific spatial-behavioral patterns in their daily lives. On the one hand, this study sheds new light on an under-researched group of transmigrants, providing data on the specific social practices and attitudes of transnational financial professionals. First results show that such highly mobile transnational professionals can be subdivided along specific socio-behavioral as well as spatial-behavioral characteristics, and categorized in at least two sub-groups. On the other hand, the research in a selected urban area, in this case Tokyo, the actual geographical patterns of these transmigrants which accompany their behavioral characteristics, - i.e. the transnational space(s) of highly skilled and mobile transnational professionals -, could be concretely nailed down and characterized. These geographical patterns illustrate the differences in spatial and behavioral preferences of the sub-groups within the transnational professionals' community.

Life in the multi-local space of the family by the example of Russian au pair migrants in Germany

Caterina Rohde (Bielefeld Graduate School in History and Sociology)

The au pair migration programme was originally founded to promote the exchange of cultures by arranging a one year sojourn of foreign young people in a local host family. Nevertheless, recent publications assume that au pair mobility sometimes is used as a 'springboard' to immigration (compare for example Hess 2006). On the basis of 17 biographical interviews with young Russian women, who have worked as an au pair in Germany and thereafter settled permanently in their receiving country or returned after some years to Russia, I would like to discuss in my paper how young women manage the relationship to their families of origin, especially their parents who are living in Russia. The sudden spatial separation from the family is a crucial experience for young women and marks a moment of change with regard to their role and position in the family. It requires young women to construct and practice the role of a 'transnational daughter'. In my paper, I want to discuss following questions concerning this phenomenon. How are intimate relationships practically maintained in spite of spatial distance? From former research it is already well known that transnational relations very much depend upon the use of modern communication technology. I aim to further investigate in which ways the telephone, internet, skype, letters, etc. are used for maintaining the relationship to parents. Furthermore I want to take a look at the meaning of mutual visits (daughters going back to Russia, parents coming to Germany) for the transnational family. How is the role of a daughter re-interpreted due to her absence? The role of the daughter is transformed in the process of au pair migration due to the two interplaying dynamics of maturing and migration. First, au pair migration takes place in the crucial life phase of young adulthood, when typically children attain autonomy from their parents and create a more equal relationship to them. Second, due to physical absence transnational daughters are not able to provide direct care to their family members. The sending of remittances represents this change of familiar roles: The daughter adopts the role of a family provider and remittances allow her to practice care for parents in spite of physical absence. 3) How do au pair migrants legitimate absence and cope with the trauma arising from the family's separation? To explain and legitimate why they left their country and their family normally is an important issue in the biographical constructions of au pair migrants. Many hint to their parents' support for their migration process because of poor life chances in the context of origin. They use the notion that their parents want them 'to live a better life'. Others explain that they aim to bring over their parents and other family members to the receiving country or explain that they believe to return to Russia later in life.

Families Living In/Between Multiple Localities across National Borders: Fractured Identities or Reinforced Feelings of Local Belonging?

Yvonne Riaño (Department of Geography)

The spatial separation of family network members living in multiple localities across the globe is a reality of today's society of mobile individuals. As individuals move to other locations to work, study or other reasons, family networks are confronted with the reality of living geographically separated. These new forms of life have often been interpreted as « problematic » as they supposedly involve a loss of social cohesion and fractured identities. This paper argues that such an interpretation is too simplistic and proposes that transnational multilocal life also bears the potential of strengthening family cohesion and personal identity. The argument is based on an empirical case study of six transnational family networks whose members live in multiple localities across Colombia, Ecuador, and Switzerland. Transnational family networks are not a new phenomenon for Latin American societies as international migration has long been a main feature. However, in recent decades the phenomenon of transnational family lives has dramatically increased, and become more complex, as the numbers of Latin American migrants have multiplied, and the destination of many migrants has moved beyond United States, to also include European countries. The empirical study for this paper was carried out in 2010 using the methodology of « multisited ethnography », which consisted of conducting interviews and ethnographical work in various localities of Colombia, Ecuador and Switzerland with key members of six transnational family networks. The questions here addressed are: What are the multilocal practices of transnational family networks? What are social and personal consequences of such multilocal practices? The results show that a complex variety of multilocal practices exist, with implications for family life, personal identity and multilocal socio-economic development: transnational family networks create business links between localities in Colombia, Switzerland and Ecuador that generate employment possibilities for family members and widen investment opportunities for Swiss companies; they also carry the seed for transnational cultural exchange and multilocal identities. Individuals with multiple lives clearly have different identities to those in single localities. However, from the point of view of the interviewed individuals, multilocal identities are not negatively experienced but rather as a source of strength for feelings of (multi)local integration. Thus, we conclude that practising multiple places, and being embedded in multiple localities, does not necessarily imply fractured identities and local disintegration, but on the contrary reinforces feelings of local belonging, in both European as well as in South American localities. Such conclusions have implications for theories of (transnational) multilocal social space, (transnational) multilocal family lives, and social policies of migrant integration

Making Sense of Multilocality: Five Stories in Several Pictures

Marina Richter (University of Fribourg)

As geographers we are often tempted to map our data. Multilocal ways of living seem, therefore, an ideal field for geographical inquiry. They allow us to mark places on a map and think about concepts like distance and proximity, density and distribution, and other terms to describe the topography of such a multilocal web. In short, they invite us as researchers to make sense of other peoples' lives and their specific and also personal spatial constellations. Researchers have created and worked with various concepts to describe the spatial formation that emerges from multilocal ways of living. In migration research they have been termed transnational social fields (Levitt & Glick Schiller 2004) or transnational social spaces (Faist & Özveren 2004; Pries 2008). Others have rather focussed on the networks that link places (and people) far away (Featherstone et al 2007). Others again concentrate less on the multiplicity of places but conceptualise the multiplicity in the place itself. Such translocal places - most of the studies concentrate on cities - emplace 'communication circuits, organizational networks, economic linkages, and political projects that span national borders' (Smith 2011). Rather than opting for one of these concepts to analyse multilocal spatial arrangements of people, the paper asks for the concepts and meanings people construct themselves of their multilocal lives. Based on the findings of a larger project on transnational social spaces of migrants (first and second generation) and non-migrants, I will use the data of the second generation of Spanish origin in Switzerland to reconstruct how they make sense of their multiple connections to various places in Switzerland, in Spain, and maybe also elsewhere. The data that emerged from a mixed-methods approach consists of interview transcripts as well as of different kinds of visual data, such as photographs, network maps, geographical maps, and drawings. This allows me to tell the stories of five second-generation Spaniards through the visual material gathered: Five stories in several pictures. The visual material is particularly important as it addresses from different empirical but also conceptual perspectives, how multilocal spatial arrangements can become meaningful. The stories will deal with questions such as the temporality and development of the various linkages to the different places; the ways of dealing with presence and absence of, in particular, people, and the subtle intermediate stages that are enabled by technology and other means; the different ways of making sense of these spatial arrangements; and finally, what the multilocal spatiality means for them, regarding their position and positioning in society.

The mobilities, immobilities and moorings of work-life on cargo ships

Maria Borovnik (Massey University)

This paper will explore the paradoxical dichotomy between the obvious mobilities and movements and the not so obvious immobilities and moorings of cargo-ships, articulated in the work-life of seafarers in contemporary globalisation. It will emphasise on the sporadic, highly temporal, multilocal work-life of seafarers, and the coping or anchoring social and geographical strategies applied to counteract against globally driven, limiting immobilities. Ships have been defined and symbolised as both spaces and places, but mostly as marginal spaces of in-between-ness, constituting relationships between routes and roots, movements and moorings. They have been described as cocoons, protecting passengers and cargo from a marauding sea (Bachelard 1994, 124 in Stanley 2008), and yet they seem also places of statelessness or lawlessness (Stanley 2008). Sanson (2003) refers to hyperspaces as they seem unreal, placeless, Foucault to heterospaces emphasising on their fluidity and marginality. Ships transverse (or crisscross) back and forward through territorialised national and deterritorialised international ocean-space. With such movements they create connections between different environments and societies. Not only are ships, and specifically cargo-ships assemblages in their functions of loading and unloading, but also in the way people are being sporadically put together and apart from each other. Similarly to ports, ships are therefore passageways of change and temporariness, places of connections, cosmopolitanism and coercive identities. This paper will address how seafarers deal with this mobile, yet immobilising work-life on ships and temporary multilocalities involved. Specifically it will explore how multinational ship communities get on with the social and geographical containment and limitations (immobilities), the enabling social and geographical 'anchors' (moorings), and the ebb and flow loops of ship to and away from port movements created by global trade and those of people boarding and leaving.

Multilocality and urban practices in the Mediterranean cities

Carla Tedesco (University of Venice), Clara Copeta (Università di Bari)

During the second half of the XXth century, especially during the 1990s, the concept of the place (topos) as a single city, as a coherent unit, was criticized by many academics (Giddens, 1994; Harvey, 1993; Massey, Jess, 2001). Cities places had multiplied and fragmented. What is more, their 'soft', symbolic sides had started to be analyzed. Thus, places were acknowledged to be built up by urban practices giving them several successive meanings. Nowadays, due to both the increased individual mobility and globalisation processes people are present in many places. This raises new questions concerning both theoretical and empirical geographical research. Within this framework, the aim of this paper is twofold. On the one hand, it explores the notion of multilocality relating it to both Raffestin's theory of (human) territoriality (Raffestin, 1981) and reflections on urban rhythms and practices (Amin and Thrift, 2001; de Certeau, 2001; Lefebvre, 1958). It tries to understand if, how and to what extent can these theories help

us to shed light on multilocality as 'society of mobile individuals'. On the other hand, it aims at discussing some governance issues related to multilocality. In fact, in order to deal with the contemporary multicultural and multiethnic city, communicative or deliberative planning reject universalist top-down projects. New forms of planning practice, interactive and people-centered have been entered (Forester, 2009; Healey, 2010). However, it is not clear to what extent do 'spaces of deliberative opportunities' represent everyday life in cities as well as the practices of multilocality. This paper is based on field work carried out in some Southern Italy cities where these issues have specific features which can be somehow related to the peculiar urban rhythms of Mediterranean cities. Mobile Borders: The Geographies of Migration Routes Management by the European Union

John Pickles (University of North Carolina), Sebastian Cobarrubias (University of North Carolina), Maribel Casas Cortes (University of North Carolina)

Recent policies of migration control on the part of the EU suggest an increasing mobility and trans-locality of borders. This paper is based on a multi-sited research project on current European policies of border externalization towards Northern and Western Africa. The process of externalization includes the outsourcing of border control to non-EU countries, as well as the spatial extension of where EU states can intervene, thus a literal expansion of the borderline. The latest EU strategy of border policy and migration control yet to be fully implemented is called 'the Migration Routes Management Initiative'. This strategy involves spreading checkpoints, migration control experts and other dispositifs of migration management along shifting migrants' itineraries passing through sending, transit and destination countries. The Migration Routes Management strategy suggests a broader transformation in the very notion of border and the spatial practices traditionally involved in migration control: from the militarization of state-to-state lines to the management of multi-local and fluid networks. Tracking the history of 'migratory routes management' has implied interviewing EU Commission officials, detailed review of EU budgetary documents, and field-visits to think-tanks involved in relevant policy development promoting this form of migration management. In particular, this paper engages a series of EU funding streams focused on border management in third countries. Besides providing budgetary data for border policy projects abroad, these

reports contain internal evaluations of these new policies helping to outline the conceptual history and institutional development of this distinct spatiality of borders. Our research suggests how the current configuration of border management is more than a straightforward 'pushing out' of state borders. Rather, it speaks to the emergence of a potentially unique and mobile space of governance, constraining and channeling individuals' and groups' mobilities in different ways.

'Creative City' Boom and Bust: Implications for Creativity-themed Urban Development

Luke Binns (dit)

In the first decade of the C.21st much urban economic development discourse has been shaped, or at least significantly influenced, by talk of 'creative industries', a 'creative class', and the related 'creative city'. Buoyed by the apparent success of a few 'creative city' exemplars, Richard Florida and other 'creative city' proponents have built and sustained a case for developing creativity-themed urban environments, and pitched this to increasingly receptive municipal authorities around the Globe. To create a successful urban economy, municipalities are advised to follow the example set by leading 'creative cities' such as San Francisco, Barcelona or in this case Dublin (Florida, 2002: 300). And the apparent success of these exemplars is in turn seen to fuel demand for Creative City policies which seek to marshal art, artists, and artistic creativity to the urban competitiveness cause. However, by basing the case for municipal authorities to 'get creative' on the apparent success stories of a few exemplars, Florida and co are pushing a risky, potentially precarious sales pitch. For, what would happen to their argument if one or more paradigmatic cities were to suffer a reversal in fortunes? Would demand for 'creative city' policies be affected? Could omission of references to 'creativity' from policy documents ensue? Might the idea and aspiration behind the 'creative city', which has held such a privileged position at the pinnacle of urban development professionals' agendas, be put at risk of imminent collapse? This paper, which charts the rise and fall in economic fortunes of Dublin, a city previously portrayed as a paradigmatic creative city, shows how the Celtic Tiger success story and the increasing potency of Florida-esque 'creative city' discourse were used to reinforce one other: leading to inflated convictions in the soundness of both. Then, with reference to the bursting of Dublin's property price bubble and an associated free-fall in economic fortunes amid disintegrating faith in 'creative' solutions, the paper considers the extent to which the fall from grace of this paradigmatic exemplar might be undermining wider discourse on the merits of the 'creative city'.

Reconnecting places through art? Joubert Park and the Johannesburg Art Gallery in the inner city of Johannesburg (South Africa)

Pauline Guinard (Université Paris)

Created in 1906, Joubert Park is one of the biggest and oldest park in the inner city of Johannesburg, as well as the home of the Johannesburg Art Gallery, an art museum created in 1915. Even if the park - as the rest of the inner city - was very popular during the apartheid era, especially amongst Whites, it has been facing a cycle of decline from the late 1980s, marked by White flight, urban decay and violence. From then, two separate spaces made of different publics and practices have tended to emerge: the park itself on the one hand, and the gallery on the other hand, a separation further sanctioned in the mid-2000s by the construction of a fence between the two. Despite the spatial proximity of these spaces, the users and the uses of these spaces actually vary. In the park, there are people living or working in the neighbourhood, chess players, photographers or homeless people, that is to say mainly Black and poor people, coming there to relax, to meet friends or because they have nowhere else to go. On the contrary, in the gallery - except for school groups - there are only tourists, artists or art lovers, principally White and well-educated people coming to enjoy the exhibitions, and amongst them, only those who are brave enough to come to that park known as a rough place. These spaces are finally next to each other but, because of the general feeling of fear, they are set one against the other. As soon as the late 1990s, art performances have been organised in Joubert Park in an attempt to address the specific socio-economic context of the area and to reconnect the park with the gallery, and vice versa. The "Joubert Park Project", a local artists' collective, is particularly symptomatic of the "spatial turn" in South African contemporary art, since this initiative intended - according to its own words - to "take the urban context as a base material". In its view, art is indeed conceived as a response to a specific context, as a means to tackle socio-economic issues by considering space as a starting point, as a building material. Made with and by the public - and not only for a public -, art is perceived as a catalyst for urban change. But to what extent can art be a suitable tool to affect people's daily practices and perceptions of spaces? Is it possible to initiate a long-term urban change through art? How can these extra-ordinary moments influence the ordinary life of these spaces and people? Focusing especially on three art performances trying to make the publics from the park and those from the art gallery talking to each other, I will investigate the function of art as a tool to challenge socio-spatial divisions and to (re)build connexions between spaces and people. Ultimately, I will argue that art as a way to experiment space differently could be a means to change urban representations, and therefore to (re)invent the city.

As seen from The Fringe – Creative city-making in Cape Town between policy, politics and practice

Laura Wenz (Universität Münster)

Despite its name, 'The Fringe' is not one of Cape Town's many marginalized areas. Located in the eastward precinct of the CBD, it rather constitutes a spatial flagship project of Cape Town's strive towards being a leading creative city of the South which recently saw its first culmination in the successful bid towards becoming the 'World Design Capital 2014' with the accolade awarded in October 2011. The creative city idea has unequivocally become a new planning orthodoxy, materialising itself in various shapes, forms and 'glocalized' narratives across the globe. The aim of my on-going research project is to scrutinize it's manifold meanings and consequences - in terms of policy, politics and spatial practice - for post-apartheid Cape Town, adding to the as of yet limited scholarship contextualising these issues against the backdrop of distinct urban experiences in the global South. In this, the paper tries to provide a common landing strip for both approaches proposed in the session outline: In discussing scenes from my recent qualitative research on the making of 'The Fringe - Cape Town's innovation and design district', I want to present a vivid example of how different levels of government, sector representative bodies, private institutions, artists and other artistically inclined individuals are involved in actively carving out spaces for creative industries in the post-apartheid cityscape. In connection, the artist as entrepreneur is seen as intrinsic dictum of the creative industry concept that has lead to the emergence of new social hybrids such as the "culturepreneur" (Lange 2007) that tries not only to mediate but also to merge artistic and economic production in his/her individual social and spatial practices. The emerging spatial economy of 'The Fringe' cannot be analysed without consideration of its surrounding urban context. Its position directly adjacent to the rehabilitation sites of former District Six, infamous for apartheid's rigorous mass-evictions in 1968, raises questions around appropriation of place, socio-spatial legacy claims and cultural representation. In order to address these difficult questions in a holistic manner and to provide an argument that critically revisits both approaches this paper will enter into a dialogue with the paper of Anne Volvey, who looks at individual art practices in the post-apartheid city through recounting the story of the District Six Sculpture Festival.

When art claims the land in District Six (Cape Town, SA): principle and methodology of the politics of doing with space in today's contemporary art

Anne Volvey (University of Artois)

Within the proposed binary framework of the session's discussion, this paper aims at articulating and nourishing elements of the second stance: art should be no longer taken by geographers as an 'activity in space' or a 'function of the space' but rather considered as a 'doing with space'. The District Six Sculpture Project of 1997, Cape Town (South Africa), is the case study of the paper that deals, in concrete terms, with the politics of

doing with space in today's art. District Six is a late 'white group area only' of down town Cape Town (South Africa), that, once emptied from the population it housed, and pulled down, has remained an open tract of land and, as a consequence, a very symbolic one in post-apartheid South Africa. In 1997, six years after the end of the apartheid regime and its policy of spatial segregation, the District Six Museum that runs the process of returning the land to the displaced population, organized the District Six Sculpture Project 'an outdoors and in situ art event. Developed within the context of series of land claim processes, and of talks of the area being redeveloped, the festival is an impressive example of land claiming through art practices. It shows that the political dimension of the art lies in the arts of doing with multidimensional space, and underlines the spatial principle that makes work Bourriaud's relational perspective upon contemporaneous art. In consequence, the paper will focus on the festival's participative principles and methodologies, and understand the works of art within this prospect. Though held as a key moment in Cape Town public art, the festival had very little impact on connecting art to urban development in today's creative Cape Town. As the Fringe project demonstrates the urban planners rather adopt a 'spatial engineering' understanding of this connection 'art is an activity encoded, managed and located into the city by spatial engineering in order to market the territory in different ways', turning down the political effectiveness of it.

Understanding the Relocation of National Museums of Fine Arts and Assessing their Possible Impact on Industrial Cities' Regeneration: A Network Analysis of Louvre Lens and Centre Pompidou Metz Foundation Process

Guy Baudelle (University of Brittany), Gerhard Krauss (University of Brittany)

The establishment of the Guggenheim Foundation in Bilbao (1997) has prompted a number of similar projects in other European cities hit by the decline of traditional industries, attracted by the supposed positive impact of this equipment on economic development - the famous so-called 'Bilbao effect'. Our presentation focuses on two national museums of arts recently designed in this spirit by the French Ministry of Culture in old industrial regions: the new Centre Pompidou opened in Metz (Lorraine) in 2011 and the future Louvre to be opened in Lens (Nord-Pas-de-Calais) at the end of 2012. These cities chosen among other candidates were considered as unlikely to welcome so famous museums due to their weak cultural orientation. So, our first objective is to clarify the genesis of these cultural projects by questioning the importance of the extent of social networks mobilized to support them. We identify the main protagonists of the political and cultural spheres involved locally and analyze their relationships with external actors. Indeed, our theoretical assumption is that only the creation of a sustainable social network dynamics makes the success possible: we interpret the cultural project as a trigger for setting in motion actors previously segregated. Our study confirms the necessity for the actors to be both embedded in local networks and open to wider external new relationships. Our two case studies contribute also to reassess some apparently well established conditions of the success according to the literature: 1) the need for an iconic, unconventional architecture to attract a large number of visitors and beyond to improve the city image ; 2) the political use of art for a city global branding policy as these two museums have been launched by national institutions and are mainly funded by the regional authorities - how far the initial social goal of bringing museums to a local public culturally distant from the art can be achieved together with a global reputation management policy? 3) the need for global players 'world famous architects, museographers, planners and landscape designers' as a prerequisite to reach such a global strategy. Beside the question of the idea emergence and of its implementation, we also try to identify possible future spillover effects by creating links between players inside and outside the sphere of culture in order to outline the formation of a new economic system conducive to an overall conversion, in accordance with the expected 'Guggenheim effect'. We evaluate the initial relative importance of economic and urban revitalization objectives and the possible future impacts both on the urban regeneration

and on the local and regional economic revitalisation, especially thanks to the development of creative industries and districts in connection with the new museums of art.

Art ateliers and studios: places for artists and/or for policymakers? The case of La Fabrique in the emerging creative arts district of Nantes, France

Valérie Sauter (University of Neuchâtel)

Urban policy strategies using culture and art for urban rehabilitation and economic growth have not always been beneficial for local communities and artists. Culture-led development strategies focusing on large cultural infrastructures have often led to gentrification and the eviction of artists in need of affordable workspaces. However, with new strategies aiming at developing « creative clusters », it has become interesting for policymakers to make « creatives » more visible and thus to promote places for innovation and artistic production (ateliers and studios). In this context, artists' and local municipalities' interests could potentially converge. This is what we will investigate with a case study of La Fabrique, located in the new creative arts district of the French city of Nantes. La Fabrique is a place built by the municipality to « support emerging artists and new forms of creation as well as to address the expectations of artists and creative people » and to « better [respond] to their needs in the areas of production and creation ». It is a project which « combines land planning and cultural networking ». How does such a project emerge? Do artists' interests converge with the city's aspirations, and, if not, what negotiations are taking place in this co-constructed project? What types of places are resulting from these partly shared aspirations? These are the questions to which my presentation will provide a series of possible replies. This paper, based on textual analysis, semi-structured interviews and non-participant observation done during recent fieldwork in Nantes, is part of a larger project dealing with the mobilisation of art and culture in urban project and aiming for a better knowledge of urban art regimes. Keywords: urban geography, cultural geography, culture-led regeneration, urban development

L'artialisation-in-situ, vecteur et révélateur de la réappropriation territoriale d'espaces à forte valeur environnementale Regards croisés dans les moyennes montagnes de France et d'Afrique du Sud

Sylvain Guyot (Université de Limoges)

L'artialisation in situ peut être une des conditions de la valorisation environnementale et du développement territorial dans des espaces en déprise rurale. Dans ce contexte l'artiste est un acteur essentiel du processus de réappropriation territoriale. Il en est l'initiateur ou le révélateur. Dans le premier cas (initiative), l'artiste est un avant-gardiste spatial. Qu'il soit autochtone ou allochtone à l'espace considéré, il réside sur place et exerce une stratégie foncière. Son activité artistique, matérialisée par différentes formes

d'artialisation in situ, va permettre à un lieu souvent marginalisé ou oublié de se reconnecter à un système réticulaire englobant. Un artiste en attire souvent d'autres. Ces collectifs d'artistes constituent une tête de pont très efficace pour attirer d'autres partenaires engagés dans des actions de protection de la nature, de valorisation paysagère et touristique. Dans le second cas (révélation), l'artiste est convoqué pour redynamiser un espace en manque d'attractivité. Sauf à valoriser le travail d'artistes résidant déjà sur place, les artistes ainsi ciblés par la commande publique sont extérieurs à l'espace considéré. Leur activité artistique répond à une commande qui va s'inscrire de manière pérenne ou saisonnière et événementielle dans le paysage. On voit là tout l'intérêt que peuvent avoir les acteurs politiques, à différentes échelles, à instrumentaliser ces processus et à mettre ainsi en scène les lieux et les territoires. Je propose d'utiliser cette distinction (initiative/révélation) pour analyser deux exemples, en Afrique du Sud et en France. Le cas sud-africain (Hogsback, Eastern Cape) relève plutôt du premier processus d'initiative. Le cas français (Circuit des refuges d'art, Alpes de Haute Provence) relève plutôt du second processus de révélation. Dans les deux cas je cherche à comprendre quelle est la portée réelle du processus d'artialisation in situ en termes de développement territorial et comment il est instrumentalisé par des acteurs aux représentations souvent divergentes.

The uneven spatialities of unconventional art festivals: The case of Paratissima

Francesca Silvia Rota (Politecnico di Torino)

The paper deals with the effects produced on (and within) the urban space by practices of contemporary art. Moving from the hypothesis that 'the arts' allow for the creation of uneven spatialities that are related not only to the physical place where the works of art are either installed or performed, but also to the ways the spatial practices of the artists, the visitors, the sponsors and the citizenships are influenced by these works, the paper aims at investigating both these dimensions of the spatial effect of the arts with reference to a specific type of practice: urban 'happening' exhibitions of contemporary art. In 'happening' exhibitions, in fact, often the urban space becomes a dimension of public practice that goes far beyond the aesthetic dimension. Particularly in the case of 'unconventional' festivals, criticizing the 'art world' for the way it encodes the arts and merchandises their products, new spatial practices that are either uneven or unintended are likely to arise. A reason for this is that unconventional practices tend to assume a more open, innovative and democratic format than their 'official' counterparts, giving larger space to the proposals and initiatives of everyone. At least, this is certainly the case of Paratissima, the happening exhibition of contemporary art yearly organised in Turin (Italy) by a local independent association to coincide with Turin's most renowned international art fair Artissima. As showed by the results of a interview-based survey with the various types of actors (artists, organisers, sponsors, visitors, residents...) involved in the 2011 edition of Paratissima, this exhibition had in fact the capacity to use the

spatialities related to the art works (i.e. specific ways of exhibiting, selling, using and consuming the art objects/performances) to create a specific 'sense of place'. Yet, as the paper aims at demonstrate, this effect was often limited to specific portions of the urban space and the urban society.

C08.07-12 - The Uses of Art in Public Space 1

Chair: Julia Lossau, Quentin Stevens

The Non-use, Re-use and Mis-use of Public Art in the Vilakazi Street Precinct (Soweto, South Africa)

Pauline Guinard (Université Paris)

Since 2007, the City of Johannesburg has been implemented a "Public Art Policy", designed to encourage the creation of artworks in public spaces. This policy is to be seen in a triple context in which art is conceived as a means: to support urban regeneration; to address the unbalances of the commemorating South African landscape, that is still dominated by a biased and partial vision of history as endorsed by the apartheid regime; and, to promote social cohesion. First experimented in the inner city, the "Public Art Policy" is progressively put in place in townships ' the previously deprived areas assigned to 'Non-White' population ', and particularly in Soweto. The Vilakazi Street Precinct (VSP) programme is one of these projects. Conceived as both a heritage and a tourist project, it aims - through art - at commemorating the history of the neighbourhood and at attracting tourists. Allegedly participative, the VSP project was supposed to be achieved not only for the inhabitants of the neighbourhood but also by or at least with them. Nevertheless the project had trouble involving them in the decision-making process. That implies a narrowing of their possibilities to "use" art - that is to say to appropriate it, to reclaim it or even to exploit it for their own interest - in this conception phase. Thus, one can wonder if this lack of engagement endangers the potential "use" of art by the inhabitants once the artworks created. The responses from the locals to the completion of the project in May 2010 seem indeed to vary from indifference to rejection, from 'non-use' to 'mis-use'. Thanks to observations and interviews realised in 2010 and 2011 in the neighbourhood, I will argue that it is possible to identify different types of attitudes to this public art project: - "non-use", that is to say disregard for the artworks, since most of the inhabitants do not feel concerned in any way by the project, but reclaims it only through the tourist figure and its potential economic outcomes. - playful or utilitarian "re-use" of public art, especially by children who use the artworks as a playground and sometimes collect the information contained in the heritage panels to do their homework. - "mis-use" or even "anti-use" of the project - understood as a rejection of it - that manifests itself: through the expression of a feeling of dispossession by some of the inhabitants; through a targeted vandalism aiming at defacing the outcomes of the project; or through the creation of new artworks by young people from the area, constituting a parallel and contesting artistic proposition to the official public art project. The VSP project is finally an interesting case study to understand the different "uses" of art at different stages of the project.

The Australian National Memorial at Villiers-Bretonneux: Monument, practice, meaning

Shanti Sumartojo (Australian University)

National monuments are a particular form of public art rich with layered meanings. They bear the strong imprint of their creators and the symbolic language of the time in which they were built, whilst also seeking to appear 'timeless' and to collapse the national past and future into its present. They also have very specific narrative intent. Whether they commemorate war, political change or national cultures, they are designed to be unambiguous in their messages. However, as with other forms of public art, they are subject to public use, which does not always conform to their designers' intentions. This paper focuses on once such monument, the Australian National Memorial at Villiers-Bretonneux, the biggest of several Australian war cemeteries in northwest France. It explores the relationship between the national narratives of loss and memory evident in the Memorial's built environment and the use of the site by visitors. In doing so, this paper draws on Nora's (1989) notion of lieux de mémoire, sites of national memory where the past is explicitly evoked and represented, and which act as conduits for official versions of the past and seek to proscribe 'appropriate' public responses. It also examines the uses of the national past in the present, and the notion that such sites are as much about forgetting as they are about remembering or memorialising. This paper explores how the meaning and import of such monuments rely on their practiced nature, and are determined in the discursive relationship between hegemonic official narratives and public responses to such narratives. Such public and quotidian engagements occur in relation to powerful spatial narratives that different users must negotiate in different ways, not least because certain types of uses (and users) are inevitably privileged in any spatial structuring. In doing so, I seek to highlight the power relationships that are exercised and negotiated through the use of place, discussing the capacity of practice to shape the meaning of place, in a discursive, dialectical power relationship with dominant cultural narratives. Focusing on the preparation and observance of Anzac Day events at the Australian National Memorial in Villiers-Bretonneux, this paper examines the 'top-down' narratives at work during these national days. It also seeks to unpick the vernacular and quotidian uses of the sites. By examining the relationships amongst the practices to which these sites are subjected, it explores how the Memorial can act as a nexus between public art and symbolic narratives of national power on the one hand, and public quotidian practice and use on the other.

Curating and programming for change – urban transformation through temporary art

Bettina Lamm (Copenhagen University), Charlotte Bagger-Brandt (Raaderum)

The scope of this article is to present and discuss the exhibition Urban Play that will take place in the transforming harbour of Køge, Denmark. Eight international artists and

architects are invited to create temporary installations on site during spring of 2012. Urban Play is developed by the authors - a landscape architect and a curator. Both curating and programming are significant as artists and architects commissioned are challenged with requirements for involvement opportunities, materials and location. LLaes fonetisk The aim is installations that stage and involve - responding both to the architectural context and inviting users to engage. The notion of play is significant as a way to invite visitors to inhabit the installations and hence the former industrial spaces. The theory is that embodied play can insert life, commitment and involvement similar to the qualities of art. The intersection between art and play has - as we see it - a potential for a dynamic way to inhabit public space and thereby contributing to the development of urban life and the quality of the urban sphere. The harbor is a major place for the shipping of wood. Also grains and sand is stored and transported on site. These materials will be incorporated into the art projects reflecting to local condition and contextualizing the art installations. They play a vital role in the narrative and tactile of the place bridging the past to the present. In this article the case of Urban Play is used as departure points for a reflection on temporary art interventions as part of urban transformations. A particular focus will be put on how the installations can contribute to the interpretation and reprogramming of site through materiality, play and embodiment.

of temporary public art as an important lens through which to examine dynamic responses by artists, arts administrators and policy makers to shifting imperatives for the articulation, measurement and evaluation of public art.

Public Art and Evaluation: A Temporary Turn?

Ruth Fazakerley (RMIT University)

The formation of 'public art' as a distinctive category of cultural practice and policy in the late 1960s is linked to the emergent phenomenon of art as a special field of government responsibility, and to the widespread reassessment of art itself (its forms, functions and social relations). New practices of environmental, site-specific and installation art claimed the centrality of active audience experience; unsettling the 'proper' locations for displaying and viewing art, blurring the boundaries between art and other things, and between artistic production and reception. 'Public art' might equally be said, however, to have emerged in Australian cultural policy throughout this period as the result of 'supply-side' lobbying for models of 'advanced', professional art and artists; models that have tended to leave the traditional relations of art remarkably intact. These observations point to some of the ongoing tensions embedded in diverse institutional and professional rationales for placing artwork in public places, and consequently the very different criteria against which public art might be evaluated. This paper provides a brief overview of recent Australian local government public art programs and policy, examining some specific cases in detail. These are discussed with respect to both the rich academic literature on the evaluation of culture, and the ever-widening range of claims made for public art's instrumental and intrinsic benefits to cities, communities, citizens, artists and sponsors, frequently predicated on assumptions about the public benefits of active, audience engagement with art. In particular, the increasing attention within contemporary Australian public art programs and policy to issues of temporality, suggests the category

The Social Life of Artworks in Public Spaces

Laurent Piché-Vernet (Institut national de la recherche scientifique - Centre Urbanisation Culture Société)

Who are the publics of artworks in public spaces? When compiled, the contributions of art historians who have discussed these issues form a polarized typology of publics. On one hand, the notion of "the public" can be described as inclusive: discussions of controversies for instance tend to put all citizens under the same umbrella. On the other, the viewer's experience has been described using the singular form, analyzing his everyday life practice of the artwork. But, between "someone" and "everyone", could there be a spectrum of publics? I would argue that two interrelated factors have contributed to these framings of the public. First, since Rosalyn Deutsche's major contribution (1996), the meaning of "public" in "public art" has been defined according to Jürgen Habermas' conception of the public sphere: an ideological site between the State and society (1974). Second, while the public sphere has been used in art historical discussions of public art without being questioned, Habermas' public sphere has been hiding another kind of public space. This one can be found in urban sociology, and should not be confused with Habermas' site of debate. Parks, streets, squares and plazas are physical public spaces that serve as support for urban sociability: they are the sites where individuals express their individualities, and where they learn to live together. By using a definition of public spaces that is common in urban studies, the art historian opens a field of theoretical and, most importantly, empirical possibilities. Focusing on the social life in urban spaces is now possible in a concrete way, and it appears to be the first step towards the identification of publics. In his 1988 documentary film *The Social Life of Small Urban Spaces*, William H. Whyte shortly opened this door by filming how people use artworks in public spaces, and how they act and interact around them. Filmed observation still seems to be an appropriate and valid research method to study the publics. Unsatisfied by the theoretical discussions on the publics, and inspired by Whyte's movie, my doctoral research consists of filming the social life of artworks in Montréal public spaces. The notion of "uses" is here crucial because, as preliminary research has shown, it is the entry point to explore how the users actually become part of a public. During this conference, with the help of video excerpts, I would present my first thoughts on how uses of artworks can be analyzed, and how they can lead to the identification of publics. Aural ethnography: Experiencing sound art

Angharad Saunders (University of Glamorgan), Kate Moles (Cardiff University)

Aural Ethnography: experiencing sound art Angharad Saunders (University of Glamorgan) Kate Moles (WISERD, Cardiff University) Over the past decade there has been a growth in sound art projects (Cardiff, 1999; Butler, 2006). Part of the motivation for these projects has been the desire to destabilise the privilege we accord to the visual by revealing how sound and soundscapes encourage us to experience and understand place in alternative ways. While academic responses to sound art are growing (Pinder, 2001; Butler, 2006; 2007) there is, as yet, little sustained analysis of the everyday experiences of more popular interactions with sound art: how does sound art affect us; how do we interact with it; how (if at all) do we create meaning from and through our experience? This paper begins to explore more popular engagements with sound art through an aural ethnography of a community audio walk project. In 2011 a group of young people came together to create a series of audio walks around their neighbourhood in Cardiff, South Wales. These walks were part of a project called 'Sounding the Way' that sought to give voice to groups whose knowledges of the world are traditionally marginalised. On the launch of this project local people were invited to 'take a walk' along the audio trails, and share with us their thoughts, feelings and responses to the walks as sounds art. The result is an aural ethnography that gives us insight in to way sound art can shape and affect our understanding of, and engagement with, place.

The Ergonomics of Public Art

Quentin Stevens (University College London)

This paper is a theoretical and empirical exploration of the different kinds of direct bodily encounters that occur between people and public artworks. This is a geographical study at a very small scale; the focus is on how well the material forms of public artworks fit to the size and movements of the human body. Whatever the intentions of their clients and designers, public artworks are often good for sitting on, leaning against, lying down on, using as a table for work or leisure activities, to rest bags or other objects on, to stand on to see something better, or, more generally, as play equipment for pedestrians, cyclists and skaters. The paper analyses the different postures and movements that occur on and around public artworks, to identify particular characteristics of scale, material, surface and form that appear to allow or encourage specific actions, in line with Gibson's (1979) concept of environmental affordances. My use of the term 'ergonomic' to characterize the relations between these classes of objects and actions is ironic, because ergonomics relates specifically to workplaces, to the optimisation of narrowly-defined work-related functions, and to designing equipment that helps in conducting those activities efficiently, safely and comfortably. In the examples illustrated in this paper, neither action nor object seeks to be efficient. The actions illustrated often seem to be unintended by the artworks? designers, and by definition, art is rarely optimally practical. The actions largely ignore the discursive aspects of artworks; they emphasise materiality and touching rather

than representation and viewing. While in some cases, people do make contact with artworks to be more comfortable at rest, a wide range of uses of public art appear to involve exploration and risk. Observation of people's bodily encounters with public art reveals two groups whose actions are particularly varied: young children who are just starting to explore the world, and young men who are approaching the height of their physical prowess. The paper examines the ways these groups test out the material affordances of public art.

London Playing Fields

Nicolas Whybrow (Theatre and Performance Studies)

'The Uses of Art in Public Space' International Geographical Congress, Cologne, August 2012 (panel convenors Dr Quentin Stevens, UCL, UK/RMIT University, Melbourne, Australia and Professor Julia Lossau, Humboldt University, Berlin) London Playing Fields Dr Nicolas Whybrow School of Theatre, Performance and Cultural Policy Studies, University of Warwick, UK The paper's point of departure is the phenomenon of play, which has experienced an increased practical application recently in a number of ways within different art forms. More often than not, these instances are dependent, first, on the quotidian city as 'play-ground' and, second, on 'participating publics' whose roles vary. Noticeable, so the paper will argue, is the way there is a highly fertile, if only implicit, dialogue taking place between 'unofficial public practices' such as flash mobbing, free running and other forms of 'underground' art making (or, as the case may be, political activism), and those of high-profile artists such as Antony Gormley, Marc Quinn, Mark Wallinger and Martin Creed. Thus a highly-determined public site such as Trafalgar Square in central London - arguably a theatre to the memory of imperialism and war - might reveal critical linkages between, for instance, a 'frozen mob' event occurring in 2008, nineteenth-century statuary (Nelson's Column et al), and the recent activation of a changing programme of artworks sited on the Square's so-called 'Fourth Plinth': Quinn's sculpture Alison Lapper Pregnant, which retained its position there for almost two years between 2004 and 2006, or Gormley's 'collective, democratic portrait of the UK', One and Other, which, in the summer of 2010 witnessed a rotating occupation of the empty plinth by selected members of the public on an hourly basis, 24-hours a day for a period of one hundred days. The latter in particular brings into play issues around the creation of narratives of national identity in urban space in the way it seeks to position a form of fragmentary, improvised 'popular stage' in immediate counterpoint to the rhetorical assertion of 'secure national history' projected by the 'elevated heroism' of an Admiral Lord Nelson or, indeed, the neo-classical National Gallery that dominates the Square's northern side. The paper's purpose, then, is to show, first, how artists are incorporating aspects of 'the street' and developing playful visions or articulations of urban space in the work they make and, second, how the public's engagement with such artworks increasingly takes the form not merely of reception but participation.

Territorial knowledge dynamics between path dependency and path plasticity

Simone Strambach (Universität Marburg)

The changing nature of innovation processes is a significant feature of the global structural transformation towards knowledge economies and knowledge societies. What is widely acknowledged about innovation processes is the growing importance of external knowledge which requires the collaboration of a variety of actors outside the focal firm, located in different technological, sectoral, regional and national contexts. Even though several innovation approaches such as distributed innovation (Coombs, Harvey, Tether 2003), open innovation (Chesbrough et al. 2006; Cooke 2005), or the organisational decomposition of innovation (Schmitz, Strambach 2009) put emphasis on the increasing significance of external knowledge, the underlying knowledge dynamics which form the basis for innovation have so far received little attention. While technology-driven innovation, the growing importance of user involvement and the co-creation of values with customers indicate the increase of non-technological knowledge as a driving force for innovation, the hidden qualitative shift in knowledge dynamics towards combinatorial knowledge has not been reflected in more detail in innovation research. The geography of these knowledge dynamics on the micro level is at the centre of this contribution. Traditionally socio-economic development has been seen as reflecting path-dependent cumulative knowledge dynamics characterised by parallel co-evolution of technological innovation and social institutions that results in 'new developments' being primarily incremental adjustments of existing practices. Geography influences knowledge dynamics not only through the mechanism of proximity but also through the mechanism of path dependency and place specific institution building (Martin/Sunley 2006, Oinas/Malecki 2002). Knowledge cannot be transferred easily either among actors or combined randomly due to its inherent tacit dimension, its context sensitivity and its process character. As collective learning processes are territorially situated, institutional and organisational characteristics are potentially important to understand how knowledge dynamics unfold in time and space. However, paths are not coherent and there is always a degree of path plasticity (Strambach 2010), i.e. scope for variation in time and space within similar institutional settings. The scope for path plasticity has been increased by the growing importance of combinatorial knowledge within economic development which in turn has widened the field within social actors can innovate. The contribution intends to explore the ways in which space and place shape cumulative and combinatorial knowledge dynamics by proximity economies and the institutional embeddedness of actors, and in turn reshape territory and territorial configurations of actors. Knowing more

about these interrelations may provide an improved basis to understand the production of emerging economic spaces.

Airports reconsidered. An emerging knowledge-economy-based space

Sven Conventz (University of Munich), Alain Thierstein (University of Munich)

Following Castells (2000) seminal work on space of flows societies are centered around all kinds of flows: financial flows, flows of information, knowledge, technologies, flows of images, sounds, and symbols. Through their capability of concentrating different kind of flows - from local to global spatial scale - airports have advanced to key nodes within the networked economy. In recent years airports have rapidly become new urban growth generators, hubs of information and knowledge exchange and centers of competence. At the beginning of last decade Gueller (2003) stated 'airports are not just airports anymore'. Indeed, airports have morphed from pure large-scale technical infrastructure facilities into multilayered real estate sites for commercial, retail and leisure activities and their impacts on rewriting the metropolitan geography have been tremendous. Successively, knowledge-intensive companies have settled their regional, national and sometimes supranational branches in close spatial proximity to airports. Despite the deep impacts of airports on shaping the metropolitan geography little is known about the spatial drivers of this new economic entity. It seems to be that changed locational requirements and reajusted locational behavior of advanced producer services and high-tech companies is one key in understanding the new spatial articulation around airports. The paper reflects the first empirical results of an ongoing research project using the cases of Amsterdam, Munich, Frankfurt, Duesseldorf and Zurich. The contribution asks the following questions: What do we know about the complex interplay between a punctual network-infrastructure such as an airport and their impacts on the spatial restructuring process? Which role plays the knowledge generation of firms and their need for geographical and relational proximity? What role plays the airport within the value chains of knowledge-intensive companies? What role plays an airport within a multi-branch multi-location firm's decision making process about locating activities? First empirical results indicate that the airport is not primarily perceived as a transportation node but as an advantageous business location that supplies a rare competitive advantage: accessibility. With changed locational requirements of the knowledge economy and thus perception and evaluation of airports a new urbanizing space is emerging.

Multinational enterprises, globalization and labor division in semiconductor industry

Egor Yablokov (St. Petersburg University)

Digital revolution with all its electronic devices and gadgets would not be possible without the invention and constant development of transistors and very-large-scale integration circuits (VLSI) or, more easily, integrated circuits (ICs). Every IC is a result of

semiconductor industry work, one of the most complicated industries in modern world. Every year this industry generates a revenue of approximately 280 billion dollars and creates many thousands workplaces around the globe. Semiconductor industry spatial development is impacted and formed under the influence of technological, economic, political and some other factors. The structure of the industry is presented with stages of research and development (R&D) activities, differentiated manufacturing stages and some logistics and specific market-orientated activities. Semiconductor industry is one of the industries where currently there are no more than a few 'local' players. It's an industry where all stages - from R&D to manufacturing and to after-sales support - develop according to the interests of multinational enterprises (MNEs). MNEs control every stage of supply chain and form a unique geographical spread of the industry. An average customer of gadgets, e.g. smart phone, built by Samsung at one of its Korean, Chinese or even European plants, may even not to suspect that the central part of this electronic device, making possible all its amazing functions, - a small piece of a silicon, containing a few hundred millions transistors, named 'system on a chip', - was produced in Austin (US) using intellectual property of a medium-range UK firm, that even don't have any manufacturing facility. At the same time a lot of electronic devices and computer components in our days are made by the MNEs, that don't produce anything at all. Anything except technology and intellectual property. US-based Qualcomm, manufacturer of the core components for a huge percent of all cell phones and smart phones, Nvidia, whose graphic chips make all the visual experiences in modern PCs possible, its rival AMD (also produce central processor units), Broadcom, creator of communication and multimedia chips, - all of these MNEs, generated more than a few billion dollars of revenue every year each other, - don't manufacture ICs at all. But why are they listed among the world's largest semiconductor manufacturers? The answer is because they take advantage of globalization, economy on scale and specific division of labor in the semiconductor industry. All their production take place at fabrication facilities of Taiwanese MNEs like TSMC, UMC and some others or - even more curious example - Global Foundries, a truly called MNE, due to its global presence, manufacturing facilities in Dresden (Germany), Singapore and Saratoga County (New York, US), and core investments from Abu-Dhabi state-owned fund.

Emerging Economic Geographies in the EU: Spatial Patterns and Determinants of Turkish Direct Investment in the European Union

Nuri Yavan (Ankara University)

After Turkey was officially recognized as a 'candidate country' for European Union (EU) membership in 1999, European foreign direct investment (FDI) into Turkey has received a great deal of attention from scholars and policy makers. Indeed, the question of Turkish accession provokes intense debate in every part of the EU and Turkey. Therefore, many studies have focus on EU FDI in Turkey. On the other hand, one of the most important features of today's global economy is the growing outward FDI (OFDI) by multinational

firms from some developing countries and in particular firms from Turkey. Recently, UNCTAD defined Turkey as 'a leading source of FDI from West Asia, emerging OFDI countries'. Indeed, over the past decade, many Turkish firms have begun to invest abroad and thus Turkey's outward FDI has increased impressively. Even though there is a growing literature on European FDI in Turkey, so far no study is available on Turkish outward FDI in EU. In this context, this paper examines spatial distribution of Turkish outward FDI in Europe with emphasize on location choice from a geographical perspective. Using both regression analysis and geographic information system techniques, we test our hypotheses employing official Turkish outward FDI data collected between 2001 and 2010. Our descriptive analysis indicates that, spatially, the favorite targets of Turkish FDI firms have been the Netherlands, Malta, Germany, United Kingdom and then Romania but significant agglomerations of Turkish investments can be found in western parts of the Europe. On the other hand, our empirical analysis suggests that the locations of Turkish firms have been heavily biased toward the largest Turkish population in European cities. Additionally, Turkish direct investments in EU countries are most attracted to countries with large amount of FDI agglomerations, countries that are well-established trading partners with Turkey. We also find that both geographic and cultural proximity as well as patent and exchange rate are significant location determinants. As a result, we can argue that Turkey has already integrated with EU regions at least in terms of economic space. Key words: Economic Geography, Turkish Outward FDI, Location choice, EU, Multinational Firms

C08.08-02 - Universities, Clusters, and Industry Emergence

The emergence of Toledo's solar energy industry: A new industry in an old economic space

Neil Reid (University of Toledo), Michael Carroll (Bowling Green State University)

Toledo, Ohio is a classic example of an old industrial city that is struggling to find its place in a rapidly changing global economy. The traditional industries of glass and automotive are in decline with the result that the city is facing the challenges of population decrease, high unemployment, and the associated social problems that economic dislocation brings. In response to these economic challenges the city (and the broader region of northwest Ohio) has invested a considerable amount of resources in developing a viable and sustainable solar energy industry. This initiative has met with considerable success. Led by the region's major research university (the University of Toledo) the region has become an internationally-recognized center for cutting-edge research in second-generation solar panel technology. This research, conducted by university scientists, has resulted in a number of spin-off companies that are beginning to employ workers displaced by other industries. The region has also begun to attract foreign direct investment as overseas investors are attracted to the regions emerging and growing solar energy cluster. In this presentation we will outline the growth of northwest Ohio's solar energy industry, describe the strategic processes employed by the region in growing the industry, and conclude by looking at the challenges that are facing the region if it wants to maintain its current growth trajectory.

The Influence of Architectural Innovation on the Spatial Configuration of Industries: The Example of On-shore and Off-shore Wind Energy

Pascal Sommer (University of Hamburg), Max-Peter Menzel (University of Hamburg)

Theories describe the spatial evolution of industries usually in connection to the sequence from radical/product innovation to incremental/process innovation (Storper and Walker 1989). However, studies show that industries are regularly disrupted by what Henderson and Clark (1990) call 'architectural innovation'. Architectural innovation describes not a change of the different components that make a product, but a change in the relation between them, i.e. the product architecture. The effects of architectural innovations on industry incumbents are comparable to those of a radical innovation. Despite the effects architectural innovations have on industries, their influence on the spatial configuration of industries is somehow ignored. What misses is how architectural innovations affect the

spatiality of industry relations, the established locations of the industry as well as on the larger geographical scale the pattern of center and periphery. The proposed paper shall be a first step to fill this gap with the example of on-shore and off-shore wind energy industry in Europe. On the first glance, off-shore wind parks require wind turbines comparable to traditional ones, with the addition of a special fundament and cabling. However, only few firms were able to successfully install off-shore wind turbines. Additionally, these firms split off their off-shore business from on-shore business. Furthermore, new production sites for off-shore wind industry emerged, mostly outside the established centers. By using the framework proposed by Murmann and Frenken (2006), we could define off-shore wind energy as architectural innovation. As one component of wind turbines, their fundament, developed from a peripheral to a core component, the whole architecture of wind turbines changed. We argue that this change, especially the new importance of the fundament, result in new spatial requirements of industry relations and thus a spatial reconfiguration. We analyse the spatial differences between on-shore and off-shore wind energy production using an original data base, which contains data on the plant level regarding business segment (on- and offshore, final assembly supplier etc.), location, time of entry and exit for 750 sites from 1974 till 2011. Henderson, R. M. and Clark, K. B. (1990): Architectural Innovation - the Reconfiguration of Existing Product Technologies and the Failure of Established Firms. In: Administrative Science Quarterly 35(1), 9-30. Murmann, J. P. and Frenken, K. (2006): Toward a systematic framework for research on dominant designs, technological innovations, and industrial change. In: Research Policy 35(7), 925-952.

University Scientists Bridging Geographical Scales of Knowledge Production – Two Perspectives, One Approach

Marcel Vojnic (RWTH-Aachen), Martina Fromhold-Eisebith (RWTH-Aachen)

Economic geographers and regional economists, as well as agents of socio-political development, have ascribed various roles to universities. Beside their basic activities of research and teaching, positive effects of academic activities on the regional economy have been put centre stage. Universities carry the mission to generate knowledge, information and technology and to transfer it to the benefit of the regional economy. Apart from interacting with local partners, however, universities are further characterized by their integration into national and global knowledge networks. The ability to link between geographical scales and to participate in world-spanning networks of information exchange is one of their fundamental and outstanding attributes. Yet, it is not 'the university' that actively operates this way, but the individual scientists who interconnect between scales in fairly individual ways. Attempts that aim at investigating knowledge networking at the micro-level are rare and rely either solely on quantitative or on qualitative data. Up to now, there has been no investigation that systematically combines both approaches. Quantitative approaches, on the one hand, capture a broad range and amount of data on the issue, but are not capable to produce deeper insights beyond

scratching the surface. Qualitative approaches, on the other hand, allow creating an in-depth picture of scientific collaboration patterns and motivations. However, they cannot depict the whole spectrum of relevant information across large samples. Based on these preliminary theoretical considerations, we have applied a combinatorial strategy of the two methodical approaches in order to capture both quantitative and qualitative data on the knowledge networking behaviour of university scientists. In addition, drawing on a 'matched pairs' setting, we have made scientists subject to a comparative analysis who represent different application oriented scientific disciplines at two different universities (RWTH Aachen and TU Delft). This approach aims at the frequently neglected micro-level of the individual in its local embeddedness, and it analyses their ego networks in terms of scale-bridging (regional/ national/ international) interactions with knowledge collaboration partners in the same epistemic community and beyond. Moreover, in order to depict the innovation network centring on the scientist as accurate as possible, university-industry linkages merit specific consideration. The suggested presentation will depict theoretical underpinnings as well as first empirical findings of this DFG/NWO-funded project. It fruitfully combines the perspectives, methods and heuristics of different scientific disciplines and is currently collaboratively conducted by economic geographers and innovation economists at the Technical Universities of Aachen and Delft.

Industrial Restructuring and the Cluster Evolution: The Case of Seoul Digital Industrial Complex

Yangmi Koo (Seoul University)

The purpose of this paper is to analyze the paths of industrial restructuring of Seoul Digital Industrial Complex (SDIC). The SDIC, located in the southwestern part of Seoul, has led industrial development as the only designated industrial zone in Seoul. New industries and related focal firms have been generally created in Seoul metropolitan area and then diffused to other regions at growth and mature stages. Under the broad framework of industrial evolution in the Seoul metropolitan area, this study will especially focus on the SDIC, which has played an important role as the first national industrial complex in Korea. Path of industrial development in the region was the renewal of the existing industries and diversification into related industries. New path of the region was also created by indigenous development or external transfer of new technologies and industries. In this paper, these restructuring processes will be explored with relation to the evolutionary perspective of economic geography. The SDIC, originally called as the Korea Export Industrial Complex at Guro, started with an export-oriented industrial strategies focusing on labor-intensive industries in the 1960s. In the late 1980s, this complex faced with the first industrial restructuring by high labor costs, frequent labor conflicts, and hollowing out of manufacturing sectors. Since the late 1990s, Guro as a traditional low-tech industrial complex has experienced the second industrial restructuring. It has been changing into a high-tech cluster by attracting technology-intensive small and medium-sized firms and knowledge-intensive service firms. The major actors of the industrial

development or restructuring have changed from national government in the 1960s and 1970s to private firms and real estate developers after the late 1990s. Throughout the industrial changes of the SDIC, path dependence and path creation processes have been coexisted because of the diverse developmental path of industries and firms.

South-South economic relations and the role of natural resources in Chilean exports to Asia

Johannes Rehner (Universidad de Chile)

Increasing 'South-South' relations are changing the spatial patterns of global trade and financial flows. Asia has become one of the most relevant trade partners of Latin American countries, in particular Chile. Given the rapidly growing Chilean exports to Asian countries, the specific contribution of international trade and its prospects in the medium and long term are critical to regional development. Nevertheless the composition of Chile's bilateral trade with Asia is not necessarily generating higher benefits than north-south trade does. Oriented by international trade theories, certain elements of the 'resource course' thesis and some theoretical approaches to foreign direct investment (FDI) the paper contributes to the discussion of trade policies and economic development. Due to the increasing importance of FDI and its complementarity with foreign trade, an analysis of FDI flows is included. In terms of methodology, this paper presents a quantitative analysis of trade relations for the period 1990-2010. The analysis is based on official trade statistics between Chile and PR China, Japan, Korea and India, complemented by FDI data. Applying different indices it examines structural features and trends of Chilean exports to Asian countries. The prominence of some Asian partners changes the spatial export structure without providing a clear diversification of export products. In some cases it has deepened export specialization in raw materials and products based on mining and agriculture. We expect increasingly unbalanced benefits and impacts of foreign trade in Chile and also that FDI from Asian countries in Chile are still focused in Chilean export sectors or are related to the distribution of Asian imports in Chile. Therefore they potentially enhance the productive development of export regions, increasing development gaps. With Japan there are traditional commercial ties, both in terms of Chilean exports, and Japanese FDI in Chile. Although often related to mining these show a higher level of diversification. The commercial link between Chile and Korea shows some similarities to the case of Japan. In its relation to China, Chile recorded a positive trade balance, but its export structure is extremely focused on copper and fueled by China's demand for primary products. As for the structure of Chilean trade with India are found a trade surplus but high concentration on the export of copper and its derivatives. However, it should be considered as one of the most promising Asian partners. Even though Chile's financial benefits from foreign trade are evident and the role of Asian countries is increasing, from a sustainable development perspective, there are obvious constraints of a strategy based on the exploitation of raw materials, so it is still necessary to discuss its implications on regional development and evaluating strategic trade alternatives.

Creating a New Domestic Niche Market for Merino Lamb Meat in New Zealand: A Case Study of Small Company Experimentation.

Michael Roche (Massey University)

Widespread State sector restructuring and economic deregulation in New Zealand in the 1980s and 1990, locally labelled 'Rogernomics' after its domestic architect provided New Zealand geographers with an unprecedented opportunity to contribute theoretically and empirically to studies of Neo Liberalism in action, in which the agrifood sector has featured large. But as an isolated export dependent economy, a situation deepened by the development of refrigeration and the beginning of large scale dairy and meat exports in the 1880s, in New Zealand 'internationalisation' and more latterly 'globalisation' have arguably long been part of an academic frame of reference. Historical links to the UK and early connections with US geography have also meant that New Zealand geographers have tended to relate their work to the world of Anglo-American geographical scholarship. This paper consciously explores the new forms of economic organisation in the local setting; the bulk of sheep meat is exported and local meat consumption has tended to be overlooked by New Zealand geographers, even though it is the 'normal' context, in which many other agrifood workers are situated and in which they produce theoretical and substantive work. A small scale Merino lamb producing company based in the Central Otago region of New Zealand's South Island provides the specific context for this presentation which looks at the meat commodity production chain in New Zealand. The Merino breed has typically been valued for its fine wool rather than its meat. The paper concludes by discussing what a consideration of New Zealand's 'local' conditions can add to the wider field.

Facteurs géographiques et naturels de la croissance au sein de l'Union Economique et Monétaire Ouest Africaine (UEMOA)

Atsé Alexis Bernard N'Guessan (Université de Cocody-Abidjan)

Résumé Organisation économique régionale en Afrique de l'Ouest, l'UEMOA regroupe huit Etats membres et couvre une superficie de 3 509 600 Km², pour une population de plus de 80 millions d'habitants. Ces Etats sont pour la majorité d'anciennes colonies françaises qui ont appartenu au grand ensemble de l'Afrique Occidentale Française (AOF). Le territoire de l'organisation s'étend sur des espaces aux caractéristiques géographiques et naturelles diverses. Les structures économique et démographique au sein de l'union se dessinent dans le même sillage pendant que des différences se présentent au plan naturel. Le taux de croissance de l'ordre de 5,9% par an au sein de l'union de 1995 à 1999, a fléchi pour atteindre 2,8% par an de 2000 à 2009, une période pourtant plus longue que la première. La présente étude veut mettre en relief les déterminants géographiques et naturels qui interviennent dans cette croissance, somme toute controversée, et proposer des options pour une contribution optimale de ces facteurs à la croissance. Une revue des conditions naturelles et géographiques montre

que les Etats ont des potentiels à même d'impulser un développement plus accru au sein de l'union, mais qui sont insuffisamment ou mal exploités. Une analyse approfondie de la situation indique que la mise en place de politiques adéquates peut apporter une participation plus grande de ces facteurs à la croissance et au développement.

The sustainable development and Romania's energetic resources potential

Costela Iordache (Universite de Craiova)

The natural resources represent the natural capital, a constituent of Romania's richness. Turning to account the natural resources by exploiting the irreproducible raw materials as well as the reproducible ones and their process to obtain goods determines the level of economic and social development of the country, the situation of the environment and population's conditions of life. The economic and social evolution of our country depends directly on the energetic resources. Romania has a richness of lean resources, with a rapid exhausting the known resources of oil and natural gas, with considerable no qualitative and inefficient stocks of lignite and swell, with weak capitalized hydraulic and nuclear energy. After 1995, Romania became an importer of row energetic resources and the existing production technologies are considered dirty, intensive pollution and expensive. The loss and intensity (the row resources consumption on energy production ratio) are unfavorable due to some false price and many subventions, a wrong extensive industrial and economic policy.

C08.08-04 - Emerging Economic Spaces in Europe

Chair: Neil Reid, Christine Tamasy, Mike Taylor

“Cognitive Economic Geography” – evolution of regional strategies in emerging economic spaces

Piotr Pachura (Czestochowa University)

The aim of this article is to present the role of cognitive approach in economic geography based on theory evolution as well as the case of regional development strategies evolution for an old industrial region in Central Europe. In the first part, the theoretical approaches will be presented as an overview of economic geography theories in the regional development process. The second part, as case study will focus on practical issues of the evolution of regional innovation strategy - 'from chaos to cognitivism'. The cognitive approach to regional innovativeness will be analyze like a 'new paradigm' in economic geography. The research methods used will be based on: desk research; the historical-comparative analysis, qualitative analysis and practical observations and experiences of the author's work on regional innovation strategies.

Absorption of the cohesion policy funds vs. emergence of growth and stagnation areas in Poland

Pawel Churski (Adam Mickiewicz University), Robert Perdal (University Poznan), Anna Borowczak (Adam Mickiewicz University)

Pawel Churski Anna Borowczak Robert Perdal Institute of Socio-Economic Geography and Spatial Management Adam Mickiewicz University One of the fundamental goals of the European Union is to create conditions conducive to sustainable growth in the Union's entire territory. The need for economic and social cohesion has been emphasized since the early years of the European Community. Lamentably, the successive accessions of new member states have further accentuated the internal developmental differences. This, in turn, has led to tightening up intervention measures aimed at an effective improvement in cohesion and extension of the content-related range of this concept. This process has resulted in the present change in the focus of the European Union's regional policy on the cohesion policy. In the current financial perspective, the major goal is to achieve the highest possible level of cohesion in as many as three dimensions: economic, social and territorial. The attempt at boosting the competitiveness of the EU economy on a global scale has been a very important conditioning of the cohesion policy, now even gaining in importance. Europe lost its dominant position in the global economic competition after World War II. In the face of China's and India's economic growth and the excessively social policies administered by the members states, with the Union plagued with a high unemployment rate and an inconsistent financial policy regime, it has become even harder to regain that dominant position. This

has led to a heated dispute over the future of the cohesion policy and its focus. Involved in this dispute are supporters of continuing the compensation model and its opponents who highlight the need for inclusion of polarisation models into intervention measures. They also emphasize the legitimacy of underpinning growth extremes, giving them an opportunity to gain a global competitive advantage and positively affect their environment. This article's goal is to identify the relations between the scale of intervention as part of the cohesion policy and the emergence of economic growth and stagnation areas in Poland by regions and sub-regions. The research process consists of two stages; at stage one, areas of economic growth and stagnation in Poland are identified as a result of a cluster analysis on the NUTS-2 and NUTS-4/LAU-1 level. Stage two includes an analysis of relations between regional and sub-regional diversities in the structural funds intervention and the distribution of economic growth and stagnation areas in Poland. Here, factor analysis methods are employed. This article is an element of summing up of stage one of a research project conducted by the National Science Centre (NN306791940): Socio-economic growth vs. development of economic growth and stagnation areas handled by a Team headed by this article's author.

The role of the business environment in regional development in Poland

Joanna Dominiak (Adam Mickiewicz University)

Keywords: business environment, regional development, Poland, innovative environment In the modern transformation of the socio-economic environment shaped the economic activity is an important factor of development. Business environment can be defined in a narrow or wide range. In the literature most often refers to three main components of the business environment: institutional infrastructure, innovative environment and social climate. Business environment is one of the major factors activating the region's development in modern economic transformation in Poland. Properly shaped, the business environment on the one hand is a factor in business location, on the other hand - determines the dynamic socio-economic development. Influence of business environment on the development of the region can be analyzed in many ways. Business institutions have an impact on the investment attractiveness of the region, the level of its competitiveness. Through the relationship of innovation - the industry contribute to the development of high technology industries, innovativeness in the region, and also to the formation of knowledge-based economy. These institutions also directly support economic activity in particular small and medium-size firms, providing support information, advisory and training (training and consultancy) and financial (loan and guarantee funds) for doing business. Taking an active part in networks of relations of science and business practices allow the formation of the modern economy of the region This article aims to analyze the level and dynamics of development of the business environment in 2000-2009 in a regional context and the characteristics of the relationship between the level of development of business environment and the level of socio-economic development of regions. This article is an attempt to answer the following

questions: (1) what is the regional differentiation of business environment development in Poland, (2) what was the dynamics of business development in the regions in 2000-2009, and (3) what is the relationship between level of development of business environment and regional level of socio-economic development. Characteristics of the level of development of business environment in the Polish regions conducted in the system is the most important components of the business environment: innovation environment - institutional and commercial equipment business services. The result of this analysis is the classification of regions on the scale level of development of the business environment.

Non-metropolitan industrialization in the EU periphery: the case of Poland

Boleslaw Domanski (Jagiellonian University)

Non-metropolitan industrialization is a phenomenon which became a popular theme in the United States more than 30 years ago. It was accounted for, on the one hand by growing costs and other disadvantages of industrial location in metropolitan regions, on the other by the endogenous development of small and medium-sized enterprises in non-metropolitan areas, e.g. in the postfordist approach. At the same time, industrial growth in the emerging economies was mainly connected with major urban agglomerations which offered bigger market, skilled labor, better infrastructure and accessibility. As a result, it was largely believed that industrialization processes in emerging economies contributed to growing urban agglomerations and regional disparities. This could be explained by various theoretical concepts, among other things, product life cycle theory, cluster approach and innovative milieu. In this context, it is interesting to explore the processes of industrialization in the eastern periphery of the European Union. Non-metropolitan areas of Poland, Eastern regions of the country in particular, are regarded as one of the poorest and least industrialized parts of the EU. Moreover, they have suffered from large out-migration for more than 60 years and lagged behind fast growing metropolitan areas in the post-communist period. The aim of the paper is to provide new insight into the mechanisms and effects of non-metropolitan industrialization of the peripheral areas of the EU. The authors take a long-term perspective, that is the contemporary processes are analyzed and interpreted in the context of the economic and social development of these regions since the nineteenth century. These processes include: the fall of some traditional industries, e.g. the 19th century textiles and the armaments production from the Cold War era, the successful restructuring and exports-oriented growth of some other sectors, from furniture and milk products to advanced aerospace components, as well as the rise of entirely new clusters, from standard plastic products to innovative women's underwear and automotive parts. There are significant differences in the role of foreign investors, large domestic enterprises and the local firms in various sectors. The positive effects of local industrialization are found most of all in the case of indigenous producers, giving support to the theoretical concepts putting emphasis on endogenous development. On the whole, the non-metropolitan eastern

regions of Poland have proved surprisingly successful in manufacturing in the last two decades, in contrast to their relatively poor performance in services and agriculture, that is the sectors generally recommended for these areas in regional policy. All this shows a highly complex picture of reconfigurations of local and regional economic spaces affected by the historically embedded local conditions and capabilities on the one hand, and the global forces on the other.

C08.08-05 - Emerging Economic Spaces in Asia

Chair: Neil Reid, Christine Tamasy, Mike Taylor

Inside Indian IT spaces: reading one global change by the major role of State(s)

Divya Leducq (University of Lille)

This paper aims to compare two trajectories of economic spaces in order to demonstrate that State still has - and maybe more than never before in the mid-term slowdown of economy - a strong role to play in shaping innovative and resiliency capacities in the globalized world. Taking as example an emerging giant, India is a country which slowly became one of the most global players within Information Technologies sector - and more specifically in software conception, after the different level of public decision undertook some policy and drawn some agenda to strengthen their scientific, technological and commercial environment. This issue illustrates more than an academic controversy lying in Indian economic literature, but also a main debate dividing the political sphere and the contemporary business class. Firstly, we would like to show that addition and regular evolution of policies, undertaken in a reform context at the central and regional level, are the first point of a clustering dynamic in an under-industrialized country. The second point of the paper would like to underline the main actors and bifurcation times in the construction of the sector. Of course, State(s) government - either initiator, either facilitator - are not forever the main actors of multiscaled clusters. If the policy frame gave enough confidence to the private sector, then appear the key figures of entrepreneurs and stakeholders networks within a promptly changing context. Those various actors enter in the systemic production of emerging economic spaces. Moreover in case of sector crisis, we argue that is the most important point of the resiliency capacities of a territory. In fact, the deep involvement of entrepreneur and scientists in social, scientific and professional networks implements good conditions for the innovative spatial systems evolution. So, our two studied cases, the regional state of Maharashtra and the regional state of Kerala, represent some interesting and quiet different labs - one communist and the other neo-liberal - to observe cumulative effects of the technopolitan process. Based on my thesis, this paper mix some quantitative and qualitative analysis of turnover and efficiency factsheets, official documentation, direct interviews with public and private actors and direct observations. Key-words Cluster - Innovation - Information Technologies - Evolutionism - India References (short list) Leducq D., 2011, Geography of innovative spatial systems of software in urban India. Learning from the cities of Pune, Thiruvananthapuram and Kochi, PhD Thesis: Economic geography and Town planning, University of Lille 1, 435 p.

Dressing the World - Integrating Bangladesh's Ready Made Garments Industry into a Global Market

Elvira Graner (South Asia Institute), Mahboob Elahi Akhter (University Dhaka)

The integration of so-called developing countries into the global economy is often depicted as a vital remedy in order to overcome 'structural' disadvantages. Yet, many scholars from social sciences question such an optimistic interpretation, pointing out to processes that increase rather than overcome regional and social disparities. These ideas have been outlined by the German geographer Scholz in his model of 'fragmenting development'. Thus, he depicts such places as 'globally integrated urban frag-ments' (ibid. 2000, 10) and epitomises the integration as ephemeral and fragile. In a similar line of argument, the French economist Pierre Veltz has characterised these economies as 'économie d'archipel' (1996). While such a metaphor might be quite appropriate for a country like Bangladesh in the age of Climate Change, such a term is usually confined to natural phenomena, but not applied to the economy. Empirically, our research project is based the Ready Made Garment (RMG) industry and the integration of Bangladesh into the 'global' economy. This sector has been set up during the late 1970s and Bangladesh has rapidly advanced as a major production site. With growth rates that still reach nearly double-digit figures, this has contributed decisively to bringing about a moderately affluent middle class. On the other hand, developments, or rather the lack of it, for the vast labour force, have given rise to strong concerns, worldwide. Until today, wages range at global minimum levels, and stiff competition to China and Vietnam is usually taken as an argument why wages can not be increased. While low costs of living have allowed the 4-5 million workers to achieve modest levels of living for quite a while, the highly inflationary costs over the past decade have threatened the livelihoods of many workers. Our study aims at conceptualising and analysing these economic developments from the vantage point of institutional economic theory. When doing so, the rules and regulations at any given locality are understood as the outcomes of (re-) negotiation processes among the key agents, from the public and private sectors and civil society. Our core argument is that the power positions of these stakeholders are distinctly different, and that the 'rules' (such as wages) reflect these positions of power and powerlessness. Of particular interest is the role of the state in supporting some stakeholders. This research project is based on a series of key informant interviews with core stakeholders during the past few months, at the national, local and 'global' level, including policy makers, industrialists, buyers, workers, and NGOs who are engaged in this field.

The Spatial Characterization for Regional Disparity of Tourism Development: A New Perspective

Rui Liu (CAS), Lihua Li (CAS), Wei Tang (Institute of Mountain Hazards and Environment), Difei Fu (CAS)

Despite there having been large number of researches concerning the regional disparity of tourism development, few of them have been conducted from the perspective of spatial characterization. In this paper, we attempt to study regional disparity in tourism development by simulating the position of 'spatial balance point' of 'tourism economy force' and its temporary-spatial transfer, rather than by statistics-based index system. To this effect, we use the Center-of-Gravity Model to study the regional disparity of tourism development, employing 'Economic Center-of-Gravity' as the spatial balance point. The model is applied to Sichuan, a southwestern province featured with tourism of China. In this way, we study the degree of regional disparity in tourism of Sichuan, in terms of annual tourism revenue and number of tourists. Finally, we analyze the characteristic and mechanism of the spatial distribution and temporary-spatial transfer of 'Tourism-Revenue Center-of-Gravity' and 'Number-of-Tourists Center-of-Gravity'.

Spatial Organization of Multinational Corporations in China

Canfei He (Peking University)

Facing considerable institutional uncertainties and lacking local knowledge, multinational corporations (MNCs) would sequentially invest multiple times on an activity-by-activity basis in transitional economies like China. Sequential investments allow MNCs to accumulate local knowledge through their own prior investments or learning from others, especially those from the same country of origin, leading to the intra-firm clustering and the country of origin agglomeration. Using data on investments in China from fortune global 500 MNCs based in Japan, United States and European Union during 1979-2008, this study found that MNCs have gradually expanded their functions and geographies within China and have indeed invested sequentially in different activities ranging from regional headquarters, R&D centers, business services, to production and marketing and sales. Statistical results suggest significant intra-firm clustering resulting from sequential investments. Japanese MNCs considerably benefit from country of origin agglomeration while the spatial clustering of American and EU affiliates are largely due to the intra-firm clustering. The disaggregated analysis found some evidence of functional agglomeration and co-agglomeration of MNCs, however with significant impacts of country of origin effects.

C08.08-06 - Emerging Economic Spaces Europe

Chair: Neil Reid, Christine Tamasy, Mike Taylor

Hungarian Industry and its Crisis

Kiss Eva (HAS Research Centre for Astronomy and Earth Sciences Geographical Research Institute)

After the change in the political system relevant changes (structural, organisational etc.) have taken place in the Hungarian economy. The spatial pattern of industry has also transformed in the 1990s. Industrial parks which are the new scenes of industrial production, are especially important because they have played an outstanding role in it, and because they concentrate the most important industrial enterprises. Beside old, traditional branches of industry some new ones (like car industry) have also appeared after 1989, and nowadays they are the most dynamically developing branches. The different branches of industry are separated in space depending on many factors. Based upon different data and empirical researches the main purpose of the presentation is to reveal the differences in the impacts of the recent economic crisis on the new and old branches of industry. It is also analysed whether there is any relationship between the "shape" of the crisis and in its spatial manifestation. The crisis has mostly affected the new branches of the industry because they are integrated into the global economy the most.

Between Transition and Globalization: The Impact of Privatization Processes on Spatial Disparities in Serbia

Andreas Winkler (University of Bamberg)

Various fragmentations and disparities have to be identified when dealing with the socio-economic developments of the past two decades in Southeast Europe. According to this approach, such disparities are strongly affected by the transition into a market economy, in particular by processes related to the privatization of state-owned enterprises. The economic transition and the global economic integration of Serbia - as often as it has been interrupted and delayed - deserves to be examined as a unique case and is one of Europe's last examples of a current highly active privatization process. The socio-economic fragmentations, which emerged or were intensified during this process, are reflected in the spatial scale and lead to spatial disparities. In Serbia, these huge development inequalities traditionally exist between north and south, urban and rural as well as central and peripheral areas. Getting to the bottom of these spatial differences and their current trends is one of the fundamental scientific and planning challenges of the region. For the Serbian case, this research adds the aspect of privatization in transition to the field of research in regional disparity. Furthermore, it provides basic knowledge about the spatial relevance and geographical aspects of privatization to the

numerous economic studies on restructuring state-owned firms in transition states. Thus, the crucial question of this paper is: To what extent can changes in Serbia's socio-economic disparities be explained by privatization processes? This approach to underdeveloped areas is examined on the basis of quantitative and qualitative analyses. A first design step was a GIS-based spatial analysis of secondary statistical data of the Serbian territory. The intention thereby was to identify spatial disparities and to characterize and categorize them. A second step was a statistical and qualitative examination of the recent privatization progress and its regional distribution. As a result, this paper shows how privatization has changed, and will continue to change, the traditional spatial disparity picture of Serbia.

Directions and Determinants of Spatial Transformation of the Manufacturing Industries in Russia in the 1990-2000s

Igor Pilipenko (Moscow University)

The Russian economy managed to achieve a rapid GDP growth during 1999-2007 rebounding after the 1991-1997 contraction and the 1998 financial crisis. Despite the overall negative impact of the 1998 financial crisis on the Russian economy as a whole and, particularly, on standards of living of the population, the manufacturing sector was among the biggest winners, because the sharp depreciation of the national currency during 1998 made Russian enterprises price-competitive at both domestic and foreign markets. Eventually, the manufacturing sector became one of the driving forces along with the booming mining sector on the back of the rising oil and commodities prices that determined the economic revival in the first half of the 2000s. However, in the course of 2002-2007 the manufacturing sector experienced a massive employment contraction worsened by the financial crisis of 2008-2009 totaling ca. 2.7 million jobs lost. On the one hand, it evidenced the continuous decline in both price/quality and cost competitiveness of the Russian manufacturing industries and the reallocation of labour into the services sector. On the other hand, it was an objective process of adjusting during the transition from the planned economy with large and often overstaffed plants to the market economy with more efficient use of available labour resources. The current financial crisis affected negatively the growth rates of manufacturing activities, but the other side of the coin is that it might stimulate a new restructuring of the manufacturing sector thus improving its quality and cost competitiveness. This paper focuses on spatial aspects of the manufacturing sector transformation during 1998-2009 that varied greatly across industries and regions in Russia. We seek to find answers to the following questions: (1) how did employment and output change in the manufacturing industries in 1998-2009; (2) how did the regions perform in the manufacturing industries in comparison to the national average; (3) how did specialization of regions in the manufacturing industries change; (4) did the manufacturing industries become more/less spatially concentrated; (5) what is the degree of industrial concentration of the manufacturing industries in Russia in comparison to the advanced market economies; (6) what factors determine trends in

spatial concentration of the manufacturing industries across Russian regions; (7) what are the patterns of productivity differences across the manufacturing industries and regions? We use the employment and output data for 97 three-digit manufacturing industries according to the Russian Classification of Economic Activities in 82 regions of Russia over 1998-2009. To study the spatial patterns of manufacturing development we employ the economic geographical and regional economic analysis techniques coupled with the econometric analysis to reveal factors affecting spatial concentration and productivity in the regions.

An innovative breakthrough in the less developed regions on the example of Eastern Germany's Federal states. The search of adaptive model for Russia.

Ekaterina Romanova (Moscow University)

After two decades of reunification Eastern Germany still lags behind in economic development from the West. Nevertheless, some regions in the East demonstrate even higher rates of innovation development than in Western Germany, besides world-class clusters are located on their territories, for example, in microelectronics and photovoltaic, optical mechanics (Saxony, Thuringia). Why some regions are developing dynamically, while others are stagnant or in decline? The essence of new economic policy lies in the special role of science, which turned into the highly competitive field of activity in the highly developed countries. German businessmen didn't reduce volumes of R&D investment even under conditions of economic and financial crisis. The share of R&D expenditure in Germany is about 2,8% of GDP (2009). That is the best indicator for the period after reunification. Furthermore, two-thirds of R&D spending in Germany financed by business sector investment, which accounts for about 55 billion euros per year. It operates mainly in the practical research area. The state furthers the development of competitive profiles of industry and science in the regions in framework of regional policy, contributes to economic growth and successful development of new innovative enterprises, prevents the outflow of young professionals and creates favorable conditions for the development of talented young people. A key objective of accelerating economic growth is the development of advanced technologies. There are those innovative areas that have significant potential in the future and may have complex effects on the economy as a whole. Eastern Germany can now re-export its experience of innovation support to Western Germany, as the challenges of global competition are facing all regions of the country. German experts positively assess the achievements in economic development after 20 years of reunification. New special research programs can no longer be a basis for the current regional policy; rather the decision of the general structural and political problems in the East may provide a framework for further positive development. Russia has chosen the way of innovation development of economy. This need was realized particularly acute during the recent financial crisis, in which the dependence on price fluctuations in raw materials markets led to a significant economic downturn. In carrying

out the modernization of production and development of innovations Russia may use experience of other countries basing on new technologies to overcome the crisis. Russia's share in world R&D expenditures is less than Germany's - in 3 times. The scope of high-tech exports reduced significantly. Russian researchers continue to move to the West. The successful experience of Eastern Germany is interesting not only for Russia, but for many developing countries under a catching-up strategy.

C08.08-07 - Economic Geographies of Entrepreneurship

Chair: Neil Reid, Christine Tamasy, Mike Taylor

Multilevel Analysis of Entrepreneurship Determinants

Christian Hundt (Universität Bochum)

Business start-ups are an essential key component for the economic development of regions and nations. The goal of this study is to contribute to a deeper understanding of the driving forces behind new firm formation. For this purpose, more than forty national, regional and personal determinants of entrepreneurship are derived from appropriate theories and concepts and are tested on data with up to 22 innovation-based economies. A specific accomplishment of this study is to integrate the hierarchical structure of the influencing factors (multilevel perspective) and the gradual emergence of new firm formation (process-related perspective) into one consistent analytical framework. The existence of different levels of influence is explicated by Giddens' structuration theory (1984), while the procedural character of business creation is explained using Ajzen's theory of planned behavior (1991). The empirical part is based on logistic multilevel regressions using data of the Global Entrepreneurship Monitor (GEM). This helps to make use of two crucial advantages: First, the data provides information on almost 390,000 individuals based on representative telephone surveys from 2002 to 2006. Thus, the data allows for the inclusion of an adequate number of regions (105) and countries (22) as an important precondition for reliable multilevel analyses. Second, unlike aggregated data the micro data of GEM enables to constitute the hierarchical relationship between the individual entrepreneur and the regional and national context that he or she does belong to. Results show that both context levels contribute significantly to the explanation of new firm formation. Additionally to the influence of the individual level, the regional and the national environment can be regarded as two autonomous dimensions of influence. Likewise, the results show interactions between the determinants of the context and the individual level. In that way the study confirms a central assumption of Giddens' structuration theory, whereby the individual micro and contextual macro level are not isolated but interrelated dimensions. In terms of optimal entrepreneurial framework conditions, the empirical results suggest that start-up activities especially do benefit from a liberal national economic policy, a prosperous regional economic environment and also from the entrepreneurial skills and attitudes of the respective individuals. Also, the impact of these determinants varies during the process of new firm formation and for different types of start-ups. In order to encourage those types of business start-ups which are likely to contribute to employment growth and economic development, policy makers should concentrate on the consolidation of market forces and principles, including the improvement of incentive structures for entrepreneurial actions, the creation of efficient economic spatial structures and the well-directed support of competent and ambitious entrepreneurs.

Does Social Commerce boost Small Private Businesses?: The Socio-Spatial Impacts of Korean Internet-based Collective Buying Business

Kee-Bom Nahm (University of Seoul)

Does Social Commerce boost Small Private Businesses?: The Socio-Spatial Impacts of Korean Internet-based Collective Buying Business Kee-Bom Nahm (University of Seoul) Social commerce is an emerging trend in which sellers are connected in online social networks, which have made a significant impact on how Internet users communicate, search for and share data today. One of the fast-growing social commerce model is the 'Collective Buying Business' such as Groupon, LivingSocial, Timon (Ticket Monster), and WEMAP (We make price). The business has gained enormous popularity over the past years because of a steadily increasing demand for user participation in the whole web sphere. One of the societal rationale for the business is argued that it can promote petty merchants and small businesses which don't possess adequate marketing tools and networks. Another urban spatial meaning of the business is claimed that it can expand urban consumers' shopping area, which in turns means it can broaden the range of goods for the small businesses. This paper investigates these two hypotheses using sales and customers's data and demonstrates the socio-spatial impacts of Korean internet-based collective buying business. To suggest a more collaborative and 'social' shopping model, conventional social commerce as well as selected best practice cases were analyzed in detail. To meet the demands of modern consumers and social responsibility of the business, some suggestions are presented in the final part.

Branding and networking: Hotels as creators of new economic spaces in post-industrial towns

Ida Andersson (Stockholm University)

This paper has its starting point in the hotel sector as an economic catalyst in post-industrial towns in the western capitalist world. One of the main arguments is that hotels increasingly are given the role of 'flagships' in place branding activities carried out in towns, and through the branding work, also functions as generators of 'community building' boosting local sense of belonging and networking. The paper discusses how investments in hotels connect the local economy with the global one through flows of investments and visitors, making post-industrial towns emerge as new economic spaces. Through the challenges brought on by globalization and economic re-structuring including the growth of the service economy, the tourism industry has developed as a way forward to break new economic grounds in many post-industrial towns. New hotels have been constructed to function as the hub of the local economy and are given spectacular designs and luxurious standards. Hotels have become not only means for former industrial economies to develop as tourism destinations but also a way for local businesses to put their innovation capabilities and technological know how on display for

visitors. Globalization and structural changes in the world economy is also said to create and increase competition between post-industrial towns.

The new spatial configuration of luxury trade in the city of São Paulo - Brazil

Jeferson Hugo Pacheco de Rezende (University of São Paulo), Tabata Pistori (University of São Paulo)

During the last decades, Latin America has undergone major structural changes in different fields which gave rise to the emergence of a new spatiality. The main change, namely the growth of a new class of consumers in the region, usually defined by international media as the "new middle class", preferably is described as a 'new consumer layer on the rise'. Institutes such as the UNCTAD and ECLAC published documents showing that the amount of new rich people has grown in the world. Brazil, in particular, is highlighted in these studies. Currently, the European and American markets remain important sources of income for the sector of luxury goods, but in the so-called 'BRIC' countries, formed by Brazil, Russia, India and China, the best results in sales and profit are observed. Nowadays, important Latin American cities have luxury trade shops, with São Paulo, being the main pole of luxury goods consumption in the continent. This research starts by investigating data from the late 1980's, a period that coincides with two other important events to understand the current socio-cultural and economic situation in São Paulo: the era of globalization and the progress in the "technical-scientific informational means?". Authors such as Santos, Carreras, Sassen and Lemos will describe this period and its impact as a landmark that marked the transition from the production model as seen in the industrial city towards a model based on services. This has led to the development of new spaces, which Santos et al., defines as 'spaces of territory prepared for the development of these new functions'. Thus, the specific research objectives are: A) To examine the expansion of the 'new consumer layer on the rise' in São Paulo and the endogenous and exogenous processes which have led to this development; B) Identify the spaces produced by these new consumers and the structural changes the zones that accommodate the luxury stores nowadays have undergone. The major theoretical sources are studies of globalization and a recent research on trade and urban consumption, by researchers of the University of Barcelona. The theoretical-methodological foundation is given by the previously cited authors and also by other important authors, such as Smith, Allères, Baudrillard, Bijou-Garnier, Harvey, Mombeig, George, Sombart, among others. At the end of the research, we hope to be able to understand the world-wide formation of new spaces embedded in the urban fabric to meet the demands and needs of the new consumer layer mainly formed by people in high positions and professionals who are successful in their careers. They transformed into the new yuppies of consumption related with the processes of globalization and the opening of the Brazilian market.

C08.08-08 - Global Value/Commodity Chains and Economic Governance

Chair: Neil Reid, Christine Tamasy, Mike Taylor

Compressed development and the adaptive state in contemporary India

Bill Pritchard (University of Sydney)

The concept of 'compressed development' has recently been advocated as a successor to 'late development' models of economic and social transformation. This concept is claimed to reflect conditions in which economic change takes place not through a sequencing of transitions, but via uneven, simultaneous 'stacking', of changes as particular segments of an economy are incorporated as modular components within global value chains. The net effect is to create highly disjunctive, and apparently contradictory, economic landscapes. To date, compressed development has been explored and applied most extensively with regards to East Asia, and especially, China. This paper extends its empirical remit to India. It contends that the concept sheds relevant light on the contemporary Indian experience of economic transformation, however cannot be translated unproblematically from its East Asian origins to the very different settings of South Asia.

Patterns of collective interpretation changing economic spaces: Global value chains and regions

Martina Fuchs (University of Cologne)

The social construction of the spatial world and spatial imaginaries have become central topics in economic geography and related fields. In sociology, a specific discussion on patterns of collective interpretation has generated considerable dynamism. The idea is that perception and interpretation can be analyzed on the subjective as well as the social resp. collective level. Patterns of interpretation direct action and interaction and help to explain the relations between institutions, routines and activities. Thus, patterns of collective interpretation can serve as a bridge between converging and diverging approaches and 'turns'. The concept refers to the daily action of social actors in constructing markets, firms and economies, as well as to the system resp. structural level, where it includes institutions as frameworks for (re-)producing meaning, action and interaction, and routines as recurring patterns and sequences of action. While routines refer to observable behaviour, patterns of collective interpretation also emphasize cognitive-interpretative facets. Patterns of collective interpretation help to explain why institutions do not lead directly to specific action, but are transformed in the 'gap' between structure and action. The paper will elaborate on the concept of patterns of collective interpretation. It will show two examples of the relevance of patterns of collective interpretation: First, the paper will demonstrate their importance for

reconstruction of global value chains after the catastrophe in Japan 2011 with the tsunami, the earthquake and the nuclear reactor accidents. Second, the paper will explain their significance for regional activities to overcome the financial crisis 2008/2009 in selected German regions. Both examples are taken from metalworking industries and regions coined by metalworking industries.

Bringing the economic geography perspective back in: Global cities, global commodity chains, and the geography of economic governance

Christof Parnreiter (Inst. f. Geographie)

Since the development of the 'interlocking network model' (INM) by the GaWC-group (Taylor 1997, 2004), measures of cross-border connections of cities through an analysis of big data sets on the global inter-firm networks of producer service firms or of transnational corporations have become very popular. Yet, despite the undeniable merits of these studies, this quantizing approach has turned away research from the economic geography spirit, which has guided the seminal works on world / global cities (Friedmann 1986; Sassen 1991). Due to its exclusive focus on the (assumed) intra-firm flows in the producer service sector, the INM ignores the flows between producer service firms in global cities and other firms operating in global commodity chains. This neglect has important conceptual consequences, because it implies that the INM does not take into account the theoretical core of the global city paradigm, namely the fact that global cities are places wherefrom the world economy is managed and controlled. The INM does, therefore, not allow to address the issue of the governance of global commodity chains, wherefore little is known about how firms in global cities actually exercise management and command functions. This flaw undermines the strength of the global city argument. Moreover, the INM entails the risk to divert research from the analytical focus (the function of cities in globalization processes) to a description of rankings. If being used to assess the geography of economic governance, the empirical results of the INM might even be misleading, because the INM does not distinguish between the sub-sectors of the producer service economy. Such differences do, however, exist: A minor office of a global law firm might have more bearing on how resources are allocated within (specific segments of) a global commodity chain than a mid-sized office of an accountancy firm in the same city. Thus, it is risky to equate gross network connectivity values with governance functions. In light of this critique, I suggest returning to the original economic geography perspective. In particular, I propose to add a) further geographical scales (in particular the national and sub-national ones) to scrutinize producer service flows and b) further firms as recipients of producer service flows. This extension can be based on quantitative information (e.g. input-output analysis), but in many cases it will entail qualitative research to uncover the inter- and intra-firm relations of a city's producer service sector firms. Friedmann, John: 1986 The World City Hypothesis. In: Development and Change 17, 69-83. Sassen, Saskia: 1991 The Global City. New York, London, Tokyo. Princeton. Taylor, P. J.: 1997 Hierarchical tendencies amongst world cities: a

The “geography of uncertainty” in the Italian most-important cities. From the economic crisis to the governance of the territorial processes.

Alessandro Ricci (University of Rome)

The economic crisis that the Western States are living it is not only financial. In fact, it has also an heavy impact on the territorial dynamics. In particular, the crisis has affected some of the most important Italian cities, especially the ones that represent the national economic, social and strategic centres. The starting point of this analysis is the consideration that the economy represents one of the most important point of reference of contemporary society. Economy is one of the 'interest centers' (using the words of Carl Schmitt) of the 'post modern' society. For this reason economy plays a crucial role in the territorial strategies, and in the redefinition of the administrative priorities and local policies. From the geographic point of view, it is important to understand which is the impact of economy on the territory, especially in a period of crisis, and the concerning perspectives of Italian cities. Moreover, the concept of uncertainty, more often used in the sociological and economic 'dictionaries', can be also associated to the geographical dimension, and in particular to the difficulties in the development of the cities and to the uncertainty of the territorial evolution. This analysis will not only consider the geographical aspects, but also the social and economic ones, starting from an international scale and then focusing on more specific Italian cases. By doing so the analysis will try to contribute to the commission's topic with a study that will analyze the local scale, discussing the consequences of the economic crisis on the territorial processes. In this perspective, the structural elements that from financial economy have an impact on the strategic choices of the local administrations will eventually emerge. The problems, the critical situations, and the positive perspectives in this particular and difficult moment will be taken in consideration while also pondering the fluctuations, the off-putting movements of European and Western economics.

Stages of human settlement in Northern Eurasia (Eastern Europe and Siberia)

Andrey Velichko (Russian Academy of Science)

There are two principal stages recognizable in the human society evolution and in that of environments within the studied territory: Palaeolithic epoch and subsequent stages. The Palaeolithic was predominantly epoch of hunting which reached then its peak. At the end of the Late Pleistocene an impact of primitive communities becomes quite distinctly seen in the environments. The most significant event in the Early man history dated to the end of Pleistocene (12-10 ka BP) was disintegration of a single zone of appropriating economy and the onset spatially differentiated zones of productive economy. The late glacial/post glacial transition dated by radiocarbon at 10 300 BP is generally taken as the Holocene lower boundary. At that time a drastic restructuring of the East European landscapes occurred, and a hyperzonal type dominated by periglacial landscapes was replaced by polyzonal type, various forest zones coming into being. During the Holocene, the area of productive economy gradually expanded over Eurasia, the earliest urbanistic and proto-urbanistic civilizations appearing in some regions. Some forms of appropriating economy, however, persisted for long time in the vast boreal zone, where such economy was most effective. The Mesolithic stage in Northern Eurasia is considered to be a transitional stage, when the Man and his economy became adapted to a new, more differentiated, structure of natural landscapes. Two principal cultural and economic regions developed within the limits of the East Europe. A stable pattern of settlement was developed in the course of the Mesolithic time: rather large base winter sites were mostly located on elevations protected from cold winds, while relatively small summer campsites concentrated along water streams. Bronze Age cultures are attributed to late Subboreal. There are several cultures of the Bronze Age found within forest zone of the East European Plain and dated at the 3rd-2nd millennia BP.

Ecological theory, paleoenvironment and people: Prospects for moving beyond correlation

Loukas Barton (University of Pittsburgh), Robert Bettinger (University of California)

The purpose of this session is to explore different ways of improving our ability to evaluate the relationship between environmental change and human evolution. Opinions in ecology

and paleontology are divided over the importance of environmental change in speciation, extinction, and the derivation of novel physical attributes. And for each of these issues, blanket correlations between global patterns of environmental change and patterns of biological evolution, are insufficient for proper evaluation. In each case, models that view change through time and space for its effects on meta-populations get closer to the issue, and highlight the appropriate scales of data necessary to test the hypotheses about environment and evolution. Likewise, anthropologists, geographers and historians argue over the role of environmental change in human cultural evolution, including the development and collapse of complex urban polities. Yet the case clearly isn't closed, in part because even the simplest correlations can fall apart under the microscope, and because even the best correlations lack processual modeling that would permit evaluation of cause and consequence. Here we present a simple model articulating resource abundance, human behavior, and technology. When combined with the right kinds of paleoenvironmental and archaeological data, we can begin to evaluate the impact of environmental change on human populations. Case studies of prehistoric hunter-gatherers from northern China and western Alaska illustrate the limitations of the model and the data, and provide avenues for improving the analytical framework of these questions.

How Neolithic and Chalcolithic people occupied the northeastern edge of the Tibetan Plateau

Fahu Chen (Lanzhou University), Guanghui Dong (Lanzhou University), Xin Jia (Lanzhou University)

The Tibetan Plateau is one of the places in the world that have the harshest environment for human colonization. How ancient human occupied the Tibetan Plateau has been intensively studied. Archaeological studies indicate that human began to occupy the Tibetan Plateau during the Late Pleistocene, but extensively inhabited the high Plateau in Neolithic and Chalcolithic periods, mostly in east Qinghai Province located at the northeastern edge of the Tibetan Plateau. This hypothesis has also been confirmed by mitochondrial genome studies. In order to study how Neolithic and Chalcolithic people occupied the northeastern edge of the Tibetan Plateau, we investigated more than 100 Neolithic and Chalcolithic sites in this area and collected floatation and dating samples. Various plant remains and 30 AMS radiocarbon dates directly on charred crop seeds were obtained. Based on these data, we studied the spatial and temporal variation of human settlements and agricultural development in east Qinghai Province during Neolithic and Chalcolithic periods. We also reviewed mid-late Holocene climate change studies in Tibetan Plateau, to examine how climate change influenced human colonization of the northeastern edge of the Tibetan Plateau in that period. Our results show that Neolithic people first widely occupied the northeastern edge of the Tibetan Plateau around 5000 Cal a BP, and reached the upper Yellow River valley and Huangshui River valley below 2500 m a.s.l, when millet agriculture spread to this region synchronously. Favorable

climate in this period probably promoted Neolithic human occupation in the area by facilitating agricultural production. Climate deteriorated evidently in east Qinghai Province after 4000 a BP and the coldest climate occurred around 3000 a BP. During 4000-3000 a BP, barley and wheat that originated in West Asia diffused to the region but foxtail and common millets were still the most important crops. During this period, site density in this region obviously dropped. But evidence shows that human extensively migrated westward and occupied high regions after 2800 Cal a BP, though climate during this period was still much cooler and dryer than that of 5000-4000 a BP. Naked barley became the most important crops in Chalcolithic sites above 2800 m a.s.l., suggesting late Chalcolithic people recognized that naked barley could grow in high elevation and cold environments and adopted this crop as their main plant resources, which guaranteed them to permanently settle down in the high Tibetan Plateau and adapt to the plateau environment. We argue that, though climate change probably promoted human occupation in the northeastern edge of the Tibetan Plateau in Neolithic and Chalcolithic periods, agriculture diffusion and development, and advancement of human ability to adapt to climate change were the key factors that enabled Neolithic and Chalcolithic people to widely and permanently occupy the northeastern edge of the Tibetan Plateau.

The Archaeology of Rapid Climate Change during the Holocene in the Eastern Mediterranean

Bernhard Weninger (University of Cologne)

This paper discusses the impact of Rapid Climate Change (RCC) sensu Rohling et al., 2002 and Mayewski et al., 2004 on prehistoric communities in the Eastern Mediterranean during the Early and Middle Holocene. Focus is on the societal impact of a specific set of climatic RCC-anomalies that are caused by major polar air outbreaks into the eastern Mediterranean due to expansion and intensification of the Siberian High. For archaeological RCC-studies, due to its high dating resolution we use the Greenland GISP2 $\delta^{18}O$ -record (Mayewski et al., 1997) as proxy to delimit a) the time-windows for which strongest RCC-events may be expected and b) the climatically most sensitive geographic regions (Weninger et al., 2009; Clare and Weninger, 2010). In certain cases the atmospheric RCC-conditions can be further intensified by synchronous (or partially overlapping) changes in the North Atlantic ocean circulation due to abrupt freshwater influx (e.g. 10.2 ka calBP event, 9.3 ka calBP event; 8.2 ka calBP Hudson Bay outflow). The present paper puts focus on Near-Eastern and S-European archaeology during the following RCC-intervals: ' 11.6 ka calBP: End of Younger Dryas; foundation of (unexpectedly) large Protoneolithic domestic settlements (e.g. Körtektepe, Hallan Cemi) and of major religious sites (Göbekli Tepe) in SE-Anatolia. ' 10.2 ka calBP: End of the Golden Age of the Pre-Pottery Neolithic (PPNA), followed by major expansion (and later abrupt desertion) of PPNB-sites, most notably in Jordan (where desertion leads to following probably slow accumulation of deep rubble layers), in-phase with major oscillations of Dead-Sea lake levels (Migowski et al., 2004). ' 8.6-8.0 ka calBP RCC-

Interval: migration of farming communities from Central Anatolia to the Turkish West Coast; following the end of RCC: the spread of early farming to SE-Europe. ' 6.2-5.2 ka calBP RCC-Interval: The end of the SE-European Copper Age, with widespread desertion of multilayer tells in Greece, Bulgaria and Romania at the onset of the RCC-interval, with again abrupt re-occupation of the tells at the end of RCC. ' 3.05-2.98 ka calBP RCC-Interval: temporary desertion of many long-inhabited major Bronze Age settlements (e.g. Thessaloniki Toumba, Agios Mamas, Troy) in-phase with RCC-conditions (decadal-scale dating resolution).

Late Paleolithic Records and Human Adaptation in Western Chinese Loess Plateau

Dongju Zhang (Lanzhou University), Fahu Chen (Lanzhou University), Robert Bettinger (University of California), Christopher Morgan (Utah University), Loukas Barton (University of Pittsburgh)

The subject of human adaptation during Late Pleistocene is vital to understanding human behavioral and biological evolution, a period of time when environments changed rapidly, modern humans evolved or appeared throughout Africa and Eurasia, and Upper Paleolithic technological innovations revolutionized the way humans operated in ecological context. Except for a few human fossils and a small number of excavated sites well dated to this period, very little is known of these adaptations in East Asia. Within this context, this paper presents results of research on China's Western Loess Plateau, where archaeology, geochronology and paleoenvironment are well studied at 76 Paleolithic sites located in a 400 km² study area. The chronological framework built with absolute dating results and loess-paleosol sequence comparison shows that humans first appear in the area during MIS5, may have abandoned the area in MIS4, reappeared in MIS3 and continued thereafter. A comprehensive study of 3727 pieces of stone artifacts shows that a flake-tool-tradition is dominant through most of the Upper Pleistocene and microblade technology appeared and prevailed after the LGM. Combined with paleoenvironmental reconstruction, settlement patterns indicate that Upper Pleistocene hunter-gatherers in the region exploited multiple landforms during MIS 3, while more central-place strategies were employed beginning during the LGM. The high resolution chronology established in the area indicates that Chinese Paleolithic core-flake technology persisted since at least the middle of MIS3 and coexisted with microblade technology after around 18 ka BP, possibly indicating that modern humans from elsewhere arrived in the region during or immediately after the LGM, substantially altering technological and settlement patterns as they did so.

The impact of subsistence strategy variety and climate change on human settlement, in Qinghai Lake area, northeastern Tibetan Plateau, China, during late Pleistocene and early-mid Holocene

Guanghui Dong (Lanzhou University), Fahu Chen (Lanzhou University), Xin Jia (Lanzhou University), Dongju Zhang (Lanzhou University)

How ancient human occupied and adapted to the harsh environment of the Tibetan Plateau has been increasingly concerned in recent years. In this paper, based on the application of floatation and radiocarbon dating at five sites of Qijia culture (2183-1635 BC) and Kayue culture (1600-600 BC) around Qinghai lake that locate in northeastern Tibetan Plateau, China, we studied human subsistence strategies during late Neolithic and Chalcolithic period in the area. The archaeological and paleoclimatic records in Qinghai lake area are also reviewed to further study the prehistoric human settlements in the area and their adaptation to the climate and environment change in northeastern Tibetan Plateau during late Pleistocene and early-mid Holocene. As shown in the results, animal resource procurement including fishing, herding and hunting was the primary food procurement strategy for human, while utilization of plant resources probably was an auxiliary strategy in Qinghai lake area during 4000-2900 Cal yr BP. The adopted animal and plants include sheep, cattle, marmot, rodent, bird and barley, common millet, and caper. Paleolithic hunter and gatherers occupied Qinghai lake area during 15000-12500 Cal yr BP and 9000-5000 Cal yr BP, when warm and wet climate and better vegetation during those periods probably enabled human's inhabitation. Climate remarkably deteriorated during late Neolithic and Chalcolithic periods in Qinghai lake area, however, the introduction of domestic sheep and the fishing-herding-hunting strategies guaranteed ancient human successfully settled in Qinghai lake area during that period, although climate was cold and dry.

Migration of Neolithic settlements in the Dongting Lake area of the middle Yangtze River basin, China: Lake-level and monsoon climate responses

Tao Liu (East China University), Zhong Yuan Chen (East China University), Qian Li Sun (East China University)

The vast Dongting Lake in the middle Yangtze River basin, China, was occupied by Chinese Neolithic settlements starting 10,000 yrs ago, and rice cultivation there is probably the earliest in the world. The numerous Neolithic settlements identified by previous archaeological surveys represent the five major Neolithic cultural stages, i.e. the Pengtoushan (9000-7900 cal yrs BP), Zaoshixiaceng (7900-6800 cal yrs BP), Daxi (6800-5500 cal yrs BP), Qujialing (5500-5000 cal yrs BP), and Shijiahe (5000-4000 cal yrs BP). Using sedimentological and geoarchaeological approaches, this paper analyses the drivers of basin scale settlement relocation in relation to lake-level fluctuations and monsoon climate variations in the Holocene. The relocation of Neolithic sites around the lake shoreline and on the adjacent floodplain, together with radiocarbon-dated

stratigraphy, clearly indicates that the shape of the lake basin was an incised and elongated valley occupied by a lake in the early Holocene, which became a broader and shallower depression in the mid- to late Holocene. The established lowest habitable base of the settlements positioned on the lake shore assists reconstruction of the change in lake level from 22 m at 9000 cal yrs BP to 26 m at 5500-4000 cal yrs BP, although higher and lower lake levels occurred during the intervening cultural stages. The pollen spectra reveal a warming trend throughout Holocene with at least 4 major temperature cycles, driven by monsoon variations between temperate- and warm-humid conditions. In the early Holocene the climate changed from cool-dry to warm-humid, and this played a key role in developing the earliest Pengtoushan culture in the region. Subsequent climate fluctuations fit well with the advance and retreat of the lake shore, also coevally with Neolithic site movements in the lake region. In this study we show how geoarchaeological evidence can be used in environmental reconstruction during the Holocene. Keywords: Neolithic, river-basin, settlement relocation, lake level, monsoon climate, Yangtze River

Cultural Responses to Climate Changes at Xiaohuangshan Site (8-10ka BP) in the Lower Valley of Yangtze River, China

Fei Hu (University of Science and Technology of China)

The transitional period from Paleolithic to Neolithic ages has got worldwide archaeologists' attention because they intend to study the origin of crops cultivation and domestication of animals as well as their dispersal routes by use of the particularity of this period. Abundant prehistoric remains and cultural relics related to ancient human being have been found in Xiaohuangshan site, 8-10ka BP, which located in the lower valley of Yangtze River, China. Based on the analysis of artificial storage pits, potteries, stone objects (millstones, grindstones and so on.), abundant rice phytoliths examined in the cultural layers and a great variety of starches extracted from the potteries and stone objects, we know that effective adaptive adjustments have happened on the aspect of gathering or cultivation of rice and other crops responding to the climate changes contrast with other Neolithic sites such as Xianrendong site etc. Therefore, Xiaohuangshan site will play an important role in understanding the evolution of archaeological cultures in the lower valley of Yangtze River, China. By comparing the distribution characteristics of clay mineral assemblage, geochemical data and magnetic susceptibility determined in cultural strata at Xiaohuangshan site with the ice cores, loess and sea level records during the late Pleistocene and early Holocene, the authors find climatic fluctuations happened in the sequence of heating up, cooling down, re-heating up till to the warm time of Holocene in Xiaohuangshan site. Based on the coupling between these climatic changes data and prehistoric archaeological materials of Xiaohuangshan site, the internal relation between violent change in climate and rapid evolution in prehistoric culture of Xiaohuangshan site will be clarified, which will provide us with some innovative thoughts for human responses to climatic changes.

Origin and Dispersal of Rice Cultivation Agriculture in the Valleys of Yellow River and Huaihe River

Juzhong Zhang (University of China)

Global climate has changed severely for many times since the last glaciation and Megathermal, and ancient human beings also changed their lifestyles from hunting and gathering which lasted for millions of years to primitive agriculture in the tremendous climate warming process of the last deglacial. Just as the area along Great Wall, the valleys of Yellow River and Huaihe River also located at a climatic transitional zone between the north and South China. Although the valleys of Yellow River and Huaihe River were not as sensitive as the Great Wall zone to environmental change, it played a determinative role in shaping a new surviving mode of ancient human living in this zone. The development process of human society was continuous and also abundant information about gathering, fishing, hunting and agricultural activities which were kept in the valleys of Huang River and Huaihe River since the beginning of Holocene. Furthermore, this region was the concentrated and intersection area of rice cultivation and rice-millet mixed agriculture, as well as the interlaced distribution belt of prehistoric rice cultivation and dry farming agriculture. Simultaneously, this zone was also the main region of cultural clashes and fusion between Yangtze and Yellow River as well as three tribal groups of Huaxia, Dongyi and Miaoman. Therefore, the region had an irreplaceable role in studying the origin and development of rice cultivation agriculture as a consequence of its historic geological location. In recent decades, some important progresses have been made on the studies of the relationship between the origin and development of rice-dry farming agriculture and the paleoenvironment in this zone. However, some important scientific problems still exist, for instance, where did the rice cultivation agriculture concept come from? When did the origin of rice cultivation agriculture happen? What were the causes and mechanisms of this transmitting? How did the rice cultivation agriculture dispersal responding to the climate change? What was the relationship amongst the migration and activities of human, paleoenvironment change and the development of rice cultivation agriculture? How did the rice cultivation agriculture influence the surviving mode of ancient people living in this zone? What was the relationship between the changes of the rice -dry farming agriculture and the climate change? And how did rice cultivation agriculture influence the development of human society? All this scientific problems are still eagerly necessary to be explored. This paper is intended to discuss the origin and dispersal of the rice cultivation agriculture in the valleys of Yellow river and Huaihe River, and we also try to put forward some thinking on this problem.

Plants and Food Production of Neolithic Southeastern Shandong, China

Xuexiang Chen (Shandong University), Hui Fang (Shandong University)

In Shandong province, eastern part of China, the currently accepted archaeological cultural sequence for the Neolithic is Houli culture (6500-5500 B.C.), Beixin culture (5000-4100 B.C.), Dawenkou culture (4100-2600 B.C.), Longshan culture (2600-1900 B.C.). The archaeological and environmental data show that during the Neolithic Age, climate in Shandong Province was warmer and more humid than today which is similar as the present Jiang Huai area. Earliest food production evidence in this area reported was from the Yuezhuang site, Jinan city of Houli culture. Thanks to the flotation samples, archaeologists recovered rice, broomcorn millet and foxtail millet at the site, and other plant and animal remains from wild resources. However, there is no site of Houli culture found in the Southeastern Shandong. Earliest Neolithic finds were from Beixin culture. The full-coverage archaeological survey organized by Shandong University, Field Museum and Yale University revealed changes in regional settlement patterns in this area. Based on the survey of 1995-2006, scholars suspect that the agricultural colonization of this coastal region occurred primarily during the later half of the Neolithic and was rapidly followed by the development of a four-tiered settlement hierarchy with two primary centers during the Early Longshan period. As part of the survey, flotation samples from 12 sites were collected. The assemblage of carbonized plant remains covered a time span between 5000-1900 B.C., from Beixin culture to Longshan culture. The plant remains document a long sequence of crops, weeds, and other plants in the area. Broomcorn millet (*Panicum miliaceum*) from Nantunling site of Beixin culture was the first domesticated crop when the population was really small. The site is located in a piedmont zone and there was possibly water place nearby since one lotus (*Nelumbo nucifera*) seed was present in the sample. The specimen was found throughout the sequence but significantly less important in Longshan culture. It appears that the Late Dawenkou populations that entered this coastal region arrived with an established agrarian economy and social hierarchy. In the Dawenkou samples, the crop assemblage included broomcorn millet, foxtail millet (*Setaria italica* subsp. *italica*) and rice (*Oryza sativa*). Settlements situated in both alluvial and piedmont settings supplied environmental supports for both dry-land and wet-land agriculture. During the Longshan period, the pattern of settlement shifted dramatically as the number of sites increased to over 400. The number and frequency of crops of Longshan sites are much higher than that of previous cultures. Wheat was added to the crop assemblage and plants such as legumes, perilla, might have been cultivated as well. The sequence suggests that both dry crops (broomcorn millet, foxtail millet, wheat) and rice were import food in this coastal area. Weed assemblage diversified through time and indicated landscape changes.

Impact of Shifting Cultivation: A Factor of Environmental Degradation in North East India

Manabjyoti Barkakaty (Gauhati University)

North East India is a land where we find mountainous terrain, plateau and plains, criss-cross disproportionately divided by rivers and rivulets, bounded in the north by Great Himalaya and the Great Brahmaputra river has been flowing from the east to west. This is a distinct geographical entity having variegated natural landscape with diverse colourful ethnic groups. Because of heavy rainfall, the northeast India was clothed with forest having different types of trees for which communication was not easy and the area had to live in isolation in early days. North East India comprises seven states namely 'Assam, Manipur, Meghalay, Nagaland, Tripura, Arunachal Pradesh and Mizoram. Sikkim is lately incorporated within this region. It is inhabited by hundreds of communities including tribes and sub- tribes. The pace development of these communities is not uniform. Keywords: Ethnic group, communities, sub- tribes

remarkable broadening of the spectrum of questions and increased the scientific level of analysis. The strategies that have functioned for the Chalcolithic communities demonstrate a really different management from what is believed about their economy. The sharing of some kind of resources proved to be different and source areas were different than those presumed (under this can also be included the structure and characteristics of alimentary diet, existing strategies for managing economic resources, types of activities and their intensity at different times, etc.). It is clear that much of the surrounding area was part of these communities' social space. The sedimentological researches conducted in the zone of the tell revealed that the settlement is situated on an erosion remnant from the lower terrace of loess, with a relative altitude of approx. 5.40 m. Field research and archaeological survey have identified areas of occupation attributed to temporary or seasonal Neolithic settlements. A sedimentological coring survey, as well as multi- proxies analysis of soils and sediments, is carrying on in order to understand the evolution of this area with important alluvial activity from the Neolithic period until now.

Human environment co-evolution during Chalcolithic in the wetland area of Balta lalomi'e

Constantin Haila (National Museum of Romania History), Dragomir Popovici (National Museum of Romania History), Adrian Balasescu (National Museum of Romania History), Valentin Radu (National Museum of Romania History), Mihai Florea (National Museum of Romania History)

The studied zone is situated in the "Balta lalomitei" meadow, a floodplain area between two parts of the Danube, the Old Danube and Borcea, which presents natural areas permanently or occasionally flooded and dammed areas with artificial or natural forests. Analysis of topographic maps showed that the area has undergone significant changes as a result of geomorphologic evolution, being affected by the draining and damming works of the last half century in a lesser extent than previously thought. The military map at 1:20.000 scale on the basis of measurements made at the end of the nineteenth century, illustrates a situation closer to the present, except for major changes caused by human interventions in the twentieth century. "Popina Bordusani" is the most important prehistoric settlement known so far in "Balta lalomitei". It is one of the largest tells in the south-eastern Europe under current archaeological research by a multidisciplinary team. The first communities who settled here were members of the Boian Neolithic culture (ca. 6500 years BP); they were followed by those of Gumelnita Chalcolithic culture and Latene Iron Age occupation. The occupation continued with some gaps in the classical period, up in the middle Ages until today. The Gumelnita occupation demonstrates the specificity of integration into the natural environment with a remarkable ingenuity of the solutions found for the management of natural resources. The structuration of the built space and the differentiation of passage areas between zones used for housing are just examples. The pluridisciplinary character of the research conducted at "Popina Bordusani" allowed a

Late Holocene vegetation and climate dynamics and human- environment interaction in the forest-steppe zone of the East European Plain

Elena Novenko (RAS)

The late Holocene dynamics of forest-steppe landscapes of Central East European plain and the history of its agricultural land-use have been reconstructed on the base of pollen, plant macrofossil and radiocarbon data from a number of sections in the Upper Don River basin (the Kulikovo Battle-Field). The mire Bolsheberesovskoe and two sections of flood plain have been sampled and studied. The reconstruction of main parameters of past climate (mean July and January temperature and annual precipitation) was carried out with the use of Klimanov's (1984) transfer function. The study of the key sections of the area of the Kulikovo Battle-field enabled us to follow up the evolution of landscapes in the forest and steppe ecotone in the Upper Don basin over the last 7 thousand years and also to assess the human impact on natural environment in the region. In the middle Holocene the territory was occupied by steppe landscapes. Significant changes in the plant cover of the Kulikovo Battle-field area are attributed to the termination of the Atlantic phase and the early Subboreal. The high biodiversity of the forest-steppe area made this region a very attractive for early human groups. Signals of anthropogenic changes in the vegetation and clearly pronounced in the pollen spectra since the middle Atlantic. Neolithic hunter-gatherers were fully adapted to natural environments, and their impact on the vegetation was negligible. During the Bronze Age, several indices of agricultural activities are appeared in the pollen spectra, however the human-induced changes in the vegetation are remained very small until the medieval period. Large-scale landscape changes and the degradation of natural vegetation became conspicuous only over the past two of three centuries. The present-day state of plant communities in the Upper Don River basin is totally controlled by anthropogenic factors. This work was supported by RFBR grant 11-05-00557.

Seventeenth-Century Crisis in Europe: A Human-Ecological Disaster Induced by Climate Change

David Zhang (University of Hong Kong), Harry Lee (University of Hong Kong)

Seventeenth century was one of the darkest eras in European history characterized by widespread economic, social, demographic, and political chaos. Despite the historical significance of this incident, there is no consensus about its cause. In this study, we

proved that the seventeenth-century crisis in Europe is a human ecological disaster primarily caused by global cooling. Firstly, we proposed a conceptual model to illustrate the possible linkages from climate change to agricultural production, price, social stability, and population change. Then, based upon various fine-grained paleo-temperature and historical socio-economic data, we examined statistically the climate-society relationship in Europe in AD 1500 - 1800. Results show that when temperature dropped in the seventeenth century, European agricultural production reduced significantly. As European population size had been saturated during the time, such an agricultural shrinkage inflated cereal prices, resulting in wars, famines, epidemics, and political upheavals across Europe. Finally, population collapse followed. The crisis ended in the eighteenth century when the population size was reduced and climate became favorable. Our study confirmed that at the macro-scale, climate change was the underlying driver of war-peace cycles and also the trigger of 'positive checks' in recent history. This finding may challenge some well-accepted theories regarding historical war-peace cycles and demographic changes.

Principles of the paleoanalogs' use for estimating the consequences of the global warming in the 21st century

Andrei Velichko (Russian Academy of Science)

The paleogeographic analog method has been applied to estimate changes in the state of the main components of ecosystems at three time intervals within the 21st century (the 2030s, 2050s, and 2080s). Two warm epochs of the past, the Holocene optimum (c. 5.5 kyr BP) and the Mikulino (Eemian) interglacial optimum (c. 125 kyr BP) have been chosen as the paleoanalogs; those intervals featured mean global temperature higher than at present by 0.7 to 2.0°C, respectively. Such ranges of global warming are close to those to be expected in the 2030s and 2080s, according to scenario B1 IPCC. As the main components of ecosystems have various characteristic rates of reaction to the climate changes, in the first decades of the 21st century the most probable vegetation changes will occur in the composition of herbaceous plants and tree undergrowth. Considering limitations imposed by migration rate of trees, it is only by the end of the century that the tree species penetration into new areas and shifts of zonal boundaries may be expected. The predicted increase in potential evaporation in Northern Eurasia (by 100 mm above the present-day values at the middle of the century) may result in reduction of wetlands and slower peat formation. Changes in the soil cover will be much slower. In the north of the East European Plain, soil-forming processes will presumably respond to warming mainly by accelerated humification. Somewhat intensified processes of litter decay and illuviation would be typical for the subzone of podzolic soils at the end of the century, bringing about the initial phase of sod-podzolic soil formation. The area of chestnut soils will show a tendency to decrease as compared with the present days.

Human impact on soil formation and the change from natural to cultural landscapes in NW-Germany

Eileen Eckmeier (University of Bonn), Peter Fischer (University of Mainz), Alexandra Hilgers (University of Cologne), Renate Gerlach (LVR-Amt für Bodendenkmalpflege im Rheinland)

During Late to End-Neolithic (3500-2200 BC), agricultural practice in the Lower Rhine Basin (NW-Germany) changed from ploughless agriculture to a presumably fire-based livestock farming. These changes were connected to a strong human impact visible in nearly all terrestrial archives (e.g. extensive changes in tree species composition). The natural landscape was transformed into a cultural landscape. We found that those environmental changes were also recorded in soils. Dark soil horizons (Bht horizons, Luvic Phaeozem) are common features of the loess areas of the Lower Rhine Region, and they are always connected to man-made pits. We investigated these Bht horizons and pit fillings by combining methods from (geo-) archaeology (geographical distribution within the landscape, shape of the pits, soil texture), geochemistry (carbon, pyrogenic carbon, nitrogen and lipids), palaeobotany (species determination of charcoals), AMS ¹⁴C measurements and luminescence dating. Dark soil horizons and associated pits occurred as a patchwork of kilometer-sized islands independent of natural conditions (e.g. slope, parent material). The soil material itself was characterized by specific patterns of lipid compounds and high contents of charred organic matter, which are relics of biomass burning. Considering its Holocene age, determined by radiocarbon dating, the occurrence of the finely distributed charcoal can only be explained by human-caused vegetation fires because temperate deciduous forests could not be easily ignited naturally. IRSL and OSL ages showed that the Bht horizons did not form in Pleistocene loess parent material, but in colluvial sediments that date to the Younger Neolithic (4400-3500 BC). Thus, the history of human induced soil erosion and the accumulation of correlating colluvial sediments in the investigated area started more than 1000 years earlier than assumed before. There is archaeobotanic evidence for sustained fire-based agricultural practices in the Baltic Sea area and the Alpine Foreland since ca. 4400 BC. We concluded that the investigated dark soils are relics of prehistoric agricultural burning activities in NW-Germany, possibly providing the basis for the change to a cultural landscape in Late-Neolithic. They are not, as was presumed before, relics of naturally occurring Early Holocene steppe-soils (Chernozems).

Yangtze delta-coast of China: Prehistoric water conservancy and early agricultural implications

Yan Liu (East China University), Zhong Yuan Chen (East China University)

This paper tends to discuss the archaeological findings as represented by the large-scale water conservancy facilities emerged on the inner Yangtze delta coast, and its relation to early agricultural implications. A set of higher dykes consisting entirely of earth (sediment) are about 9 km long, 20-30 m wide and about 10 m high above the adjacent delta plain. Dykes are immediately positioned in parallel to the mountains (ca. 300-500 m above mean sea level) to north, only about 200-300 m in distance. To the south, there occurred the famous Liangzhu ancient city (2 x 3 km) excavated recently, and dated archaeologically at 5000-4000 a BP. This area is also well-known for the early Chinese rice cultivation. Our preliminary dating result using OSL has shown that the dykes were built up at about 4000 years ago. Furthermore, our magnetic measurement (anisotropy magnetic susceptibility) has witnessed: 1) magnetic alignments (n=57) of the dykes are disordered in distribution, showing the nature of dykes through human construction, and 2) magnetic alignments (n=77) below the dykes are in general to be directed southward, implying the alluvial deposition. This has manifested the initiation of dykes in relation to the early agricultural farming on the Yangtze delta coast. Our pollen study of the study area has demonstrated the processes of cultivated rice and related farming habitation during the time period of 5000-4000 years ago. We reason that the emergence of the water conservancy of the study area was initially considered as the means for flood mitigation in association with the early agricultural civilization. This provides an example for better understanding of adaptation of Neolithic development on the megadelta coast of China.

Observation of Spatial-Temporal Change in Erzurum and Surrounding (Turkey)

Halil Gunek (University of Firat), Ilhan Oguz Akdemir (University of Firat), Veysel Kuscu (University of Firat)

Urbanization is the developments in the city and its district as a result of population increase. Urbanization causes great changes in the land use. Since the natural vegetation and structure are occupied with pavements, streets and buildings due to changes in land use; cities have typically become dry lands being polluted impermeably, roughly and

intensively. These disadvantages cause natural environment change negatively in the city. Moreover it also causes climate change. We can determine land use and land change easily with the help of remote sensing system and GIS. In this study, the change of spatial and temporal land use was observed in Erzurum which was located in the east of Turkey at 1900 m elevation. By using remote sensing system and GIS techniques together, changes brought by urban housing on the land use in the last 25 years and its dimensions were defined. When the establishment of city is considered, the settlement which dates back to old-times is settlement of city which expands around the castle. When the first texture of the city is analyzed, it is seen that the city is composed of dense-textured, narrow streets and low-rise small houses. However after 1980's, a rapid urbanization has started due to new residential lands and housing possibilities. As a result of this suburbanization, an expansion was observed outwards urban inner areas and shack town. The development in this period was restricted with the population increase of the city, but a rapid expansion was experienced due to migrations from rural area and close areas. Shanty houses are generally established on unproductive and inclined land where there is much treasure land. However, new settlements are generally established on flat land. According to the results it is determined that the expansion of Erzurum towards plain base is not rapid. The expansion is rather towards South-west.

The natural and anthropogenic causes of climate change and its consequences

Christina Hakopian (Yerevan University)

Numerous studies, based on paleoclimatic or indirect data show that climate change would take place in past, in all geological periods. Of the most significant climate alterations is the cycle of about 100 000 years, the ice ages, when the climate on the Earth was mainly colder compared with that in present, and that was followed by warmer inter-glacial periods. Those climate changes were caused by natural factors. Some of them would occur for relatively short periods of time. With the rapid industrial development at the beginning of 20th century, climate change processes also accelerated. From then, not only the natural, but also the anthropogenic factor fostered climate changes. Under the impact on human activity, the natural chemical composition of the atmosphere changed considerably (due to green-house gas emissions, such as carbon dioxide and methane). This change affects the global climate of the planet. The natural factors of climate change are: Earth orbit displacement and angle of incline (in relation to the planet's axis position), alterations in solar activity, volcanic eruptions and changes in atmospheric aerosol of natural origin distribution. The anthropogenic factors of climate change are: greenhouse gases, formed as a result of human activity, aerosols, changes in land-use, urbanization growth, and others. The climate changes that took place in the last 20 years affected all the components of the environment, and through them, influenced on human activity and health. In the last years, climate changes caused droughts and fires in some regions of the world, while some others suffered floods,

mudflows and landslides, etc. This resulted in both physical extermination of live organisms and humans, and caused traumas, made some diseases acute or caused some other imbalances. The natural and anthropogenic causes of climate change will be studied and analysed in this paper, with the main emphasis on the consequences of these changes, as well as measures of their mitigation.

Water balance of boreal forest ecosystems of the north-east of European Russia during the Holocene

Alexander Olchev (RAS)

The temporal variability of the main components of water balance (e.g. actual evapotranspiration (E) and potential evaporation (PE) and annual transpiration (TR)) of mature forests grown in European part of Russia in the Holocene was reconstructed using a simple regression model. As input parameters the model uses the paleoclimatic and paleobotanical data (air temperature, precipitation, forest species compositions). The model is based on nonlinear approximations of annual values of E, TR and PE by the Levenberg–Marquardt method using the results of numerical simulations of E, TR and PE provided by a Mixfor-SVAT model for the forests with different species compositions under various thermal and moistening conditions. The results of E, TR and PE reconstructions for the Holocene show a large variability and high correlation with the air temperature pattern. Minimal values of E and PE are obtained for the Younger Dryas cold phase (10.2 – 9.5 14' kyr. BP) when τ varied between 320 and 370 mm year⁻¹ and PE - between 410 and 480 mm year⁻¹. During the late Atlantic periods of the Holocene (4.5-4.8 14C kyr. BP) τ and PE reached maximal values (430-450 mm year⁻¹ and PE - 550-570 mm year⁻¹). Obtained data can be used for better understanding of land use and vegetation changes in past epochs and for prediction of vegetation dynamics in future.

Focusing on the Major Function Oriented Zone: New Spatial Planning Approach and Practices

Jie Fan (Chinese Academy of Sciences), Dong Chen (Chinese Academy of Sciences), Wangshu Hu (Chinese Academy of Sciences)

Spatial planning occupies a prominent place in China's 12th Five Year Plan as Part Five of the Plan put forwards new initiatives in coordinated regional development and Part Six address the challenge of resources and environment. The paper by Fan Jie and his team explains the key policy concept underlying this latest thinking. Fan, a professor at the Chinese Academy of Science and the chief scientist of the research team on the project, proposed a major function-oriented zone (MFOZs) approach to regional development. His work explains how this concept comes about, the details of the multiple indices used and the methodology adopted. According to this approach, four kinds of MFOZs are identified in regulating land use in China: "development-restricted zones", "development-oriented zones", "development-prioritized zones" and "development-prohibited zones". Their team has undertaken the research and proposed this approach to the central government, which has then adopted it as a national policy framework in the 12th FYP. However, only two-fifths of the land in China will be covered by the national zoning, whereas zoning of the remaining three-fifths of land will be carried out by the provinces. Such a top-down approach in defining territorial functions through zoning has the advantage of slowing and stopping the rapid loss of arable land and areas endangered by industrialization and urban development. Unlike previous attempts, a detailed index system backed up by extensive research by Professor Fan's team will provide detailed guidelines and technical standards for zoning at the provincial level. Further, instruments such as remote sensing images, field monitoring and surveys, among others, will be employed to build up a data base under the supervision of the Chinese Academy of Science to offer a dynamic assessment of changes in national level MFOZs. This is also one of the few examples where scientific knowledge has been incorporated into national development and regional planning. Nonetheless, the complexity in this undertaking of zoning in a vast country like China and the political incentive of promoting economic and industrial growth by China's local governments pose challenges to the full implementation of such a far-sighted policy.

Socio-Economic and Environmental Impact of Renuka Dam, HP: A Case Study

Jagdish Chand (Govt. College, Chamba)

Water and energy are indispensable for human sustenance. The demand for water and energy on a global scale is assessed to boost significantly in the future, in accordance with population growth and improved living standard. As such, in the 21st century are required to secure water resources and to introduce renewable energy sources that are environmental friendly. Throughout history, dams and reservoirs have been used successfully in collecting, storing and managing water needed to sustain civilisation. In this paper, Renuka Dam Project, which has proposed to be constructed across river Giri near Dadahu 400 m downstream of the confluence of river Giri and Jogar ka Khala, envisages construction of a concrete gravity dam of 178 m height (from the deepest foundation level) has been studied. The submergence area of the Dam reaches upto the Khairi Bridge, 35 km from Dam site. The dam lies in district Sirmour of Himachal Pradesh. The project has been designed for the purpose of water storage for the supply of the same to the state of Delhi. The study makes use of both primary and secondary data. Extensive field work has been done by conducting structured questionnaires, schedules, interviews and personnel observations in order to collect primary data. The proposed reservoir will be submerged an area of 1281 hectare of land consisting of 485 hectare forestland (including 49 hectare of sanctuary area), 313 hectare of revenue and education land, and 436 hectare private land. The details of affected families have been obtained through field survey conducted at household levels. The records of land likely to be acquired in different (project affected) villages have been obtained from the concerned Revenue Authorities and Himachal Pradesh Power Corporation Limited. The impacts on land environment due to construction of 'Renuka Dam project' have been evaluated and it was found that terrain around project site is going to have permanent and temporary changes in the landscape. The major impacts will be change in land-use leading to fragmentation due to submergence and construction of the project. Generation of additional muck and localized increase in erosion due to excavation of tunnel, powerhouse and other appurtenant components and other will be localized fall off temperature in and around reservoir. There will be lot of degradation/destruction of local natural fauna and flora of the dam site. The adverse socio-economic and environmental impacts of large dams can be mitigated through informed decision-making, transparency and engagement of all stakeholders. In all probability, the advantages and disadvantages of hydro-power structures, large or small, have to be discussed with people transparently. Based on the evaluation of baseline data and predicted impacts, suitable management plans to reorganize the negative impacts in the sphere of land, water, air, noise, biological and socioeconomic environments need to be formulated.

What About Women? Gendered Space and Human Security in Sri Lanka

Ali Brown (University of Amsterdam)

I intend to present findings on research conducted early 2012 on women's daily mobility patterns in relation to their livelihood strategies, natural resource use and perceptions of human security in a fishing village in Northern Sri Lanka. The social constructions of space have real implications on the patterns of daily life, especially for women in post-war areas. Social constructions, limitations and uses of space in a militarized area have implications for livelihood strategies, the natural environment and perceptions of human security. Many women have become heads of their own households as a result of the war and fishing activities have also been restricted, which decreases economic opportunity. As such, it is important to investigate the current perceptions and uses of space in building livelihoods and security in order to understand the possible impacts of development initiatives in the region.

La ségrégation hommes-femmes dans le métro: Comment en arrive-t-on là?

Marion Tillous (Université Paris)

Il existe dans le monde dix réseaux de transports urbains ferrés (métros, trains de banlieue et métros légers) dans lesquels certains wagons sont réservés aux femmes, parfois seulement aux heures de pointe, parfois pendant toute la durée du service. Ces réseaux ne se trouvent pas dans une même aire culturelle (il en existe au Japon aussi bien qu'au Mexique, en Egypte ou en Inde), mais tous relient, dans leur communication autour de ces réseaux, la séparation homme-femme aux questions de sécurité. La compagnie Tokyo Metro indique ainsi sur son site : « Tokyo Metro has adopted "women-only" cars during the morning rush hour so that women, elementary school students and younger children can ride with a sense of security ». Tout se passe comme si, pour répondre à une vulnérabilité constatée, la solution la plus pertinente avait été de séparer la population à risque de l'aléa, en l'occurrence de l'agression par un homme. C'est ce déroulement dans la prise de décision que nous souhaitons interroger : comment le problème a-t-il été identifié - Par qui : la puissance décisionnaire ou la population vulnérable concernée - Pourquoi face à ce problème, la solution de ségrégation est-elle apparue comme la meilleure - A quelles autres solutions a-t-elle été confrontée au moment du choix - La décision a-t-elle seulement été prise pour répondre à un problème - N'a-t-elle pas par exemple été prise pour obtenir les faveurs d'un groupe (dans un contexte électoral, notamment) - Ou encore pour répondre à un code moral qui semblait

aller de soi aux décisionnaires - En d'autres termes : y a-t-il vraiment eu choix ? Pour répondre à cet ensemble de questions, nous avons choisi d'interroger les responsables des opérateurs et autorités organisatrices des dix réseaux concernés selon un protocole commun, visant à identifier le moment de la décision, le réseau d'acteurs impliqué et les controverses qui se sont engagées à la suite de cette décision. Pour pouvoir mener les dix terrains de front, nous avons pris le parti de réaliser ces enquêtes par échanges de mails. Des recherches dans la presse nationale et internationale ont permis de compléter ces informations.

Home as productive space in rural Los Tuxtlas (Veracruz, Mexico)

Isis Arlene Diaz-Carrion (Universidad de Madrid)

In rural Mexico home is often considered not only a reproductive space but also a productive one; however, even though either men or women are used to performance productive work at home the use of time/space involves reproductive work mainly for women. As a result, for women, productive work at home is one of strategies used to make compatible their roles of caregiver and breadwinner. Through a qualitative approach (in-depth interviews and observation) quotidian life of women and men are studying in order to identify the differences in using private space in order to perform productive work as well as the limitations imposed by the reproductive one. Key words: gender, productive work, rural, Los Tuxtlas.

Neighbourhoods on the making: Audiovisual recollections of gendered spaces in the barrio La Romànica (Barcelona)

Rosa Cerarols (Universitat Pompeu Fabra), Antonio Luna-Garcia (Universitat Pompeu Fabra Barcelona), Fabi Díaz (University of Leeds)

Our research topic deals with the social construction of place and daily life in a local scale, especially at neighborhoods. We are also very interested in urban transformations faced during last century at what we know now as the Metropolitan Area of Barcelona (MAB). In the beginning of 20th century most of the area that now is heavily constructed and populated was a vast extension of fields. From this starting point, we try to explain and understand from a geographical and social perspective the birth and growth of La Romànica, a tiny neighborhood of Barberà del Vallès, a MAB suburbial town. To understand the sense of place of this community is very important to combine historical inquiry of social and material neighborhood's evolution. Our approach goes beyond the official reconstruction of the neighborhood and wants to deal with local people contributions and their remembrances in place. To analyze its significance we will recover their memories using audiovisual methodologies. On the one hand we will follow up some local figures that can explain us how the place was, how it has changed and how it has been consolidated as a collectivity with a real neighborhood identity. On the other hand, we will try to figure out by video how daily life is now, considering age, class and gender.

Audiovisual methodologies are rich but complex. They allow creating and mixing diverse information that was not possible before. Through them, new discourses are elaborated, becoming a useful and powerful tool of analysis, but sometimes too demagogical. In our study, by using audiovisual methodologies we will try to give voice and empowerment to local people and to narrate their own history and lives, adding meaning to space as well as explaining the social construction of La Romànica.

Lived world of elderly people in Japan: Analyzing their life history

Yoko Yoshida (Nara University)

Human geography studies of the elderly in Japan have largely drawn from previous studies in the English-speaking world. However, it appears that human geography studies in Japan have taken a masculinist point of view. This approach has been widely criticized by feminist geographers. This has occurred because geographers, whether from Western countries or Japan, do not take into account their own positionality when conducting research. This study takes an interest in human geographical researchers' positionality when they do research into elderly people who have different social and economic backgrounds. The factors that influence the social history of a person include gender, class, ethnicity, disability, sexuality, etc. These factors contribute to the differences in lives that people lead. To date, very few studies of Japanese human geography have focused on the issues of gender, disability, sexuality, etc. However, some studies of elderly people have made reference to population distribution, residential mobility and surroundings, and behavioral patterns by taking into account varying income groups and physical conditions. Gender, disability, sexuality, etc. are factors which can contribute to inequality and exclusion in society. It is clear that employing a feminist perspective should be significant for a researcher (even if a female researcher unconsciously falls into a masculinist perspective due to the researcher's priorities) to analyze the life history of elderly person by conducting interviews. However, Japanese human geographers have not to date approached their research from a feminist perspective. The majority of the discourse in this area has taken a masculinist perspective. Thus this study emphasizes the social relations (including gender) which have been missing in the human geography studies of the elderly in Japan. This study attempts to understand a constructing process of identity for each elderly person from birth to today. It does this by focusing on the person's life history. In particular, the study looks at social relations (including gender relations) that an elderly person will have encountered in their life. Making a time-space matrix is one of the useful methods of understanding the lived world of elderly people who live in different places (a large city, the suburbs, an agricultural and fishing village). Many previous works concerning the elderly tended to focus on the present condition surrounding everyday life, but it is important that we also study the person's lived world (that is a constructing process of identity). This study presents some issues that the elderly face in their everyday life and points out their urgent needs, using the notion of time geography which looks at a person's past experiences and social relationships. My presentation will include detailed data.

Female workers in the fishing industry in Rio Grande, RS, Brazil

Susana Maria Veleda da Silva (Universidade do Rio Grande)

This paper reports empirical results and reflections upon the situation of female workers in fishing industries in Rio Grande, a city located in the south of Brazil. Our premise is that this activity is influenced by the position that women still have in the patriarchal society, (re)producing the sexual division of work based on the gender relations that stigmatize them in the world of paid work. This study aimed at outlining the female workers' profiles in the sexual division of work and identifying resistance and emancipation strategies. Therefore, we chose a qualitative methodology from a feminist perspective. The operationalization consisted in the analysis/reflection upon the following categories: stigmas, family, sexual division of work, precarious work and empowerment. The research showed that the female workers in fishing industries have still been submitted to forms of exploitation that can be based on gender relations regarding management positions taken by male workers and tasks related to women's roles in reproductive work.

Feminization of labor force in Japan and changing women's life course

Yoshimichi Yui (Hiroshima University)

After 1990s, globalization and relaxation of regulations in labor market have drastically changed working conditions in Japan. The revision to the Law for dispatch workers and the Law for Equal Employment Opportunity of Men and Women had increase part-time or non-permanent workers. Especially, female work turned to cheap part-time jobs or unstable dispatched jobs. And the economic depression force to push housewives to restart to work in order to subsidize their households' income. In this ways, the ratio of female workers is increasing. This means that feminization in labor market has progressed in Japan. Originally it was popular that women leave a job after marriage or childbearing before 1990. However this trend and women's life course have been changed. It is increased that young women continues to work after marriage and that married women restart to work on a part-time basis. Furthermore, the trend toward service economy need more cheap female part-time workers in service sector. Married women are convenient as flexible workforce for employers or business owners. This study tries to analyze the work and life of women's care workers and call center agents in order to clarify the feminization of personal service sector in Hiroshima and Okinawa. These service industries are typical growing industries in Japan and both industries depend on women's irregular employments. And reasons of selection of case studies are follows; one is that care service works are growing service sectors in Okinawa. And another one is that care service industries are important in rural regions because care service industry is only one industry in rural regions. Care service is the most feminized sector in labor market in step with the aging of the population. Most of labor force is women's part-time worker. That is why this service needs the experience of nursing work and flexible work. Usually care service is assembled with short segments of part-timers

works. So, their work is extremely flexible. In some case, care service women work in two specific days per week or in two or three hours in everyday. Married women don't want to get full-time job, because they think it is difficult to satisfy both of work and housework. However there is little assistance by their husband. Therefore, unstable and low income jobs force to change women's life course. Young unmarried women continue to work and keep their marital status. And married women tend to restart to work as part-timers. However their work is very serious without government assistances.

Gendered pathways into the labour market

Karin Schwiter (University of Zurich)

In most countries women and men are disproportionately concentrated in particular occupations and in particular sectors of the economy. Men seldom become nurses, and only few women work as taxi drivers. Although many other indicators of gender inequality have decreased within the last decades, gendered occupational segregation has shown remarkable persistence. Its extent and patterns, however, vary considerably between countries. While gendered occupational segregation is comparatively low in the US and in Canada for example, it prevails especially pronounced in the German speaking countries (Germany, Austria and Switzerland). This paper aims at shedding light on the complex and intertwined mechanisms that contribute to the disproportionate concentration of men and women in particular occupations and on its patterns. After an overview of the existing literature, it presents results of a longitudinal Swiss study which followed the transition process from education to employment of a statistically representative cohort of young adults for ten years. The findings presented in the paper are based on analyses of this quantitative longitudinal data and of retrospective narrative interviews with a number of respondents from this sample. The paper will highlight and critically discuss the mechanisms which shape young adult's pathways into feminised or masculinised occupations in Switzerland and draw comparisons to other countries.

C08.10-03 - Gender and Geography 3: Migration and transnationalism

Chair: Janice Monk

Illegal immigration and the social representations of the Brazilian female professionals of sex in Spain

Joseli Maria Silva (University of Ponta Grossa State)

This investigation has as its main objective to analyze the association between the illegal immigration and the social representations of the Brazilian female professionals of sex in Spain. Thus, the intelligibility of the defining elements of the transcontinental female immigration for the practice of commercial sexual activity is constructed, and the relations among body, identity, Brazilian territory and sexual practices in foreign countries are contemplated in order to know the meanings constructed by Brazilian women on their socio-spatial experience of illegal immigration. The immigration routes, the immigrants and the actions of the organized groups in the commercial sexual activity have been the object of international researches showing that Spain and Portugal are the major destination countries and people in transit to other rich countries of the illegal immigrants and, also, of people being trafficked for sexual exploitation. Since 2007, the Brazilian government has made efforts to understand the complexity of these relations and outlined policies to fight against emigration of Brazilian males/females who have suffered exploitation processes and then started living illegally and in precarious citizenship conditions in rich countries. As a globalized world, it is up to Geography to contribute with the spatio-temporal comprehension of this phenomenon which has been object of many conflicts and international treaties. Keywords: illegal immigration, Brazilian women, commercial sexual activity

Japanese Women in Hawaii

Honami Kageyama (Sugiyama Jogakuen University)

This paper will clarify the identity of Japanese women living in Hawaii after World War ' by analyzing the article in a Japanese journal published and distributed only in Hawaii. After World War ', many Japanese women emigrated to Hawaii for mainly four reasons: (1)they married to American soldiers and moved to Hawaii as 'War Brides'; (2)they followed their Japanese husbands, who were the representatives of Japanese enterprises; (3)they personally visited Hawaii then later married and stabilized there and (4)they came to look for a job. After moving to Hawaii, some of them started making their own social networks in order to acquire their 'home'. However, the way they built those networks was different from that in Japan. In Japan, many of them had to ask for permission from their husbands in order to attend some social communities whereas they did not have to do so in Hawaii. This means that they are free from the traditional Japanese family tie:they

can do what they want. Although it seems that Japanese women living in Hawaii have won their freedom, in reality they are still bound by the traditional image of 'Japanese women'. They tend to play their gender role as humble and submissive 'Japanese women' unconsciously because they think that they are expected to do so. In this way, they inwardly reproduce and reinforce an identity of conservative Japanese women. In this paper, I will analyze articles from a newspaper called 'East-West Journal' by focused on is 'Gambaru Hawaii no Shin-Issei (Powerful Japanese First Generation livin in Hawaii)'. There were 144 articles about this topic and 34 featured Japanese women living in Hawaii. Through analyzing these articles, I would like to investigate how they built their own 'dwelling space' in Honolulu: a space that has been culturally and socially created as a living space where its residents can live actively and creatively. 'The dwelling space' is an integrated place between 'production space' and 'reproduction space, and it is a place where 'residing' persons who are active in integrating production and reproduction can continue to act creatively in even living in the residential area.(Kageyama 2010, 2004).

Gender and Circuits of Labor Migration: A Case Study on Urban Communities of Metropolitan Manila

Makiko Ota (Osaka University)

Studies of cities in developing countries have been conducted focusing on domestic rural-urban migration. Most studies have examined characteristic phenomena of dwelling and working in such cities, in both slums and informal sectors. They have been analyzed with respect to social and cultural continuities between cities and rural areas. However, these studies have not discussed the international labor migration in such context, although some developing countries have a large number of migrants to developed countries. Furthermore, women's migration has been overlooked, because the studies tend to focus on migration of heads of households, who are usually men. Recently, "feminization of migration", which implies the increase in the number of female migrants, is observed at a global level. In the Philippines, the number of women among overseas contractual workers has been increasing since the 1990s. Cities should be analyzed from the perspective of feminization of labor migration, since emigration has already spread as an option among women in some developing countries. In this presentation, I introduce two perspectives, gender and global migration, for an analysis of migration structure of urban low-income communities in metropolitan Manila, the Philippines. The presentation is based on data collected through a field study of households in the communities that send migrants overseas. I explore gendered circuits of migration from the communities by focusing on the effects of economy restructuring process and "feminization of labor" in Manila on each research community. The following data will be analyzed to verify the characteristics of emigration structure of the communities: gendered local economy, segmented labor markets, household patterns, decision-making process of female and male overseas workers, migration pattern of women and men from the province,

formation processes of the communities, and economic-cultural relationship between migration target countries and the analyzed communities. The circuits of migration are examined in terms of the continuities of rural-urban movement and overseas migration; both have been caused under the influence of the growth of the service sector and export-oriented economy in the Philippines.

Social Inequalities and the Habitus in Transnationalizing Societies

Nina Schuster (TU Dortmund)

Social processes are closely associated to the bodies of the persons who are interacting in social practices. The body is shaped by many socially constructed differentiations, which are mould into social categories - like gender, sexuality, ethnicity, class, age, ability. A person's habitus, as Pierre Bourdieu calls it, is shaped by a person's social surroundings and circumstances when growing up, structuring her_his social practices. It is built on a system of classifications and hierarchies that get incorporated and influence in the way in which a person uses her_his body. As categories intersect, the habitus of a person is shaped by more than one of the categories named above. This dimension of social differentiation becomes extremely significant when people from different social and cultural contexts interact, as it is more and more the case in globalizing societies that are shaped by transnational mobilities, and, as a result, by tendencies of a social transnationalization. In this context, intersectional perspectives within social inequalities have to be studied carefully. One possible approach for this study may be the dimension of the body. My paper argues that the body represents a crucial, often neglected part of socio-spatial practice analysis in the context of the analysis of transnationalizing societies. If we share the ideal of a society that should be based on equal terms, it is crucial to be aware that there are diverse, hierarchically arranged habitus and thus diverging social orders represented in one place, in order to be able to reconceptualize transnationalized social processes. Social processes are especially susceptible to be misread if embodied social hierarchies, interwoven by power and dominance are not included into the analysis. As every global social process is rooted in local structures, an analysis coping with a local scale or a micro social perspective on space may be helpful. This local perspective has to consider the dimension of the habitus of people involved. This conceptual paper will discuss the role that intersectionally shaped social positions play in social processes within a wider focus of a concept of a transnationalized society. Bringing debates on social inequality and its bodily incorporations into the focus, it discusses how inequalities as well as discriminations and social exclusions are produced unwittingly, and often are not reflected as problems of unequal, hierarchical social structures.

C08.10-04 - Gender and Geography 4: Planning and development

Chair: Elisabeth Buehler

Feminization of social exclusion: a case of the transitional Ukraine

Ganna Gerasyenko (Institute for Demography and Social Studies)

Development of the concept of social exclusion was facilitated by a transition from the monetary approach to poverty studies to the deprivation approach, which suggests exclusion form a normal social life, common for a society. In this regard, gender analysis of inequality is particularly important, as women tend to be more discriminated against than men all over the world; women face higher risks of poverty and their poverty tends to be more intractable. Moreover, gender inequality affects also such poverty dimensions as opportunities, empowerment and security. An increase in gender inequality in terms of poverty and social exclusion has become a prominent feature of the transition period in Ukraine. The proposed paper provides a brief analysis of the recent poverty trends in terms of various criteria; it also presents the main poverty profiles formed by certain sociodemographic population groups, which are clearly gendered. A particular attention is paid to problems of poverty feminization, which are rather urgent in Ukraine, and analysis of the gender bias in social exclusion problems. The regional analysis of social exclusion in transition economies reveals a particular rural-urban divide in terms of access to public services, infrastructure, opportunities of leisure, etc. The state policy on incorporating of gender approaches to the poverty alleviating and social inclusion strategies are critically analysed; the respective policy recommendations are outlined in the conclusions. The paper is based on the results of the 2007 Social Exclusion Survey in Ukraine, which has been realized by Institute for Demography and Social Studies of the National Academy of Sciences of Ukraine; it also operates with data of household budget surveys.

Background of Decreasing Fertility Rate in Japan Compared with the United Kingdom

Eriko Ikeya (Kochi College of Technology)

Low fertility in Japan is very serious. After World Health Statistics 2011 by WHO, rank of Total Fertility Rate in Japan was the 182nd among 191 countries in 2009. Other low rank countries were in South East Asia, Eastern and Southern Europe. Fertility rates are assumed to reflect not only thought of people about having children but also reproductive health rights situation and life conditions. And low fertility is feared to cause economic decline from shortage of demand and working age population and burden for young people in aged society. After previous studies, causes of declining TFR were explained as late childbearing and decreasing number of children per woman in increasing labor

participant opportunities. But, late childbearing is common in industrialized countries and some of those countries reveal relatively high TFR. For example, TFR of France is 1.99; the United Kingdom is 1.94 in 2009. So, I want to investigate backgrounds of low TFR in Japan by comparative research. As a country to compare with Japan, I selected the United Kingdom. The U.K. has similar size country to Japan and has history of industrialization. Comparing the TFR with the U.K., TFR of both countries decreased in 1950 to mid-1980s. TFR of Japan continued to decrease from 1.76 in 1985 to around 1.3 in the late 1990s and the 2000s. On the other hand, TFR of the U. K. kept around 1.7 and increased in the 2000s to 1.94. The backgrounds of these differences of TFR of both countries are thought as below. 1. Gender equality and Labor rights in the U.K. are more guaranteed compared with Japan. In addition, work life balance policy is more developed in the U.K. So, working female can have children not only in their 20s but also in 30s and 40s in the U.K. In Japan, 60% of female quit the job before or after giving birth, 26% of them had difficulties to balance work and life and 9% were fired or suggested to resign. 2. There are choices for child care in the U.K. They use nannies, child-minders, au pairs, nurseries and husbands or grandparents take care of children. In Japan, choices for child care are almost limited to use nurseries or kindergartens. Nursery seats cover only 33% of children in 2011 and especially seats for infants are insufficient. 3 years old myth that infants should taken care by their mother and Japanese-style Welfare policy of LDP prevented to establish enough nurseries. 3. Safety net plays important role in keeping fertility in the U.K. The U.K. has strong net compared with Japan as Welfare State. Economic security in everyday life declined heavily in Japan by globalization. Factories moved to Asian countries and prices collapsed, so young people could not get well paid, stable jobs. Working poor widely spread. Marriage and fertility rates of young are declining in this circumstance. Safety net in Japan is not enough. It should be enhanced.

Territorial Structures of the Economy of the Pacific Russia – Tendencies of Dynamics and Inertia

Petr Baklanov (Pacific Geographical Institute)

In the respect of growing economic and geographic inclination of the eastern areas of Russia to the Pacific Ocean (to its natural resources and transit potential), and taking into account the state sovereignty over the sea economic zone, we called the Far Eastern region of Russia as Pacific Russia. Lately we studied the geographic factors and tendencies of changing territorial structures in this region in long-term perspective (till 2050). We consider territorial structures of the economy (ÖSEs) as two-level, two-layer formations (Baklanov, 1986, 2007): separate enterprises, companies, industrial nodes, the flows of resources and finished goods of the nodes and territorial zones of influence of separate nodes, social-infrastructure zones, resource-ecological zones, and also market zones within the framework of resource and consumer structures. In the framework of this approach, we consider the features of territorial structures of the economy within the limits of the Pacific Russia. One can allocate a number of properties

of territorial structures of the economy; the basic ones are as follows: dynamism, stability, inertia. A fundamental property of OSEs of any level is their dynamism; that is, the spatial-temporal variability of structures and their links, and inertia'the ability to keep invariable in some measure the basic structural features for a long time (years). We carried out generalized estimations of the main kinds of activity developed in the Far East of the USSR (within the Far Eastern economic district) in the 1970s; that is, with an approximately 40-year retrospective (a period equal to the perspective of 2010 up to 2050). Modern kinds of activity in the region, including the separate Far Eastern subjects of the Russian Federation, are estimated. Taking into account the tendencies involved in the strategy of social and economic development of the Far East and the Baikal region to 2025 and predictions of development priorities, generalized predictions are made of the possible kinds of basic economic activities that will be taking place in the region by 2050. On the whole, it is necessary to allocate some levels of the analysis of territorial-structural transformations of the economy: common regional levels, the levels of the Russian Federation subjects within the Far East, the levels of economic centers and cities, and the levels of the primary territorial structures formed by separate enterprises. The enterprises of specialized economic centers are chosen last. On this basis, it is possible to predict more strictly the transformation of territorial structures of the economy over the long term. Finally, predictive economic maps for certain areas of the Pacific region of Russia can be compiled.

Pattern of Social Change and Development among the Tribal Women in Assam (India)

Madhushree Das (Gauhati University)

Social change, which is a multidimensional and complex process, occurs in all societies irrespective of their structure, compactness, integrity and stage of development. But for a change to be termed development, it must occur continuously in a desirable dimension and direction. These desired goals are specified by the values and needs of the society concerned. While change results in modification or alteration or replacement of the old by the new ones, development aims to achieve human well-being and enhance the quality of life. Like other societies, the tribal society of Assam, located in India's North East, is also witnessing the spurt of social change and development due to a variety of factors. Having diverse ethnic origins, representing racial stock from Proto-Austroloid to Mongoloid, with a distinctive socio-cultural system, own cultural ethos, and an unique way of adaptation to different ecological niches, these tribal groups seem to respond to processes of social change and development quite differently compared to other communities. In this context the role of women is vital as women are an active agent of change. However, the pattern of social change and development is no way uniform throughout the state. It is different among the women of different tribal groups and in varying spatial contexts. Besides, the effects of change also seem to assume different orders and pattern. Depending on historical background, locational factors, tribal and non-tribal interaction and

infrastructural base, the level of socio-economic development of women among the major tribal groups in Assam present a highly varied picture. It is in this backdrop, an attempt is made in this paper to understand the patterns of social change and various dimensions of Women's development among eight major tribal groups (Boro, Mising, Karbi, Rabha, Sonowal Kachari, Tiwa, Dimasa, and Deori) living here. The study is based on both primary and secondary data. While secondary data has been obtained from relevant Census of India publications for the period 1971-2001, necessary primary data have been collected through a field survey in the dominant pockets of eight major tribal groups (2009-2011). Further, to understand the pattern of social change and development among the women of the different tribal groups, quantitative techniques like Social Change Index, Composite Z Score and Principal Component Analysis have been used.

C08.10-05 - Gender and Geography 5 - Panel Discussion: International practices in gender geography: bridges and barriers

Chair: Maria Dolors Garcia-Ramon

International Practices in Gender Geography: Bridges and Barriers

Maria-Dolors Garcia-Ramon (Universitat de Barcelona), Jan Monk (University of Arizona), Antonio Luna-Garcia (Universitat Barcelona), Susana Maria Veleda da Silva (Universidade Federal do Rio Grande), Joos Droogleever Fortuijn (University of Amsterdam), Ruth Fincher (University of Melbourne)

International Practices in Gender Geography: Bridges and Barriers Jan Monk (University of Arizona)& Maria-Dolors Garcia-Ramon (Universitat Autònoma de Barcelona) This panel session will address three themes related to contemporary practices and challenges within and across national contexts in gender studies in geography. It will identify strategies that have fostered and could enhance communication and support for international work in this aspect of the discipline. The panel organizers will open with a reflection on the initiation and work of the IGU Commission on Gender and Geography offering some examples they have identified of the barriers, strategies, and progress in the development gender studies in geography internationally and in selected national settings. Second, they will take up the complexities of identifying and addressing Anglophone hegemonies in research publications and the significance of language in constructing thought and expressions. Third, they will report approaches to teaching in higher education that aim to foster students' understandings of international perspectives and identities. Following the introductory presentation, discussion groups led by members who are active in the leadership and participation of the Commission will address questions related to ways forward for advancing the field in diverse settings nationally and internationally. The session will conclude with short reports from the discussion groups.

Panelists

Jan Monk (University of Arizona)

Antonio Luna-Garcia (Universitat Barcelona)

Susana Maria Veleda da Silva (Universidade do Rio Grande)

Joos Droogleever Fortuijn (University of Amsterdam)

Ruth Fincher (University of Melbourne)

Chair: Yvonne Schleicher, Osvaldo Muñiz

Contributions of transdisciplinary teaching and learning strategies supported by Geographic Information Systems to Education for Sustainable Development – the point of view of the teacher

Vânia Carlos (University of Aveiro), António Moreira (University of Aveiro)

The need to educate citizens towards understanding complex problems as a demand of Education for Sustainable Development (ESD) gives prominence to transdisciplinarity and holistic learning (Unesco, 2009). The pivotal position of Geographical Education (GE) makes it an excellent space for transdisciplinarity (Haubrich, Reinfried, & Schleicher, 2007). GE also plays an important role in ESD (Haubrich, 2007) preparing students to think space and intervene in their local environment through spatial thinking (Bednarz & Kemp, 2011). The democratization of Geographic Information Systems (GIS) comes with the features of Web 2.0 allowing collaborative cartography and promoting transdisciplinary approaches (Lee & Bednarz, 2009). This ongoing study follows an action-research methodology and aims to contribute to the implementation of transdisciplinary teaching strategies, by answering: Do teachers consider transdisciplinary planning beneficial for ESD goals? What characteristics of GE promote transdisciplinary approaches in ESD? What are the main difficulties of integration of specific subject contents? Do GIS help support a more holistic teaching of ESD? It uses 2 groups of 5 teachers attending a teacher-training course. Data was collected from an individual questionnaire and a Focus Group interview, to reveal their representations before and after teaching (Cohen, Manion, Morrison, & Morrison, 2007), at the beginning and end of each of 2 action-research cycles, triangulated with class observation during the implementation of the teaching and learning strategies (McNiff & Whitehead, 2009). Preliminary results will be put forth on the teachers' reflections about their learning process and what changed in their perceptions on how to teach ESD through GE. We believe that this study can reveal qualitative changes in the practices of participating teachers regarding ESD. We will also discuss some reflections that we believe will motivate and prepare other teachers for ESD. Bednarz, S. W., & Kemp, K. (2011). Best Practices about Education for Sustainable Development in Nursery and Primary School

Sonia Ziliotto (University of Bozen)

This paper abstract presents a part of the results from my doctoral thesis. The research subject is Education for Sustainable Development (ESS) from the point of view of geography, through an international comparison of Padua in Veneto (I) with Würzburg in Bavaria (D). In particular, the focus is based on activities and projects carried out by formal (nursery and primary school) as well as non-formal (associations and local authorities) institutions. The research starts with a questionnaire to examine the teacher's beliefs about geographical education. A part of the results shows that the connection of ESS to geographical education is seen by teachers as very weak. This result was confirmed through the continuation of the research, which focused on projects carried out with regard to 13 ESS themes, chosen from the literature and from international documents. The outcomes highlight the existence of ESS best practices, both in the formal and in the non-formal fields. In particular themes connected with Environment Education have been broached more than themes connected with Development Education. Furthermore, the themes tackled take in consideration first environmental, then social and finally economic aspects. Results showed interviewees to be quite confused and scarcely aware both of the meaning of sustainable development and of ESS. In particular, people working in associations are more informed about core principles of sustainable development, but they prefer to use the name "Environment Education" because they claim it is better understood by the community, whereas most teachers don't see differences between ESS and Environment Education. The analysis of school programs showed that there is confusion about what ESS is: in no case is ESS presented like a perspective different from Environment Education. On the whole, interviewees turned out to be more focussed on "practice" than on "theory". As a matter of fact, they dealt with interesting projects, but they don't know full well the theoretical approach that is at the base of ESS, which actually has several points of convergence with that of geography. In this sense, the research increases the value of the synergy between ESS and geographical education, because if on the one hand geography could give clear and meaningful theoretical remarks on ESS, on the other hand ESS could offer to geographical education the opportunity to be updated and to overcome its isolation from society, also in terms of a higher number of hours added to the curriculum.

Education for Sustainable Development via geography and management: the right climate for change in South African schools

Luiza de Sousa (North-West University), Barend Richter (North-West University), Schalk Raath (North-West University)

Some four decades ago, environmental education (EE) was incorporated into the South African curriculum and formal school system with challenges. More recently, the goals of the United Nations' Decade of Education for Sustainable Development have not been fulfilled by the government and the Department of Basic Education (DBE) of South Africa, despite environmental issues having become important topics on world agendas. The DBE has, only as recently as 2011, called a workshop to discuss the best practice around education for sustainable development (ESD). It is only currently in the process of developing a policy for primary and secondary schools. Geography is the only subject that distinctively aims to develop a commitment towards sustainable development and sustainable living. The environment features in an integrated manner within the curriculum from Grades R-12, but the only reference to EE in subjects, other than Geography, is superficial and alludes to references of health and the environment. Research found that whole-school programmes that had implemented environmental management systems (EMS) as a means of ensuring that environmental principles were put into practice, was rare in South Africa. It was important to establish how the curriculum, management and all role-players in a school promote ESD when using an EMS. The paper will elaborate on how research has shown that Geography teachers through their resourcefulness and planning of the curriculum ensure that ESD materialises inside and outside their classrooms. The purpose of this paper is to report on how the curriculum, especially Geography as a subject, together with management are factors central to the success of promoting ESD when an EMS is implemented at a school. The paper will also make reference to an EMS framework designed for South African primary schools with the aim of using environmental management to promote ESD in rural, urban and township* schools. The framework highlights how schools in rural communities, urban areas and townships can ensure a greater integration of the environment in Geography teaching and learning, and management practices, and create an awareness of sustainable living. * A South African term referring to an underdeveloped living area built on the periphery of towns and cities. Keywords: education for sustainable development; environmental management systems; environmental education; management; primary school

Fostering Systems Thinking in Education for Sustainable Development

Stephan Schuler (Universität Frankfurt a. M.), Werner Rieß (University of Education)

According to the Lucerne Declaration on Geographical Education for Sustainable Development (ESD) the geographic vision on ESD is based on the concept of the 'human-earth' ecosystem. Knowledge and understanding of the major natural systems

and the major socio-economic systems of the earth are considered to be important competences which are crucial for implementing sustainable development. In order to foster an understanding of these systems, the demand to promote the understanding of systems thinking in schools arises. This conclusion had already been reached in the fields of Education for Sustainable Development (ESD), Science education and Geography Education as well. The aim to promote systems thinking at school is based on the assumption that students can only actively participate in sustainable development if they are able to identify and understand complex, global relations. But how can teachers foster the system competence of their students in the field of ESD? Which competences do teachers require to plan effective lessons and how can they gain these competences? These questions are the point of departure for our research project 'System Thinking in Ecological and Multidimensional Areas (SysThema)'. SysThema is a cooperation project between biology education, geography education and educational psychology and is funded by the Federal Ministry of Education and Research in Germany (BMBF). Through several empirical and experimental studies with student teachers we want to examine how special university courses can help to develop both, the system competence of the student teachers and their ability to arrange system-thinking lessons in the field of ESD. Besides systems thinking also epistemological beliefs are an important part of our concept of system competence. The courses deal with different ESD contexts from local natural ecosystems (e.g. forests) to global multidimensional systems (e.g. syndromes of global change). The students shall acquire content knowledge of these contexts and pedagogical content knowledge of system thinking and ESD as well. Before presenting the theoretical framework and design of the SysThema- project we will report some findings of prior research on reasonable teaching methods to promote student's systems thinking in the field of ESD which are an interesting and important base to the new project.

Chair: Anke Uhlenwinkel, Lex Chalmers

Climate Change in Geography Textbooks of International Selection. (Un)Sustainable Representations

Péter Bagoly-Simó (Universität zu Berlin)

Twenty years after the Rio Conference implementation of sustainable development continues to be an issue of (subject) education. Topics as globalization, climate change, poverty or urbanization are not only included in the Agenda 21 but are also central geographical themes. This paper deals with the question, how climate change is introduced in textbooks of international selection. For this study, textbooks for lower secondary education from Germany, Romania, and Mexico were considered. Mix-method content analysis was carried out and the curricular framework was also considered. The results show the individual understanding of climate change and its dynamics in three countries with different perspectives on geographical education. Differences in scaling, time perspective, and nature-society relationships are some of the paper's main findings.

Education for Sustainable Environment in the Mediterranean

Habib Ben Boubaker (Université de Manouba), Ftouhi Mohamed (Faculty of Pedagogy), Acoullas Michael (University of Athens)

The Mediterranean region, cradle of important civilizations, is an exceptional eco-region. This is due to its geographical and historical characteristics, its natural and cultural heritage, but also to the feeling shared by its inhabitants of belonging to 'the Mediterranean world'. This Mediterranean has encountered much ecological disruption during the 20th century. Nowadays, it faces great challenges: A major recent sociopolitical restructuring in its southern and eastern shores, a deep economic crisis in the north. Will it be able to collectively find a pattern of development that could bring people together, share and save a common environment? The main condition is to guarantee a sustainable development, including economic vitality, justice, social cohesion, environmental protection and the sustainable management of natural resources, so as to meet the needs of the present generation without compromising the ability of future generations to meet their needs. To make this vision real, the Mediterranean Strategy for Sustainable Development (MSSD) recognises that education in the Mediterranean needs strengthening by introducing sustainable development, through a holistic approach, into educational curricula, from primary school right up to universities and graduate schools (MSSD, 2005). Indeed, education, in addition to being a

human right, is a prerequisite for achieving sustainable development and an essential tool for good governance, informed decision-making and the promotion of democracy. Therefore, education for sustainable development can help translate our vision into reality. Education for sustainable development strengthens the capacity of individuals, groups, communities, organizations and countries to make judgements and choices in favour of sustainable development. It can promote a shift in people's mindsets and in so doing enable them to make our world better, safer, healthier and more prosperous, thereby improving the quality of life and intergenerational equity. Education for sustainable development can provide critical reflection and greater awareness and empowerment so that new visions and concepts can be explored and new methods and tools developed.

Environmental education: late adopters of the John Muir message in a national curriculum

Lex Chalmers (University of Waikato)

Environmental education: late adopters of the John Muir message in a national curriculum
The rapid exploration and resource exploitation of the 'new world' in the eighteenth and nineteenth Century generated a considerable debate about preservation of wilderness, conservation measures and wise use of natural resources. George Perkins Marsh, John Muir and Aldo Leopold are all names associated with an increasing environmental awareness in North America, with Muir's work probably the most widely known. These pioneers are early contributors to environmental education at national and international communities, and their levels of current citation indicate that their concerns are enduring. Increasing pressure on resources and environments in the twentieth Century have meant international agreement on the importance of sustainable use of our resources is now established, acknowledged in a signal manner by the Brundtland report of 1987, the Rio Conference of 1992 and the declaration of the UN Decade of Education for Sustainable Development, 2005- 2014. Reportage of progress in the decade committed to environmental education is explored. This paper argues that international concerns about sustainable development are best introduced in the compulsory levels of formal education, and notes the strength of these arguments in a review of the literature on geographical education. Using a case study of curriculum development, it explores the case for cross curriculum teaching and learning in environmental education, with a particular focus on sustainable use of resources. Geography often claims to be the 'home' territory for sustainability education, with intentions to integrate economic, environmental and social sustainability approaches to the understanding of place. The paper then reflects on the visit of an early environmentalist to New Zealand, noting that the prophetic words of John Muir in 1904 have only recently been incorporated in national curricula dealing with environmental education and that teaching resources and assessment outcomes have yet to satisfy the core needs of environmental education in New Zealand.

The Relevance of Place-based Education in ESD in Geography

Johanna Schockemöhle (University of Vechta)

The Relevance of Place-based Education in ESD in Geography One of the main ideas of ESD is that learners are supported not only to think globally but also to be locally relevant. In order to be able to have a directed influence on local issues, places and problem situations, it is necessary to possess a local situational knowledge, to feel connected to places at a local level and to bring in experiences arising from real actions. This contribution considers the question as to whether it can be a task of geography teaching to develop these competencies in students. For this purpose, the close connection between 'place' as a field of action on local level and the principally characteristics, objectives, contents and methods of geography teaching are first of all set out. In a second step, using the example of selected German curricula, the low level of attunement of the above-mentioned competencies to the objectives of geography education in Germany are presented. There is consequently a gap between one of the main ideas of ESD - to be locally relevant - and the competencies which are to be developed in geography teaching, at least at the formal level. The contribution focuses on the approach of place-based education (PBE) as a way of closing this gap. Central characteristics of this learning approach as well as empirical evidence for its ability to develop local situational knowledge, connectedness to local places and action experiences are outlined. On the basis of selected examples of practice, ways are shown in which PBE can be integrated into geography teaching. Finally, the findings are summarized in such a way to show how it can be an important task of geography education to support local action and to more strongly integrate learning approaches such as PBE into lessons.

C08.11-03 - Education for Sustainable Development & Global Learning 3

Environmental Education – Overview and Challenges: A Case Study of Schools in Mumbai

Archana Thakur (Sheth N.K.T.T. College, Thane), Sudha Srivastava (University of Mumbai)

In this study the researchers intend to focus on the issues related to environmental education and its implementation. The objective of introducing this curriculum is to augment the environmentally responsible behaviour, attitude and knowledge level of students concerning the environment. The aim is to find out whether there is noteworthy enhancement in environmental awareness among the students at secondary and higher secondary level (Class IX - Class XII). The methodology implemented in the study includes literature unearthing and analysis of results obtained from a survey conducted in different schools of Mumbai. Students were selected randomly from the above-mentioned classes and were assessed on the basis of their responses. The Likert type scale was designed in the questionnaires for obtaining data in the quantitative form. The data was analyzed by using basic statistical techniques and inferences drawn. This study highlights contrasting results, bringing out the variations in the impact of environmental education at different levels of formal education. The study exposes serious gaps in the implementation of environmental education and puts forth recommendations to make environmental education more meaningful with far-reaching effects so as to create an environment-conscious culture among the future generation so that they put forward environment-friendly development proposals to ensure sustainable development. Key words: Environmental Education, Environmentally responsible behaviour, Knowledge and Awareness, Sustainable Development.

Education for Sustainable Development in India: Understanding complex factors of water supply through argumentation

Stephanie Leder (University of Cologne)

In the context of Education of Sustainable Development it is necessary to promote awareness as well as communication skills on interdisciplinary topics of future concern in geography class. Argumentation skills deepen the understanding of complex man-environment relations and enable students as future decision makers for societal participation to promote sustainable development. The distribution of drinking water as the essential resource for life is a globally relevant problem which can be explained through complex physical as well as anthropogeographical factors and their

interdependencies. Through interviews with scientists, stakeholders, students and teachers, the current status of sustainable aspects in the context of water education is investigated in the Indian city Pune. A matrix for thematic and methodological evaluation of teaching material under sustainability aspects is presented. Through the matrix, the different understandings of students in secondary high schools concerning the access to drinking water as well as class material on water issues used in Indian school books are examined concerning the central goals of Education for Sustainable Development. A concept for promoting the understanding of complex man-environment relations within aspects of sustainability through argumentation will be presented which can be transferred to other urban structures and cultural contexts. Furthermore, opportunities of water education as globally and locally relevant topic for Education for Sustainable Development are shown. The international concept of Education for Sustainable Development in the local context of drinking water supply in Pune and its international transferability is analysed critically.

Expanding Worldviews

Audrey Mohan (National Council for Geographic Education)

Fieldwork is an important, and possibly the most essential, component to the academic training of geographers. To work within, live within, or experience another place or culture influences an individual's knowledge, perceptions, and worldview. While few would argue with these statements, it is interesting that this significant learning experience is lacking in the preparation of our geography teachers. Few teachers are able to travel extensively. For those who cannot travel, what they learn, and therefore teach, of geography generally comes from a textbook, limited coursework in geography, and vicarious experiences of other places (through TV, the Internet, or other people's experiences). However, for the teachers who are able to travel or conduct fieldwork, these first-hand experiences can transform their knowledge and practice in the geography classroom, motivate them to continue learning geography, and instill a sense of passion and commitment to the discipline. This paper discusses the experience of 14 geography educators who traveled and studied in Ecuador for four weeks on a Fulbright-Hays Group Project Abroad. Research includes results from pre- and post-assessments using the Intercultural Development Inventory and participant journals on their learning experience. Significant changes in the group's cultural worldview are noted, as well as changes in their knowledge of geography, culture, and sustainability (the three themes that guided the program). The paper discusses the importance of fieldwork, travel, and experiential learning in influencing what our teachers teach and how they teach it in geography classrooms.

Cognition of Multi-scalar Sense of Place and Identities, Practice of Social Equity and Environmental Justice as the Ecological Multiple Citizenship

Kwangtaek Sim (Chinju University)

Learners' cognition of their sense of place and identities in social studies is the source of becoming good citizens. If learners recover their sense of place, they will empathize with others' sufferings. If learners recognize their identities of individual, society, nation, and world, they will understand the relationships between individual and the others. Ecological multiple citizenships in multicultural society of network stage help the learners bring up skills and attitudes based on cognition of multi-scalar sense of place and identities to practice social equity and environmental justice for ensuring lives of individuals and sustainable future of mankind. Key words: sense of place, identity, social equity, environmental justice, ecological multiple citizenships.

C08.11-04 - Examples of Best Practice in Geography Education and Teacher Preparation 1

Chair: Michael Solem, Christiane Meyer

Professional Development and Instructional Materials in Geography

Audrey Mohan (National Council for Geographic Education)

The National Geographic Society received a 2-year, \$2.2 million grant from the U.S. National Science Foundation to develop a strategic plan for improving geographic education for the nation. Entitled 'Establishing a Roadmap for Large-Scale Improvement of K-12 Education in the Geographical Sciences', this project brought together experts in geography, education, and research from across the U.S. to create reports focused on four key issues for educational improvement: instructional materials for students, education of teachers, assessment, and research. The four key issues were divided among three committees: the Assessment Committee, charged with developing a framework for assessing progress toward geographic literacy across the progression from kindergarten through high school; the Professional Development and Instructional Materials Committee, charged with making recommendations about approaches to the design of instructional materials and the education of teachers; and the Educational Research Committee charged with developing an agenda for educational research that lays out questions about learning, teaching, and educational change that must be answered to improve the effectiveness of geographic education into the future. The Professional Development and Instructional Materials Committee's task included:

- Synthesizing research on student learning, teacher learning, and the design of instructional materials focused on improving teacher education, professional development for teachers, and materials to support instruction in geography.
- Creating recommendations and guidelines for teacher educators and materials developers that will enable them to develop, share, and implement research-based programs in cost-effective manners. To accomplish this task, the committee conducted an extensive review of the literature on professional development and instructional materials, both within the discipline of geography and across related fields. The committee used the literature review to inform the development of recommendations and guidelines for the design, implementation and evaluation of professional development for geography teachers, as well as instructional materials that support teaching and learning in geography. These recommendations and guidelines have undergone an internal and external, public review. The committee met five times between January 2011 and May 2012, and consulted experts in geography, geography education, and educational research as part of this task. This presentation will highlight each of the recommendations for professional development and instructional materials in geography, and discuss the use of the guidelines for developing and evaluating professional development and instructional materials.

Needs Analysis of Pre-Service Education for Geography Teachers in Turkey

Eyüp Artvinli (University of London), Hsan Bulut (Ataturk University)

The purpose of this study is to determine the necessity of pre-service training of geography teachers in Turkey. After geography curriculum has been changed in Turkey in 2005, pre-service training of geography teachers has become one of the most important phase in front of geography curricula. In this study, the situation of pre-service education of geography teachers in Turkey has been analyzed from the teachers' perspectives. Thus it has been applied a survey for geography teachers and the results has been analyzed by SPSS. In this paper it is presented how teachers are trained to teach geography and what are the main necessities in pre-service education of geography teachers. It is suggested that it must be developed a new approach within the curricula by the departments of geography education to educate students' teachers according to new standards of the ministry and geography curriculum.

Current Affairs Teaching Styles in College Geography Courses

Yael Sneh (Oranim College)

This study will investigate the knowledge of current affairs among teacher trainers, knowledge that they employ when they integrate current affairs in their geography teaching. The study focuses on the subjects' stances on geographic content and ideas that are influenced by current affairs, and their perception of the students' grasp of current affairs and geography, as well as their attitudes regarding the preferred methods for teaching current affairs in geography. This study shows that the connection between familiarity with the country and knowledge of teaching geography may be stronger or weaker based on the use, mention, utilization and teaching of one-off, continuous, and/or cyclical current affairs events. The teaching of current affairs by the study's subjects comprises different styles, including teaching 'current events and phenomena' and teaching 'current processes.' Teacher trainers who participated in the study teach geography and current affairs at the college as part a study program that is flexible in respect to its content, goals and expected outcomes. Thus, it was to be expected that the study would reveal shared or similar teaching styles by all of its subjects. We chose the qualitative research method in order to study the inner world of the geography teacher trainers in terms of their stances and approaches to the integration of current affairs in their instruction. We will find that the topics, titles, and examples of current affairs that the study's subjects use in their lessons can be divided into the following teaching styles:

Pre-Service Teachers' Attitude towards Teaching Environmental Education (EE) during Practicum in Malaysian Primary Schools

Punitha Muniandy (Universiti Sains Malaysia), Habibah Lateh

Environmental Education (EE) has been introduced in Malaysian Curriculum since 1992. Almost 20 years EE was implemented and integrated across curriculum in primary and secondary schools in Malaysia. At primary level, Geography subject is not included in curriculum. As a result they will learn EE and local studies in this stage. The importance of EE was highlighted in the National Policy on the Environment 2002-Green Strategies on "Education & Awareness". Related to that, EE was found as an important subject that must be known by the teachers, prior to teach EE indirectly in the classroom. Problems occurred while implementing EE in schools such as; less knowledge about EE among teachers, thinking EE as an extra burden for them to teach and etc. At Teachers Training Institute (TTI), EE is a compulsory subject due to complete their training. This study was carried out to identify the attitude of teaching EE among pre-service teachers in TTI. One hundred and twenty five respondents among pre-service teacher were analyzed and the reliability was shown (.712) cronbach alpha. Studies on teachers' attitude was important to identify willingness of teachers to transfer their skills, knowledge and values in teaching process while in classroom, which will strongly effect the students understanding and achievement. Previous studies showed that there were significance between teachers' attitude and behavior in classroom. Study about attitude as a component of affective which includes negative and positive feelings among teachers would be interesting to study about.

Learning and teaching in an integrated geographical education: A project seminar on climate change

Antje Schlottmann (Goethe Universität Frankfurt), Eva Noethen (Goethe Universität Frankfurt)

Geography education for teachers at German universities suffers today from major difficulties: firstly, due to a poor level of integration of universities and schools in academic education and because of limited time resources for practice oriented concerns there are few possibilities for students to gather required teaching experience at an early stage. Secondly, due to an ongoing specialization in the scientific field and a growing gap between Human and Physical Geography, there are few offers of courses that deal with the unity of the discipline which teachers are obliged to represent in their future

professional performance. This seems all the more unfortunate as key problems of our time in the context of global change have an integrative character by nature and that geography could be the prior scholarly field to deal with them. Furthermore, it seems to be indicated to worry about how to acquire young academics for educational research. Our paper presents the concept for a teaching module that aims to meet these deficiencies. Against the background of a pilot project seminar on the issue of climate change we consider past experiences as well as future challenges. The idea of the module and its combined courses is a three stage educational process that integrates theoretical and practical education as well as it integrates physical and social dimensions of climate change (i.e. allocation of and entitlement to disposal of water resources). In terms of a transdisciplinary approach the students are first lead to identify, define and explore particular problems of climate change on a scientific level, in a second step they are advised on the development of a respective teaching unit by means of provided didactical methodology. In a third step the students get the opportunity to teach a class of a secondary school. The analysis of the fourfold feedback by the academic staff, the form teacher, the peers and, not least, the pupils allows for an empirically substantiated supervision. According to the concept of learning via exploring we intend to empower students to convey issues of global change in terms of a modern geography education and to arouse enthusiasm for educational research.

Geographical Education in Time of Crisis – Some Reflections on Teaching Practice

Manuela Ferreira (Universidade Aberta), Branca Miranda (Universidade Aberta)

This paper address how the teaching of Geography can help young people to understand in an informed manner the economic, social and political crisis that Portugal is facing and can act as conscientious citizens and stakeholders in addressing the issues at global, national, regional and local levels. This implies teacher preparation and reflection. We propose the use of inquiry and problem solving learning in Geography in Secondary Education. The general causes of the current crisis are demographic: the low birth rate and consequent aging of the population that has serious consequences as population and labor force decline; economic and financial causes: the progressive abandonment of the activities of the primary sector, agriculture and fishing and consequently Portugal was progressively more dependent on imports of food and feed for livestock; the forest that is important in the Portuguese economy is poorly cared; in the secondary sector traditional industries are declining due to competition of the so-called "emerging economies" and the process of innovation is weak; tertiary activities have an excess of employees in the central and municipal government, the adjustment to the new currency, the euro, was too difficult, the population income is too directed to home ownership and consumer goods. Other causes concern education, social welfare, public administration and governance, unemployment. These are general causes but students should do an inquiry on the specific causes at regional and local levels. Geographical Education should also give a

global perspective of the society and give a contribution to understand the interdependencies between the global and the local. It is also necessary that students try to seek solutions for the regional and local problems by discussing them in an open and informed manner and if possible have some action at local level, which will help young people to become aware of the present realities and look for new perspectives for the future. In Portugal the Geography Curriculum for Secondary Education includes the study of Portugal and of the European Community, but is necessary an adequate management of the syllabuses in order to contribute to students understand the relationship between global and local issues, so to understand the causes and possible solutions to the current crisis. This implies a careful teacher preparation and reflection on action.

The geographical inquiry: Developing intercultural competences for sustainability

Branca Miranda (Universidade Aberta), Manuela Malheiro (Centre of Studies of Migrations and Intercultural Relations)

In this paper is presented the strategy of geographical inquiry, its different phases and highlighted its contribution to the development of intercultural competences with a view to sustainability. The geographical inquiry should be structured in order to respond to a set of questions: What? Where? How? Why? How could it be? How will become? What decision making? What is the impact? What I think about it? What to do? (Roberts, 2003). These questions serve as a guide and requires that students have an active participation in the the construction of knowledge, expressing their opinions according their values. The Geographical Inquiry starts by questioning, the second phase is the collect of information, the third phase is the treatment and analysis of the collected information (students develop critical thinking and decision making competences) and finally students should develop a meta-analysis of the results and of the whole inquiry process. A proposal to develop a geographical inquiry about "how to live in society, respecting the other and the environment in the present and in the future will be presented". Sustainability will be a reality if it is reached a level of equitable distribution of economic and social wellbeing and if environmental conservation is a priority and if is taken into account the needs of present and future generations and the cultural differences. (Roberts, M. 2003, Learning through inquiry, Sheffield, Geographical Association).

Training geography teachers in times of change: Practices and problems

Felisbela Martins (University of Porto)

The Faculty of Arts of the University of Porto, through its Geography Department, has been involved in developing the initial training of Geography teachers since 1988. Even though over this almost quarter century this training has followed different models, such as integrated training, a specialisation course and currently as a Master's degree in Teaching, aggregated with History, it was taken into consideration at all times that the students, as future teachers, should be aware of the relevance and specificity of geographical education, dealing with issues such as curriculum management, teaching methodologies, and the analysis of students' learning processes. These themes have always anchored the conception of a teacher who is questioning and problem-solving, capable of thinking of and on his/her actions. Following on from these guiding principles, we are facing a new challenge arising from the fact that currently many students come from an undergraduate degree in History with a minor in Geography. That is, during their degree, their training in Geography is based on only 9 subjects selected from a set of 14 options. Despite these difficulties, the prime aim has always been to provide these master's students with pedagogical and didactical training, which will enable them to manage the Geography curriculum, both in Basic and Secondary Education, as well as encourage their development in future professional practices. This paper intends to introduce the instruments used to manage the curriculum, such as potential thematic scripts and guides, the planning of didactical modules based on educational situations, and the planning of classes. We will also explore how the practices are implemented and particularly the instruments used by teachers, such as, for example, class diaries, which can ultimately enable them to reflect on both specific actions and their own performance.

Geography, history and landscape: An educational experience of knowledge integration within a field trip

Hélder Oliveira (University of Porto)

Given the new profile of the initial training of History and Geography teachers in Portugal and the need to promote an integral and inclusive education with each student, in the context of a society increasingly specialized, it was considered relevant to fulfil interdisciplinary teaching-learning experience, involving the disciplines of History and Geography. The theoretical work focuses on the problem of integration of knowledge and interdisciplinarity, regarding to an integral and inclusive education of the students. We believe therefore that is school function to seek to foster the integration of knowledge.

Developed in the context of initiation into the professional practice of the Master's Degree in History and Geography Teaching of the Faculty of Arts of University of Porto, this case fulfilled itself by carrying out a field trip, aiming the integration of Geography and History knowledge relative to seventh graders from the school E. B. 2,3 de Santiago - Custóias, where took place the study. It was therefore considered, as a fundamental strategy of operation of interdisciplinarity, the use of the educational potencial of the landscape. For the collection and processing of the data were instruments and methods of distinctive areas, in order to analyze the development of the learning carried out by the students, as well as the analysis to the content of opinions expressed by students regarding the field trip, intending to determine which moments stand out from the teaching-learning integrated experience. By analyzing the content of selected answers for the purpose, we tried to analyze more specifically the potential of direct observation of landscapes in teaching. The analysis of all these data revealed differences in the performance between the two groups, in terms of what they had learned, as well as losses in the learning process, especially in the afternoon period. From the analysis of the content of students opinions was confirmed their joining to the teaching-learning experience, due to several factors. It was also clear that the landscape presents numerous educational potencial, regarding history and geography as a resource for teaching-learning, because it is motivating and raises the development of learning content.

Using mysteries to promote thinking through geography

Joop van der Schee (University of Amsterdam), Jan Karkdijk (Calvijn College)

Using mysteries to promote thinking through geography Geography teachers in many countries report that mysteries are popular in secondary education (Leat & Nicols, 2000; Van der Schee, Vankan & Leat, 2006; Vankan, Rohwer & Schuler, 2007). Many teachers report that these strategies are powerful to stimulate thinking geographically. However, how do we know that this is true? Empirical evidence is scarce. This contribution reports about an experiment using mysteries, one of the more famous Thinking Through Geography strategies (Leat, 1998). This article describes the outcomes of an experiment in which the effect of mysteries on the skills of students in relating phenomena has been investigated. A multilevel analysis on the results of the post test showed that students that used mysteries in geography lessons scored significantly more correct geographical relations than students who did not use mysteries. This article concludes with the advice to integrate mysteries more in geography teaching as training to reach a higher level of thinking in geography. In addition, complementary research in this field should be started to get a better idea about students' geographical thinking and learning. The question, however, still is what the crucial independent variables are to improve students geographical thinking. Teacher reports suggest that the student motivation evoked by a mystery is important but there is more. Reasoning has to be externalised. Many geography class room practices encourage superficial learning, concentrating on recall of factual or conceptual knowledge. "Mysteries lend themselves well to ascertaining the

degree to which pupils understand and can explain causes, processes, and consequences" (Leat & Nicols, 2000). Geography tells the fascinating and complex story of the changing world around us. Teaching geography is not easy if we want to give students a well-structured and up to date overview of differences and relations in and between regions. Mysteries can help us to think about down to earth issues within and outside the domain of geography as well as about learning goals and learning processes. Keywords: Mysteries, geographical thinking, empirical research, motivation

VideoANT as Web-based 2.0 Technology in Geography Micro-teaching

Christo Van der Westhuizen (North-West University)

This paper discusses the process and findings of a case study where web-based 2.0 technologies were implemented in the micro-teaching of fourth-year Geography student teachers. These technologies ensured adequate feedback and reflection, which in general is a shortcoming of micro-lesson facilitation. 'VideoANT' is a web-based video with timeline-based text annotations, and was imported into the university's web-based Learning Management System (LMS). The digital videos of students' geography micro-lessons on VideoANT not only produced easily accessible micro-lessons through the LMS, but more importantly, enabled students to assess fellow students' micro-lessons in a collaborative learning environment, as well as to do adequate self-reflection. Both qualitative and quantitative data were collected, and the results indicate that geography student teachers held positive views on the implementation of these technologies for reaching the outcomes of micro-teaching as well as for their teaching careers beyond their training. Key words: Micro-teaching and web 2.0 technologies, geography education and web 2.0 technologies, web-based technologies in micro-teaching, teacher training and modern technologies.

C08.11-07 - Higher Education

Chair: Péter Bagoly-Simó, Michael Solem

Which professional action skills should teachers have in context with education for sustainable development (ESD)? First results of a an expert consultation.

Gabriele Schrüfer (Universität Münster), Ingrid Hemmer (Universität Eichstätt-Ingolstadt), Michael Hemmer (Universität Münster), Gesine Hellberg-Rode, Péter Bagoly-Simó (Universität zu Berlin)

To achieve an effective education for sustainable development (ESD) in the content-based teaching of the school system, specific professional actions skills are needed for the teaching staff. The success of the content-based teaching is mostly defined by the specific professional knowledge (content knowledge, pedagogical content and general pedagogical knowledge). On national as well as on international level, professional action skills are considered as a prerequisite for a successful teaching. Current studies about the quality of teaching see the analysis of teachers, differentiated into job-related knowledge and skills, as a key factor for a successful process of teaching. The success of teaching actions is mostly determined by specific professional knowledge especially in the spheres of content and context-related competences content and pedagogical content knowledge. The basic competence realizing ESD in class is usually postulated for teachers of all school types. Although, it cannot be assumed that all teachers achieved the needed competence via their teacher training. During a Delphi method different experts and protagonists (mainly in universities, schools, Ministries of Culture and NGOs) will be asked for their opinion related to the required competence of action skills in context with ESD. The first results of this Delphi method will be introduced at the presentation.

Field trips in geography lessons: Promotion of competence in didactic of field trips in teacher training

Kim Pascal Miener (Universität Münster), Michael Hemmer (Universität Münster)

Based on an overview of current concepts for student field trips in geography education and the required didactic and methodic competences that a teacher has to possess, the lecture will show up, how the training concept at our site in Münster uses field trips to gradually build and promote competence in didactics of field trips. For this purpose modular field trips (e.g. to Ruhr area, Spiekeroog or Berlin) for students in secondary school education (students aged from 10 to 18) were developed by our

The Value of Geography in Professional Life: Insights from Geographers in Business, Government, and Nonprofit Organizations

Michael Solem (Association of American Geographers), Jan Monk (University of Arizona)

Drawing on North American experience, this paper presents examples of contemporary geographic practice in private and public sector organizations and analyzes how geographers apply their knowledge, skills and perspectives for problem solving in relation to globalization, environment and society, risks and conflicts, and urbanization and demographic change. The examples stem from interviews conducted with more than fifty geographers for the new AAG book, *Practicing Geography: Careers for Enhancing Society and the Environment*. Among the issues discussed will be how geographers through their professional work act as conduits translating geographic research into business, public policy, advocacy, and consultancy contexts. Our paper addresses broader debates in the discipline as to the value of geography as a professional field and what reforms may be necessary to improve its positioning within the academy and society. There has been rapid growth in career opportunities and need for geographic expertise across the public and private sectors, from small business in local communities to international companies and nongovernmental organizations (NGOs). At the same time, some of these opportunities are in new areas of employment for geographers, and often employers are seeking new combinations of geographical and other skills. Improvements can be made in our undergraduate and graduate programs in the ways that educators inform and advise students about workforce trends and how to connect their skills and abilities to the needs of employers. There is a broad need for professional geographers to be able to perform general skills ranging from time management, writing and collaborating in team efforts to working effectively with computers and applying critical thinking skills for problem solving. With regard to geographic skills, many employers seek individuals who possess competency in field methods, have the ability to work across disciplinary boundaries, and can apply principles of spatial thinking and other forms of geographical analysis to support a variety of tasks and needs. Although many of these general and geographical skills are included in typical geography curricula, it would seem that there is substantial potential for developing methods for cross-training students through greater use of pedagogies such as problem-based learning, inquiry, and service learning, as well as providing more students with opportunities to apply their abilities in professional settings through internships. Improvements can also be made at the doctoral level, where often the hidden assumption is that all or most students are moving toward academic careers. Although the Ph.D. remains an apprenticeship in research, it has also become a qualification for a wide range of challenging careers and executive positions.

Detection of Urban Heat Island Using Student Observations and My World GIS

Kevin Czajkowski (University of Toledo), Mikell-Lynne Hedley (University of Toledo), Todd Ensign (NASA IV&V Facility)

Students have been taking surface temperature measurements through the SATELLITES Program during intensive field campaigns in 2006 through 2011. An Earth Exploration Toolbox lesson (<http://serc.carleton.edu/eet/>) was developed to assist students in analyzing the urban heat island effect utilizing data from the GLOBE Surface Temperature field campaigns within the My World GIS. The SATELLITES Program was established in 1999 at the University of Toledo to engage students in 'real science' and introduce Earth System Science and geospatial technologies into the K-12 environment. The SATELLITES Program has held trainings in association with the AmericaView Remote Sensing Consortium. The GLOBE database contains thousands of surface temperature observations per field campaign from around the world. My World GIS was designed by the Geode Initiative at Northwestern University. Teachers have found it easier to learn than other GIS software. My World GIS comes preloaded with many data sets including demographic information, digital elevation models, and aerial photographs to name a few. The lesson shows students how to download data from the GLOBE website and import the data into My World GIS. Due to the schools that are currently involved with the GLOBE Surface Temperature field campaign, the lesson works best in Midwestern United States or Estonia and Poland due to the number observations in those areas. Students then use the threshold function to find large cities in a region. The students separate the data by rural and urban schools using a buffer around the cities. Other complicating factors that students can check are the cover type, cloud cover, time of day the observation was taken, day of year, etc. The lesson was field tested in Ohio with eleven teachers.

C08.11-08 - Innovative Learning - New & Traditional Media

Chair: Daniela Schmeinck, Joop van der Schee

Chances and Risks of Turning Teenage Students into Researchers

Lars Keller (Universität Innsbruck), Anna Oberrauch (Institut für Geographie)

Teaching geography - i.e. 'the world as it is' - has become mission impossible due to the complex and ever increasing effects of global change. Yet, encouraging students to get the picture of concepts of global importance, like the ideas of sustainability or quality of life (QOL), and strengthening their geographic competences is an important contribution to help them understand what they perceive as 'the world' around them. The innovative research project 'LQ4U - Teenagers from Northern and Southern Tyrol develop visions on sustainable QOL' (financed by Provincia Autonoma di Bolzano Alto Adige 2011-2013) takes this challenge as a chance. In what is called a 'community of learners', students of a commercial college in Vipiteno (Italy) and a high school in Stams (Austria) work together with scientists of the University of Innsbruck over a period of two school years. Before the actual start of the project, an interactive online Learning Management System was established, serving different purposes to students, teachers and scientists. As the main means of communication it helps to bridge the geographical distance between the two schools, stores materials and results, offers links to relevant sources on and outside the platform, creates Wikis, integrates other online software etc. In LQ4U the students are encouraged to develop their own personal research questions, generate hypotheses, plan and execute interventions, evaluate results, and interpret and discuss their findings. This innovative learning strategy should enable the young people to reflect on what they find important for their own (quality of) life. They realize how important it is to think through complex ideas and processes thoroughly and as unbiased as possible. As there is a very close link between the theories of QOL and sustainability, they should begin to understand the need of synthetic thinking and looking at things from different perspectives (e.g. ecology, society, economy). Following the ideas of moderate constructivism, the teenagers turn into scientists, and discover their very own visions for the future. Apart from generating geographical knowledge on QOL and sustainability on the students' side, the university researchers of LQ4U focus on didactical questions facing the chances and risks of innovation in learning and the use of new media: How can they really raise motivation in the classroom? Which role do the new media play for innovative learning? Might these innovative learning strategies ask too much of students who have been socialized by rather instructivist teaching methods? Can school surroundings provide fertile ground for innovative learning? Mission not yet completed.

Understanding the Changing Planet: Online spatial tools tell powerful stories

Anita Palmer (GISetc), Roger Palmer (GISetc)

As the world is firmly into the second decade of the twenty-first century, education is grappling with the most effective ways to integrate twenty-first century technologies into the classroom. This is especially noticeable in primary and secondary grades. This paper addresses the use of cloud-based online map tools to augment, and in some cases replace, the use of traditional atlases to teach geographic concepts to secondary students. It examines a United States National Research Council effort to use these geospatial tools to engage the community to address pressing world issues as reported in the NRC report entitled *Understanding the Changing Planet*. This paper explores student responses to the use of cloud-based geospatial tools as well as the *Understanding the Changing Planet* web portal and ways in which these instruments might make a difference. A basic review of current research of this topic is examined.

Investigating cognitive aspects in digital maps - using VGI to create a child suitable map

Philippe Rieffel (ILS Dortmund)

Today's technical development allows us to find detailed digital map coverage for almost every place in the world through the internet. While those maps (mostly) offer an acceptable level of detail, their design is addressing adults, regarding levels of complexity and symbology. Since the quality and coverage of available free geodata has drastically improved lately, mainly driven by the OpenStreetMap project, this data is used to create similar digital map coverage, but with design patterns, that match children's perception and understanding of space and their surroundings. The work at hand consists of two main parts, an investigation on the spatial perception of children and a practical implementation which reflects these findings. For the investigation on how children perceive their environment, an empirical study has been conducted amongst school children aged 8-12 years. Based on theories of spatial understanding and mental development of children, as described by Piaget, Liben and Downs and Stückerath, the questionnaire aims at getting information about the children's ability to understand a set of different maps. Furthermore it aimed at analyzing the children's understanding of symbols, shapes and colors which are by now widely used amongst maps. This survey has been conducted in Brazil so far and is right now taking place amongst German pupils. Conducting this survey amongst different cultures allows taking cultural differences into account when creating the final map. Another aspect which can very well be handled with a digital map is the aspect of scale. When children advance in their development, the scale on which they interact with their surrounding changes, from neighborhood over urban quarter to city, country and finally the world. This development can be accompanied with a digital map, because it is dynamic in scale and level of detail. The findings from the theoretical work and the survey will be used to create a rendering style sheet to render raster maps from the freely available OpenStreetMap data. This data

and the rendering software 'mapnik', hosted on a dedicated machine will then allow the creation of a worldwide coverage of a digital map, specially designed to cater children's perception. The development of map literacy and spatial understanding of children would greatly benefit from such a digital map. It could be used in education as well as within recreational activities like geocaching or while traveling. Since the project is not finished by now, this is a work in progress report

GIS Awareness and Perception among Geography Teachers in Malaysia

Vasugiammai Muniandy (Universiti Sains Malaysia), Habibah Lateh

Technology utilization in educational purposes in schools is rapidly increasing. Geographical Information System (GIS), as an advanced technology too has been implemented across curriculum in school subjects in various art of the world. Even GIS is not included in Malaysian school syllabus, the awareness of GIS is there among the geography teachers. GIS integration in university syllabus has seeded early knowledge among these teachers. Thus, this study investigates GIS awareness and perception among geography teachers in Malaysia. The objective of this study is to determine the level of GIS awareness among the geography teachers in Malaysia. On the other hand this study also investigates the perception among the geography teachers in Malaysia towards GIS integration in schools, especially in teaching geography. Two stage stratified sampling method was used in this survey. Five hundred and ninety five geography teachers responded to this questionnaire. Questions regarding GIS awareness and GIS perception were self-developed and undergone internal consistency reliability analysis before being used in this study. Binary questions and a four-point scale items were used to determine the level of GIS awareness among geography teachers and a five-point scale items were used in determining GIS perception among teachers. The results revealed more than 50% of the teachers have heard about GIS, even only 30% have used GIS before. However, the awareness doesn't vary much between states and gender variables. Moreover, the GIS perception among these teachers were considered high and significantly contribute a bright chance of future GIS integration in teaching and learning process of geography in Malaysian schools. Keyword: Geographical Information System (GIS), awareness, perception, geography syllabus

C08.11-09 - Preconceptions in Geography and Geography Education

Chair: Fernando Alexandre, Sibylle Reinfried

Connecting argument analysis with conceptual change in a geoscience topic

Dirk Felzmann (University Hannover)

When students construct their conceptions in social interaction, arguments are verbally formulated on conceptual grounds. Being interested in the way alternative conceptions are constructed, the question arises whether there are typical argument structures. To analyse the conceptions and their development in social interaction, a qualitative research study was designed with 14-year-old students from Northern Germany focusing on the topic "glaciers and ice age". Seven teaching experiments, with three students each, were conducted to document students' conceptions. During the teaching experiments, the students were asked to describe their conceptions in group discussions. Students' conceptions about different aspects of the topic were identified by qualitative content analysis (Mayring 2008). Arguments were structured according to Toulmin's Schema (Toulmin 1958): A warrant serves as bridge between the claim (= the alternative conception) and at least one datum. Because warrants often remain unnamed, they had to be reconstructed by interpretation. The following types of arguments were found in particular: - The used datum is correct but the explicit or implicit warrant is problematic. The principle that functions as the warrant is not wrong but misjudged in respect of the limits of its validity or of the relevant dimensions. So, the students may think that the used principle is "always" - rather than "often"- valid in a specific way or the principle refers to other dimensions than the relevant ones: e.g. datum: "a glacier consists of ice", warrant: "ice can extend over big distances", claim: "glacier movement results from extending of ice". - Another type of argument, supporting the emergence of alternative conceptions, are false conclusions drawn by connecting at least two correct data, that correlate more or less with each other, in a causal way. For example: Datum # 1: "Northern Germany is flat, Middle Germany is mountainous." Datum # 2: "Northern Germany was covered by glaciers, Middle Germany was not covered by glaciers". - Within geological-historical discussions, the students often refer to valid present-day principles and transfer them into the past. So, they argue in an uniformitarian way (Frodeman 1995), when they analogize the situation during ice age with the situation during winter: "Plants outlived ice age as seeds", "birds migrated to the south". In summary, an in-depth analysis of the content and the structure of arguments in light of alternative conceptions can help to identify possible starting points for supporting conceptual change in the relevant subject area.

Down to Earth – Meteorite Impacts on Earth. Risk Assessment and Education.

Martin Müller (Accenture)

Meteorite impacts have been an ongoing phenomenon throughout Earth's history and are a fascinating topic in science education. Not only in the past but also today asteroids and comets pose a high risk for our planet. This presentation is concerned with following aspects of the topic: the geographical assessment of the impact hazard, students' concepts about meteorite impacts and the educational implications of the subject. The central aim is to show a way for the educational implementation of the topic in Geography. Geography covers both natural sciences (physical geography) and social sciences (human geography). When trying to integrate meteorite impacts into the Geography, there are multiple points of contact to human geography (e.g. consequences of an impact on rural and urban areas, consequences on infrastructure and social systems on national and international level, consequences on current global economic structures, etc.). Moreover there are tight connections to physical geography as well (e.g. geographical distribution of craters on the Earth's surface, new methods to discover previously unknown craters, consequences of an impact on hydrosphere and biosphere (including mass extinctions), comparison of the impact hazard with the current global change issues). Numerous feature films and TV shows on the impact hazard have been published in recent years and have increased public awareness. However, the content often falls short of being scientifically correct and wrong concepts about impact processes and the threat level are generated. However, many institutions and expert teams define education and public outreach as their core task. USGS, ESA, NASA and the IAA have been the key driving force behind most of activities - spanning from contacts to political stakeholders over NEO search missions to threat mitigation. Thus the geographic community should work on an approach by addressing the topic in public education. There scientific and educational requirements can be taken into consideration. A sample of secondary education curricula in Germany was analysed and the impact topic is already reflected in German curricula. Meteorite impacts are part of the Geography curriculum. Following these findings the interests and concepts of students were studied. Key results show that there is high interest in the subject. Students gather their knowledge both from school lessons and TV documentaries/cinema movies. Students' concepts highly depend on age and gender; most often non-scientific interpretations of impact statistics and size relations are prevalent. The data from questionnaires clearly shows a lack of awareness of the geological timescale ('deep time'). In summary, both the willingness for taking action on public education and the demand for a high-quality educational approach are present today. A concrete way from the impact threat to educational action could be established in Geography.

The geography that WE want to teach! The views of English trainee teachers

Emma Morley (University of Winchester)

Geography is a statutory subject in English primary schools and forms part of the current National Curriculum (DfEE, 1999) however the content of this curriculum is currently being reviewed. The Geographical Association amongst others have contributed to the consultation process regarding what the new primary geography curriculum might look like. Amid this background this paper summarises the initial findings from research conducted with one cohort of English undergraduate primary teacher trainees on point of entry to their course. The research builds on previous work by Martin (2005) who proposes a new way of conceptualising primary geography termed 'ethnogeography'. Trainees from two H.E institutions were asked about any hobbies or interests that they held and that they considered to be related to geography. Further questions were then asked about why trainees considered these hobbies and interests relevant to geography. Finally students were asked in more detail about what they thought should be included in the new English Primary Curriculum for Geography. The findings suggest that trainees perceived that they had a range of geographical related interests and hobbies that are relevant to geography and their future role as teachers of primary geography. Links are made to the work of Lambert and Morgan (2010) who describe teachers as 'curriculum-makers.' Analysis of students' responses with regard to what the content of geography curriculum should be identified five clear subject areas: environmental and futures work; fieldwork; map reading; knowledge of places and learning about current and relevant global events.

I liked it. I love it. Effects of positive school experience with geography on positive affect

Lorena Rocca (University of Padua), Angelica Moè (University of Padua), Giovanni Donadelli (University of Padua)

Positive affect plays a crucial role in teaching, learning and in creating motivational settings. Teachers share big responsibilities as main 'promoter' of their discipline for their students; therefore, what a teacher does, always marks the idea of its discipline in his/her students imaginary. This imaginary is confirmed by those who associate their emotions on a subject to the memories of the teachers who had taught it (Rocca, 2007). Recent research have shown that teachers experiencing positive affect are perceived more enthusiastic in teaching and consequently favor positive affect in students (Frenzel et al, 2009). The following paper aims at investigating which causes can favor positive affect in geography teachers. Four factors were taken into consideration as potential inputs for positive affect: beliefs toward the subject, its usefulness, satisfaction in studying and strategies used to teach. Method 60 pre-service teachers (mean age 22.58, SD = 4.46, 2 men) coming from all around the Veneto region (north-east Italy), were asked to fill in a

booklet of questionnaires as a part of geography course requirements. The questionnaire was organized in 5 different sections: Geography beliefs: 17 items each describing a belief about importance, interest and every impression the teachers got from their personal experience at school with the topic. Geography usefulness: 17 items assessed to what geography was considered useful for. Satisfaction from studying: the SWLS (Satisfaction with Life Scale) were adapted, in order to assess satisfaction from studying. Emotions: from a list of 17 negative and 13 positive emotions, participants were asked to rate the frequency they experienced each one a) during studying and b) during studying geography. Strategies: 25 strategies to teach geography was presented, and the respondents were asked to clarify their respective use. Results To start with, the ratings given to each of the 13 positive emotions experienced during studying were summed up in order to obtain a 'positive emotions' factor. Afterwards they was correlated with: a) Each of the geography beliefs, geography usefulness, and strategy-use scores. b) The satisfaction-with-life score obtained by summing up the five scores provided for each item. Results evidenced significant correlations just with the following beliefs: pleasant, interesting (I have a beautiful recall of the subject), boring (negatively), a subject I know well, a subject I would like to teach and a source of pleasant memories. Ultimately, a series of regression analysis showed the positive relationship between I have a positive recall of geography and I would like to teach geography. Discussion Positive emotions about geography are related to positive experience with the subject and favor the willingness to teach it.

C08.11-10 - Spatial Thinking I

Chair: Sarah W. Bednarz, Detlef Kanwischer

The effects of Google Earth based lessons on spatial thinking skills of Singapore secondary school students

Xiang Xi (Nanyang University)

Spatial thinking is a new frontier in geography education in Singapore. Considering the encouragement of ICT use from Ministry of Education and availability of Google Earth in Singaporean secondary schools, a pilot study was conducted to investigate effectiveness if any of using Google Earth on developing one spatial thinking skill emphasized in the geography syllabus, analyzing spatial and temporal changes in environments. This study adopted a quasi-experimental design and selected two classes from a neighborhood school through purposive sampling. Both classes learnt the topic of coast during 8 sessions of 60 minutes. Students in the experimental group used a predesigned Google Earth learning package in the computer lab, while the control group received exposition in the traditional classroom. Results showed that students using Google Earth in learning performed better in the post-test than that who received exposition, although no significant difference between groups was documented. Supplementary data collect indicated that the positive effect of Google Earth on development of the targeting spatial skill could be attributed to its multiple overviews of geographic features and clear "simulation" of geographic processes occurring at a time scale. Google Earth may be an effective tool to support acquisition of spatial skills in terms of its good visualization and interaction with geographic phenomena and environments. To validate the initial finding, more spatial skills will be intentionally taught and assessed in the discipline of geography in future studies.

Möglichkeitenräume. Eine empirisch-rekonstruktive Untersuchung zur Förderung des reflektierten Umgangs mit Raumkonstruktionen in der Sekundarstufe II

Romy Hofmann (FAU Erlangen-Nürnberg)

In times of increased flows of - often media-based - information, 'truth' is constantly produced and reproduced. News target at our attention and try to persuade us of one opinion or the other. The emerging contingency in world views is decidedly spatial in its nature though. People routinely assign meaning to spaces they inhabit and talk about. As a consequence, one place can obtain diverse values. Geographic education should thus aim at developing skills on the part of students to cope with the variety of spatial constructions - they have to be critically challenged. It is not that students would not be aware of their constructed nature but because spaces are always selectively and subjectively perceived against the background of one's own knowledge and experience.

Keeping in mind the claim of 'deconstruction' it is essential first to delineate what 'critical questioning skills' include in order to reasonably embed them into teaching processes. This leads to the central research question which strategies prove to be feasible to develop students' skills of critical spatial reflection. My dissertation is to be understood as a strategy to teach spatial literacy. Students should develop a more analytical habitus of looking at spatial constructions in their everyday lives. This is to be achieved by providing the students with a set of transdisciplinary tools - resorting to German and art didactics - which they can easily apply outside the classroom. My teaching unit is set up of 5 lessons thematically grouped around 'the city' and urban phenomena as well as current developments (gentrification, guerilla gardening, urban images, memorials). The second main featured aim is the 'constructive interference into systems' (Rhode-Jüchtern 1995: 124): The second part of the study comprises a two-days-workshop in collaboration with artists. In this mapping-process (Busse 2007) the students are animated to actively engage in the rupture of 'conventional' spatial structures. They will develop an alternative idea of its use(s) and constructively transform it. In group discussions, the students will finally recap their experiences. Departing from there, collective orientations and cognitive processes are reconstructed using documentary method (Bohnsack 2003). This last step allows for the testing of the projects' efficiency. First results will be presented. Literature: Bohnsack, R. (2003): Rekonstruktive Sozialforschung. Einführung in qualitative Methoden. Opladen. Busse, K. (2007): Vom Bild zum Ort: mapping lernen. Spatial thinking and GIS abilities – and exposure to geo-spatial technologies – of geography education students in South Africa: Extent, barriers and some solutions

Christo Van der Westhuizen (North-West University)

Following the global trend, South Africa has embraced GIS within the Curriculum and Assessment Policy Statement (CAPS document) outpacing South African educational GIS research, as desired by the e-learning whitepaper. In 2006 the South-African Department of Education introduced GIS as a compulsory part of the Geography curriculum for gr. 10-12 in the Further Education and Training (FET). Scheepers (2006) states that the level of GIS awareness is not yet very high in South Africa. Although many tertiary institutions and private vendors promote GIS through GIS-awareness initiatives, it is also apparent that GIS has diffused slowly through the South Africa education system since its introduction into the Geography curriculum in 2006. At present many higher institutions are offering GIS courses outside education faculties. Higher educational institutions like universities should play a more prominent role in training current and aspirant educators pedagogically and to use didactical methods that meet the needs of pupils to properly prepare them to become more GIS competent rather than just imparting knowledge. In practice though, teachers may often recoil from textbook GIS, because they are left to their own methods and resources to assemble and develop

materials for integration with the existing curriculum. Teachers may also lack information communication knowledge, time to study software or time to explore an appropriate teaching learning approach. Additionally, insignificant GIS teaching-learning time within the CAPS, as well as the absence of a GIS practical on computers during grade 12 exams, because of the digital divide in SA, does not promote GIS teaching as a high priority. Although the digital divide within SA presents major barriers with regards to educational developments, it can also be viewed as an opportunity for academia to meet these challenges. This presentation will firstly focus on the spatial thinking and spatial abilities in general, as well as the GIS abilities of the Geography BEd teacher students at a South African university. It will report on the exposure and knowledge the geography teacher students have had at their secondary schools regarding Geo-spatial technologies. Furthermore, it will attempt to reveal the students' level of spatial thinking skills and GIS abilities before (pre-test) and after (post-test) a six weeks practical course in GIS. Secondly, this paper will briefly report on the main GIS educational barriers experienced in schools of the FET band, and test the viability of a USB friendly GIS-application in a learner centred environment.

Promoting and assessing student's critical spatial thinking skills for significant learning in Education for Sustainable Development through geospatial technologies

Vânia Carlos (University of Aveiro), Norberto Santos (University of Coimbra)

Education for Sustainable Development (ESD) uses a variety of pedagogical techniques that promote participatory learning and higher-order thinking skills (Hopkins & McKeown, 2001), since the use of systemic, critical and creative thinking and reflection, in both local and global contexts, are prerequisites for action for Sustainable Development (SD) (Unece, 2009). Recognizing that all human action has a spatial footprint and the spatial dimension of social interaction, spatial thinking also plays an essential role in ESD (Goodchild & Janelle, 2010). Specifically, geospatial technologies can engage in inquiry for society, in society, and about society, promoting spatial thinking (Bednarz, 2004). This ongoing study follows an action-research methodology, in 2 student classes, whose transdisciplinary strategies to promote ESD, under the theme of 'Sustainable Informed Lifestyles', are supported by geospatial technologies and conceived during a teacher training course. It aims to identify and measure student's critical spatial thinking skills and processes and to answer the following research questions: How to promote and assess Critical Spatial Thinking, on the scope for ESD? Does the use of geospatial technologies promote the development and assessment of Critical Spatial Thinking? Based on a taxonomy of spatial thinking developed by Jo and Bednarz (2009) and combined with Ennis' Critical Thinking Taxonomy (1985) and Fink's Significant Learning Taxonomy (Fink, 2003), the teaching and learning strategies and assessment tools developed are presented. We believe, from student's learning outcomes presented, that this study can reveal shifts on student's lifestyle conceptions. It's also discussed the contribution of this

study as motivational for others, on the scope for ESD. References Bednarz, S. W. (2004). C08.11-11 - Spatial Thinking II

Chair: Gabi Obermaier, John Lidstone

Reason and Representation – The Difficulties of Avoiding Maps without Meaning

Anke Uhlenwinkel (University of Potsdam)

Spatial thinking can mean a number of different things to different disciplines. For cognitive scientists it is often equivalent to solving geometrical problems. In a GIS context it is frequently seen as something like map reading skills where students are expected to detect limitations in spatial representations and inconsistencies in their usage. For a geographer this last perspective has to be widened so that spatial thinking includes the understanding and critical application of geographical concepts (place, space, scale, diversity, interaction, change, perception and representation). Therefore in this context spatial thinking becomes synonymous to thinking geographically in the sense that students are expected to apply geographical concepts to develop a better understanding of the world in which they are living. In Europe you find a broader discussion of geographical concepts as a basis for teaching geography in Britain and in France. While in Britain the discussion focusses on defining the concepts and trying to ground them theoretically, the French discussion is centred round the production of croquis, a kind of map that does not attempt to show facts or data but a geographical explanation of phenomena. Croquis are never finite, but always in the making or stories-so-far. Some of the most popular French cartographers of croquis advice their readers to draw them in pencil to make this quality clear. Croquis are therefore not necessarily GIS-based; but they can be. To draw a croquis you need some knowledge of how to use croquis-specific tools of representation, but more important is the understanding of geographical concepts and their application in geographical reasoning. Only with their help students will be able to structure problems, find answers and express solutions to these problems in the form of a croquis. In the French education much space is devoted to introducing the students to the form of representation, but rather little consideration is put to the question of how the students can elaborate the subject content of a croquis. French studies show that the restructuring of the geography curriculum with the aim of promoting conceptual thinking has not yielded the envisaged results, although French geography textbooks make ample use of croquis. According to the researchers one of the main problems is that teachers did not develop a deep enough understanding of geographical concepts and their representation in the form of croquis. Successfully training teachers' ability to use these concepts is therefore vital to the introduction of conceptual thinking into the classroom. The presentation will explore the challenges and opportunities of teaching geographical thinking and reasoning using examples from German teacher students, who have been asked to create croquis from a set of given

data. Ways to promote a better geographical understanding will be discussed drawing on the British discussion of geographical concepts.

Children's independent mobility in the urban public space: the case of Riga, Latvia

Girts Burgmanis (University of Latvia)

Children after invention of a new paradigm of childhood in late 1990s in social sciences are considered as social actors capable to construct their own lifeworlds within various environments. The valuable interaction with the world beyond home occurs through independent and autonomous mobility which nowadays is endangered by manifestations of late modernity, based on increased use of the car in the everyday transport of children and parents enforced concerns on child's safety. Most of the previous studies reflecting the experiences of younger children from cities of Western Europe and North America emphasize direct correlation between gender and age and level of independent mobility. There is also evidence that unlike to younger children for whom independent mobility enhance locomotor capability and promote development of spatial cognition the autonomy of movement for teenagers allows to improve social skills, construct identities and acquire spatial knowledge of particular environment. However, despite the wide set of studies on independent mobility the experiences of older children are still studied superficially and experiences of teenagers from post-socialist cities are lost at all. In this paper children's, aged 12 to 17 years, independent mobility in Riga, Latvia urban environment is explored considering the trips to school, friends and leisure activities. The study focuses on two issues. First, it reveals which background variables affect children's level of independent mobility. Second, it elicits the effects of independent mobility on children's lives. In this paper the emphasis is on the use of quantitative data to explain children's independent mobility and freedom within urban spatial domain. The data were derived by a questionnaire survey from children aged 12 to 17 in eight both Latvian and Russian speaking randomly sampled urban schools in Riga. The findings of this study reveal that age and distance from home to activity site are crucial factors which constrain independent mobility and autonomy of children. Increase of independent mobility level promotes opportunities for children to improve social skills through sharing way from school to home or inverse with friends and acquire more detailed spatial knowledge of urban environment.

Children's Misconceptions of the Relief with the Use of Maps

Aikaterini Klonari (University of Aegean), Ekaterini Apostolopoulou (University of Aegean)

Understanding the relief with the use of maps is a key concept in geographic education in primary school. Children's map reading abilities are interrelated with spatial perception and the study of misconceptions remains an important feature in learning with maps. In

this paper we present 11-year-old pupils' misconceptions of the natural relief in map tasks from a representative sample of the Greek school population. One out of three pupils identify as steep coasts on maps capes and as steep slopes mountain peaks or mountains. North coasts are also characterized as steep, while south coasts as gentle. There is an indication that the length of the coastline determines steepness of slope, associating long coastlines with steep coasts and short coastlines with gentle coasts. According to the results the influence of everyday experience with natural landscape is positive. Pupils from rural areas more frequently identify gentle and steep slopes on maps in comparison with city pupils. However locality does not affect morphological features identification from maps of the region of residence. 3D maps enhance relief understanding as three times more pupils avoid misconceptions over 2D maps. It is concluded that 3D maps should be incorporated in geographic education and curricula should include local geography.

Building a Spatial Literacy Program in Teacher Education

Diana Sinton (University of Redlands), Kristin Alvarez (University of Redlands)

The growing interest in spatial learning has inspired educators globally to design new curricular opportunities. Though there is little in these efforts that is consistent and common, each unique endeavor provides more information about how the varieties and formats of content work with different audiences and within mixed higher educational contexts. This establishes a wide agenda for research from many perspectives, including teaching, learning, technology support, and the design of professional development. For a range of higher educational settings, we will first provide a simple framework for differentiating among learning environments, audiences, goals, and spatial learning outcomes. In the School of Education at the University of Redlands (California, USA), we launched a Graduate Certificate in Spatial Literacy for Educators two years ago. This program is also part of a Masters degree in Spatial Literacy Curriculum and Instruction. We use a definition of spatial literacy as the confident and competent use of maps, mapping, and spatial perspectives to address and understand ideas, situations, and challenges in society, our everyday lives, and the world around us. Our program is designed to model the spatial and geographic "advantage" for creative and critical thinking in general, and to support the development of spatially-informed teacher leaders who will be in a position to guide others. In this paper we will share our ideas on how foundations of spatial thinking can best be established among a group of teachers who are wholly new to these ideas. We will also discuss how spatially-informed curricula can be built and supported across a range of school subjects, and our initial explorations into multi-modal assessment.

C08.11-12 - Standards, Concepts and Experience 1

Chair: Joseph Stoltman, Armin Rempfler

Setting an Education Research Agenda in the Geographical Sciences

Sarah W. Bednarz (Texas University), Susan Heffron (Association of American Geographers), Niem Huynh (Association of American Geographers)

The National Geographic Society in association with the National Council for Geographic Education, the Association of American Geographers, and the American Geographical Society is engaged in a community-wide effort to produce a road map to guide planning, implementation, and scale-up efforts to improve geographical sciences education over the next decade. This road map, targeting policy makers, stakeholders, funding agencies, educators, and researchers, is being developed by expert committees in three areas: assessment; professional development and instructional materials; and educational research. The context for the project, funded by the US National Science Foundation, is the emergence of the modern geographical sciences and the growing national need for a spatially and geographically literate population. The challenges to large-scale improvement of spatial and geographical literacy are numerous and include: 1) the discipline of geography is not well-understood in the US and certainly not defined as a science; 2) school geography is largely taught by social studies teachers ill-prepared to teach the subject; 3) topics in science such as environmental systems, in which spatial and geographic understanding and reasoning are required, are underrepresented in the curriculum and also taught by poorly prepared teachers with little instructional support; and 4) the traditional discipline-based organization of the curriculum discourages integrative curricular development and instruction across the social sciences, science, and technology. The road map reports will address these and other challenges while identifying gaps in the existing knowledge base. The Geographical Sciences Education Research Committee is focusing on two important questions: What areas of research will be most useful for large scale efforts to improve education in the geographical sciences? What strategies and methodologies can relevant research communities develop and adopt to maximize the cumulative impact of research in geographical sciences education? The product of the Committee is a consensus report outlining a theoretical framework, with recommendations of research priorities. The report will enable scholars to select, develop, and implement research programs, whether individually or collaboratively, which contribute to the knowledge about student learning and teaching in the geographical sciences. This session describes the overall Road Map project and the report, framework, and recommendations of the Geographical Sciences Education Research Committee specifically. Contributions from and implications for the international geography education community are highlighted.

Standards for secondary education in geography – An investigation about teachers' knowledge and attitude

Sascha Haffer (University Giessen), Sandra Hof (University of Hamburg), Johann-Bernhard Haversath

The development and implementation of the educational standards (not only in Germany) has been one of the most important developments in middle school education during the recent years. In Germany, the first version of the standards was published in 2006 by the German Association for Geography. After this, several steps were required for its implementation: curricula and exam questions needed to be adapted to the standards. Furthermore, the standards needed to be included in teacher trainings and teachers' professional development. The aim of this investigative study was to get to know to which extent the educational standards in geography were known and accepted from the teachers. The research questions were: What is the awareness level of the educational standards in geography? Does a relationship between the length of in-service and the knowledge and the attitudes to the educational standards exist? Is there a difference in knowledge and attitude of teachers who studied geography and those who did not. The study was conducted with 112 middle school teachers whose average age was 42.98 years (SD=11.23). Teachers were collected from different parts all over Germany. We collected data with a questionnaire that consisted of seven scales: awareness level, knowledge of standards, attitude towards standards, implementation of standards, effects, large-scale changes and modification. The awareness level and the knowledge of standards were measured with a 'correct' or 'not correct' item, all other scales by five-point rating scales (1 'absolutely true', 2 'rather true', 3 'partly true', 4 'somewhat true', 5 'absolutely not true'). All scales of the newly developed instrument showed a sufficient internal consistency (Cronbach's α - ranges from .67-.89). The results show that 41% of the teachers know the standards but a mere 23% of them use the standards for planning and conducting geography lessons. Considering the knowledge about standards, the results show a mean of 6,3 scores (max. 10 scores). Taking a look at the length of in-service, ANOVA shows no significant difference between teachers who have started recently and those who are longer in duty. Taking a look at the difference between teachers who studied geography as school subject and those who did not (nevertheless they teach the subject). There is no significant difference between the attitude of teachers (t-test, n.s.), but there is a difference between knowledge (study geography: 6,7; no study geography: 5,6; max. 10 scores, $p < 0,05^*$). Generally, it can be asserted that concerning the standards in geography, there is a need to extend the knowledge and the awareness level. For promotion, several recent projects were started. One example can be presented at IGC conference.

Geographic skills in Czech schools: teachers' opinions and a real state

Miroslav Marada (University Prague), Dana Reznicek (Charles of Prague), Martin Hanus (University Prague)

The contribution presents a survey, which identifies ideas and opinions of primary, secondary schools and university teachers about the required performance of students in geography education. We monitored requirements on geography students at the end of the 5th and the 9th class of Czechia's elementary school (=end of primary and lower secondary stage) and at the 4th class of upper secondary schools (graduation year of school-leaving exam - 'maturita'). Survey's respondents commented on the proposal of geographic skills standard, which structure reflects an objective process of cognition (from 'Asking geographic questions' over 'Find out, acquire and process information from various secondary sources including maps' to 'Present the results by oral and written way in conjunction with maps and graphics'). The importance of individual items was assessed using a standard four-rate scale ('definitely' yes to 'definitely' no) so respondents were pushed to decide upon one pole. We assumed that responses of four professional teacher groups mentioned are influenced by factors that have different weights by groups. In particular, these could be their education, teaching experience, personal attributes as well as social representation of geography, i.e. the opinion of his mission in general education. The survey was realized on spring 2011. We obtained 541 responses in total; near one half was from upper secondary teachers. This is near 13 % of teachers addressed. We wanted to verify (a) whether there is significant variability in the measured opinions within professional groups and between them and (b) which items (skills) are acceptable for most respondent, and which not. Results of this evaluation, mainly with help of statistical methods (ANOVA, cluster analysis), were used to design tests for monitoring of real state of acquired geographical skills by Czech students. Some interesting results of these tests are presented in the contribution which is framed by general information about undergoing reform of Czechia's educational (school) system. This contribution was prepared thanks to the research project Pupils' skills in biology, geography and chemistry: research into planned, realized and achieved curriculum in implementation phase of curricular reform, No. P407/10/0514, Grant Agency of the Czech Republic. Authors are much obliged for kind support. Key words: geographic skills, questionnaire survey, primary, secondary and university teachers, Czechia

Teacher training in geography in Germany – (Mis)match between acquired and required competencies

Sandra Hof (University of Hamburg), Stefan Hennemann (University Giessen)

As a consequence of the mediocre performance in international student assessments such as TIMSS or PISA, teacher training is increasingly becoming a subject of debate in Germany. In the course of several reforms, including the introduction of national and

federal training standards, the question has arisen of how high-quality teacher training at universities and in the teacher training colleges should be structured. However, there is no general consensus concerning the required competences due to a lack of concise empirical evidence, leaving an informational gap regarding the curricular contents and the required competencies on the job. As opposed to most other countries, the German system consists of two consecutive phases. This two-stage education offers unique possibilities to assess the acquired competences, and a detailed evaluation can deliver comprehensive information for curriculum adjustment when contrasted with the competences required in the work of teachers in schools. Our objectives are to dissect and investigate the appropriateness of teacher education for the job demands in secondary schools and produce empirical evidence on the state of teacher education in German geography. The main research questions are: What geographical knowledge/pedagogical content knowledge is required in the perception of in-service teachers? What geographical knowledge/pedagogical content knowledge was taught in the two phases of teacher training? Is geographical knowledge/pedagogical content knowledge over-taught or under-taught considering current job demands? We draw on an empirical study that was conducted in summer 2011 in Germany, which covered 179 randomly recruited teachers in the state of Hesse. The main survey instrument consisted of a fully standardized questionnaire that contained more than 70 competency items, separated into geographical knowledge and pedagogical knowledge. The respondents were asked to assess their level of expertise acquired in either of the two stages of their university education on a five-point likert scale. Additionally, all competencies were assessed on a five-point likert scale with respect to current needs in school teaching. The results suggest a considerable mismatch between acquired and required competences. While the first stage of university teacher education mainly provides theoretical knowledge that can hardly be used directly in school classes, it lacks the introduction of sound pedagogical skills that are needed for transferring knowledge to the students in schools. This lack of pedagogical skills cannot be compensated for by the subsequent second stage of practical training, leaving a gap in the highly relevant ability to learn how to teach complex content. Results will be presented at the IGC conference and discussed with respect to potential consequences for the teacher education in general.

C08.11-13 - Standards, Concepts and Experience 2

Chair: Joseph Stoltman, Armin Rempfler

Bottom up – guaranteed success or problematic mission? The implementation of National Standards for school geography in a federal republic on the example of Germany

Ingrid Hemmer (Universität Eichstätt-Ingolstadt), Norma Kreuzberger (Gymnasium Lohmar)

The National Standards for school Geography in Germany for the graduation at medium level (learners aged 16) were published in 2006. A year later 14 examples of tasks presenting possibilities of teaching according to the National Standards followed. At the same time the National Standards for School Geography were translated into English, however without the examples of tasks. The National Standards were not enacted top-down by the government, but developed by a group of experts consisting of Geography educators representing higher education, school Geography teachers, and geographers of the German Association of Geography. The Standards considered among others the International Charter on Geographical Education. This paper deals with the structure of the National Standards (contribution to education, fields of competences, standards, and examples of tasks). The acceptance of and resistance to their implementation as well as ways of implementation in the federal educational system of Germany are being illustrated drawing upon examples. The problems of the bottom-up-strategy and its success will become apparent. The benefit for the teacher-training and school teaching are being discussed. Ann.: At the conference in Cologne 2012 the English version of the National Standards for school Geography in Germany, including the examples of tasks, will be available as printed version. Each attendant of the meeting will receive a copy.

Geographical Education under the Regime of Standardization

Mirka Dickel (Universität Jena)

This lecture aims at a fundamental critique on National Standards as guidelines for geographical education. Three key problems arise from contemporary changes in educational systems due to standardization: 1) The traditional and well-approved philosophical concept of "Bildung" and its basic and crucial meaning for mankind is buried in oblivion. 2) The very matters of "geography" - specific geographical contents and methods - are no longer of (major) importance, as the standards are generally framed, i.e. unspecific to the subject matter. 3) Lessons do no longer cater for personal experiences and pupil's individual development, but they do train for "competences", which focus qualifications and skills, and, thus, train for adjustment and confirmation. During the lecture the arguments supporting these statements are unfolded from an experienced-driven didactic approach that is embedded in scientific

positions that root in humanities especially in philosophical and culture-critical theories. In the course of the argument the standard-based implementations and operations within the educational systems are revealed as strategies promoting social, economic and political structures coined by neoliberalism and neo-gouvernance. In this respect the means of standardization are part of a general social transformation that can be described according to Deleuze and Foucault as the fundamental turn from a society that wields power by disciplin to a socialisation that is driven by control. Therefore, current school reforms toward the meaning of education as a process within which the pupil comes to terms with himself. In order to get back hold on the crucial moment of individual learning we have to concentrate on the particular matters of our didactical business. This means to center geographical education on personal experiences and questions that emerge from the very individual headstrong affections and concerns. It is only in the face-off between the pupil and the very geographical subject matter that the idiosyncretic learning process spins off. This process can never be foreseen, nor guaranteed by the teacher, but the opportunities for learning can be kept fortunate. Learning can never be technologically planned in advance or standardized, we can only retrospectively know, whether learning has taken place.

National Content Standards in the United States: Origin, Impact, Revision

Joseph Stoltman (Western Michigan University), Susan Heffron (Association of American Geographers)

The national content standards for geography in the United States were in response to changes in national educational policies in the early 1990s. After a lengthy development and public acceptance process, the content standards were published as Geography for Life (Geography Education Standards Project, 1994). The goal of the standards was to clearly articulate what students should know and be able to do at three specific grade benchmarks (grades 4, 8, and 12) within the school curriculum. This presentation reviews the standards process over the past two decades from three vantage points. First, the rationale behind the public educational policy changes is discussed. The policy leading to the standards development, the content and topic selections and significant influences on the content selection process will be discussed. Second, the impacts that the 1994 standards in geography have had on geography curriculum, educational materials development and assessment during the past two decades will be discussed as three elements. The initial element was the uptake of the national content standards as the curriculum components of the educational policies within the 50 states that are autonomous educational governing bodies. The second element was the effect of the national content standards on educational materials design and textbooks. The final element was the impact of the national content standards on assessment, and most specifically high stakes assessments by the states and to a lesser extent the National Assessment of Educational Progress (National Center for Education Statistics, 2011). Third, the refreshed edition of the National Content Standards in Geography for 2012 has

been completed and will be discussed. The lessons of nearly two decades of applications to teaching, learning, educational materials development, and assessment provided the basis for the 2nd edition. The major changes in access to reference materials such as the standards between the pre-digital networking work environment of 1994 and currently have resulted in a redesign to meet the demands of different groups of users. The standards in the 2nd edition are very similar in content, but are streamlined and enriched in their conceptual clarity and enhanced examples for applications to geography education. The expectation for greater accessibility by constituent groups of professionals who use the standards for content selection, teacher professional development, assessment, and educational policy implementation is an important projected outcome of Geography for Life over the next several decades. References Geography Education Standards Project. (1994). Geography for Life. Washington, DC: National Geographic Research and Exploration. National Center for Education Statistics. (2011). The Nation's Report Card: Geography 2010. Washington, DC: Institute of Education Sciences of the U.S. Department of Education.

The challenge of meeting the curriculum standards for environment and sustainability learning in school geography: A South African perspective

Di Wilmot (Rhodes University)

Since the transition to democracy in 1994, the South African school curriculum has undergone significant changes and revisions. This has included the development and implementation of national standards to guide the selection of content and pedagogy in school geography. A key finding of curriculum reviews (Chisholm, 2000; South Africa, Department of Basic Education (DBE), 2010) and the Annual National Assessments (ANA) (DBE, 2011) is that the majority of South African children are not meeting the national curriculum standards. The National Curriculum Statement (NCS) (DoE, 2002) and its most recent Curriculum and Assessment Policy Statements (CAPS) (DBE, 2011), has a very strong environmental content focus at all levels and within all subjects especially geography. It requires teachers to integrate aspects of environment and sustainable development into almost all Subjects. Geography is seen as a key subject for this integration with more than 50% of the content focused on environment and sustainability learning. Teachers are seen as having a critical role to play in enabling and supporting the intended learning so that students' successfully meet the curriculum standards. This paper provides a commentary on how the national curriculum standards for environment and sustainability learning in secondary school geography (Year 8 to 12) guide the selection of content and pedagogical decisions (Rosenberg, 2011). Secondly, it discusses a strategy for strengthening teachers' knowledge (and pedagogical content knowledge) and professional practices associated with environment and sustainability aspects of the new CAPS curriculum. A conceptualisation and implementation of a model of professional development that enables teachers to re-orient and align their teaching and assessment practice to the curriculum standards is discussed. Thirdly, a national

initiative (Lotz-Sisitka, 2012) driven by the Environmental community working in collaboration with the Department of Environmental Affairs, non-governmental organisations and teacher education institutions is discussed. The development of a set of Open Learning Resource 'exemplars' that can be used flexibly in teacher education programmes nationally, is discussed. The paper reviews the first exemplar which has a focus on Earth System Sciences and Climate Change.

State of the Art in Geography Education in Portugal

Felisbela Martins (University of Porto)

At the turn of the 21st century, a Reorganisation of the National Curriculum for Basic Education in Portugal was operated, which was organised on the basis of general competences and identified, for each disciplinary area, specific competences and educational experiences with which students should be provided. For the Geography subject, care was taken to design new curriculum guidelines, such that they reflected the directives of the National Curriculum. They were primarily intended to ensure that, at the end of Basic Education, students had become geographically competent, that is, capable of thinking of space so as to be able to act in the environment around them. Thus, a National Geography Curriculum was designed from an integrated perspective, covering the 1st to 3rd cycles of basic education (6-15 years of age). 21 specific competences were defined for the 3rd cycle (12-15 years of age), where the subject is taught independently and not as part of the curricular area of Environment Studies (1st cycle) and the subject of History and Geography of Portugal (2nd cycle). These competences are divided into three domains - Location, Knowledge of Places and Regions, and Dynamics of Interrelations between Spaces. Learning experiences are put forward, to be developed over the course of the cycles, and geography teachers are responsible for organising the teaching-learning process, determining which is the most appropriate to their school and specific class. Students should be given the opportunity to take part in activities which encourage them to observe, record and process information, raise possibilities, formulate conclusions, present results, participate in fieldwork and teamwork. In the 3rd cycle, the subject is organised around an overarching theme 'Discovering Portugal, Europe and the World', aggregating six major topics: the Earth: Studies and Representations, the Natural Environment, Population and Settlement, Economic Activities, Development Contrasts, and Environment and Society. With the exception of the first topic, the others can be taught sequentially or in an integrated manner. At the level of Secondary Education (15-18 years of age), the Curriculum Review was suspended, and the Geography programmes were issued without significant changes in relation to previous guidelines. Over the last decade, however, a number of restraints have appeared, among which successive changes in government should be highlighted. However, the Ministry of Education established learning goals for all Basic Education subjects in the 2009/10 school year. 17 goals were set for the Geography subject, based on a set of epistemological and didactical references, linked to the nature of geographical knowledge and its transposition to the school setting. This paper intends to describe the evolution of Geography curricular development in Portugal.

Changes and challenges for geography education – examples from Sweden

Gabriel Bladh (Karlstad University)

The aim of this paper is to present some perspectives on the situation of geography education in Sweden today. This will be done by presenting discussions brought up in relation to recent national curriculum changes in Geography, and by connecting those issues discussed with challenges identified from the perspective of the Swedish geography teacher education arena. Field research done in Swedish schools has shown that selective traditions of the subject dominate in Swedish school geography, especially in primary and secondary school. The debate initiated in the context of the development of a new national curriculum in geography in Sweden during 2010 illustrates the case well. A strong school subject discourse based on subject content where traditional regional geography still holds the key position is well established. On the other hand, the gaps between school geography vis-à-vis geographic perspectives treated in academic research as well as perspectives related to students' everyday contexts have increasingly expanded in a changing world. A weak national research tradition in geography education also complicates the picture. Examples from the implementation of a new syllabus in the geography teacher education at Karlstad University will be used in order to identify some challenges for geography education given by such gaps. Drawing on the time-space geography, developed by Torsten Hägerstrand and further developed by Pred and others, the need to bring forward a better understanding and application of perspectives on relational space in geography education, will be discussed through presenting some 'key-cases' used in the introductory course in geography. A material flow analysis, looking at the biography of a selected foodstuff, is presented and used to make relations between nature, society and space visible. In another case, space-time biographies in everyday landscapes are represented through a combination of time-geographical notation, photographs and diaries. Based on those examples, some themes for future research regarding geography education will be highlighted in the conclusion.

What German Students Learn about Germany from Geography Textbooks

Berta Hamann (Universität Würzburg), Dieter Böhn (Universität Würzburg)

What German Students Learn about Germany from Geography Textbooks Geography instruction tasks include, inter alia, elucidating various regions of the world to students. An investigation of textbooks intended for use in academic high schools (Gymnasium) was performed to determine what German students learn about their own country. First the administrative conditions of the German school system are presented, because they clearly differ from those familiar in other countries. One such characteristic is the fact that each federal state and each type of secondary school has its own curriculum. Despite this, only a small number of publishing houses serve this market; as a consequence, identical content is conveyed in various federal states. The analysis considers the questions of what is conveyed, which geographic approach is accentuated in doing so, in which grade(s) is Germany covered? A further question considered is whether different

depictions still persist today in western and eastern Germany, more than 20 years after reunification. The geographical concepts analyzed can be summarized in simple terms: of the three methods that are in principle possible for depicting a specific space, only traditional encyclopedic description is hardly used at all; thematically-centered regional geography and a depiction based on systematic geography that presents regional examples dominate. A more traditional approach is taken for dealing with selected cities that are of particular importance for Germany as a whole. In five federal states, an element of regional geography is explicitly included'one's own federal state is covered in a separate chapter. In all textbooks, basic topographic knowledge is established with the aid of blank maps. Germany as a space is covered twice in all federal states'at the beginning of Secondary Level I (grade 5) from a primarily regional geography perspective and at the end of Secondary Level I (grade 10) or in Secondary Level II (grades 11 and 12) where it is dealt with by addressing questions pertaining to systematic geography. Here examples of spaces in Germany are used in the context of numerous topics that address spaces on other levels of scale ranging from European to global. Consequently the student realizes that structures and processes are not national in scope, but rather extend beyond national boundaries. Division of Germany into separate countries that continued until 1990 is still tangible to a certain degree in the examples of space that are selected today. Students in eastern Germany receive much more information about western Germany than students in western Germany receive on eastern Germany. In western German textbooks, very few spaces in eastern Germany are dealt with as topical examples. Keywords: Geography textbooks, Germany, West Germany vs. East Germany

Geography for Younger Children: Some Future Directions

Simon Catling (Oxford University)

Geographical education is in a state of flux in England, as it is in Australia. In England geography has been a required subject in the National Curriculum since its inception in 1988. Currently it is in its third incarnation, but it is about to undergo further developments. The Geographical Association and others have put forward proposals as to how the fourth version of geography for younger children might look. Developments in geography education for younger pupils in Australia, where this is a new departure at a national level, bear some similarities to the curricula in England. This paper considers some of the implications for future practice in primary geography of these developments. It stresses the importance of children's own geographical experiences and of fieldwork in young children's geographical learning. It argues for a problem oriented and challenging approach to translating curriculum requirements into classroom practice, while noting the need for creative approaches to developing children's awareness and knowledge of the wider world. It identifies some of the initiatives and approaches which offer ways forward for primary teachers, while noting the need for further in-service teacher development to help achieve the best learning environments and opportunities for younger children.

Geography Teaching in Indian Schools: Geography Curriculum and Teacher's Knowledge

Thiruvadanthai Geetha (Delhi University)

The sustained positioning of geography in the school curriculum depends mainly on the issues of the scope of the subject, its relevant curriculum, the quality of teaching and the attitude of the public outside. The lack of trained graduate teachers has been the main difficulty in promoting the claim of geography as an important subject in the school curriculum. The policy decisions in terms of curriculum planning i.e. National Curriculum Framework-2005 and the recruitment policy of the government have put pressure on the already fragile status of geography in Indian schools. This study analysed the treatment of the subject and the policy decision to place the discipline in the hands of the non-geography (called social science) teachers. The geography curriculum under the banner of social science at the elementary level has not shifted its focus from the dry description of the geographical facts and a mass of unconnected details to be studied. This in turn has given the policy planners the legitimacy of recruiting teachers who need not be subject-specific experts. The study was conducted in 30 schools in Delhi with 60 social science teachers participating in it. A comprehensive questionnaire followed by unstructured interview was used. 80% of the teachers were trained in other subjects other than geography and found the content easy to 'understand' and 'teach' except physical geography concepts. Poor pedagogic knowledge and lack of specific training in their teacher-education programme perpetuated the problems associated with school geography teaching in India.

Changes in the Geography curriculum and textbooks at the upper primary level in Mauritius: The post-2006 reform

Boullé Pierre-André (Mauritius Institute of Education)

Changes in the Geography curriculum and textbooks at the upper primary level in Mauritius: the post-2006 reform. This paper is based on the analysis of the changes and innovations we brought to the Mauritian geography curriculum in the context of the 2006-2010 reform. It will give background information on the 2006 National Curriculum Framework reform which was the first of its kind at primary level in Mauritius. The paper also examines how emerging themes such as sustainable development, natural hazards, changes in land use and new economic activities in Mauritius have been integrated in the upper primary textbooks we developed in 2009/2010. These are in line with national policies in the context of Mauritius aiming at becoming a sustainable and economically viable small island developing state. It finally reflects on the opportunities that the

designing of new textbooks has provided in integrating innovative pedagogical approaches and also on the constraints which were encountered to abide by the following prerequisites: prevent overloading of the curriculum while integrating new themes and issues; contextualise the curriculum; ensure that geography is 'an informing, enabling and stimulating subject and contributes to a lifelong enjoyment and understanding of the world' (ICGE. 1992) and be innovative and creative in responding to the needs and expectations of pupils.

Undergraduate Geography Education in Canada: How engaged are our students?

Erin Joakim (University of Waterloo)

Over the past decade, there has been increased media coverage regarding declining student engagement along with high levels of entitlement in academic settings. These communications often assert that students expect high grades even with minimal work and that current generation(s) of students have higher levels of academic entitlement than previous cohorts. This study explores the concept of entitlement in relation to undergraduate geography education as well as the linkages between students' sense of entitlement and their approaches to learning. Through literature review and pilot testing, a questionnaire instrument was developed that measures four constructs: academic entitlement, deep learning, surface learning and strategic learning. Survey responses (n=583) were collected at a large public university in Canada, focusing on first and second year undergraduate geography students. This was followed by focus group discussions with students and faculty to explore the concept of entitlement and its intersections with learning styles. Responses suggest that students approach learning in mixed ways, and that approaches to learning intersect with students' sense of entitlement in complex ways. Overall, scores on the sense of entitlement scale were found to be moderate, challenging some of the assertions about today's students that have been made in the popular press. On the other hand, scores across all learning scales were balanced, suggesting a need for increased focus on deep learning strategies in university geography education. The results are then situated within the context of geography education in Canada as well as changing social and cultural norms, increased individualism, rapidly increasing technological advances, increased competition for scholarships, employment, and changing expectations regarding the role of post-secondary education.

New government, new curriculum? Geography on the controversial Spanish curricular move (1990-2012)

Miguel Pazos-Otón (Universidade de Santiago de Compostela), Ramón López Facal (Universidade de Santiago de Compostela), Valerià Paül (Universidade de Santiago de Compostela)

In November 2011 elections, Spaniards gave a wide majority to the conservative People's Party (PP). Since 1990, when the General Organisation of the Education System Act was passed, the changes of ruling party in Spain (from the Spanish Socialist Workers' Party, PSOE, to the PP, in 1996, and from the PP to the PSOE, in 2004) have meant an in-depth debate over the curriculum, affecting all the subjects, thus including geography. These discussions have not always led towards a practical shift, but have shown differences in focuses, approaches and contents, and even dissimilar ways to understand pedagogy. Although still it is very soon to grasp the extent of the predictable curricular modification after the last elections, it makes sense to reflect on the previous disputes in order to note the most controversial issues. This analysis will try to highlight the different underlying understandings of geography and the changing meanings attributed to this discipline. The examination will be basically devoted to the secondary school (both compulsory -from 12 to 16 years- and non-compulsory -from 16 to 18 years- stages), where the discussion has been more intense. Disagreements have been partially focused on the tension between the curriculum decided by the Spanish government, on the one hand, and by some of the devolved governments (autonomous regions and nationalities, so-called in Spain "autonomous communities"), on the other. Geography has been particularly affected by this centre-periphery controversy, usually in a sort of conflict between nationalist visions installed in the central government and in autonomous governments such as those of Catalonia or the Basque Country. In this respect, the paper will consider in a second stage how two autonomous nationalities with their own language, Catalonia and Galicia, have adapted the general Spanish curriculum of geography. Legally, they both are supposed to have wider curricular possibilities than regions without their own language, but surprisingly one has been more controversial than the other in curricular terms. This differential behaviour will be scrutinised as well, focusing on geography matters.

Changing governance regimes for business partners in regional and local development: the past and future of chambers of commerce

Robert Bennett (University of Cambridge)

Public-private economic partnerships are now a widespread policy approach, but the private sector partners who are essential to the partnerships vary greatly in capacity to participate. Some are designed for a 'public purpose' to act as policy partners, but most are founded and maintained primarily for business purposes. This paper examines variations between countries in the capacity of one of the leading local-regional private sector partners used in most countries: chambers of commerce. Chambers have the advantage to government that they are democratically elected from the business community, have transparent governance that offers legitimacy, and are locally-rooted. They offer advantages over ad hoc and government-appointed bodies that often carry no weight with businesses allowing governments to draw on existing networks of traded and untraded dependencies between businesses, providing engagement and dissemination of information about policy needs at low cost, with no set-up costs, and are self-maintaining. However, local chambers of commerce vary between countries in partnering capacity chiefly as a result of the different regimes that govern them: private law and public law. The paper reviews the strengths and weaknesses of these two regimes, drawing on the presenter's recent book: 'Local business voice: The history of chambers of commerce in Britain, Ireland and Revolutionary America, 1760-2011', published by Oxford University Press 2011, 926 pp. Private law chambers such as those in Britain and the USA are often small, uneven in coverage, and depend for government attention on goodwill or the weight of publicity and campaigning. Their public law counterparts in France or Germany have larger size, more uniform coverage, and assured points of entry for business views with government. As partners, private chambers are thus less predictable as participants for government, but where they do participate they are closer to market needs and have a stronger scope to diffuse participation to the business community through networks and local clusters. Public chambers are better resourced and have privileged public status, but their ability to deliver effective involvement is limited because they depend more on the state to activate, may be ignored by their 'members', and may find it difficult to advocate 'difficult' policy solutions. Both systems have experienced substantial reforms since the 1990s to encourage improved effectiveness. For the future, increasing fiscal austerity is likely to lead governments to draw more heavily on chambers as partners, either to reduce public expenditure or to improve the depth of business involvement being sought. The paper will examine some of the challenges of achieving these goals.

Is the treatment of risks different in the case of public and public-private transport projects? The case of high speed railway projects (TGV) in France

Geneviève Zembri-Mary (Université de Cergy-Pontoise)

Key words: risks, TGV, public projects, public-private projects. High speed railway lines have been planned, financed and built in France with two different types of multi levels partnerships: - public partnerships : Réseau ferré de France (RFF- which owns and develops the french railway network), the State and Region(s). - public-private partnerships (RFF-private companies) with a PPP contract or a concession contract. A PPP contract shares the financial risk between the public and the private partners. This type of contract has been criticized because of the cost which the public authority has to assume. In the case of a concession contract, a concessionary company can finance the building and operate a transport infrastructure by perceiving toll receipts from users. Transport projects can exceed certain cost limits and completion times and not always meet the initially determined objectives (like traffic forecasts, profitability forecasts). Risks, whether social or political (objection to the project from the public or local elected representatives), financial (additional costs), technical (such as a rockfall during the digging of a tunnel) or environmental (such as the effects on the ecosystem) are therefore particularly present in project decision-making processes, especially given that our society is largely concerned by uncertainty. This article examines the following research question : do each type of partnership (public or public-private) influence differently the treatment of risks and the respect of the objectives of the high speed railway projects in France ? The first part analyses different criteria (time, cost, traffic, profitability) to show if the projects have or not achieved their objectives among their are public or public-private. The second part analyses the decision making process of each project and the treatment of the social, political, financial, institutionnal risks by each partner and its impact on the cost, time, traffic, profitability of the projects. The decision making process can be the application of a procedure or an adaptation to a particular context. The third part proposes a critical analysis of the practices of the treatment of risks in the case of a public project and a private-public project. It proposes a diagnosis of the good practices and the differencies and similarities of practices of the two types of projects.

Framework Governance: A Perspective of Political Steering in Geography

Tobias Federwisch (iq consult)

During the last decades, the nation state has been fundamentally changed. One of the particular characteristics of this change is the emergence of a neoliberal state system, which is often accompanied by a territorial reorganization of the nation state in favour of sub-national (regional, urban) levels. In this context new types of governance can also be observed. According to this, a successful steering of society does no longer depend on dominant government structures, but on a network-like cooperation of different elites. Social sciences benefit from the upturn of governance. In particular, the governance approach has contributed to deepen our understanding of that new type of political

steering. However, it is problematic that the governance approach is being assumed by other disciplines without closer examination. The cognitive possibilities and scientific results of such disciplines are therefore closely connected to the dominant viewpoint of the governance approach without sufficiently taking into account the research interests of the respective disciplines. The lecture deals with the integration of the governance approach into geography and points out the consequences of a blind assumption of terms and concepts. This includes a short introduction to the history of the governance approach, from which its dominant viewpoint can be deduced. Secondly, I will explain the central deficits of the governance approach, which have to be taken into account when integrating it into geography. To conclude, I will advertise a geographical perspective which is aware of those limitations and leaves 'space' for the specific interests of geography.

If all governance is territorial, is territorial governance anything more than just governance?

Dominic Stead (Delft University)

Various publications and policy statements by international bodies such as the OECD and the Council of Europe have served to highlight the importance of place or territory in governance. These have undoubtedly contributed to greater attention to the notion of territorial governance in Europe, which can for example be found in 2009 Barca Report on Cohesion Policy reform -- it calls for a more 'place-based' approach to policy-making -- and current plans for European regional policy beyond 2014 -- it calls for greater sectoral and territorial integration of Cohesion Policy programming. Clearly the term territorial governance must imply something more than just governance alone if it is to make a meaningful contribution to policy or academic debates. So what exactly is the difference between governance and territorial governance? After all, governance is always concerned with a specific territory. This paper attempts to unravel the differences and implications. While a number of definitions of territorial governance can be identified, few of these help in clearly distinguishing between governance and territorial governance. The OECD for example defines territorial governance as 'the manner in which territories are administered and policies implemented, with particular reference to the distribution of roles and responsibilities among the different levels of government (supranational, national and sub-national) and the underlying processes of negotiation and consensus-building' (OECD, 2001a: p.142). Meanwhile, the Council of Europe define territorial governance in terms of 'the way in which the territories of a national state are administered and policies implemented, with particular reference to the distribution of roles and responsibilities among the different levels of government (supranational, national and sub-national) and the underlying processes of relationship, negotiation and consensus building' (CEMAT, 2006: p.7). With the possible exception that greater emphasis is given to the multi-level dimension, both of these definitions are not so dissimilar from general definitions of governance. This paper argues that territorial governance might be distinguished from

'plain' governance according to two key criteria: the prominence of place or territory in governance processes and the importance of sectoral integration. References CEMAT (2006). Resolution n°2 on Territorial governance: empowerment through enhanced coordination. 14 CEMAT (2006) 13 Final. Council of Europe, Strasbourg. OECD (2001). OECD Territorial Outlook. 2001 Edition. The Art of Mutual Adjustment and the Science of Critical Rationality: Theory for Reaching Decisions in Environmental Assessment

Richard Hill (University of Cape Town)

This paper presents a normative, methodological theory of the Environmental Assessment (EA) process that interlinks two primary concepts, namely, critical rationality and mutual adjustment. Originating from modernist planning theory, critical rationality is most pertinent to the assessment stage of EA in ascertaining the consequences of proposals, and later in providing justifications for decisions taken. Poststructural and postmodern critiques have disparaged rationality as an inappropriate approach to decision making. The paper argues that a reinvigorated, intersubjective, and critical approach to rationality is essential in EA. However a formalised process of mutual adjustment, sourced from theories of public sector decision making is most appropriate in the decision making (or decision shaping) that occurs in scoping and evaluation. In multi-actor decision making, participants adjust to each other's interests in agreeing on a course of action in a process that embodies social learning. Where mutual adjustment fails and consensual action is not possible, a decision must be taken and then imposed, subject to the conditions of critical rationality. This theory of the EA planning process is outlined for each of the stages of scoping, assessment, evaluation, and decision.

Seeking Environmental Governability in Mexican Protected Areas: From top-down to participatory approaches

Ludger Brenner (Universidad Autónoma Metropolitana)

Seeking Environmental Governability in Mexican Protected Areas: from top-down to participatory approaches This paper adopts a political ecology approach to analyze the increasing social-economic complexity which has faced environmental governability as well as participative governance in Mexico during the last 40 years. Based on in-depth interviews conducted with key actors over a two-year period (2006-2007) in the well-known Sian Ka'an Biosphere Reserve (Yucatán Peninsular, Mexico), three periods of different governance regimes are identified. Then, governance-related challenges are presented in chronological order. Emphasis is placed on shifts in actor constellations, opposing interests and actions that still hamper the development of integral and participative governance. Moreover, means and tools that have recently been applied to establish more participative governance structures are described and critically evaluated. Study results show that both structures and mechanisms to conciliate conflicts among

conservation-centered actors and other stakeholders are still lacking. As a consequence, involved actors continue to pursue their individual interests beyond institutional frameworks. Therefore, there is still a need for conceptual and strategic advancement to foster the effective and socially-balanced management of Protected Areas. Given this complex situation, an explicitly actor-oriented environmental governance could be an appropriate way of mediating the conflicting interests among all actors involved. Keywords: Environmental governability & governance, Biosphere Reserves, Yucatán/Mexico

Improvement of environmental quality governance in the Russian Federation based on the integration of European experience

Viktor Plyusnin (RAS), Valery Kravchenko (RAS), Adrian Hoppenstedt (University Berlin), Wolfgang Wende (University Dresden), Anja May (University Dresden)

The tools of environmental quality governance used in Europe and adapted to Russian conditions are considered. These tools are directed at improving the administrative, legal and economic mechanisms regulating the procedures of planning, coordination and implementation of planned activities. Such projects include: - Development of methodological framework for the assessment of environmental impact and performance of Environmental Approval of proposed activities; - Development of methodological framework for the regulation of intervention in the natural environment by means of a compensation mechanism of the disturbance, arising during the implementation of projected activity; - Provide the tools of landscape planning and the use of these tools as an information base for impact assessment and regulation of intervention. Russian-German Guidelines for environmental impact assessment and performance of Environmental Approval of planned activities are proposed as the first tool. The following things are described in this tutorial for the first time in Russian practice: - Scoping and screening techniques; - Current status of the environmental impact assessment, based on componentwise analysis in terms of its sensitivity and importance; - Methods of identification of influencing factors and prognosis of environment disturbance in the context of environmental condition. This tutorial introduces the preliminary assessment procedure, which allows optimizing the environmental projects monitoring and making this sufficient to guarantee the preservation of the environment. As the second tool methodical recommendations on the development of measures to prevent, reduce, compensations and replacement of damaged natural environment arising from the realization of the planned activity are proposed. These recommendations take into account the European experience and are adapted to the Russian practice Landscape planning as a tool of territorial planning and ecological zoning in Russia has no validity. There is not any law on obligatory implementation of landscape planning. However a number of laws in Russia (Land Code, Building Code, and the Law on Protected Territories) provide zoning of territories for various purposes. The main objectives of such zoning are: - zoning of territories for town-planning activity; - zoning of territories of

settlements; - zoning of separate territorial zones. Assessment of environmental condition, purposes of territory use and actions for achievement of these purposes in such documents are considered with different degree of detail depending on a document kind. As exemplified by zoning of a territory of especially protected areas the level of detail is the highest, at town-planning zoning ecological questions are considered superficially. The information contained in results of the listed kinds of zoning is not enough for the environmental impact assessment.

Reservoirs of contradictions: Damming the Amazon

Marcelo Salazar (Instituto Socioambiental), Mauricio Torres (University of Sao Paulo), Natalia Guerreiro (University of Sao Paulo), Juan Doblaz (Instituto Socioambiental)

It is a very important task to question the consistency and the objectives intended with the recent ensemble of policies directed to the Brazilian portion of the Amazon and its populations. When one does so, it becomes suddenly clear the intern incoherence of these policies: speeches that proclaim the intrinsic value of socioenvironmental practices against predatory activities coexist with measures intended to appeal major economic interests. In the latest decades, we watched the creation of several conservation units and indigenous lands in Brazil. The Amazon map has been colored with mosaics of such genre of protected areas, proudly exhibited by the Brazilian government to the world. Frequently, these actions were adopted as a response to massacres and other conflict related events that occasionally made the global press. Nevertheless, beyond formalities and in the concrete field, we have reasons to believe these public policies are far behind the minimum required to face the problem, and the mosaics as well as sociobiodiversity corridors not always fulfill their intended objectives. In fact, the government seems to go in the opposite direction, by weakening the existing environmental legislation to make it easier for large projects to be installed in the Amazon. For Almeida & Marin, this movement could be called 'an agristrategy', consisting of a political and juridical construct aimed to remove formal and legal obstacles to capital's large ventures, as well as the insertion of additional extensions of land to the market. Focusing on the water business, the governmental plan for the decade predicts 66 large hydroelectric power plants and 177 small ones. Alongside of the dams, it is expected a massive investment in mining and other sorts of infrastructure, such as roads, ports and transmission lines. With all that, we must probably witness an enormous pressure over natural resources and traditional land rights and way of life of the residing population. This paper intends to explore the premises above throughout the analysis of two hydroelectric projects. Belo Monte, in the Xingu River, and the Tapajos river complex, both in the Brazilian state of Pará. Such examples shall allow us to describe and investigate the connivance, and therefore responsibility, of Brazilian government in reported cases of disrespect to the regional sociobiodiversity. Through a dialectic prism, we understand that capitals territorialisation embeds contradictions, and we aim to demonstrate that these projects

implementation, without modifications, shall aggravate land conflicts and facilitate predatory activities, such as illegal logging, land logging, deforestation, and violation to traditional populations rights.

C08.13-03 - Governance - key theoretical and methodological issues, main research directions 3

Chair: Jan Bucek, Shannon O'Lear

'Best mayors', 'best governments' or 'best cities'? Methods for assessing the quality of local governments in major Polish cities.

Lukasz Mikula (Adam Mickiewicz University)

Effective and responsive local authorities and well-functioning public institutions are important elements of the urban competitiveness. The quality of political leadership, managerial abilities of senior officials, the organization and work standards of administrative staff have influence on the daily life of residents, the city's attractiveness to investors and the capacity to obtain external funding for urban development. The high value assigned to the public management is clearly visible in many urban rankings in Poland, which are usually prepared by scientific institutions, leading socio-economic magazines, consulting firms and national associations of local governments. Some of these rankings are even directly called 'Mayors ranking' or 'Local governments ranking'. However, there are many methodological problems in objective assessing the quality of urban governance. The main difficulty is to extract the elements related to the public governance from the characteristics relating to the city as a whole. Impact of the local public administration at the various spheres of city's life is usually very diverse. In some areas it may be of fundamental nature (shaping the structure of budgetary expenditures, raising funds from the EU to the local public investment), in others - a more limited. In the empirical part of the study, it was decided to use for the analysis such indicators and figures that can be unambiguously interpreted as relevant to the issue of local management and are possible to be objectively measured (by the Central Statistical Office). These have been divided into 4 groups: 1) the political circumstances, 2) the dynamics of local tax base, 3) efficiency in obtaining funds from the European Union, 4) the spatial policy. The 10 largest Polish cities have been taken into account. The results have been confronted with some of the most popular urban rankings in Poland, pointing out to key methodological problems. Appreciating the wide scope of information gathered in many published rankings, it must be underlined that there are some dangers associated with the use of some of the popular indicators as the base for pointing out 'better' and 'worse' mayors or governments. Key concerns being elaborated in the paper are related to the assessment of the local expenditures and cities' debts. The even more difficult problems arise when data for Polish cities are compared with urban centres of similar size within neighbouring EU countries (Germany, Czech Republic, Slovakia, Lithuania). Because of the institutional (constitutional, political, financial and planning systems) differences, making the international comparisons of local governments' 'quality', using the same methodology for each country, seems hardly possible.

Environmental Governance Rescaling

Juan Cervantes (Universität Weimar)

The impulse that the Sustainable Development has gained among the actual speech involves many paradoxes, it has assumed the importance in the moment when the global power centers declared the shortcoming of the State as promoter of development and proposed the market as its replacement, while declaring also flaws within governmental planning. All of these factors denote a deep restructuration on the modes of governance, caused in turn by an evolution and succession of intertwined social, economical and political processes. Anyway, it could be considered that they all had a common root on the contemporary processes of globalization and the economic changes it has unleashed.

Sustainable development isn't just about ecological and environmental issues, in order to instaurate a successful environmental policy, the concept must consider and include political, economical and social processes, which are intertwined with socio-spatial notions of dynamic restructuration of the modes of governance and regulation, and that in turn, involve changes in the 'state – society – market cycle' as a permanent process of selection and institutionalization.

In the understanding of the concept of rescaling as defined by Gualini (2006): '...as part of a restructuration of the modes of governance and regulation involving changes in the state-society relation and its influence on spatial relationships'. It could be considered that deepening in studies of the environmental politics and governance between developed countries; examining the political and economical national contexts as well as the creation of Sustainable Development Strategies and analyzing the fulfillment of their objectives, is a decisive step in order to evaluate how the overarching infrastructure context of each country can represent a decisive pressure that can alter the objectives of the National Sustainable Development Strategy and how this in turn may influence the environmental governance at a regional scale on very specific regions within each country.

Spatial Governance between Stability and Change - Case of the Metropolitan Region Hamburg

Sabine von Löwis (Centre Marc Bloch)

The paper addresses a case study of a finished PhD work analysing how and why interregional and cross border city regional governance structures change over time. It introduces a model to characterizing and analysing dynamics in spatial governance by using the criteria 1) goals and norms, 2) actors /actor constellations, 3) mechanisms and forms of coordination, 4) multilevel governance and 5) the relevance of resources and power. The paper discusses and reflects on changes in metropolitan governance in the city region Hamburg over a time span of 20 years with special focus on the methods and

model applied tracking and understanding reform and transformation of governance. The paper focuses on the importance of different levels of governance from local conditions to the relevance and influence of national and subnational governance levels in a multilevel context. Concerning the character of dynamics a change between stable situations of governance (e.g. small process adaptations) can be separated from dynamic situations in which strong changes happen (e.g. extension of the territory, fundamental new strategic orientation). The stable governance situations seem to be followed by dynamic situations in the way to stabilise the before developed new forms, goals, mechanisms of coordination, etc. Dynamics evolve through actors, new ideas, certain processes of interaction and coordination, a context which supports changes. All together leading to a certain outcome of a new governance structure - gained for or not. Context, actors and certain actor constellations have been shown very influential on changes in the metropolitan governance of the metropolitan region Hamburg. Within the case study of the metropolitan region Hamburg the above mentioned criteria of governance have been analysed over a time span from 1989 to 2009. The study shows that individuals have changed but the institutions they represent have been almost the same within the governance structure. Important have been the constellations of actors which lead to windows of opportunities to allow reforms. Similar to the same institutions involved, mechanisms and forms of coordination have not changed essentially. It even can be said, that a number of mechanisms persist while new ones develop over time in parallel to 'old' ones. Radical but in a rather subtle way norms and goals of governance changed. Globalisation and internationalisation as strong and dominant issue emerged while cohesion issues and sustainable development lost importance, but are still in place. The paper discusses the analysis of governance change, characterises governance transformation and through this comes to conclusions and recommendations about metropolitan dynamics illustrated by the case of the development of the spatial governance system of the metropolitan region Hamburg.

Urban project spaces in French river cities: Which governance?

Nicolas Raimbault (Université Paris Est), Jean Debrie (Université Paris)

Urban development projects involve some complex relationships between institutional public agents, who govern local territories, and economic agents, who make urban economies. These relationships between economic agents and urban agents are embodied in exact projects which are set in urban spaces. Thus, they result in geographical governance based on arbitration about available land uses between these agents, in a context of reduction of available land resources. The study of several urban projects in river cities is a fertile fieldwork to analyze this governance. In these cities, there are lots of exchanges between the agents of the field of the river (port authorities, inland waterway managers, transport and logistics firms) and the agents of the field of the urban government and development (the different local and national governments, developer firms and urban development public corporations). These exchanges, set up to run river

and port projects, are concerned with large area spaces in the heart of urban agglomerations. The land values of these areas are often much higher than the traditional industrial uses that are theirs. Thus, in river cities, the urban development stakes are characterized by tensions between urban renewal of river port wastelands and industrial and productive activities maintaining. Land negotiations are the driving forces behind governance between agents and spaces of different status. Several French cases studies will enable us to analyze this governance, i.e. these relationships between economic agents and urban agents. Both the participation of a port authority in an urban development project on port spaces and the contribution of a municipality in a port development project will be studied. On the contrary, the case of oppositions or indifferences between port authority and municipality on specific places will be also analyzed. These examples enable us to approach the different dimensions of these exchanges. French cases studies are stimulating from the perspective of a geographical approach of governance field because river and port spaces are most of all state property in France. These lands, often located in the heart of urban agglomerations, are not historically part of the field of local public policies. Thus, the negotiations between land uses in towns (residential versus production) are deployed on different property lands (urban property lands versus state property lands). By this way, they are displaying the general complexity of the compromises which have to be found in urban spaces where land resources are limited. It shows which kinds of governance are developing around specific projects and spaces.

Coltan from Central Africa, international trade and implications for any certification

Monika Dittrich, Raimund Bleischwitz (Transatlantic Academy, Wuppertal Institute)

The exploitation of coltan in Central Africa can be considered a case of conflict minerals due to its nature. Many international organizations and bodies, national governments and private sector organizations seek to address this conflict, in particular via transparency, certification and accountability along the material supply chain. This paper analyses the international trade dimension of coltan and gives evidence on the dimension of illicit trade of coltan. The authors start from the hypothesis that illicit trade of coltan sooner or later will enter the market and will be reflected in the statistics. The paper is structured in the following manner: first, a short section gives a profile of coltan production and markets; second, an overview of the mining situation in the Democratic Republic of Congo (DRC) and related actors. The third section addresses mechanisms, actors and measurement issues involved in the international trade of coltan. The final part draws lessons for certification and conflict analysis and offers some guidance for future research. The paper identifies two main possible gateways to trace illegal trade in coltan: the neighboring countries, especially Rwanda, and the importing countries for downstream production, in particular China. Our estimation is that the value of such illicit trade comes close to \$ 27 million annually (2009), roughly one fifth of the world market volume for tantalum production. With regard to any certification the paper concludes that this will become challenging for business and policy: (a) Central Africa currently is the largest supplier of coltan on the world market, many actors profit from the current situation and possess abilities to hide responsibility; (b) China will need to accept more responsibility, a first step would be the acceptance of the OECD guidelines on due diligence; (c) better regional governance in Central Africa comprises of resource taxation, a resource fund and fiscal coordination. An international task force may provide more robust data, however more research will also be needed.

A Study of Geographic Divisions of Islamic Lands

Abbas Ahmadi (ZISTA Co)

In the Name of God Abstract: Land division is one of the administrative-political methods, made to facilitate the provision of security, improvement of social circumstances and public welfare of society. This issue is based on different and distinct methods among

different nations and tribes. In Islam, land divisions of the early Islamic centuries considerably differ from those in the contemporary period. Studies reveal that divisions of Islamic lands were originally derived from the methods of forefathers, but in the next centuries, especially in the 3rd & 4th centuries of Hijra or, in other words, in the golden period of geography, geographic Islamic criteria as well as religious criteria constituted the base for division of Islamic land. Finally, in contemporary period, domestic divisions of countries and Islamic nations are based on socio-political criteria and observations. Thus, it can be concluded that the attitude toward geographic divisions of Islamic lands, both domestic and foreign, have been complying time conditions during history. Key Terms: Country Divisions, Islamic Land, Country Divisions, Arabia, Iran, Afghanistan, North Africa

In Unit with EU Real Conditions of Entry to Economic and Monetary Union in Peripheries of the European Union after Financial Crisis

Balázs György Forman (University of Budapest)

In unit with EU Real Conditions of Entry to Economic and Monetary Union in peripheries of the European Union after Financial Crisis Keywords: EURO, Optimum Currency Area, Convergence, Public Administration, Financial Crisis In A Theory of Optimum Currency Areas can know the area of economic and monetary union to adapt to asymmetric economic crises can be by budgetary transfers and or research and development in each countries and regions. In the optimum currency area, the foreign trade are between in legal to each other independent corporations between the member states. The theory did not calculate with a multinational companies and consequences and effects of its operate. The theory assumed indirectly the all member states of optimum currency were able to adapt by R+D and investments of itself own corporations. Can true conditions in peripheral countries, or can not? Attention of decision makers avoid to fact that the medium level territorial public administration and local governments are not able to its work. The causes are differentiated: . - Fragmentation of local governments - Demography: permanently declining population. - Spatial: increasing spatial differences among settlements. - Technology: in case of some task of local governments changed the technology (environmental management). - Finance: deciding question how can finance the local governments that will not raise spatial differences. - How can we interpret the concept of subsidiarity?

Branding regions

Ida Grundel (Karlstad University)

The purpose of this presentation is to discuss how different kinds of representations of regions form a part of the institutionalization and creation of new and older regions of today. As a result of the discourses of new regionalism, we see ongoing processes where culture and identity are seen as important parts to create strong and competitive regions, which have become more and more important for peripheral and weaker regions around

Europe. Regional culture and identities are seen as part of different soft factors that are seen as strengthening the regional level and in that way contribute to the attractiveness and competitiveness of the region. It is also believed that different soft factors will strengthen the inner unity in the region and thereby lead to further development. Culture and identity have to a greater extent than before been given an economic value. By enhancing the distinctive attributes and features of a region such as culture, it is said to be more competitive in an international and national context. Different representations of the regions are used to create an image of the regions. This connection between regions and regional features could be seen as a result of a political agenda where it is the uniqueness of the region that is enhanced to create an idea of the region as a base for identity construction. By creating this attractiveness within the regions in different contexts, it exist several different representations of the regions in the same time. This altogether creates the identity of the region. Earlier it was possible to say that the marketing of regions and places mainly aimed to attract visitors, but today it is rather about attracting visitors, business, investors, new inhabitants and in scarce regions even to keep the inhabitants. There is also an emphasis on cooperation across borders between regions in different border areas between the member states in the EU. But in the same time the regions are also seen as competitors both nationally and internationally. Different regional policy programs enhance the importance to create strong, attractive and competitive regions. But what does this actually mean? By studying different representations of two peripheral border regions in Europe, Värmland in Sweden, and Hedmark in Norway, the aim is to show different representations of how the discourse of new regionalism affects different regional policies in scarcer regions in Europe, mainly with focus on different ways of branding regions.

Participation and market-driven development

Jan Dohnke (Universität Berlin)

Based in the Ciudad Autonoma de Buenos Aires, the paper examines two processes that have a high local impact in the Argentine capital, the construction of high-rise housing in middle- and upper middle-class neighbourhoods and the renewal and gentrification of the historical inner city. Both processes affect different strata of the population in very distinctive ways but ultimately challenge their right to remain within their neighbourhoods under self-chosen conditions. In both cases, urban planning is guided by a laissez-faire attitude towards private investment and market-driven development, only partially framing or regulating it. As a consequence, options for participation are very limited, causing local inhabitants to organize, voice their claims and find other ways to challenge current urban development. The different strata of the population affected employ very different strategies, which are linked closely to their own resources and power relations both within their neighbourhoods as well as with political institutions. As local inhabitants try to achieve the same goal, to apply their 'right to the city' in order to achieve a more socially sustainable urban development for them, the paper shows that the on-going restructuring of the Argentine capital does not only have adverse effects but also triggers new modes of participation and resistance which might allow to counterbalance current forms of urban development.

The News Modalities of Territorial Governance in the State of Sao Paulo, Brazil

Elson Pires (Universidade Estadual Paulista), Lucas Fuini (Universidade Estadual Paulista), Rodrigo Mancini (Instituto Aequitas), Danilo Piccoli Neto (Universidade Estadual Paulista)

In Brazil the experiences of territorial governance became more evident in the year of 1990 with the advancement of political and administrative decentralization initiatives, requiring the federation of municipalities and other regional and local stakeholders a more active role in the reorganization of intra national territory. During this period new initiatives will appear in the State of São Paulo from some sectors of economic activity, pointing to new modalities of territorial governance that already indicate overlapping scales and new forms of regulation diffused from the local and regional territories, such as: Clusters, Tourist Circuit, Watershed's Committees and Sectoral House of Representatives of the Agrobusiness. Governance is no longer just sectorial and becomes territorial when it

recognizes that the territory is the spatial area of power that allows the sector its industries, the State and civil society have relations in a collective way, publicly, expressing various forms of interest and cooperation, revealing conflict, but cooperation and promoting a change of the territorial development process seen as "from the bottom", meaning that the citizens participates in the decisions taken. To show this recent phenomenon in Brazil, the article is structured in three parts, further an introduction to the problems of the study. The first part is concerned with the origins of the term territorial governance in its practices and formulations, and its relationship to the development local and regional. The second part seeks to show the process of ongoing construction of some structures of territorial governance in the State of Sao Paulo, using the examples of the Clusters, Watershed's Committees and the Sectoral House of Representatives of the Agribusinesses, sources of enlightenment about how the structures of regulation and sharing of powers in the territories may interfere in the process of negotiating of the local e regional territorial development in the country, as well as in the mechanisms of generation and distribution of resources between sectors and territories. The third part concludes the analytical framework with a critical assessment of the new born territorial governance in Brazil, considering the different sectorial, spatial and political-institutional realities. Keywords: Clusters; Watershed's Committees; Sectoral House of Representatives; Governance; Territory.

Peri-urban development in Yogyakarta – an introduction of challenges and solutions of autonomous districts in Indonesia

Christine Knie (Universität zu Köln)

Yogyakarta region, located in central Java, is one of the economic, educational and touristic hubs of Indonesia. Yogyakarta city, with half a million inhabitants, is the centre of greater Yogyakarta region. The entire region has three million inhabitants and is divided into Yogyakarta city itself and four districts. After 2000, when decentralisation was implemented in Indonesia, Yogyakarta City as well as the neighbouring districts became autonomous regions elaborating their own spatial development plans. The population figures of the peri urban districts Bantul and Sleman are increasing while the number of inhabitants of Yogyakarta city is shrinking. The peri-urban area is currently in a transition phase from a largely agricultural to urbanised service area with a high demand for new building areas in fertile traditional wet rice regions. The presentation will introduce the challenges of the current regional development and compare the administrative concepts of Bantul and Sleman with a special focus on land administration. Both local governments developed different strategies which are targeting the illegal land grabbing and at the same time supporting a modern economic development. The presentation will introduce the various actors, their conflicting interests and strategies and highlight the different methods of policy implementation. Finally it will be discussed how the different governance processes are integrated into a regional development concept.

Inequitable Accessibility in Health Care Services: Service mechanism and Urban Poor of Delhi

Pragya Tiwari gupta (International Institue of Health Management Research)

Theme of the Paper- India has been witnessing fast urbanisation since last decade. The urban population of India which is approximately 285 million people is estimated to reach 534 million by 2026. Percentage decadal growth in urban areas was 31.2% while in rural areas it was only 17.9% between 1991-2001. Delhi has a distinct status if we look at the statistics available on the growth of the city. While Delhi did not even feature in the top 30 cities of the world in 1950, it is now the world's second largest. Between 2000 and 2005, Delhi leapfrogged over Mumbai to become India's largest urban agglomeration. Mumbai, which was the 17th largest city in 1950 will go from the world's 4th to 3rd largest, overtaking Sao Paulo, over the next five years. The case of Delhi becomes even more absorbing after finding that the share of urban poor (15.7%) is also very high and estimates of consumption and expenditure in 2004-05 has recorded that 2.30 million people live below poverty line in Delhi. The ever increasing number of populace has been taking serious toll over the infrastructure and deteriorating health condition in the city. Equity is the buzz word both in the health mission statement where Equity stands as an independent goal. This paper tries to find the demand side of the health service requirement vis a vis the availability of the health services in the area. After the collection of the information by means of secondary data and primary survey the information is the interpolated spatially and analysed. Objective of the paper- The case of poor urban residence of Delhi therefore has become central theme for policy makers. Primarily this paper aims to see the urbanisation pattern in Delhi, urban poor in the city and their accessibility (Demand Side) and the availability of existing health resources (supply side), assessment of the Gap in the health services by plotting the accessibility (using ARC-GIS) on the selected study area. Method and research area- The data source for the present paper has taken from the recent Census publication and Delhi state Health society and small survey in one of the old rehabilitated slum area of North East Delhi. ARC-GIS is the software used for the accessibility analysis where WHO recommended tool AccesMod is also used to find out the Geographical accessibility of types of health care under the Plan in one of the selected study district. Conclusion- There is huge supply gap assessing the existing health facilities. And what came out from the research that not only the distance but time also one of the major constraint in health seeking behaviour. The paper divulge some of the major policy reviews which may be considered while planning physical health facilities and understanding people's perspective too while evaluating accessibility as categorised by Penchansky and Thomas (1984).

Southeast European World Heritage cities in post-socialism – an analysis of governance and heritage management in Gjirokaštër (Albania)

Matthias Bickert (Universität Bamberg)

Since the beginning of the so called 'third wave' of transition (Huntington 1991) southeast Europe is undergoing a deep economic, political and social restructuring. The region is in a specific state of transition, where the absence of vital civil society and political culture are major constraints for a successful consolidation of democracy. Especially Albania's recent development shows a stress field of extremes. After the beginning of the transition in 1991, civil-war like conditions in 1996/97 caused a setback from the achieved developments. Today, the country seems to be on the fast-track of economic growth. Those transitional socio-economic 'disruptions', as described e.g. by Hartke and Nitz, can be observed best in cultural landscapes. These influences leave deep traces in the dynamic development of Albania's urban settlements. Post-socialist phenomena of transition, such as high rates of regional and international migration, informal building activities and a little assertive state have a fatal impact on historic town centres. On the one hand many heritage towns have to deal with vacant, destroyed or collapsed heritage buildings. On the other hand especially for peripheral, medium-sized towns such as Gjirokastra the UNESCO World Heritage status causes a disproportional growth of publicity and therefore implies great potential for development. Stakeholders on every level of cultural governance from international to local are playing their own roles in governing a post-socialist World Heritage city. Many projects of different scales were and are being processed in southeast Europe, but dysfunctional political structures weaken the potential of historic town centres. For example the knowledge about official conservation constitutions and a vital international networking is usually underdeveloped. Furthermore the communication not only between the policy institutions themselves but also between the citizens and the cultural governance is a missing link. Fragile democratic structures, high rates of corruption and a weak civil society, whose needs are not involved in political decisions, show a lack of internal cooperation. For this topic the city of Gjirokaštër is good example of a medium-sized World Heritage city, whose potential is highly endangered by those problems. The loss of its World Heritage status therefore is at hand. To gain empirical data from both stakeholders - cultural governance and population -, a mix of different methods of geographical research are the key for understanding and improving the development process of World Heritage cities in southeast Europe. Qualitative expert interviews on the government level combined with the results from a survey of the citizen side can demonstrate the big variety of internal issues. Keywords: cultural governance, Albania, South-East Europe, UNESCO World Heritage

Politics of the built environment transformation in a post-socialist city

Pavel Šuška (Slovak Academy of Sciences)

Years after 1989, built environment is among the spheres of Central and Eastern European cities most significantly affected by post-socialist transitions. Although this might seem inevitable as the social settings producing urban forms changed dramatically, the political context of the urban built environment transformation provides an interesting area for geographical inquiry. The city of Bratislava, the capital of Slovakia, gives an example of how the 1989 agenda of democracy and participation have been just scarcely met in particular areas. This paper gives a relational analysis of urban governance, focusing particularly on informal groups and NGOs in Bratislava advocating the conservation agenda by promoting the symbolical value of place and opposing large-scale development initiatives. It explores how during the last two decades, these preservationists acted in and affected local political opportunity structure, and thus participated in governance shiftings.

Suburbanization during the period of systemic transformation – case study of Lublin

Mariola Ferenc (Polish Academy of Sciences)

Changes taking place in Europe at the turn of XX and XXI century affect on number planes of reality at economic, social and political way. The processes of democratization and globalization have changed both external and internal conditions of development of countries of the former socialist bloc. Economic processes of investment, employment, incomes are in the process of concentration, while the distribution of population and private construction investments become a freezing or deconcentration process. Official statistics do not reveal the size of migration in the suburban areas due to lack of required to register. The subject of study are transformations in the rural areas adjacent to Lublin after 1989. Author focus on multi-functionality and socio-economic opportunity in the countryside. The issues have been analyzed based on land use changes, statistics for the construction of houses and social statistics. The main reason to analyzing the space structure in the Lublin area is to determine the direction and pace of suburbanization in municipalities adjacent to Lublin, distinction factors and motives of population movements to the suburbs, complain rural-urban interaction and multifunctionality of land use. Suburbanization, that we can observe in the countryside has a huge impact on the quality of life. Housing development over the years was accompanied by confusion in planning documents and the law. Changes in regulations on land use in 1994 and 2003 in Poland additionally deepened the negative situation. Local authorities failed to control the spontaneous process of suburbanization, which adversely affected not only the spatial structure of municipalities, but also on local relationship, landscape and the former urban systems. The result are long-term problems associated with incompatibility rural areas to support a growing number of residents, such as failure of the social and technical infrastructure. Municipalities are trying to make their offer (lower property taxes, offer

home and garden, proximity to the city, but also to nature) favored the influx of investors because of the benefits that flow from this title to the budget. The conclusions reached contribute to the expansion of knowledge about the development of Lublin' suburban area will affect the planning decisions of local government units. There is no holistic concept of spatial development of municipalities located in the suburban area, the current activities are based mainly on local land use plans and studies of the determinants of the 90s. It is necessary to coordinate the plans of cities and municipalities comprising the suburban area.

A "new layer" consumer culture: A study on the "new class C" in the city of São Paulo.

Luiz Alberto Silva de Souza (Faculdade Paulista de Pesquisa e Ensino Superior)

Researchers in the field of geomarketing and professionals linked to the consumer sector, has observed that entrepreneurs, manufacturers and the Government itself, are currently a policy of expansion of opportunities and possibility of buying seeking to attain all layers of consumers, through funding and tax incentives as the "IPI reduced" and increasingly interest rates low. We noted then that the consumer market in the city of São Paulo has obtained substantial growth compared to previous seasons. Even in times of crisis as the world currently lives, studies show that consumption continues to grow, especially in emerging metropolises like São Paulo, as well as in other Latin American cities and countries belonging to the BRIC 's. The high-growth sector in Brazil, has as its principal cause an increase in the purchasing power of individuals involved and to standardize the consumption trend, especially in the last decade, already in the era of globalisation. The good economic momentum observed in the Brazilian economy and the various trends of consumption of movable and immovable property, became part of the Brazilian consumer preference, what changed not only the consumption habits, as created new specialities for offering these products. According to the IBGE (Brazilian Institute of Geography and Estatíticc), Brazil has a portion of consumers denominated "new class C", and that already represented 52% of Brazilian population in 2010. This new consumer layer reached in recent 5 years an exponential growth that gave him prominence. Such growth took place mostly through trade expansion with the opening of new markets for Brazilian products, reducing unemployment and better job training conquered by democratic access to University, supported and funded by various government programs. The present study aims to demonstrate how emerges the so-called "new class C" and the urban specialities configuration created by means of this consumers. The initial Hypothesis is that the emergence of this "new class C", which shows so demanding on time consuming as consumers greater purchasing power, is related to socio-governmental policies and associated with the advent of globalization, which produces new consumption habits especially in inhabitants of large cities as São Paulo. We will use as theoretical-methodological studies reference related to consumption, globalisation and

an in-depth survey on the implementation of government policies over the past 15 years, a period that coincides with the creation of the 'plano real'.

Bioenergy for sustainable development in developing countries – A Jiangsu perspective

Kesheng Shu (University of Hamburg), Jürgen Scheffran (University of Hamburg), Uwe Schneider

The use of biomass to produce bioenergy for a wide range of energy services and to produce biomaterials as substitutes for petro-chemical based goods is an integrating response to several global problems including climate change, fossil fuels shortage and so on. Out of this, bioenergy has gained a rapid growth in the past decades. However, more people start to concern about its negative impacts on the environment, land use, water resources and food security. In addition, the development path of bioenergy displays differently between developed countries and developing countries but the existed researches for developing countries are insufficient. In order to strengthen the benefits and reduce the risks of bioenergy in developing countries, this paper plans to design a tailored sustainable development approach of bioenergy for China. This paper points out that the construction of bioenergy industry is an effective and feasible method for the developing countries. After analyzes the particular characters of Jiangsu province, an eastern coastal province in China, we integrates the bioenergy life cycle into local situation and defines the two layers of stakeholders in the bioenergy industry. The basic layer of actors is central stakeholders including farmers or forest owners, haulers, and energy industry or plant operators. It is the supply chain of bioenergy, whose behavior determines the success or failure of the bioenergy industry. The upper layer of actors named peripheral stakeholders, involving governments, non-governmental organizations and research institutes, residents and local communities, energy end users and the general public, is the aggregation of actors who are impacted by bioenergy production but in turn also affect the supply chain, positively or negatively. Furthermore, this paper discusses the communication mechanism between these two groups. That is the challenges and benefits in social, economic and environment aspects induced by bioenergy projects execution. In other words, the benefits are the positive impacts of bioenergy project operations on periphery stakeholders. Through the benefit sharing mechanism and positive externality, central stakeholders can persuade the periphery ones to execute the projects together. Simultaneously, the challenges are the negative

impacts or externalities on periphery stakeholders or the problems proposed by them to which the central stakeholders have to face. These factors together compose the internal structure of bioenergy industry. As to the external structure of bioenergy industry, this paper draws a framework picture to demonstrate the bioenergy-centered industrial cluster. Through literature research from empirical aspect, we think three critical issues in the process of industrial cluster construction need to be further considered: the selection of feedstock, the innovation of supply chain infrastructure and the integration of energy market.

Intra- and Intercommunal disparities of communal infrastructure in rural Vietnam – A multilevel analysis based on the Vietnamese Housing and Living Standard Survey 2008

Antje Wegner (Karlsruhe Institute of Technology)

Ensuring sustainable access to safe drinking water and waste water treatment for the population in developing countries is still a challenging task although in south-east Asia the majority of countries is on track to meet the Millennium Development Goals. For instance in sum 94% of the Vietnamese population had access to improved drinking water supply in 2008, but there are still large disparities between the quality of water supply in urban and rural areas, where centralized water supply is often lacking. Aggregated statistical data as published by the WHO Joint Monitoring Programme or in the Living Standard Survey of the Governmental Statistics Office of Vietnam is useful to get an overview and provides a rough quantification, but hardly reflects disparities on lower levels of spatial aggregation and fails to identify their potential causes. Based on household and communal data of the Vietnamese Housing and Living Standard Survey (VHLSS) 2008 the presentation examines how household and communal characteristics influence water supply and sanitation of households. Whereas on the household level sociodemographic and -economic characteristics of a household are considered, the communal level variables encompass factors like the participation in governmental programmes or projects initiated by non-governmental or supranational institutions, the geographical setting in terms of accessibility of the commune, the spatial distance to larger towns or the availability of communal infrastructure and public utilities. Since in Vietnam commune leading cadres have a strong impact on the development of rural areas the analysis additionally aims at revealing, how the quality of commune leading cadres (e.g. in terms of their educational and professional background or work experience) effects water supply and sanitation in the respective communes. The multilevel approach allows to separate the contribution of household and communal level effects to overall variance and to model interactions between both levels of analysis. Thus multilevel analysis proves to be a powerful tool to analyse the impact of programmes, policies or spatial effects. Finally the presentation discusses advantages and requirements of multilevel analysis based on the empirical findings from the VHLSS 2008.

Aging in small paulista municipalities (< 10 000 inhabitants) means better quality of life? The role of local administrations – 1980 - 2010

Odeibler Guidugli (University of São Paulo)

Does the concentration of the elderly occur more often in big cities? Do the small towns signify good quality of living? Do the elderly who live in them have quality of living superior to the one of those who live in large cities? The data does not enable us to give positive answers to these questions. The term urban is widely used and have been focused on the metropolises and megalopolises, showing the insufficiency of studies and, in the marginalization of the small towns and of the tiny ones. However, they have demographic and spatial significance. How to plan the development, without considering them? The research tried to answer the questions mentioned for the small municipalities (< 10000 inhab.) of the State of S.Paulo, between 1980-2010. In 1980 there were 271 municipalities, 208 had been researched. The others, in 2010, had lost the demographic delimitation. In 1980, they represented 33% of the universe of the state and means only 3.6% of the population. In the census of 2010 the participation decreased to 2.6%. This data contrasted with the 54 522 km² of the area, or 22.0% of the total. Three integrated parts compose the study: first one, of theoretical/methodological nature evaluating the meaning of the geographic studies, focused on the small towns. Developed, dominantly, in national and international journals, the results have revealed a quantitative shortage and the non-importance of this category of towns and the marginalization of qualitative problems involving debates inside of the science, not only for the conceptualization of town, but in the characterization of the ones considered tiny ones. The second one focused on the historical and demographic dynamics of the past and of nowadays. Which processes led to their appearing and their remaining small, in the most developed state of the country? How to find out their future considering the process of globalization? Demographically relevant questions were observed: the comprehension of their reductions (negative growths), being that, of the total 32.2% registered absolute decrease; the role of the migratory processes and, the accentuated aging - the total population grew 18.5% while the elderly one - 60 years and over - 139%. In the end, the study focused the integrated evaluation of the municipalities from the critical use of different indexes and indicators: Municipal Human development Index; Paulista Index of Social Vulnerability and Futurity Index. The MHDl registered the decrease of 37 (17.8%) and only 15, classified at the high level. Finally it was verified the theoretical methodological insufficiency of the studies and the predominance of a quantitative profile. Demographically the challenge of aging in a society with demographic and economic decrease. Finally, the analysis of the data have made connections and disconnections come out composing a set of challenges in order to find out the necessary alternatives of development for these towns.

C08.13-08 - Governing development in regions, cities and rural communities 5

Military territorial structures of Latvian borderland: Comparison past and contemporary situation

Janis Balodis (University of Latvia)

This paper is written of new regional development policy which is related with military geographical aspects. Latvian Armed forces are dividend separately in all country. In literature is called military training areas. Soviet regime in the Baltic Sea and Riga bay coast area was 'closed zone'. This zone was 1,25 km wide and very strictly guarded. Other Latvian borderlands (inland) were more secure, and that's explenation why military structures were more developed in coast borderland. In contemporary situation of Latvian military teritorial structure is unregulated because terms and legislations of military regions of Latvia are weak legal entry. Military regions is fundamental research object of military geography. Latvian Ministry of Defence now create new administrative policy of military teritorial structure - military regions. There are three practical indispensibilities why this legislation is important. Significance is the obligation to the respect the distinction between military objectives and non military objects as well as between persons participating in the hostilities and members of the civilian population remains a fundemental principle of the international law in force. 1) It is important for local authorities whose made teritorial planning and development programmes for local community, who lives in potential military regions. 2) Environmental protection suggest that an integrated network of protected areas can made administrative borders of military regions. There has focused the Soviet state's military interests and civilian movement was restricted. Both this fact and the power of economic development model, which eliminated the collective farms, estates and developed centers, forced residents of the seaside villages to move to other areas of life. Now this is a inovation basement of regional development in coastal and inland borderlands. Polygon was used for practicing shooting from handguns, cannons and missile installations; battle simulations with tanks, helicopters and planes were also carried out. The existence of the polygon was top secret and to maintain ultimate secrecy, false name was used in legal documents. Latvian Ministry of Defence cooperation with Latvian Ministry of Regional development made new teritorial cohesion. It is a cross - border cooperation where border regions have been established with the aim to lower the state borders and to promote economic development in border areas. This presentation will structinize the current borderland economical development management. Key topics: borderlands, military geography, community management, territorial legislation, cohesion

Indigenous Migration and Development: Oaxaca and Chiapas in a Comparative Perspective.

Sascha Krannich (Princeton University)

The two most Southern states of Mexico are relatively similar when it comes to economic and social underdevelopment of their communities, but they are fundamentally different in the migration patterns of their people in the US. Driven by poverty and human right violations, Oaxacan migration to the US became a mass phenomenon during the Bracero program in the early 1960s, whereas Chiapanecan migration to the US became a mass phenomenon just in the last 20 years. In this regard, Oaxacan migrants organize in higher numbers and for more years than Chiapanecan ones in the US. Thereby, indigenous people represent an important amount of migrants from both states. Most of them are Mixtecos and Zapotecos emigrated from Oaxaca, and Tzeltales and Tzotziles emigrated from Chiapas. While one can find well-established indigenous migrant organizations from Oaxaca in California, indigenous migrant organizations from Chiapas mushroom just recently all over the US. At this stage, after years of ignorance and distrust, the Oaxacan and Chiapanecan governments try to reach out to their indigenous diasporas in the US. In doing so, they have vital interests in collaborating with these migrant organizations to develop their underdeveloped indigenous municipalities. Some indigenous migrant organizations seem very excited to cooperate with their home state governments, whereas others react reluctant. Nevertheless, most migrant organizations, especially hometown organizations, have a deep interest in the development of their home states and home municipalities. This leads inevitably to the question, which role indigenous Oaxacan and Chiapanecan migrant organizations play in the development process of their home states? To answer that question, I will focus on indigenous migrant organizations with their transnational networks, forms of identity, specific relationships to their home governments, and their social and public development projects in selected indigenous communities in Oaxaca and Chiapas. At this comparison, fundamental differences between indigenous migrant organizations and their various development efforts in home regions become evident.

Dealing with the Requirement of Producing Exploitable Knowledge – Differences Between Social And Natural Sciences. Case Study in an Argentinean Peripheral Research Institute

Angelika Hubl (Universität Frankfurt)

For some time past there is a global debate about today's mission of universities and research institutions as providers of education, research and knowledge transfer (third mission). Especially the future orientation of these institutions is hard debated. They have to justify themselves as providers of social benefits for society and economy. Due to globalization this debate was spread from Europe and the United States to emerging and developing countries in the global south. As one of Latin America's economically leading

countries Argentina as well takes place in the worldwide discussion. Argentina is a very centralistic state. Therefore the offer and reputation of universities and research institutions is very centralistic as well. That's why especially institutions in rural areas have to justify themselves exceedingly and have to struggle for reputation and funding. The case study will focus on a research institute and its close by university in the north-east of Argentina, which is a region of extremes and contrasts. Especially in population aspects it is one of the regions of Argentina with the highest social inequality and very diverse habitants like little farmers, indigenous people and marginalized people. Since this region is so peripheral, the research institutes' task to vindicate itself is very important. The goal of the case study is to examine how the knowledge transfer at the Argentinean research institute CONICET Tucumán works, how the institution and the researchers deal with the requirement of producing exploitable knowledge and what are thereby the differences between social and natural sciences. The field studies will be carried out between February 2012 and April 2012 at CONICET Tucumán. As method semi-structured interviews with the management of the CONICET Tucumán, the heads of the various research groups, and particularly with selected scientists of innovative research areas in the sense of knowledge transfer will be conducted. The interviews will be evaluated interpretative-reductively. The hypothesis that there are significant differences between social and natural sciences in dealing with the requirement of producing exploitable knowledge will be examined during the field study and will be extended with new insights about the role of research areas for knowledge transfer and adaption in this institute and in general. Therefore it will be an important Latin American case study as an example for dealing with the requirement of producing exploitable knowledge in peripheral regions. Results will be available in June and will be ready to be presented in my master's thesis and at ICG in August 2012.

Regional policy and regional disparities – Institutionalisation of spatial development in Serbia with focus on the Autonomous Province of Vojvodina

Andreas Winkler (University of Bamberg), Zoltan Takac (Scientific Association for Hungarology Research Subotica)

Serbia's delayed transition into a market economy and Serbia's institutional transition into a highly centralized state intensified old and created new regional disparities. Spatial inequality - in a socio-economic sense - has to be seen as a permanent development problem of the Republic of Serbia. At the same time, the Serbian government and state bureaucracy is also showing inequality and asymmetry in regional governance and within their spatial development policies. The traditional polarisation picture of socio-economic differences between north and south, urban and rural as well as central and peripheral areas is still accurate. But - according to this study - the distribution of the spatial disparities is getting more and more unclear and fragmented. In other words, whole regions can't be regarded as favoured or undeveloped areas anymore. Within the newly defined statistical NUTS regions in Serbia, spatial differences are huge and are showing

strong dynamics. Simultaneously, after years of neglect of the regional level, a new institutionalisation of the regional policy has been implemented by the Serbian state; mainly forced by European integration ambitions. Since 2007 new organisations, institutions and agencies for regional development have been obliged to carry out tasks of former central state bodies. But this new approach to underdeveloped areas is still bearing elements of neglect of the regional level and system inefficiency of former times. Operations are still centralised and highly politicised, which is evident in the example of the Vojvodina region. The complex regional institutions of the Autonomous Province of Vojvodina can be regarded as a model for a future regionalisation of the whole state. Moreover, the province remained a whole, unified NUTS 2 region, when the regulations on NUTS were finally put in a legal framework in 2010. To put it in a nutshell, this paper summarizes the new Serbian regional policy with a focus on the Province of Vojvodina. It depicts the new institutions and shows with a quantitative approach of spatial analysis, the socio-economic differentiation within the newly installed NUTS regions in Serbia. The paper closes with the identified institutional problems and some institutional requirements of planning within the inhomogeneous statistical units.

C08.13-09 - Innovations in public sector - public administration reforms, public sector reorganizations, local finance and progress in planning

Chair: Eran Razin, Xiaohong Zhang

Fiscal Strategies of Russian Regions and Municipalities

Vladimir Klimanov (Institute for Public Finance Reform), Anna Mikhaylova (Institute for Public Finance Reform)

The paper is devoted to analysis of first experience of introducing long-term fiscal planning on sub-national level in Russia. Theoretically, development of any public strategies, at both federal and local levels, should be closely linked to the expansion of budget planning. But in practice, there is lack of experience of introduction of any fiscal strategy in Russian regions and municipalities. Besides, during last years, the reform of intergovernmental fiscal relations in Russia has solved some problems. For example, it has led to specification and expansion of responsibilities of regional and municipal authorities of the subjects of the Russian Federation and municipal formations. On the one hand, federal and regional finance authorities were offered a complex reform program for the budget system in the 2000s. Measures for reforming public finance at the regional and municipal levels were implemented on a systemic basis. Successful implementation of the first steps predetermined need to strengthen the results achieved and identified new priorities for further reform efforts. On the other hand, more than 60 subjects of the Russian Federation (among 83 ones) and several dozens of cities adopted and approved their own long-term strategies for economic development during the 2000s, in the pre-crisis years. Further steps to improve the management of regional and municipal finances will largely relate to readiness for adaptation of the budgetary innovations offered at the federal level. Thus, the most important financial innovation in Russia in the near future will be the formation of so-called program budget implementation and expansion of program-oriented principle of organization of public administration. In addition, in the presence of debt and budget deficits in the region or city debt management strategy as an integral part of the budget strategy should create conditions to ensure that minimize the cost of borrowed funds. The implementation of the budget strategy will involve increasing need for justification of strategic decisions and effective use of budget resources and the need to consider long-term budget constraints require the formation of reasonable and realistic programs to address the priorities of the territory. In general, while improving coordination of strategic and long-term fiscal planning budget policies at regional or local level, should be focused on the strategic objectives of the economic and social development of the territory.

The role of central state in regional self-government building in post-socialist conditions: The case of Slovakia

Jan Bucek (Comenius University)

Among various changes that introduced many post-socialist countries, we can find those concerning regional government. Its introduction as new level government, or as adaptation of older regional institutional environment to new purposes, it has been strongly influenced by central state. This paper focuses on central state - regional self-government relations in Slovakia, within East Central European context. It has been introduced after decade of attempts in 2002. We discuss procedures and processes of its development in relation to central state approaches. Regional self-governments established their institutions, and had been adapted to execution of decentralised powers. Later it obtained more fiscal autonomy within the processes of fiscal decentralisation. Focusing in details predominantly on powers and finances of the regional self government, we document their weaker position. This process has been negatively influenced by the consequences of economic and public debt crisis. Until now, regional self-government has been less successful in rapid and full scale strengthening of its position with Slovak system of government. Despite relative successes, it is still less powerful level of the government. It can be perceived more as developing central state based project and not as sufficiently autonomous level of government. It is still lacking extensive own initiative and stronger position in intergovernmental relations. Besides relatively weaker position towards central state, it is also less well established partner to other societal actors, as well as to citizens. Part of the problem caused political and technocratic delineation of its borders by central state and missing regional identity in respect to such territorial units. It has limited and decelerated bottom up processes and stronger identification with new regions.

The regional adoption of the European Growth Plan for coming out of the crisis: The challenging translation of the Europe 2020 Strategy to the regional scale

Rubén Camilo Lois-González (Universidade de Santiago de Compostela), Carlos Macía (Universidade de Santiago de Compostela), Alejandra Feal Pérez (Universidade de Santiago de Compostela), Valerià Paül (Universidade de Santiago de Compostela)

Since the outbreak of the global economic and financial crisis, European Union (EU) institutions have responded to the new, and mostly unexpected, critical situation on a broader scale. In particular, the European Commission launched the 'Europe 2020 Strategy' (EU2020S) that was finally adopted in June 2010. The EU2020S fundamentally constitutes a growth plan for the decade 2010-2020 that aims for EU recovery from the current ongoing crisis. Structurally, the EU2020S consists of three mutually reinforcing priorities: smart growth, sustainable growth and inclusive growth. Derived from these

three pillars for growth, seven particular flagship initiatives are proposed, each one including specific actions. In addition, the EU2020S contains a list of numerical goals (so-called headline targets) that set specific figures for measuring its purposes. The EU2020S is the common framework that each one of the member states of the EU is committed to adapt to the respective national situations by means of the Annual Growth Survey. In this document each member state establishes its own national targets developing the EU headline targets contained in the EU2020S. Beyond this national adoption, the EU2020S loses spatial scope. Indeed this is the point of departure of this paper: how the EU2020S can be understood at the regional scale. In other words, while the growth scheme for the European and the national levels is clear, it is not obvious how this plan can work in regions. In order to provide answers to this problem, two approaches are considered in the paper. First of all, the headline targets and other numerical goals contained in the flagship initiatives are mapped for all the EU regions. This provides a picture on the uneven geographies of the EU2020S implementation, including a specific consideration of the "problematic" types of regions (outermost, rural, border regions, etc.) as defined by the EU. Secondly, some strategic reflections on the possible ways to implement the EU2020S at the regional scale are raised. These strategies are basically devoted to those regions empowered in political terms (federal states or regions with devolved governments). To sum up, although apparently economic growth and development strategies seem to be only in hands of the EU and member state governments, this paper reflects on these issues at the regional scale. This is consistent with the EU2020S itself, which claims that "It is essential that the benefits of economic growth spread to all parts of the Union, including its outermost regions, thus strengthening territorial cohesion". This paper is prepared as part of the research project entitled "Spatial Indicators for a 'Europe 2020' Territorial Analysis" (SIESTA), funded by the ESPON 2013 (Applied Research 2013/1/18) and partly financed by the European Regional Development Fund.

Inter-local fiscal transfer and tourism management in Bali: How cultural thickness triggers regional collaborative governance

Luh K. Katherina (Institut Teknologi Bandung/ Akatiga), Delik Hudalah (University of Groningen)

Intercity networking is increasingly suggested as an alternative form of regional governance in the face of globalizing world and declining influence of the nation state. However, inter-local governmental networking is rarely practiced in Indonesia, partly due to uncontrolled presence of local egoism and the structural constraints of decentralization policies. This paper explores the rare success story of intercity networking in Bali, which has been consistently practiced since 1972. The networking is manifested in inter-local fiscal transfer as means of sustaining the island's cultural tourism industry. With the facilitation of the province, the municipalities and districts receiving high revenues from the tourism industry have long agreed to transfer parts of their revenues to their

neighbors experiencing fiscal deficit from tourism. The objective of this paper is to identify the process, the challenges, and the factors influencing the success of this intercity networking. Our investigation revealed that the success of the inter-city networking in Bali is influenced by the geographical proximity among the municipalities and districts as compared to other regions in Indonesia. The proximity has increased dependency among the regions because while tourist attractions spread across the island, the hotel, restaurants and other facilities are concentrated only in designated areas. This economic dependency is reinforced by the pervasive role of Balinese culture; the culture that belongs not to particular municipalities but to the whole Island community. The local leaders had long perceived that the benefits gained from the existence of this culture should be enjoyed by all people of Bali. This cultural thickness has been responsible for the building of trust between local governments in Bali. In such a cultural-based society, cooperation is not necessarily based on sound legal basis but the mutual agreement among the leaders.

Chair: Mark Wilson, Maria Paradiso

Daily spatial mobilities: Nature, features and dimensions

Aharon Kellerman (University of Haifa)

This presentation intends to introduce the new book entitled *Daily Spatial Mobilities: Corporeal and Virtual* (Ashgate 2012) by its author. Daily spatial mobilities are typified by several aspects: they are two-way mobilities; frequently performed; constituting a major element of our daily routine lives; and they are inclusive of both corporeal and/or virtual mobilities. Major daily movements include commuting, shopping, social ties, information, banking, news, studies, business meetings, etc. The roots for daily spatial mobilities and their nature are varied, and the needs and triggers for their performance include psychological, geographical and political perspectives. Of special interest in this regard are the social roots and norms for personal mobility and for personal autonomy as expressed in daily spatial mobilities. The exploration of the various roots for daily spatial mobilities permits to further examine potential mobilities as a mental and preparatory phase for eventual practiced ones. An additional element of the nature of daily spatial mobilities is the functional nature of these mobilities, which is highlighted through a discussion of the question whether terrestrial, virtual and aerial mobilities constitute a joint mobility category or whether they are rather three distinct ones. Another dimension of daily spatial mobilities relates to the modes of daily spatial mobilities, highlighting separately the nature and dimensions of terrestrial, virtual and aerial daily mobilities. The understanding of daily spatial mobilities requires not only to explore their very identity and nature, but also to discuss their spatial implications, notably three major ones: urban spatial reorganization in the information age; mobility terminals, namely central railway and bus stations, as well as airport terminals, notably international ones; and, finally, global locational opportunities for individuals potentially becoming possible by daily virtual mobilities through the Internet, mainly for online shopping, e-learning, home-based business/work, and social networking.

Development of the network-type career education program using ICT: A case of Housuu-juku in Saga, Japan

Kenji Hashimoto (Waseda University)

It is one of the important roles expected from ICTs to offer a both directions type educational program between remote places. Housuu-juku is one of the NPOs which perform career education in Saga Prefecture in Kyushu, and it has furthered development of the network type educational program using ICTs, such as a system which distributes a lecture from the Tokyo metropolitan area, and a system by which a participant performs

exchange of opinions on on-line. Now, in Japan, same NPOs come to be established all over the country, and Housuu-juku is regarded as those innovators. This report would like to explain the educational program which Housuu-juku developed from the viewpoint of advanced use of ICTs, and analyze about the influence which these programs had on the area or regional economies.

Social relations, the internet and decisions to move among urban young adults in Sweden

Bertil Vilhelmson (University of Gothenburg), Eva Thulin (University of Gothenburg)

The Internet and social media encourage distant personal contact and social interaction. Social networks also offer important support when life decisions are made, for example whether to move elsewhere or to stay. Also, social factors (related to family and friends) are important motives for migration and choice of destination. Drawing on these premises, this paper examines to what extent the Internet is perceived to influence the migration decision process. It is based on data from a 2009 survey of 750 young adults in Sweden and twenty four in-depth interviews. Results show that the Internet supports individuals' plans to move as well as to stay. This split is further analyzed when several factors are taken into account: Internet-based social contact intensity, recent migration experiences, future migration plans and certain demographic, socio-economic and geographical factors. Key words Internet, social contact, interregional migration, migration plans, migration experience, survey, interviews, young adults, Sweden

Global Urban Analysis: Exploring the link between demographics, economics, and network connectivity among the leading world cities

Douglas Sathler (UFVJM), Gilvan Guedes (Vale do Rio Doce University)

Globalization has deeply transformed the way people, and as a consequence, urban areas connect with each other. The advance in information and communication technology, including social media, mobile gadgets, and faster and cheaper ways of transport has redefined the way individuals interact. Although urban centralities are still characterized by the stock of material power, financial and informational flows reshaped the time-space dimension of urban centralities, allowing their citizens to establish space-free and real-time interactions with other citizens worldwide. As a consequence, the Global Urban Network has been more integrated and experienced a recent proliferation of centralities able to mediate the various types of material and immaterial flows in both developed and developing countries. Despite the long theoretical tradition on the relevance of information in explaining the ranking of leading cities, was not until recent that empirical support started to emerge. Using data on GDP, population size and network connectivity indicators applied to the latent class model, this study aims to contribute to the literature on global urban analysis by bringing empirical evidence on the

heterogeneity among the leading world cities. The model identified six types of urban areas with markedly different characteristics: Marginal Connectivity Centers, Integrated Centers, Emerging Centers, Large Emerging Centers, Consolidated Centers and Large Consolidated Centers. The spatial distribution of these classes assumes a defined spatial pattern around the globe, suggesting that although GDP is still relevant in explaining urban ranking, the role of immaterial flows, such as the network connectivity indicators used, is key to better qualify how different same-size, equally rich cities are in a reshaped, and increasingly immaterial world.

C08.14-02 - Global Information Society: ICT, Knowledge & Media 2

Chair: Mark Wilson, Maria Paradiso

Knowledge city and digital development. The case of Montpellier, France.

Henry Bakis (University Montpellier), Alexandre Schon (University Montpellier)

Montpellier Metropolitan Area, located in County Languedoc-Roussillon, is in a context of high demographical growth. In the mid 60s, the town's selection as the County's Capital city determined the implantation of numerous public research centers in the Health and the Agronomy sectors in particular. At the same time, the implantation of an IBM factory, and the settlement of many IBM subcontractors added a specialization in the field of electronics, data processing and communication. Nowadays, Montpellier has a high Scientific and intellectual potential. The Region Languedoc-Roussillon comes second after ile-de-France (Paris county) in the number of innovative company's settling yearly. Some innovative companies are driven in their creation by Business Incubators under a Public supervision. The height French city in terms of population size, Montpellier is number four (after Paris, Grenoble, and Toulouse) in terms of strategic employment concentration (within the high tertiary sector) which guarantees good conditions for the implantation of innovative companies (highly qualified workforce is available). This communication will introduce the main specialties of the Montpellier Metropolitan Area (medicine, agronomy, communication), and highlight the recent development of numerical infrastructures (Pegase and L3LR. mainly) within the Agglomeration in relation with places of services activities and innovatives parks. Key Words - Numerical infrastructures. Internet. Pegase. Num'hérault. L3LR. Opérateurs. Haut débit. Montpellier. Region Languedoc-Roussillon. Département de l'Hérault. Innovative companies. Technoparc.

Innovation and technology strategies, growth and regionality in Finland. Reflecting on period 2011–2015.

Tommi Inkinen (University of Helsinki)

This paper examines theories and practices of innovation and technology policy in Finland. A starting point may be detected to the classical agglomeration theory from where I proceed towards the analysis of innovation creation and economic development traceable back to the ideas of Schumpeter and evolutionary economics. I will consider elements of networking, dispersed production models and location in their relation to innovation policy in Finland. I will discuss the empirical case of the current (latest) Finnish innovation and technology policy documentation. The paper provides a critical view on how regional development and spatial clustering of economic activity are integrated and visible, or non visible, in the policy documentations. The technological development (e.g. cloud services) of the production of immaterial services (and goods) on the internet are

considered. The transferability of and accessibility to information is considerably easier and faster than before the time of the information networks. The strategy guidance of Finnish innovation policy provides an up-to-date view to policymakers' appreciations and beliefs concerning the near future (till 2015) and the role of innovation in economic development. Key words: regional economy, economic geography, innovation, technological development, clusters

A consideration on the changes of telemedicine users' behaviours by operating the telemedicine system

Sookyung Park (Sangmyung University), Yuki Hanashima

Telemedicine may take specialized care to medical care centres in the distance places and restructure the time-space configuration of medical care opportunities. Despite of the rise of the attention toward it, the reconsideration of telemedicine users' behaviours by operating the telemedicine system has been never studied by geographers. In this sense, the purpose of this research is to take a closer look at the question as to how telemedicine influences on the behaviours and trajectories of telemedicine users empirically within the framework of time geography suggested by Hägerstrand. The time-space path, devised by Hägerstrand, shows the movement of an individual in the spatial-temporal environment with the constraints placed on the individual. With this context, by exploring time and space changes in medical care related to telemedicine, we consider not only where an opportunity for medical care is located, but also when it is available more effectively. Under the notion of Hägerstrand, in-depth and open-ended interviews of physicians and patients in Togane general hospital (Japan) were conducted from February and June in 2011 and looked into the comparison of telemedicine users' behaviours between before and after diagnosing via the telemedicine system. And 'Extended Time-Geographic Framework Tools Extension for ArcGIS 9.3', which generates space-time paths from appropriate input data sets and facilitates interactive visualization of space-time paths in a space-time GIS environment, was used. From a perspective of patients' behaviours, telemedicine contributes to the fact that patients can avoid the costs and dangers of transporting patients to external medical institutions. Especially, the changes of waiting times for diagnosis, transportation fee, and transportation methods are outstanding. Considering that most of the patients are chronically ill and elder patients, the telemedicine system is helpful. Besides, there are no considerable changes in time for diagnosis and medical expenses. In addition, physicians as the other telemedicine user could provide core medical treatments to patients with ease and made a profit without any movement. But they have the burden to attend a regular meeting provided by Togane general hospital and spend considerable time. Even though they take the trouble, the participation of the regular meeting is regarded as one of the important activities among them in order to avoid a misdiagnosis and share their opinions or specialized knowledge. Telemedicine can overcome the 'tyranny of distance'; therefore, it improves the unequal geographic distribution of health care resources and

ameliorates inadequate access to health care. According to the results of this research, the range of practical use is limited because telemedicine is regarded as an ancillary method of health care delivery.

Technology as a factor of the States' power: the example of the Lybian war

Olivier Lefebvre (Consultant)

Technology as a factor of States' power: the example of the Lybian war. The Lybian war was an example of efficiency of military technology, which was at disposal on the NATO side (the coalition gathered USA, Great Britain and France, mainly). It is not always the case. What are the specific conditions of this war? What are the lessons brought by this war, concerning the military technology as a factor of the States' power? Gadaffi committed three errors, political, diplomatic and strategic. It explains he was won by a coalition made up of three allies: Lybian insurgents, NATO and the United Nations. The political error concerned his own political regime, which was undermined by the revolt of a majority in the population (in particular the Army chose rebellion). The diplomatic error was the international isolation of the Gadaffi's regime, which allowed the United Nations to authorize NATO to support insurgents, because Gadaffi himself announced he will not respect the Human Rights. The strategic error was to neglect the efficiency of military technology used by NATO. Air Power allowed blocking the Lybian troops where they were, destroying their mobility, so the insurgents on the ground were able to win them one after the other. The tactical support by the aircraft of NATO helped them, also. These specific conditions explain the efficiency of military technology (remote sensing satellites, Unmanned Aerial Vehicles, cruise missiles, accurate bombings ...) during this war. Obviously, it is not the same in all the cases (since counter insurgency failed in Irak and Afghanistan). Probably the most powerful countries (USA, European Union, Russia, China) will continue acquiring sophisticated weapons. even, the interest of the Mahanian ideas on Sea Power (and ideas on Air Power) is re-launched. But we have to recall the limits of the efficiency of military technology: - it is very costly, and we are in times of reduction of budgetary expenses - some conditions are required for the military technology to be efficient. The Lybian war allows for a reflection on this topic. In particular, counter insurgency cannot succeed thanks to military technology, only. Also, this technology is easy to use in coastal regions, and is more difficult to use in the heart of continents.

Chair: Mark Wilson, Maria Paradiso

The transformation towards an information society and its relevance to urban management

Joana Kowalewski

The transformation to an information society is reflected in various socially relevant areas. Though there is still no common definition on the knowledge concept, which underlies the information society, trends can be noted that shape this transformation process: technization of different areas of life, growing importance of creative industries, or more generally the knowledge economy and a modified approach to knowledge and its generation (KUEBLER 2004, 2009). A penetration of all social systems is currently visible in broad terms. But for the foreseeable future the different areas (economy, politics, science, education, family, etc.) are not yet fully penetrated. Prerequisite for this would be free access and usage of information and knowledge. A common and accepted "open-source idea" and the repeal of personal or institutional barriers to the use of digital media (Digital Divide) are associated with it (FORSTLEITNER / PAWEL 2007). Under the assumption that there is a penetration of society in this sense, the paper shows the relevance of this transformation to urban planning and management. Initially, the change in the dimensions of economy, society and space are described and in accordance with the basic assumptions their future development is demonstrated. Based on these hypotheses the paper highlights what kinds of questions can arise for urban planning and what solutions seem viable. Already today new approaches following an "open-source logic", which is more open-ended and flexible (e.g. in the field of participation or the use of urban brownfield sites and vacant properties), can be seen. "Open Source" means here not only free access to information and knowledge, but also the involvement and mobilization of knowledge of all relevant groups confronted with the planning process (STOLLORZ 2011; WILLINGER 2011). The paper shows examples of appropriation of spaces, which are novel in the usage and utilization of knowledge and identifies new partnerships between private and public actors.

Can oases appear in medical desert via information network? The spatiality of health care changing in Japan

Tsutomu Nakamura (University of Tokyo)

This presentation examines the ways in which information and communication technology (ICT) is used with a view to improving medical desert for some cases concerning regional medical information networks in the disaster areas, Japan. Geographical research has

estimated the role of information systems as a means of providing public services. As such services involve public funding; accessibility as well as cost-efficient use should be taken into account in their provision. In Japan, each prefecture implements its own regional health care program for the appropriate allocation of medical resources. However, regional disparities in such allocation have not yet been resolved. The Japanese government considers that the function of each medical institution should be defined, medical networks suitable for each type of disease should be constructed to make good use of human resources such as medical professionals and medical equipment, and that medical services should be decided according to the health condition of patients. For this purpose, the development of ICT as an information infrastructure is a matter of great urgency. The existing ICT are developed to process information effectively. However, the role of ICT as an information infrastructure has been spotlighted after the Great East Japan Earthquake. Before the earthquake, the information infrastructure had been built in itself. The earthquake brings about changes in people's awareness that the real world should be restructured via the infrastructure. Because there are many examples that the paper-based health or medication records were washed away by the tsunami, effectiveness of cloud-based electronic health record is attracting attention. The reasons electronic health record have failed to become widespread are (1) high operational costs; (2) a lack of compatibility with other systems; (3) and a lack of doctors' appreciation of cost effectiveness. The presentation illustrates the current conditions and challenges of the development of medical information network in Japan. The survey items are as follows. Why have medical information not been made electronically available via cloud-computing up to now? Why does former paper-based medical information become increasingly digitized recently? How cloud-based electronic health records are being utilized to help the solution for medial desert?

Regional revitalization by using virtual contents: A case study of Nipponbashi electric shopping street, Osaka

Takashi Wada (Tokuyama University)

Recently, many local municipalities and economic organizations make positive efforts to support contents industry and to revitalize local economies by using virtual contents made either by themselves or by content creative companies in Japan. For example, cartoon or animation museums have been built at many cities and many tourists visit them. And many enthusiastic fans of specific works visit the places drawn in the works. This phenomenon is called 'Seichi-Junrei (pilgrimage to holly sites)'. More, the shopping areas, such as Akihabara (Tokyo) and Nipponbashi (Osaka), have developed from electronics quarters to agglomerations of shops dealing with subculture products and services. Nipponbashi electric shopping street once flourished as the 2nd biggest electric shopping district in Japan. But the number of the electronics stores has declined since 1990s because of the bubble recession and advance of major electronics stores around Nipponbashi. As a result, the number of the shops dealing with game software, CDs,

DVDs, books, instruments and hobbies has increased instead of that of electronics stores. For this situation, 19 owners of retail stores established a new company 'Nipponbashi Machizukuri Shinko Co.' to revitalize Nipponbashi electric shopping street in 2004. The company has carried out some unique projects. Those are the event to promote both electronics stores and subculture shops, creation of town map to introduce subculture shops, management of incubation facilities for CG animation authors, support for robot-related industries. And the company created a virtual idol 'Neon and Hikari' to promote Nipponbashi shopping street as a subculture holly site mainly for young people. With the change of stores configuration, Nipponbashi has become a hobby town. The enthusiasts of each hobby (content) usually enjoy their own hobby (content) at home and communicate one another on the Internet (cyberspace), and they visit the shops (real space) dealing with the products they love on holidays. They buy the products at the shops and enjoy communication with salespersons with knowledge of the products. The events held by each shop and the company are great opportunities for the enthusiasts of each hobby (content) to communicate with one another in face to face. Then, they write a diary about their visit to Nipponbashi on the weblog or the twitter they manage, and another enthusiasts make comments on the diary. But the enthusiasts who love different hobbies (contents) rarely communicate with one another. The virtual idol 'Neon and Hikari' and the event 'Nipponbashi street festival' held by the company have become the symbols of Nipponbashi electric shopping street. But they are nothing but symbols. Each enthusiast only enjoys his or her own hobbies (contents) both in real space and cyberspace.

E-capital in Helsinki Metropolitan Area

Maria Merisalo (University of Helsinki)

This paper applies and redefines the concept of electronic capital (e-capital). It refers to individual willingness, capability and possibility to use ICT, social media and electronic services. Here, e-capital relates to theories of human capital, or educational talent, and of social capital or individuals' capability to create social networks. The study examines the level of e-capital and explores its socio-economic and -spatial dimensions across the Helsinki Metropolitan Area (HMA). The data were gathered with a stratified postal survey (n=971) conducted in the HMA in 2010. Cross-tabs, chi-square -tests, and logistic regression analyses were used to examine the data. The results show that education is related to e-capital: higher educated and knowledge intensive workers have higher e-capital. The level of e-capital is statistically connected to income level and occupational position. Additionally, teleworking relates to the use of ICT and social media. The use of social media for networking purposes, i.e. formation of social capital via social media, relates to socio-economic position within the respondents. Thus, the study argues that a high 'level' of e-capital can be considered as an asset compared to nonusers. Previous studies have shown that networking and creating and maintaining of social relations have an impact on individual well-being. Furthermore, both human and social capital are

already recognised as the driving forces behind economic development. Thus, the relation between e-capital, human capital and social capital indicates that the high level of e-capital within a region has a connection to economic development, regional knowledge intensiveness and well-being. Keywords: social media, electronic services, information and communication technology, social capital, human capital, Helsinki Metropolitan Area.

Chair: Mark Wilson, Dorothea Kleine

Mobile Communication and the Transformation of Social Structures in Dhaka, Bangladesh

Harald Sterly (University of Cologne)

Mobile Communication and the Transformation of Social Structures in Dhaka, Bangladesh The past decade has witnessed a tremendous growth in the number of mobile phone users especially in developing countries - in Bangladesh their share has risen from 0,2% to 46% during the time from 2000 to 2010. Through device sharing and access to call centers the share of actual mobile phone users among the two lowest-income quintiles in Bangladesh was estimated as high as 96% in 2009. Substantial research has been carried out on the social implications of ICT and mobile communication in high-income countries, whereas in developing countries the research focus has largely been on economic benefits of mobile communication based on access to information. The presentation will discuss the transformation of communication practices and social structures among low-income rural-urban migrants in Dhaka, induced through the practices of mobile phone use. A special focus lies on the dynamics of long-distance family relations and shifts in gender as well as power relations. The study uses a theoretical framework based on structure-agency theories as well as aspects of the capabilities' approach by Amartya Sen.

ICTs for Education and Development in Rural Vietnam

Minh Nguyen (VNU University of Science)

Information and communication technologies (ICTs) are great human inventions. They bring many social and economic benefits and dramatically change our daily life in all six continents. Vietnam is a SE Asian country with a large population living in rural areas. It is in the process of urbanization and is striving to basically become an industrialized nation by 2020 through efficient development of natural and human resources. To this end, ICTs play a very important role in creating good opportunities for education at all levels and development across the country. This paper attempts to answer the questions related to the country's experiences in implementing ICT programs and projects that lead to better rural connectivity for education and development in Vietnam based on literature review, site visits, and interviews with ICT managers, educators, researchers, and students. It is believed that an insight into these issues will serve as a sound basis for further national and international, public and private cooperation activities to maintain and upgrade ICT infrastructure, services and capacity building to prepare a qualified workforce capable of

conducting successful socio-economic and environmental applications of ICTs for sustainable development in the country in the years to come.

Web maps for visually impaired: Strengthening eInclusion & eAccessibility

Sabine Hennig (OeAW GIScience)

Advance of information and communication technologies (ICT) changed the way we communicate, exchange information, and catch up on contents. Virtual globes, web mapping services, GPS, and many other geographical digital tools are intimately linked to computer-based communication processes. With the rise of Web 2.0 dynamic web maps (providing interactions and multimedia integration) became more and more popular while using digital devices such as PCs, tablet PCs, and smartphones. Given current demand this opens up new opportunities for e-inclusion: On the one hand, society is asked to create an environment in which all people have equal, easy and dignified access to all kinds of infrastructure. On the other hand ICT applications can support disabled people in living more independently and self-determined (e.g. more, improved mobility). Thus, for instance provision of ICT tools suitable for visually impaired gains in importance as number of people with age-related visual impairment is increasing, due to demographic change, i.e. rapid aging of population,. While a number of guidelines and standards is available on providing partially sighted or blind people with (digital) non-spatial information (e.g. inclusive Design, WCAG, ISO 28803, ISO/ TR 22411), less material exists when it comes to publish spatial information digitally for visually impaired. Current applications make use of web maps for visually impaired difficult or even impossible. Hence, several open questions exist on appropriate design of web maps centering visual impaired: What should user interfaces (graphical, speech etc.) and interactivities look like? Which map content is asked for by this target group? Which cartographic design parameters are most useful to enhance accessibility? How can the map content be described textually (semantic spatial description)? The AccessibleMap project, funded by the Austrian Federal Ministry of Transport, Innovation & Technology (Benefit program) addresses the above questions. While creating a web map application the project targets at methods to make web maps on urban space more easily accessible for visually impaired (test area: a district of Vienna). AccessibleMap centers on graphical design and functionalities suitable for people with low vision and color vision deficiencies, and on providing semantic spatial descriptions on the map content (automatically generated from vector data) to meet blind users' needs. User requirements which are grouped under different categories of target user groups, i.e. people with low vision, color blind, and blind people, are specified based on literature review, online user survey, and close cooperation with experts and persons concerned. Engaging experts and users in the ongoing software development process (participatory design) ensures the usability of this application being platform-independent, executable on PC, tablet PC, and smartphone.

Leveraging buying power for development – Exploring “ethical” state e-procurement

Dorothea Kleine (University of London), Maria Das Graças Brightwell (University of London)

Individual ethical consumption choices are one way in which people with sufficient resources can express their views on what kind of economy they support and what kind of society they want to live in. In the terms of Amartya Sen's version of the capabilities approach, they can be part of the freedom people have to live the life they have reason to value, which in turn is key to development and human wellbeing (Sen 1999). Such individual choices stand in contrast to state procurement, where representatives of the state make decisions on behalf of the collective of citizens. ICTs are increasingly affecting both processes: the ability of individuals to make informed consumption choices and the move to more transparent state e-procurement. The paper will present selected findings from two projects: the EPSRC Fair Tracing Project (2006-2009) which used smartphone technology to give consumers independent product information at point of sale, and the recently launched ESRC-DFID Choices Project (2011-2013) on ethical consumption and ethical procurement in Brazil and Chile. In this project, a partnership between universities from three countries, we are exploring through participatory processes what Chilean and Brazilian citizens themselves define as “ethical” consumption. As policy makers in the two countries seek to steer their public procurement markets, together worth 63 billion USD, towards more ecological sustainability, the project asks what criteria citizens themselves would like to see applied. Drawing inspiration from Brazilian experiences in participatory budgeting, and the potential of ICTs for public discourse and collective decision-making, the projects seeks to explore ways in which public e-procurement can be aligned with citizens' individual and collective choices.

The feasibility of the animation industry in local regions: A case study of working conditions at an animation studio in Okinawa

Kenta Yamamoto (Kyushu University)

The animation industry is agglomerated in the Tokyo, Seoul, and Shanghai regions in East Asia. But, in recent years, some Japanese studios have established subsidiaries in local regions of Japan. This presentation examines the feasibility of developing the animation industry in local regions by showing the working conditions at a studio in Okinawa. In this process, we compare conditions with those of a studio in Tokyo. The studio in Okinawa was established with 26 employees in 2009 as the subsidiary of a Tokyo studio. Okinawa implemented a new industry policy whose aim was to generate employment from 2009 to 2010, and the studio in Okinawa was established to receive support from that policy. So half of the estimated 35 million yen they received through the policy as their budget for the project was used to hire jobless people living in the region. And the studio was obligated to produce and broadcast an animation program by March 2011 as part of

their fulfillment of the policy. When the studio was established, there were few local workers with experience in the animation industry in Okinawa. Workers at the Okinawa studio come into work at around 11 and leave work at around 20. These are healthy working hours in Japan. Creators belonging to the Okinawa studio work in the daytime because their working hours are strictly controlled due to the policy. On the other hand, at the Tokyo studio, workers often stay past midnight and rest in the morning. It is necessary for the Okinawa studio to cooperate with the Tokyo studio when they produce animation as they have no technological agglomeration. There is a small but critical time gap between them. As a result, the animators at the Tokyo studio produce the animation instead of the animators at the Okinawa studio. In this case study, we can find the following lesson. It is important for the studio to receive financial support from the Okinawan prefectural government so as to avoid investment risks when establishing new studios. However, the support from the prefecture also imposes restrictions on the studio, especially regarding the working conditions and the time allotted for technical training. Workers with talents and skills are essential for this kind of creative industry; however, such talented people cannot be trained and prepared in a short space of time. It is quite difficult to create quality products after only a couple years of training. The Okinawa studio achieved a certain result by providing jobs to the region. On the other hand, it is hard to say whether the studio can continually produce content. This case study implies that long term and continuous support, such as stepwise capital support, which also includes the measure to enforce the independence of the studio, is important in developing creative industries in the region.

The Gender Digital Divide in Rural Pakistan: How Wide is it and How to Bridge it?

Karin Astrid Siegmann (University Rotterdam)

While Pakistan's National Information Technology (IT) Policy aims at harnessing the potential of information and communication technologies (ICTs) for development, especially in the underserved rural areas, it ignores the role of existing gender inequalities on the possible benefits of ICTs. We have investigated aspects of the 'gender digital divide' in rural areas of Pakistan in order to enable an evidence-based gender-sensitive revision of the policy as well as ICT-related interventions from which both females and males gain. The study took place in four of the most marginalized rural districts of the country where this divide is likely to be most pronounced. We found mobile phones to be the ICT that is most commonly available in rural Pakistan. Radios and TV sets are the second most widespread technologies in marginalised rural areas. However, mobile sets at hand are largely owned by women's husbands, fathers and brothers, whose permission to make calls is required by a large share of all female respondents. I, therefore, argue that availability and gendered use of ICTs are two different things altogether. Social norms related to women and girls' access to education as well as regulating their mobility prevent them from using ICTs. These norms have to be taken into account in policies and interventions to ensure women and girls' access to and beneficial use of ICTs.

The Use of Communication Tools for Child-rearing Information among Mothers Living in Central Tokyo

Mikoto Kukimoto Fujita (Tokyo University)

This study clarifies the use of communication tools among working mothers to build mothering community in central Tokyo, an area lacking in childcare services and parental support. Recently, the problem of 'isolated mothers' has been gaining more media and public attention in Japan. The decrease in the number of children because of the lower fertility rate has created difficulties for mothers in exchanging child-rearing information and supporting each other. At the same time, centripetal population movements in the Tokyo metropolitan area and changes in the construction of condominiums since the latter half of the 1990s have been reported. In these areas, more families with small children have moved in, which are now facing a lack of childcare support, child-rearing community, and childcare facilities for the mothers who need to work outside home. Especially, in

redeveloped area in Tokyo, there are large number of new families with small children who has no child-rearing information or support resources in community. This situation increases the importance of communication tools including mailing list with mobile phone, blog and SNS in bringing mothers together. In this study, a questionnaire survey and interviews to working mothers with small children were conducted, in order to explore how the mothers with small children in central Tokyo acquire and exchange child-rearing information. The research area is "Toyosu" in Koto ward, the place in which the population has increased rapidly in the 2000s because of the growing number of super high-rise condominiums. According to the questionnaire survey, more than 90% of mothers don't have daily parental support because of long distance from their parents. They use telephone or email to acquire emotional support from their parents. Also, in an acute situation, such as mothers' or children's sick or business journey, their mothers(grand mothers of children) come to help beyond geographical distances. They are facing severe competition to use limited childcare facilities such as daycare nursery or medical support because of explosion of childcare needs in local level. Therefore, acquiring information about availability of childcare facilities as soon as possible is important for working mothers to balance work with family life. According interviews to working mothers, mailing list, blog and SNS play an important role for mothers to acquire information. First, mailing list is a significant tool to acquire new information about childcare facilities or pediatric service in Toyosu area. Most of mothers use mailing list on the mobile phone, which tell them new information wherever they are. Second, blog and SNS are places they not only acquire information but also exchange information or word-of-mouth about available childcare support. Some SNS communities are password-protected, which is more useful to the mothers who value their privacy.

Internet Accessibility and Related Issues in a Developing Country : A Case Study of Guwahati City, Assam, India

Rupali Bhuyan (Cotton College), Ruksana Sultana (Cotton College)

In the recent years, the development of technology has changed the world rapidly. One such technology is the internet, which is a part of telecommunications. The internet has enabled and accelerated the creation of new forms of human interactions through instant messaging, internet forums and social networking sites. Information is probably the biggest advantage internet has to offer. But the benefit of this digital revolution could not reach every nook and corner of the world. There is a huge digital divide among the rich and the poor. In the case of developed, developing countries, it can be seen that almost all the developed countries have more than 50 per cent internet users but developing countries only have about 15 per cent of it. This is because, with the exception of affluent and high middle class, a large chunk of people in less developed and developing countries do not have the infrastructure (computer, mobile or internet) to use the internet regularly. In India, where internet was first introduced in 1995 by VSNL, the growth of internet has been phenomenal. However, India still has only 6.9 per cent internet users

(81,000,000 out of a total population of 1,173,108,018 according to Internet Usage Statistics and Telecommunication Market Report, 2010). In Guwahati, internet was first introduced in 1999. Guwahati is the premier city and the most important cultural, commercial and industrial centre of North Eastern India. It is a home to a variety of people from different socio- cultural and economic backgrounds belonging to different age groups, and hence their needs and priorities regarding the use of internet are also not similar. Many internet cafes in every part of the city have sprung up to cater to people with weak economic background who do not have the infrastructure at home. Moreover, students residing in hostels without internet connection frequent these cafes. It is the young generation, especially the teenagers who are more interested in using the internet. Besides being a source of entertainment and social networking, internet has become an indispensable part of the education system. But though innovations in internet services were done with the best of intentions, many people nowadays misuse it, causing harm to the social atmosphere. Fraud advertisements, online robbery and use of pornographic sites are some of the problems the city is facing in the recent times. The study is primarily based on field survey. 100 samples of people from different age groups using internet facility have been collected from offices, institutions, homes and cyber cafes. A well-designed questionnaire covering all the aspects of internet accessibility and related issues has been used. This type of study has not been done in the study area so far. It is, therefore, expected that the proposed study will have immense academic significance and practical value.

Becoming Smart? On the Implementation of a Smart City Project Using Information and Communication Technologies in Germany

Lena Hatzelhoeffer (Bonn University)

In 2007 the City of Friedrichshafen, located at Lake Constance in Southern Germany, was declared winner of the T-City contest initiated by Deutsche Telekom. The T-City project aims to increase quality of life and location by implementing innovative solutions based on information and communication technologies (ICT). Given its history of technological innovation, Friedrichshafen seems to be the ideal place to realize a smart city project. However, the progress of the project using ICT to build an example for raising quality of everyday life has encountered difficulties and the reception by the citizens did not meet private and public partners' expectations. Different project cultures and organizational structures of Deutsche Telekom and the City of Friedrichshafen pose a major obstacle for a successful realization. In addition, the lack of visibility of ICT solutions hinders the public perception of the project. In Friedrichshafen many citizens regard ICT as a possibility to simplify certain aspects of their everyday life, but so far only a few citizens benefit from the multitude of individual projects within T-City which are targeted at specific audiences. Users of the project's solutions judge the core idea of T-City noticeably more positive than non-users. The evaluation of the T-City project is taking place over a five-year period and combines quantitative analysis with interview-based

explorations in order to reveal the achievements and difficulties regarding the project's implementation as well as opportunities for Friedrichshafen's development on its way to become a smart city.

Remediating the Urban. Implications of Mobile Phone Use on Urban Practices

Carola Wagenseil (University of Erlangen-Nuremberg)

How are mobile phone use and non-material dimensions of the urban connected? How does the usage of mobile phone as an integral device of every day life shape urban practices and urban lifestyle, and as a consequence urbanity? Located in the broader context of ICT and urban geography, the presentation will highlight these aspects with a focus on young adults living in Nuremberg, Germany. Research methods in the ongoing explorative study are narrative interviews and a GPS-based study of cell phone use in urban space. First results show that the selected age group is very heterogenous in using the mobile phone. This concerns both usage data like frequency and location of use and the mode of mobile phone use in a call situation. The same heterogeneity also applies for the perception and assessment of other people's mobile phone usage. The empirical findings furthermore suggest tendencies to a reorganisation of communication and coordination of individuals in the city as well as modifications in the individual's way dealing with privacy. Urban practices e.g. exploring the city in a very spontaneous way, lingering with friends in public space or presenting oneself in the public seem to be strengthened while other properties of a "classical urban" lifestyle e.g. being confronted with strangers seem to be weakened in a mobile phone society. Many aspects of the German discussion about urbanity are touched by these processes, for example anonymity, private vs. public sphere, city as place where strangers meet (e.g. Simmel) and others. Urban society in the age of mobile phone seems to be constituted by some new practices and rules, but these new developments don't contrast former ideas of urbanity, they rather modify and reshape them in different ways. So findings of the study don't affirm arguments that suggest a general shift in urban spheres and urban society. In the presentation I will discuss if these processes could rather be linked to the concept of 'remediation' (Bolter & Grusin 1999), a concept developed in media science and originally limited to a narrower media context.

C08.15

Geography of Tourism, Leisure, and Global Change

C08.15-01 - Global Change and Tourism: Socio-Cultural Issues

Chair: Jarkko Saarinen, Alan Lew

The Place of the Luxury Hotels Metropolitan Context of Sao Paulo (Brazil) and Buenos Aires (Argentina)

Carlos Henrique Costa da Silva (Universidade de São Carlos)

This work does an analysis about the role of the big international hotel chains and the concentration process of the luxury hotels in determined parts of São Paulo and Buenos Aires metropolises, with the setting of new centrality areas, which came from new articulations between local and worldwide plans. At first, we highlight that the location of these hotels is linked to the places of larger concentrations of the most important commercial, services and company management sectors activities. These are the places where the global economy contemporary businesses are done. The discussion includes an analysis of the globalization process and how the big companies have articulated themselves to guarantee their profit, what, in our understanding, ends up producing the corporative and fragmented metropolis as presented by Santos (1994). For a better understanding of the hotel business dynamics in these two metropolises it's crucial to highlight the tourism sector and its direct relationship with the real state and financial sectors. Tourism and its businesses, or better, the businesses which have pushed the tourism development in the most important cities in the world, must be seen as an important factor for the raising and discussion of subjects which consider this socialspatial practice beyond leisure. Today tourism is no longer an activity subdued to others, for many times, it presents itself as one of the few ways to generate certain richness for some places.

Tourism for Development? Local perspectives to tourism and its role in socio-cultural change in Northern Botswana

Jarkko Saarinen (University of Oulu), Julius Athlapheng (University of Botswana)

Tourism as a global scale and growing industry has great potential to provide benefits to its destination areas and communities. In southern Africa, including Botswana, tourism is seen as a good strategy for the development and economic diversification of the country. The current tourism related policies encourage increasing local participation in tourism development and there are also emphases on the need to create better awareness of tourism among the local people, in order to capitalise on the prospects of growing tourism. This paper overviews the basic nature of tourism in Botswana and the current policy context of tourism development in the country. Based on community interviews the paper aims to analyse the local perspectives to tourism and its socio-cultural impacts in

Northern Botswana. The results indicate that local people are relatively aware of the tourism industry and the nature of its' local operations and impacts but very few are actually involved with the industry or benefit directly from it. This raises questions related to the sustainability and practices of the industry and the implementation of the national tourism policies. Keywords: tourism development, benefits, awareness, impacts, communities, policies, Botswana.

Writings as cultural symbol writing the places in China's tourism destinations

Jie Zhang (Nanjing University)

Calligraphic landscape was defined as a portion of geographical space with a specific visual characteristics and special sense of place resulting from the laying-out of assemblies of calligraphy as landscape elements. As Chinese calligraphy is a typical symbol of Chinese culture, calligraphic landscape was typical traditional Chinese culture landscape and an important part of cultural landscape of both urban and town. On the basis of different character of calligraphic landscape, this paper developed an index of calligraphic landscape to measure the Spatial differentiation of calligraphic landscape with respect to its scripts. Almost twenty surveys of calligraphic landscape were done to detect the spatial differentiation all over the cities and towns in China with different background of globalization and modernization. Survey areas included those areas well-affected by globalization, like Beijing, Sichuan, Jiangsu, Hong Kong and relatively less-affected by globalization like Anhui Province and those vernacular townships. The statistical results of calligraphic landscape showed obvious spatial differentiation phenomenon. Spatial differentiation not only existed among the cities and towns with different cultural attributes and functional attributes, and also existed between the peripheral zone and the core zone within the same cultural or business block. The important factor forcing this Spatial differentiation of calligraphic landscape was subconscious cognitive and cultural identity to calligraphy of shopkeepers. The spatial agglomeration of different shops which forced by the pursuit of the agglomeration benefits was another important factor. Considering calligraphy as symbol of landscape and culture in subconscious of Chinese people made calligraphic landscape having functions of space delineation and definition and may contribute to the formation of cultural symbolic space of cities and towns. Research of calligraphic landscape has practical meanings to the protection of traditional Chinese cultural landscape under the process of globalization and urbanization. It is supposed to be a kind of national identity in globalization era. So Chinese writings of calligraphy as symbols in landscape writes the different places in tourist destinations.

Spatio-Temporal Development of Tourism in Tamil Nadu State of India: Socio-economic Assessment

Gambhir Singh Chauhan (University Madhya Pradesh)

Tourism is a major engine of economic growth and harnessing. In the changing globalized economy of 21st Century, there is a great pressure on modern living and life style and as a result, large number of people is trying to get away from stress and strain of modern urban life and relax in a healthy and peaceful atmosphere. Tourism has emerged as the most significant industry in India. In case of India, particularly in Tamil Nadu state, travel and tourism business is growing at very fast speed during the last 10 years. India is one of the major destinations of the foreign Tourists particularly the state of Tamil Nadu which has a rich cultural heritage among the Indian states. The statistical figures reveal that major lion share of total tourist's arrivals both foreign and domestic are coming to Tamil Nadu. The results of temporal analysis of both domestic tourists inflow reveal that in 1993 only 14.21 million (1,42,11,900) domestic visited which further touched the highest 39.21 million tourists (3,92,14,721) in 2006. Where as in case of foreign tourists inflow the total number visited in 1993 were 0.43 million (4,35,473) which has further witnessed the remarkable increase i.e. 1.33 million (13,35,661) in 2006 in Tamil Nadu state. Tourism has direct and indirect multiple impacts on various anthropogenic activities of the human society. It makes an important contribution to socio-economic growth, employments and foreign exchange earnings. It has immense potentiality in order to generate substantial income and employment opportunities and ultimately strengthen the national as well as local economy. Tourism is a unique and dynamic tool which has substantial potential to change the socio-economic conditions of major line shares population of specific region. Key words: Lion share, anthropogenic activities, immense potentiality.

C08.15-02 - Sustainable Tourism 1

Chair: Jie Zhang, Carolin Funck

Tourism observatory and indicators: Challenge in the sustainable tourism Agenda in Mexico

Oscar Frausto (Universidad de Quintana Roo)

Tourism Observatory and indicators: challenge in the sustainability tourism Agenda in Mexico The monitoring and controlling of indicators of the Tourism Agenda, across the local tourism observatories, is of recent creation in Mexico. The observatories are local organizations that link the governmental sector and the civil society with the expert researchers as for local, human development and sustainable of the destinations. The present work has systematized finally the experiences of the Program Habitat in the item of the creation and state that there guard the local tourism observatories of Mexico and the results of the monitoring of the indicators for the period 2000 - 2005. The design and development of general indicator systems for diverse regions and areas has been difficult and had discouraging results, especially in the field of tourism. The result of the experimental programme on sustainable indicators and observatories for Mexico illustrates this trend. In the present contribution, 44 experiences of sustainability tourism indicator development for a specific regional context are presented. The examples from Mexican destinations underline the necessity to develop indicator concepts based on the specific problems and goals for the region without neglecting the global principles of sustainability and tourism. Furthermore, the description of both case studies (methodology of selection, indicators and its application) illustrates the problems and challenges of indicator concepts for a specific region. Finally, the authors give some recommendations for the development of a Tourism Agenda for a specific regional context in Mexico.

Mallorca and sustainable tourism – synonym or oxymoron(?), and the challenges ahead

Angela Hof (Universität Bochum), Macià Blázquez-Salom (Earth Science Department), Thomas Schmitt (Geography Department, Chair Landscape Ecology/Biogeography)

Starting from a review of tourism development and the relevance sustainability has gained in the last fifty years of tourism in Mallorca, Balearic Islands (Spain), the paper discusses future pathways, options, and challenges in the face of climate change and the limits of growth on the island. As one of the major Mediterranean tourist resorts with an internationally acclaimed Local Agenda 21 and sustainable development as its overarching policy objective, the municipality of Calvià is a paradigmatic example to unfold this critical discussion. Passed in 1999 and coined as a sustainable strategy for a

tourism destination, the innovative Local Agenda 21 formulates the limitation of urban growth and a reduction of water consumption as main development objectives. The Agenda 21 came alongside a strategy of more diversified tourism development and tourist specialization. Already in 1990, the municipality started to retrofit its mass tourist success model by so-called 'quality tourism' and 'tourist excellence'. Specialization in conjunction with the development of the real estate market, international capital flows, economics, institutions and policies has produced another tourist boom. As a result, 12% of the yacht berths and 25% of Mallorca's golf courses are concentrated in the municipality which has a proportion of more than 60% second homes and is characterised by an urbanised coastline with residential resorts and villas around mass tourist centres. Notwithstanding, limitations to urban growth have been abandoned as a political mainstream goal, as far as new conservative governments have implemented the neoliberal agenda to Mallorca's regional planning. The paper presents results from interdisciplinary research over the last two decades: spatially explicit landscape analysis and environmental indicators document habitat loss, accelerated water consumption, energy demand and waste generation, and cast a critical light on sustainability in the long run. Water management in particular is a key challenge for the economic and ecological sustainability of tourism. With its significant vulnerabilities to climate change and an already critical water demand-supply ratio, Mallorca is beginning to experience the challenges that many resorts will probably have to face in the near future. The paper sums these findings and new questions up by discussing whether the concept of ecosystem services may be a new opportunity to steer future development into a direction which attaches values to nonmarket commodities and recognizes the important role natural areas, landscape heterogeneity and sustainable water management play in promoting the tourist product in the long-term. The revision of the sustainability key indicators for Calvià, taken as a paradigmatic tourism destination, can help to reconsider tourism sustainability in the context of glocal change and capitalism's crisis.

Whale watching as sustainable tourism development strategy in El Vizcaíno Biosphere Reserve, Mexico

Marius Mayer (Universität Würzburg), Bernadette Schauss (Universität München)

Whale watching tourism (WWT) shows increasing importance in world tourism. The economic effects of WWT constitute an important argument for protecting whales and continuing the banning of whaling. As a sustainable tourism activity WWT reconciles the strict protection of the marine mammals with the economic interests of local people. One of the best WWT spots in the northern hemisphere is the biosphere reserve El Vizcaíno (BREV), Baja California Sur, Mexico. At the destination level the demand- as well as the supply-side are analysed in order to deal with the following research questions: - How high is the regional economic impact of WWT in BREV? - Can WWT serve as a sustainable regional development strategy for the peripheral area of Central Baja California? The BREV is located in the north of the state of Baja California Sur on the

Mexican peninsula of Baja California. The tourist frequentation of the region goes hand in hand with the hibernation of thousands of Californian gray whales in two lagoons. Thus WWT is the principal type of tourism and dominates the structure of the local tourism industry due to an extreme seasonality with four months of high frequentation. During the WW season 2006/07 a sample of 382 WW tourists were asked for their trip motivation, expenditure patterns and sociodemographic characteristics. Parallel counting of WW tourists validated the official visitor numbers. Nearly all tourism enterprises (in total 40) were interviewed qualitatively in 2007. Thus we were able to estimate the economic impact of WWT from the demand as well as from the supply side, which enhances the reliability of the results. In a conservative demand-side estimate 13,000 WW tourists generated a gross turnover of USD 2.79 million in the WW season 2006/07. For more than 90% of the visitors the whales were the main reason to come to BREV. On average, an individual tourist spends USD 69.48 per day in BREV, thereof 35% on the WW tour, and stays on average 2.94 days in the destination. These results are supported by the supply side study which calculated a gross turnover of tourism in BREV summing up to USD 2.85 million. In total, WWT in BREV creates 334 seasonal and 180 year-round jobs. The importance of tourism for the local economy varies significantly between the small town Guerrero Negro (3.3% of the total workforce; the world's largest natural salt production plant is located there) and the village of San Ignacio (18.1% year-round, 45.8% seasonal). Furthermore, the supply-side study reveals a high outflow of tourism revenues of 75%, mainly for intermediate inputs. Thus, WWT in the BREV constitutes an important economic factor for the region, but its economic impact should not be overestimated because of limited visitor numbers, an extreme seasonality and a high leakage rate.

Sequential characteristics of emotions during hiking experiences in nature-based tourist destination

Koun Sugimoto (Tokyo University)

Hiking is one of the most popular activities in nature-based tourist destinations. People enjoy walking on trails while seeing landscapes. Therefore, how to design trails has been an important topic for tourism planning in every nature park. The present study discusses the interaction between human activities and trail environment. The main purpose of this study is to clarify sequential characteristics of one-day hiking experiences in a national park. Our research was conducted in the Mt. Mitake-Hinodeyama walking trail in Chichibu-Tama-Kai National Park in Tokyo, Japan. This trail is the model courses introduced in a tourist brochure. The trail goes through forest environment and passes by Mitake Temple, some commercial facilities at the top of Mt. Mitake, scenic view points at the top of Mt. Hinode, and a hot spring facility at the end of the trail. A group of university students were asked to answer a questionnaire for describing their emotions and feelings at seven locations on the trail. Questions were constructed with 17 emotional factors related to their experiences: attracting, boring, challenging, crowded, depressing,

enjoyable, exciting, exhausting, frustrating, interesting, lonely, motivating, nervous, pleasing, promising, relaxing, surprising. Multivariate analysis was applied to those data sets. First, MDS method was used to visualize the similarities and dissimilarities among factors. We interpreted that Dimension-1 represented a positive-negative relation, while Dimension-2 corresponded to an intrinsic-extrinsic relation. Next, hierarchical clustering was applied in order to extract clusters of similar emotional factors. As a result, four clusters were identified. Cluster-1 (attracting, enjoyable, exciting, and pleasing) showed high values when the participants hiked Hinode Mountain and rested at the hot spring facility. Cluster-2 (challenging, interesting, motivating, promising, and surprising) was relatively high in the beginning, but the values tended to fall gradually as the participants went on. Cluster-3 (crowded and relaxing) fluctuated irregularly. This was probably because crowded and relaxing were strongly influenced by extrinsic factors such as the characteristic of locations. In the case of cluster-4 (boring, depressing, exhausting, frustrating, lonely, and nervous), the values of emotions except exhausting continued low, but the values increased during the descent from Hinode Mountain. The value of exhausting was higher than those of other emotional factors of cluster-4 at all survey locations, but interestingly, it showed a very similar fluctuation with the values of others. Thus, we concluded that tourists' emotions during a recreational activity were not stable, but unique sequence patterns were formed for each emotion type.

Chair: Jie Zhang, Carolin Funck

Indicators to assess the environmental and socio-economic impacts of tourism on protected areas of Mongolia

Navchaa Tugjamba (University of Humanities), Erdenetuul Sereeter (University of Humanities)

The Protected Area Network of Mongolia cover over 14.5 percent of the total country's territory and has become major destinations for rapidly growing tourism and recreational activities for its natural beauty, rare species of wildlife and historical and cultural heritage sites. According to the Millennium Development Goals, the Government of Mongolia made the legislative commitment to set aside 30% of its territory as protected areas by 2015. Over 80 percent of Mongolian protected areas are occupied by tourism and related activities which impose such adverse impacts as environmental pollution, land degradation, loss and damage of historic and cultural heritage sites. On the other hand, tourism is the main source for funding Protected Area administrations. Therefore, it is crucial to develop indicators to assess the environmental and socio-economical impacts of tourism on Protected Areas. Development of such indicators will enable the policy makers, project initiators and project beneficiaries to duly monitor, evaluate the project implementation in order to promote and sustain positive outcomes while preventing and minimizing adverse impacts. Our research team purposed to develop the assessment indicators of the environmental, socio-economical, management and infrastructural impacts of tourism on Protected Area. Field research study was conducted on "Orkhon Valley" National Park in order to verify the development and implementation plan of proposed methodologies and indicators. The main paper consists of four sections and "Introduction" part explores the understanding of Protected Areas, legal framework of tourism activities on Protected Areas (PA), in case of Mongolia and challenging issues of tourism development on PAs. The comparative studies on assessment indicators of tourism impacts to PAs made in case of international and national levels. Second section describes the "Indicators of environmental and socio-economical impacts of tourism on PAs". Moreover, this part explains the indicators' frame and limitations, application principles, estimating units and evaluation periods. Third section identifies the assessment methodologies of the indicators. Environmental, socio-cultural and economic indicators would be evaluated by -3 up +3 scores. -3 shows the lowest negative impact and +3 expresses the most positive impacts. 0 means no tourism impacts. Final section includes the legal frame of indicator application. And some recommendations and options to make change in legal documents and related regulations for the purpose of maximize positive impacts and minimize negative impacts of tourism on PAs were included.

Sustainability and tourism transport: Regional impacts of ski-incoming tourism by plane to the Alps

Tobias Behnen (Universität Göttingen)

Due to the topography air transport in a high mountain region is subject to special ecological, social and economical but also technical circumstances. Therefore the impacts of actual growth processes in tourism for the airports and their surroundings often contradict the goals of sustainable development. Despite the volatility of the market during the last decades many airports in the Alps have had a significant increase of the passenger numbers. The incoming ski tourism is a main push factor. It is carried out with scheduled flights by full service carriers and low cost carriers but also with charter flights. The aim of this paper is to characterize and discuss the development and its sustainability referring to typical airports and to show which regions, institutions and persons profit from the process and which are affected adversely. Own quantitative and qualitative empirical research was conducted at Salzburg, Innsbruck, Klagenfurt (all Austria), Bolzano (Italy), Berne (Switzerland) and Ljubljana (Slovenia). Most of the ski-tourists which especially come from the British Isles, Scandinavia, the Netherlands, Germany and Russia arrive on Saturdays where some airports have to manage overloading at the airside and at the landside. It is another remarkable result that the flights for tourists do not only substitute other means of transport (car, bus, train) but induce entire new journeys to the Alps. The road towards more sustainability would include efforts and regulations concerning noise, land use, inter-modality and modal shift but most notably a better communication and participation of all stakeholders in ski tourism.

Territorial dynamics in Brazilian Pantanal wetland: Impacts of the tourism and planning proposals

Carla Moura de Paulo (USP)

Pantanal wetland, study area of the present work, is in a good state of conservation and has a biodiversity strictly related to its local dynamic, especially due to the flood pulse. The natural attributes reveal a favorable scenario for the development of tourism activity, which has been growing since 90's. Though, this practice may represent a serious threat due to the changes in the natural environment and to the establishment of infrastructure in wild locations. In this way, this research has established an analysis of the territorial dynamics influenced by the tourism in four municipalities of Pantanal: Aquidauana, Corumbá, Poconé and Cáceres. The main characteristics of these municipalities were identified, also the urban and periurban areas of each municipality were studied and the uses of Pantanal by the tourism sector were identified. The main environmental impacts were analyzed, besides the planning instruments capable to diminish these impacts and the policies that are related to the theme. The study of the instruments and policies - analyzed in global, federal, state and municipality scales - has shown a strong necessity that this issue be addressed in regional scale. In the meaning of constrain the individual

actions of municipalities and, in the other hand, to strength the decisions that consider the whole Pantanal wetland and not only those that benefit the administrative boundaries without a natural logic. In case of consideration of these conditions, the tourism could be an allied for the Pantanal's conservation, as this activity depends on a good state of the natural environment to the attraction of tourists. Keywords: Pantanal, tourism, environmental planning, environmental impacts, public policies.

Recreation development features in Russian protected areas

Leonid Korytnyy (Russian Academy of Science), Natalia Luzhkova (Russian Academy of Science)

In the Era of Climate Change and Human Impact, existence of protected nature areas is essential for the Biosphere sustainability. Strict reserves are the leading category in pristine wilderness conservation. In 2011 Russian Government passed the 'Strategy 2020' on the Federal Protected Nature Areas development, where they were proposed to put ecotourism into service to increase self-efficiency. To implement this first recreation project nine model territories were selected and granted funding. According to environmentalists, the selection was controversial because these 2011 - 2013 Federal Budget Allocations were provided to Strictly Protected Nature Reserves (or zapovedniks), the most nature protecting category in Russia and Worldwide. For decades Zapovedniks have been the most spread category of environment component protection with the mission to conserve unique and typical nature through complete human activity prohibition. With the first Barguzinsky Zapovednik establishment in 1916 their number has grown to 102, covering more than 2% of Russian territory and delivering unique philosophy of strict protection. Hypothetically, now all this vast land can be unveiled to the World society. As the decision on Zapovedniks has been made, a number of actions have to be taken to make upcoming changes both environmentally friendly and sustainable for the nature and people. Two (Baikalsky and Baikal-Lensky) of nine selected reserves are located in the Lake Baikal Natural Territory. The Federal Legislation and UNESCO Nature World Heritage Site Status protect Lake Baikal and its watershed from certain industrial developments. So the protected areas have to develop tourism and meet sustainability criteria at the same time. Our main research has been conducted in Baikalsky Biosphere Zapovednik established in 1969 in Southern Lake Baikal. Under its bylaws main factors of sustainable recreation development were identified for Baikalsky Reserve: 1. Environmental. Protection of all inhabitant components is primary, therefore only environmentally friendly types of tourism may be introduced. 2. Social. Collaboration with all stakeholders is important to gain positive attitude to the upcoming changes. However success depends on the partnership level between the Reserve staff and locals. Residents can prosper though providing services to reserve visitors. 3. Managerial. The zapovednik has to elaborate a gradual conception of recreation infrastructure development and discover effective management tools. 4. Economical. Each recreation activity has to be justified and calculated as well as the contribution and profit of

bordering establishments to provide full tour packages. Hiking tourism is foreseen as a sustainable type of tourism and our trail classification is been implemented as an effective management tool in Baikalsky Reserve. The gained experience can be further used in other Reserves and National Parks.

C08.15-04 - Tourism Development and Management

Chair: Jie Zhang

Institutional Initiatives on Tourism Policy and Creation of Sustainable Tourism Concept

Anna Torres-Delgado (University of Barcelona), Francesc López-Palomeque (University of Barcelona)

In the last two decades sustainability as a concept has strongly emerged in tourism sector, reorienting and enhancing public management of tourism and inducing the process of formalizing the sustainable tourism concept. In this context, numerous institutional initiatives have defined a framework for theoretical and applied development of sustainable tourism, which has allowed generalizing the sustainability paradigm in the new contemporary tourism. Gradually these initiatives have been outlining and determining the current conception of sustainable tourism; therefore a process of institutionalization of the concept has occurred. Policies and institutional initiatives have progressively evolved from a green sense, exclusively based on environmental conservation, to a more comprehensive meaning which considers the balance between society, environment and economy. In this evolutionary process sustainable tourism has been created as a concept in itself, acquiring meaning and value, until today when it has become a maxim in any desired tourism model. Based on this framework, this paper presents the results of an analysis and evaluation of several institutional initiatives on tourism policy at international, European and Spanish level. It provides knowledge about the process of creation and use of sustainable tourism concept, through studying initiatives that have been developed over the past 20 years. The systematic analysis of 55 institutional documents at international, European and Spanish level has pointed out the importance of these initiatives in introducing the principle of sustainability in the tourism sector and, moreover, their contribution in creating and promoting the sustainable tourism concept.

Tourism in Croatia: Projects for a sustainable future

Ornella Albolino (University of Naples)

Tourism in Croatia: projects for a sustainable future Ornella Albolino The paper aims to consider the development and evolution of the tourist sector in Croatia and its economic and social impact. Croatia can be considered an interesting case study on the relationship between tourism and sustainable development. In particular a special attention to local specificities seems to be present in policy planning and project implementation. Even if seaside tourism is prevailing, initiatives towards sustainability are concentrated on environmental, rural and cultural tourism. Tourism development in Croatia has been a meaningful pattern since the 60s of the XX Century when some

infrastructure constructions, such as the Jadranska magistrala and the airports of Split, Pula and Zadar, reinforced the international profile of the touristic flux. After the dramatic events of 1991, there was an overall blockage of this development and even tourist attractions were often considered war targets. It's with the creation of the new independent state that tourism received a new spurt, being it considered as an integrated asset of the economic development of the Country. After the war, the first investments were devoted to re-establish the infrastructures: the reopening of Dubrovnik and Split Harbours were the first steps to relaunch the tourism industry even if the perception of Croatia as war zone damaged its international image. Since the beginning the investments have been made on multiple fronts: ' territorial marketing campaigns to reinforce the image of a safe land, ' an opening - even if cautious - to the international capital, Policies and projects are inspired to the conservation and the valorization of the cultural and environmental heritage and, even if the coastal areas were the most renewed international destinations, the government promoted meaningful initiatives in in-land and rural areas as well as in natural parks and protected zones. Among the most interesting actions it should be considered the COAST project (Conservation and Sustainable Use of Biodiversity in the Dalmatian Coast) sponsored by UNDP, targeted towards sustainable policies in order to integrate tourism, fishery and agriculture with a special attention to eco-tourism. However, there are also weaknesses: despite the various initiatives implemented at local level, a coordinated and integrated planning at national scale is absent. Nevertheless, different best practices makes Croatia an interesting example for the Mediterranean Region.

The Development of Antarctic Tourism: Implications of Multilevel Spatial Management

Andrii Fedchuk (National Antarctic Scientific Centre)

Over the past two decades tourist activities have grown and diversified rapidly, and now tourism represents an increasingly important aspect of the Antarctic economy in terms of the number of participants and modes of transport. The absence of local authorities in the Antarctic region makes spatial management a useful strategic approach for regulating human activities, particularly tourism. Key elements for sustainable tourism development in Antarctica have been developed through joint efforts of governments, inter-governmental, and non-governmental bodies, as well as business initiatives. A multitude of good tourism management practices exists throughout Antarctic that should be evaluated for either expansion to new regions or modification for current tourist activity areas. The site-specific guidelines have already been created for most of these frequently visited sites, with the intention to provide a code of conduct and allow for a flexible approach to in situ visit management. Tourism development at these frequently visited sites is monitored to assess the effectiveness of these site-specific guidelines. This piece of research also describes how environmental and management changes affect the spatial extent and diversification of human activities in certain area in Antarctica. The

activities in the area of Ukrainian Vernadsky station (former British Faraday station) are shown as an example. Vernadsky station may be considered representative in touristic term because it has been regularly visited by seaborne tourists since 1968. The visitor sites in the station area became tourist destinations as a result of varied factors, including its natural and historic attractions as well as annual sea ice conditions with a tendency to improve accessibility of the station location due to regional climate warming. On the other hand, the increase in the number of visitors is also due to the fact that the station has changed its governance since 1996. As a result, in the period of 1995-2011 visits of both cruise ships and yachts have increased considerably. It is suggested to elaborate a broad-scale management system for the area which is under the influence of Vernadsky station.

C08.15-05 - Sustainability Related with Second Homes

Chair: Jie Zhang, Carolin Funck

Assessing Sustainable Development of Second Home Tourism and Same Day Visits in Northern Rural Areas of Tehran Metropolis

Mohammad Reza Rezvani (University of Tehran), Saeed Reza Akbarian (University of Tehran)

Introduction: There are many attractions and resources in rural areas to develop of tourism activities. These attractions in rural areas of around of metropolises have more importance due to special conditions of urban environments including mass market, environmental pollution, and need to leisure spaces. There is much tourism attractions in northern rural areas of Tehran metropolis and people of this city highly depended to these areas. The second home tourism and same day visits are two important pattern of tourism in these villages. In Shemiranat County as a metropolitan rural area, there are about 4705 second homes (%38.76 total house) according to field observations. The expansion of rural tourism in this area has had many effects and impacts on local people and villages in environmental, economic and social dimensions. The assessing tourism effects and sustainability of two patterns of second home tourism and same day visits are very important. **Methodology:** The current research is applied and its method is descriptive. The required data is gathered by questionnaire that made by researchers. Statistical populations are four groups including local managers, local residences, second homes tourists, and same day visitors. Sample sizes 17 villages and as well as 34 managers, 281 same day visitors, 164 second home tourists and 281 local residences. According to three sustainable development dimensions, 13 index and 87 indicators of economic, social and environmental is selected and is measured by Likert scale type of question from strongly disagree to strongly agree. The validation of indicators and index is assessed by Delphi method and a panel of 35 tourism researches and experts. Finally, the gathered data is processed and analyzed by SPSS. **Results:** The research results indicate that mean value for economic sustainability indicators is 2.99, social sustainability indicators 2.93, and for environmental sustainability indicators is 2.94. Also these values for second home tourism are 3.24, 3.23 and 3.17 and for same day visits are 2.74, 2.62 and 2.7 respectively. Furthermore, the mean value for all of indicators for second home tourism is 3.21 and for same day visits is 2.69. Therefore; sustainability of second home tourism is more than same day visits relatively. This increase is seen in all of sustainability dimensions. **Conclusion:** As the study showed, sustainability of tourism in study area is average, but there existed meaningful differences between the two patterns. Therefore the planning and management of tourism activities to increase of tourism sustainability is necessary through community participation. **Key words:** Second Home Tourism, Same Day Visits, Rural Tourism, Sustainable Tourism, Tehran Metropolitan Area

Second Home Tourism as a Factor for Sustainable Development: Case Lake Engure Watershed, Latvia

Maija Rozite (School of Business Administration Turība), Daina Vinklere (School of Business Administration Turība)

The fishing in coastal municipalities is losing its significance and tourism is becoming one of the significant activities and it is important to promote tourism and recreation development while balancing the socio-economic interests of the local inhabitants and preservation of the natural environment. The paper analyses the impact of tourism not only on the nature reserve territory but also on a wider scale - the whole Engure's Lake drainage basin area. Researches on tourism impact until now have been usually focused on traditional tourists and same day visitors whereas second home tourists were never taken into account and their impact has not been evaluated. The aim of the research is to evaluate role and impact of second home tourism on sustainable regional development in the Latvian coastal region, a part of which is also the specially protected nature reserve territory. Owners of summer houses and recreationists were surveyed, their behaviour, the local services availed, the involvement of local municipality in the process and their future plans were studied to evaluate the possible impact of second house tourism. The research results show that so far tourism pressure in the whole Engures Lake drainage basin has been relatively low. Results of research validate that project area is not single tourism destination, but at least 3 tourism zones (2 well expressed zones and one zone with separate tourism clusters) with different tourism pressure on environment. As Engure Lake is not primary destination for tourists, main travel motivation is transit and short-term recreation. Therefore equal attention should be paid to recreation and tourism development and impacts. The most impact is forecasted from second home tourism. The coastal territory already has a lot of summer houses and a part of the previous living houses are used only during the summer season. With the improvement in the economic situation the project region coast could appeal to more affluent migrants who could due to the relative proximity of the capital city relocate to the attractive sea coast as a permanent place of residence commuting to their workplaces in the capital city. The main results gathered analysing field work and survey results indicates that this activity creates pressure and changes the environment and landscape, but it would still be less compared to the pressure created by commercial tourist accommodations. Holidaymakers contribute not only to the local economy but also are a lot more responsible towards the environment and try to preserve the value and uniqueness of the natural environment as they consider themselves belonging to the place. Therefore municipalities have to develop a special development policy not only for tourism but also for recreation. Simultaneously cooperation should be developed with second home owners, who reside here not only during the season but also very often during weekends all year long.

Sustainability, urbanization and tourism: New challenges for second home tourism in a global crisis context in the interior of Catalonia (Spain)

Alfonso Daniel Martínez Casal (Universitat de Barcelona)

The process of generalization, democratization and expansion of tourism, which in recent decades, are knowing most of spaces and social groups, is leading to a process of turistification of the territories from the new dimensions and facilities of the spatial mobility and the hierarchisation of territorial functions (Vera et al, 1997). In this general context, the second homes have known strong expansion throughout the Mediterranean area. When there are doubts about the sustainability of this model of urbanization, from different administrative scales attempt to justify the need to reach the functional diversity of the territory and its economic development. Second home tourism is closely linked to the saturation of large cities and metropolitan and the need to scape of them on holidays and leisure (free) time. In addition, also is linked to economic development since the 1960s, an increase of employment benefits or changes in transport and communications network (reduction of working hours, increased purchasing power...) which have generated demand for the purchase of this type of second home over the past decades, although must take into account the current context of economic crisis that has slowed (but paralyzed) the second home development. For this reason, the formulation of initiatives and proposals to regulate the second home development in the current crisis economic requires to tend towards a sustainability model of territory. However, the lack of an integrated territorial planning reveals inconsistencies between the bet on the residentialism and the warnings about their social and economic impacts (Millán Escriche, 2005). The second home tourism can be understood as economic activity oriented urbanization, construction and sale of housing unrelated traditional hotel and touristic sector, whose users use them as accommodation to spend their usual periods of leisure and rest outside their places of residence and respond to new forms of mobility and living causing obvious territorial effect in the spaces where they settle (Mazón and Aledo, 2005). Under these premises, this paper will analyse the role of the second home in the process of urbanization of Catalonia and the complex relationships that presents residential tourism with traditional tourist activity in the interior of Catalonia giving raise to the residential specialization of many municipalities in interior, which has contributed, on the one hand, to revive the economy and set population of many interior spaces, and on the other hand, to generate significant territorial changes in pre-existing territorial structures. Territorial effects that have altered the spatial organization of these places, and which therefore need an adequate response from the public and private actors responsible for planning and land management to local and regional level in order to achieve a balanced and sustainable territorial development.

Community involvement and the sustainability debate: A study of homestay operations in the Kumasi Metropolis

Elizabeth Agyeiwaah (University of Cape Coast)

Sustainable development has been replicated in tourism studies due to the enormous benefits it brings to stakeholders of tourism. More importantly, the dependence of most communities on tourism returns requires that the phenomenon is developed sustainably. The purpose of this study was to assess the sustainability of homestay operations in the Kumasi Metropolis. Specifically, the study explored the sustainability of homestay operations in the metropolis and the participation of locals in the homestay business, the preservation of the culture of the host families and enhancement of the experience of tourists. From a quantitative perspective, 151 international guests were sampled accidentally. While, 10 host families who have been in homestay operations for at least three years were selected purposively and interviewed using in-depth interview guide. The study revealed that socio-cultural, economic and educational motives propelled host families into homestay business. Homestay registration fees and service requirements were considered flexible by host families making it easier for them to get involved. The study further suggests that homestay business in the Kumasi Metropolis is sustainable with bright future prospects. Specifically, the management of homestay operations were done exclusively by host families and the hosts' culture was preserved through socio-cultural interactions with guests which made them stay for longer periods. More importantly, the availability of intermediaries such as NGOs and tour operators who supply host families with an all year round customer base makes the homestay business lucrative and sustainable. In addition to this, homestay operators charged cheaper rates per night (US\$9-15) compared to hotels (US\$60-137). There is also the existence of homestay regulations by the Ghana Tourism Authority to facilitate and sustain homestay operations in the metropolis. For guests (90.1%), the home setting provided the opportunity to learn new things which would not have been possible in hotels. However, delayed payment by some intermediaries is a challenge faced by homestay operators. It is recommended that intermediaries make timely payments for a successful homestay operation.

C08.15-06 - Tourism sustainability with GIS and zoning systems

Chair: Jie Zhang, Carolin Funck

A GIS based MADM model about tourist resort for post mining land use (Case study: Darreh-Zereshk)

Nazila Najafi (Azad University), Ahmad Pourmoroufard (Azad University)

In order to perform a sustainable mining activity, mining area should not be left useless and abandoned. One of the options for post-mining land use is reclamation and development of a tourist site. Darreh - Zereshk deposit alongside other deposits is planned to provide copper ore feed to Taft Copper Complex in Yazd province in Iran. Darreh-Zereshk deposit is situated underneath a village with the same name. In order to mining activities be commenced, the village should be dislocated and obviously, during mining activities all agricultural lands will be covered and concealed by mine stockpile. This study discusses about changing the above mentioned mine after abandonment to a tourist resort to provide sustainability in this area by studying the impacts of mining activities including social and environmental effects of mining, dislocation of an old farmer community and substitution with a new blood industrial community, created and lost jobs, financial and economic factors, quality of life index, infrastructures and post-mining land use. For obtaining the goals of this study and careful illustrating of existing variables in the subject, this study was performed by documentary, descriptive-analytical method and field studies. Also during this study GIS software was utilized to process and provide sufficient data for decision making by MADM (Multi Attribute Decision Making) method. And finally; financial studies has been performed to find out its viability, considering green accounting method. It should be mentioned that there is not any back ground of post mining use in Iran. That is why there were some considerable source limitations to be referred to. The results of these studies, revealed that despite all negative impacts of operating a mine in rural areas such as contaminated, unstable and dangerous mining constructions which make the area an unattractive place to live and since tourism is a common option for the sustainable regeneration of mined lands and communities and considering the infrastructures developed for mine such as private roads, power, water, communication facilities, plants, obtained incomes and community change and green areas and lakes has been created by mine reclamation can potentially improve this area to a higher level of living standards and also bring clean and safe employment to the area. With the help of all these infrastructures we can create accommodations, tourist recreational centers, lake and other facilities in the region and change it to a novel tourism opportunity.

Sustainable Mountain Resort Development in Colorado: In Search of a 'Green' Resort Environment and Preserved Historic Landscapes

Rudi Hartmann (University of Colorado Denver)

In the last few years considerable efforts have been made by the resort industry and mountain communities in Colorado to develop and implement environmentally friendly policies as well as to preserve traditional landscapes which have been threatened by continued expansions of the resort environment. This paper examines the success of strategies and measures taken so far in ski resorts of the Colorado Rocky Mountains to promote a 'greener' environment. Nationwide, the "Sustainable Slopes Program" launched by the U.S. National Ski Areas Association in 2004 formed one of the voluntary initiatives to promote a higher environmental performance. The main part of the paper focuses on two case studies: (a) a review of Aspen Ski Company, a corporation operating four ski areas in or near Aspen, Colorado and their decision to include far-reaching environmental stewardship programs and (b) the preservation efforts of local and regional non-profit organizations in the Town of Steamboat Springs (nicknamed "Ski Town USA") in Routt County. Many structures from the traditional ranching economy have been saved and/or found new functions in the current resort economy. In the final part of the paper, the potential and limits of "getting green done" will be discussed.

Registration and tourism assessment of Greek geosites using G.I.S. techniques

Athanasios Skentos (University of Athens), Maria Triantaphyllou (University of Athens)

The geotectonic and paleogeographic evolution of the Greek area during the Cenozoic era is marked by significant changes in the Greek landform. The characteristics of these changes, combined with more recent endogenous and external earth processes, are reflected today in specific geological places, known as geosites. The purpose of this paper is to highlight and promote geosites by recording and evaluating them as a tourism product of great importance for the Greek region. The methodology is based on the calibration of a series of criteria for each geological place that compose a geodatabase. Criteria cover the topics of geology, ecology, culture, tourism and aesthetics. Each criterion is evaluated on a scale ranging 1 (low significance) to 5 (high significance). The average number represents the total score of a geosite, which is responsible for the final calibration in the national list of geosites. The whole idea of the study is to transform qualitative data into quantitative geocoding data. In this way it becomes easy to manage and analyze information with statistical and geoprocessing tools. The final result of the assessment of the selected geosites is the designing of the geotouristic map of Greece that will reveal possible perspectives of the country for sustainable tourism in a local or regional level, including ecotourism and educational activities.

Toward New Management Framework for the Place Impacted by Tourism Activities

Takayuki Arima (Tokyo University)

Tourism activities still cause negative impacts on many places. However many researches revealed the degrees of tourism negative impacts, their results are not much developed to apply to land management. This presentation proposes harmonious management framework with outcomes of on-site studies for the places impacted by tourism activities, particularly the natural area such as national parks. The frame mainly consists of geographical layer concepts using GIS. It is divided into analysis-face and apply-face with on-site surveys. In analysis-face, the on-site surveys have conducted in Fraser Island, Australia as a case study, which faces severe track degradation problems. The results yield three major points of understanding. First, the track-widening and track-deepening degradations were found to be unrelated each other. Second, the track-widening degradation was found to be dependent mainly on the activities of the historical timber logging industry on the island. Third, the track-deepening degradation was found to be related to certain aspects of tourism activities. These results also have been described some geographical characteristics. Although land zoning systems such as Recreational Opportunity Spectrum were useful methods for land management from tourism activities, practice of the management is rather complicated and involves several human concerns. In apply-face, demands of tourists and management authorities are reflected for new zoning system. The tourist demands are originated from their activities and accounted for the system. The demands of management authorities are also important and accounted. Finally, the zoning using AHP method is carried out by using several criteria. Although the results indicate that the vehicle tracks always require highly maintenances, natural conditions and tourism behaviours affect the classification of management importance. This new management framework can be modified for use with any region to maintain its lands and landscapes from tourism activities.

C08.15-07 - Tourism and Global Environmental Change: Climate Change Issues

Chair: Jarkko Saarinen, Colin Michael Hall

The impact of climate change on water demand and energy consumption in Austrian and Swiss ski areas

Robert Steiger (Centre for Climate Change Adaptation Technologies), Bruno Abegg (HTW Chur)

Climate change is a threat to the snow-dependent winter tourism industry. This important economic sector is confronted with decreasing snow trends and less frequent cold spells necessary for snow production. The ski area managers' faith in technology is likely to lead to further investments in snowmaking facilities in order to conserve the status quo. Such a development would cause considerable ecological impacts related to water demand and energy consumption. A recent study for Austria showed that a 2°C warming would require a doubling of current snow production in the average in order to reach desired ski season lengths. In this contribution, the ski season simulation model SkiSim 2.0 will be applied to four case studies in Switzerland (with current low level of snowmaking) and Austria (with already high level of snowmaking) to assess potential changes in water demand and energy consumption related to an increased use of snowmaking. In contrast to previous studies assuming a certain percentage of slopes being equipped with snowmaking without validation of the modelled produced snow volumes, our contribution uses real operational data on snowmaking (e.g. water & energy consumption) to validate model results. In order to consider different climatic conditions, ski areas from more humid and drier regions of both countries were chosen. Regional climate model data for the 21st century will be used as input for the assessment of future snow and snowmaking conditions. The resulting required increases in water demand and energy consumption will be put in relation to the number of residents and tourists and to other touristic infrastructure. Up to now we have validated the model at all four sites with real snowmaking data. In the upcoming months we will run the climate change scenarios and analyse potential impacts as described above.

Changement climatique sur les côtes atlantiques. Quel développement touristique peut espérer une station balnéaire qui égare sa plage ? « Cas des littoraux ; Aquitaine et Sud marocain (Souss Massa Draa) »

Soumia SABBA (Université Bordeaux), Laurent Couderchet (Université Michel de Montaigne)

La France et le Maroc, à l'instar d'autres pays côtiers, figurent parmi les destinations touristiques privilégiées à travers le monde. Le tourisme occupe dans ces deux territoires

une place primordiale dans le développement socio-économique ; certes il est très diversifié mais très largement concentré dans les zones côtières, notamment sur la frange littorale, où il représente un caractère fortement saisonnier. A partir du moment où les réputations et les choix de destinations se fondent sur les images que le climat génère, le changement climatique annoncé pour les décennies à venir peut transformer la nature et la configuration du tourisme balnéaire avec l'élévation attendue du niveau de la mer et l'intensification de l'érosion des plages. Pour l'heure, la situation n'a pas de caractère dramatique, mais à plus long terme, les perspectives sont moins rassurantes ! Cet article tente un état des lieux des stations balnéaires pour les deux provinces atlantiques, l'aquitaine et le Souss Massa Draa, et une mise en évidence du degré de vulnérabilité de ces systèmes touristiques face au changement climatique. Il traduit l'importance d'envisager des stratégies d'adaptation pertinentes et d'action dans un contexte d'incertitude. Mots clés : changement climatique, tourisme balnéaire, littoral atlantique, incertitude, région Aquitaine (France), Souss Massa Drâa (Maroc), vulnérabilité et stratégies d'adaptation.

Temperature and destination choice – a pan-European perspective

Carl Marcussen (Centre for Regional and Tourism Research)

This paper explores the relation between temperature and the propensity to spend nights in commercial accommodations. As far as leisure tourism is concerned, it is expected that there will be a strong tendency for the demand for bednights to be concentrated in the warmest months of year, with the exception of a few alpine and other dual season tourism destinations. Business and leisure tourism seasons are different, with business tourism only partly affected by temperature. Thus the meeting industry has a high season in September, when the holiday season is finished, but when the weather is still nice. As far as travel outside of Europe is concerned, destinations with relatively high temperatures seem to be preferred in the European winter months. It is the contention of this paper that temperature drives tourism both domestically and internationally. Domestically the demand for bednights is concentrated in the summer months. This, both has natural and institutional causes, namely temperature as a natural cause, and school summer holidays as an institutional cause. Temperature also drives tourism internationally, since in the summer holiday season, Europeans tend to prefer the warmer to the cooler destinations. Thus holiday-makers from northern Europe tend to travel south, to the higher temperatures and more sun safe destinations, for their summer holiday. The question is, though, to what extent are the choice of the warmer destinations driven by a desire for higher temperature or lower prices or other attributes of the destinations? Costs consist of transportation costs and costs at the destination (for accommodation and other things). If the travel is straight south, from northern Europe, this could indicate both a desire for higher temperatures, and a desire for low travel costs. If the destination has relatively low prices, this could indicate that also low prices play a role for destination choice. If the travel deviates from the straight south direction, this could indicate that

other things than the desire for higher temperatures play a role. In light of the increasing average temperatures, this paper will show, if the peak summer months of July and August has accounted for a declining percentage of all bednights in Europe over the last two decades, and if so, it will be discussed to what extent this is related to climate change or other factors. The main data set applied in this study is monthly bednight statistics for all European countries (4 segments: hotel/other, domestic/international) for the period 1990-2010. The research question of this paper is: What is the role of temperature in destination choice? And hereunder: To what extent is destination choice for holidays and leisure travel in general by the desire for (higher) temperature or (lower) prices? - Has climate change affected seasonality (and destination choice)?

Management Strategy for Recreational Diving in Bleached and Damaged Coral Reefs

Thamasak Yeemin (Ramkhamhaeng University), Makamas Sutthacheep (Ramkhamhaeng University), Sittiporn Pengsakun (Ramkhamhaeng University), Mathinee Yucharoen (Ramkhamhaeng University)

The severe mass coral reef bleaching events have led to coral mortality in several diving sites of Thailand. The present study aims to assess ecological and socio-economic impacts of the coral bleaching events and to propose management strategy for sustainable diving tourism. The 1998 coral reef bleaching event severely affected coral reefs in the Gulf of Thailand. Some reefs showed a declining trend in live coral cover, but other sites exhibited slight increases of live coral cover. However the 2010 coral bleaching event caused coral degradation more severe and extensive in the Andaman Sea than in the Gulf of Thailand, with the inner Gulf of Thailand exhibiting the lowest bleaching impact. The questionnaire surveys, secondary data sources and interviews of key informants in several diving sites revealed that 52-91% of the tourists interviewed were aware of the 2010 coral reef bleaching event. About 27-50% of tourists in the samples was their first SCUBA diving/snorkeling at the diving sites. The tourists mentioned that the diving was not as good as they expected before coming to the diving sites. About 34% of tourists who have visited the diving sites before said that SCUBA diving/snorkeling was not as good as they expected because of coral bleaching and they were happy to pay the extra money 74 USD to see better coral reef condition. About 85-95% of tourists interviewed said that they would like to visit the diving sites again. A proposed management strategy for recreational diving sites in Thailand was provided. The main issues include; prevent coral damages from snorkeling in the shallow reefs, sediment load from coastal development, wastewater discharge from boats and land-based activities into coral reefs; temporary closure of diving sites; establish new diving sites; conduct research and monitoring program for coral conservation and restoration; inform people and tourists concerning status of coral bleaching; provide sufficient manpower and budget to relevant government agencies; establish effective networks of universities, government agencies, province offices, local administration offices, NGOs,

private companies, and conservation groups. Effective mechanisms for project implementation under Thailand's national coral reef management plan are also needed. A list of research topics towards adaptation to coral bleaching was provided by relevant experts and organizations. Development of young researchers and raising public awareness are urgently required for coral reef conservation in Thailand in the period of increasing human and climate change impacts.

C08.15-08 - Tourism and Regional Development 1

Chair: Dieter Müller, Dallen Timothy

Clusters without content? Investigating Icelandic regional tourism policy

Edward Huijbens (Icelandic Tourism Research Centre)

This paper explores the relationship between Icelandic regional policy and tourism development. It is inspired by the efforts of the Icelandic government to base tourism development strategies on their Vision 20/20 strategy for regional development, which in turn is premised on cluster thinking. With tourism gaining increasing recognition as a central pillar of the national economy and clustering being seen as central means to success, the paper proceeds with a critical evaluation of the cluster concept. The introduction of cluster thinking in Icelandic regional policy is illustrated through the tourism strategy 2011-2020 as approved by parliament and how it manifests in a regional context. A specific focus will be on North Iceland, where the cluster approach to general regional development and tourism has been used for the longest and gone through two successive stages. This case underpins the central argument of the paper that cluster thinking by the Icelandic government is merely being paid lip-service to, with no serious effort to work out the theory in practice. The paper argues that this stems from a lack of engagement with regional socio-spatial specificities. These specificities need to be recognised and worked with in order to establish the necessary foundations for any successful cluster initiative and ultimately regional tourism policy. Thus the paper concludes with questioning the efficiency of top-down governance approach in enhancing regional tourism development.

Tourism Development in the Polish-Slovak Borderland

Marek Wieckowski (IGiPZ PAN)

The paper presents selected problems of development of tourism within the areas of the Carpathian Mts in Poland and Slovakia. The essential objective of this study has been to analyse the role and significance of tourism in the functioning of this borderland. Currently, economies are characterised by a shift in the functional development of regions towards the services sector, including also as regards opportunities related to tourist development. Within borderlands, tourism is considered the most important branch of the economy, and one that is often treated as the sole opportunity for development, at the same time becoming the primary domain of transboundary integration. It was important to make apparent the influence of a boundary on the development of tourism structure (tourist traffic and tourist infrastructure) within Polish-Slovak borderland. The Carpathian Mts., both in Poland and in Slovakia, constitute one of the most important tourist regions of the two countries. Over the decades the Polish and Slovak's parts were being developed separately, and separately touristically used. The geopolitical and socio-

economic changes in East-Central Europe that has been started at the beginning of the 1990s has brought about a radical change in the function of boundaries, the status of border zones and the character of cross-border relationships. The Polish-Slovak border after Poland's and Slovakia's accession to the European Union and to the Schengen Zone changes their status, and comes to existence as the full open border. The prospect of Poland joining the Schengen Agreement determines the potential spatial effects of the changes in the magnitude of movement on the border inside of the European Union. The main effects of these changes was the increase of the tourist flow and creation of a new tourist space especially close to the border. Resulting from the increase in the number of trips, new tourist developments, supported by accompanying services, come into being, or else existing ones are extended. Tourist space develops there, where the area is attractive for tourists (e.g. thanks to attractions being associated with the boundary, peripheral location, nature). In the paper the influence of the most important elements on tourist attractiveness of a mountainous borderland are presented. Tourism in the Polish-Slovak borderland is based upon an attractive nature (including in National Parks) and a cultural heritage. Additionally, regions and departments try to develop new ski-centers and new event tourism, both in national level and international (even transboundary). An analysis has been done of regional development due to tourism especially in the fields of: tourist function, tourist flow, spatial organization, functioning and creation of tourist attractions and products, both in national level in each country and in transboundary level.

Custom and tourism in Wedr

Anne-Marie d'Hauteserre (University of Waikato)

This presentation will demonstrate that customary practices can be used to foster economic returns while minimising negative impacts. It will present a potential model for economic growth that is controlled from the grassroots. The usual discourse is that Indigenous custom is antithetical to any form of economic improvement, in particular because of communal and inalienable land property rights. The 'When age makes multilocal grand chef' of Wedr, a district in an outer island of New Caledonia, is busy proving the contrary as small entrepreneurs, residents in the area, progressively improve economic returns to the various tribes of his jurisdiction. He has used different forms of customary practices to obtain cooperation for development of activities and attractions as well as consensus for continued high maintenance of the main site used to welcome visitors. He is cooperatively and dynamically moulding the future of his residents, having taken up the challenge to move forward rather than lament losses. The roots of this development lie in the cooperative creation of a dance troop by members of his tribe twenty years ago that has successfully represented Kanak culture on the main island and across the world. Outmigration is a major problem for the outer islands of New Caledonia as it threatens cultural survival in an area that had suffered less than the rest of New Caledonia from the ravages of colonialism. It is also very difficult for the migrants to

recreate their culture on the main island as they have no land base there. Not all migrants find work either, especially young adults. The development occurring in Wedr, one of the three communes of the island of Lifou, is from the grassroots: decisions are taken by the local population who has fully committed to them before requests are made for subsidies to implement them. Plans have been valid enough that foreign investors are participating rather than demanding compliance to their wishes. It is a form of local economic development tailored to local conditions to ensure its durability.

Community-Based Tourism and Regional Development - the example of Wasini Island, Kenya

Hubert Job (University of Würzburg)

Community-based tourism (CBT) is held as an important concept to reduce poverty and to develop rural areas of developing countries. It relies on the participation of the local people and takes into account the specific local situation with its endemic resources. This study analyses the potential of CBT to foster regional development in the area surrounding the peripheral Kenyan Marine National Park Kisite Mpunguti. For this purpose, a value-added-analysis of the area's intra- and extra-regional economic system was carried out in order to show the influence of the local participation in CBT on the economic effects of the National Park on the island of Wasini. Taking the examples of the two villages of the island and two enterprises with different local interrelations, the role of varying extents of participation in tourism is highlighted.

As for Wasini village the participation in CBT led to increased income, reduction of poverty and an improvement of the living standards. In the village a large part of the jobs depend directly or indirectly on tourism, along with the relatively high income per capita of the people. At Wasini village, tourism is not only of great economic importance, but has also made other subsistence livelihoods nearly redundant. The great attractions for tourism as an employment generator can be proven by both the growing number of population, and the disappearance of subsistence economy and ways of life. For instance, the population growth until 2008, which was high above the Kenyan average, was mainly due to rise of the economic migrants from the neighbouring coastal region and the Shimba Hills from the hinterland. In addition to this, tourism also prevented the exodus of young people, which is typical for many peripheral rural areas in Kenya.

The difference between the data for the two villages reflects the result of the participation of local people in CBT. All the positive effects of tourism observed in Wasini village are missing in the village of Mkwiro, where the inhabitants hardly participate in tourism ventures, but work either in agriculture or fishery sectors and in extreme cases, abandon their village.

The comparison of the two tourism enterprises shows that tourism does not necessarily contribute to poverty-reduction. Whereas the local business manager is personally interested in promoting regional products and distributing profits among the employees,

the international enterprise tends to reduce costs by bulk purchase in Mombasa and transferring profits abroad. Therefore extremely different leakage rates can be explained. Tourism is also sensitive to external shocks such as political conflicts. The study showed the weakening of the tourism system by the external influences such as the absence of the visitors after the post-electoral riots in Kenya 2007/08.

In summary, intensive local participation is a prerequisite for CBT which enables the people for, but does not assure poverty-reduction. Beside the strong local participation, it is important to note that the tourism based long term development depends upon a stable political and social framework.

The Impact of World Heritage Tourism upon the Local Rural Area: The Case of Horse-Riding Tourism in the Villages around Lashihai Lake, Lijiang

Guoqing Du (Rikkyo University)

Located in the Northwestern China, the Old Town of Lijiang in Yunnan Province became one of the most popular tourist destination since its registration of World Heritage in 1997. The visitors increased significantly and the development of tourism has created a great impact upon not only the Old Town itself but also the suburban villages and agricultural areas. Visiting of a big amount of tourists for horse-riding leisure changed the villages around Lashihai Lake, which is located about 10km from the Old Town of Lijiang, into one of the a-day-trip destinations. By this research, we try to investigate the development and collaboration management of horse-riding sites in each village, and clarify the impact of peasants' independent tourism management upon local society and world heritage tourism.

The shift from hotels and lodges to second home villages and mountain resort accommodation in Norway

Thor Flognfeldt (Lillehammer University College)

The importance of private-owned second-home villages compared to the traditional accommodation industry has been little studied and is not well understood. A common belief amongst planners and decision-makers is that the hotels constitute the gravitational point of the ski resort. Yet both data and general observation suggest that this orthodoxy has ceased to reflect the changes that have occurred over last couple of decades. The reason this phenomenon has acquired little attention may be that the developers and the providers who have had a role in the chalet- or second-home development typically have been the landowners and local small-business owners. They have been less visible than the large tour operators and other accommodation providers. Another reason the second-home business and the dwellers have received little attention as part of the tourism industry may be that much of their activity traditionally has been attributed to other industrial categories like the building sector (contractors), janitorial and domestic services (e.g., snow removal), and commodity trades (e.g., for clothing and groceries). Consequently, neither trade journalists nor tourism organizations are yet fully aware of the changes in accommodation preferences that have taken place. Norway now has more than 430 000 registered second-home buildings. The actual number of second homes is higher, partly because several second-home units in an apartment building are registered (in public records) as a single second-home unit. This paper seeks to illuminate and discuss the market shift from 'accommodation markets' to 'second-home markets' and

its consequences. This can be understood by examining the history of the development of the second-home industry and the migration of visitors from the hotels to chalets and apartments. We are able to conclude that economically the second-home dwellings in rural areas have today become more important than the hotels. Thus, the second-home villages have become the new gravitational point of Norwegian winter tourism resorts, and the sector needs to act accordingly. The local communities have gradually come to realize the economic importance of second homes, but the general public and the decision-makers have not. The traditional accommodation providers, on the other hand, face increasing challenges, and may choose 1) to stay in their traditional markets and lower their prices, 2) to reduce the number of commercial beds and become active providers of food and beverages to the second-home dweller, or 3) to close down completely and to sell out to estate developers that will convert hotels or lodges into apartments for the second-home market. A continued focus on how to save the traditional accommodation industry that has lost its customers to the second-home market is misguided. Instead a push is needed to nurture and develop the opportunities created by the rapid development of the second-home villages.

Why always tourism? Questioning a default strategy in regional development

Holger Lehmeier (Universität Bamberg)

There is hardly a development strategy for peripheral regions which does not include the tourism sector. Especially project-based, endogenous regional development initiatives rely heavily on the positive outcomes of tourism; it should stimulate the local economy and help to improve the regional image. Nevertheless, the actual economic impacts are often not directly examined and a great amount of ambiguity about them remains. Thus, regional decision-makers act in a field of uncertainty, which leads to an increased dependence on institutional factors. It is necessary to identify these hidden motives to understand the wide-spread choice of tourism-focused projects. The presented study examines two regional development programs in the German federal state of Bavaria which cover 84 local initiatives. A qualitative empirical approach involving interviews and textual analysis is applied. Additional quantitative data is used to strengthen the empirical evidence. The paper is based on the neo-institutionalist idea of institutional isomorphism (Meyer/Rowan 1977, Powell/Dimaggio 1983) and aims to discover structures that can lead to three distinct kinds of homogenization in terms of development strategies. Firstly, coercive effects can occur, when formal or informal rules lead to similar outcomes. Secondly, the wide-spread use of best-practices leads to mimetic effects, especially when the cause-consequence-relations are not known exactly. Thirdly, professionalization causes normative effects, when closely-linked actors share similar opinions about good or bad strategies. First results show that the conditions for several isomorphic effects exist. The key roles of local politicians can convert development initiatives into objects of regional politics, subjecting them to short- and medium-termed

interests. Projects promising quick success are preferred; concepts with uncertain outcomes or only long-term effects are less popular, leading to the choice of the (seemingly) easy field of tourism. The concept of normative isomorphism also contributes to the understanding of regional development strategies. All of the initiatives examined are, to some degree, dependant on professional regional planners with scientific backgrounds: The majority of the regional managers possess university education in a narrow range of subjects, most notably geography, economics and planning. Moreover, the documents defining the local development strategies are often written by professional consulting companies with similar scientific personnel. All in all, the study contributes to the understanding of decision-making in regional development initiatives. Therefore, it helps to identify and ultimately avoid ineffective use of public funds.

Whose winescape? A political ecology of wine tourism in Salta (Argentina)

Gerhard Rainer (Universität Innsbruck)

The Calchaquí valleys in the province of Salta constitute one of the most important historical regions of Argentina. In addition, the favorable characteristics of soil and the arid climate have enabled the creation of the world's highest wine region. This combination of viticulture, Andean landscape and historical sites has contributed to the creation of a unique winescape. The growth of wine tourism all around the world has shown that the combination of wine and tourism represents opportunities for regional development in a globalized economy. Studies on wine tourism have frequently stressed these potentials. Nevertheless, issues of power relations in the development of wine tourism, distribution of environmental benefits and costs and social equity have mostly been untouched. Those issues are especially important in third world regions, where a main goal of sustainable regional development must be to overcome a long history of social polarization. The multi-scalar political ecology approach that focuses on the contrasting interests of actors and their capacities to take an active role in the negotiation processes within a politicized environment puts those issues at the core of research. In the case of the Calchaquí valleys the orientation towards global wine tourism markets started in the first decade of the 21 century. International investors began to buy vineyards and wine cellars from the regional elite, composed of big landowners holding important political offices, and initiated an orientation towards quality in wine production. This process was accompanied by the growing importance of wine cellar visitation and cellar door sales, the creation of a wine route and of a high-class hotel and resort infrastructure demanded by this specific tourism segment. While the regional elite and the international investors make huge profits from the global integration of the regional economy local people are still marginalized from economic development. Recent socio-ecological processes in the context of this arid mountain environment can be seen as an expression and as a result of the continuation and adaptation of traditional power-dependence relations to new global logics. While gated second-home communities in the small town of Cafayate count on privately owned wells and artificial lakes local people in some

neighborhoods are still suffering from water shortages. The strong demand for land caused by the growth of wine and tourism industry has led to a rapid increase of property prices, making it impossible for local people to buy land. The spatial expression of this socially uneven access to land, well-known from South-American cities, is the strong contrast between secluded or even gated resorts with high-quality infrastructure, leaving the municipality bereft of tax revenues and densely populated neighborhoods lacking basic infrastructure.

A Journey to Self-employment: Tourism and Ethnic Minority Enterprise in Thailand

Alexander Trupp (University of Vienna)

The highland ethnic minorities of Thailand ('hilltribes') are one of the major tourist attractions of the country. In ethnic tourism, the visited ethnic groups are marketed and presented as exotic as possible in order to fulfill the tourist's quest for authenticity. Tourists visit peripheral regions in order to 'consume' the local inhabitants and their cultural practices. Since recently, however, one can observe an inverse development. Due to lack of land rights and no perspectives for education and job opportunities in their home regions as well as a variety of other factors an increasing number of ethnic minorities move to richer urbanised areas to seek sources of income and opportunities to work. While most urban-based minorities who work at petrol stations or restaurants remain invisible for tourists and other outsiders, one part of a migrant group visually stands out and is about becoming an integral feature of Thailand's urban and beach-sided tourist centres such as Bangkok, Phuket or Pattaya. Eye-catching female Akha handicraft and souvenir sellers, often wearing colourful and richly decorated hats, became part of an informal sector that is linked to the global tourism economy. This PhD project deals with the ethnic minority of Akha, and specifically Akha women, who have been migrating into Thailand's tourist areas in order to sell handicrafts and souvenirs. They have become entrepreneurs or self-employed street merchants at international tourist destination. In this research, I study the embeddedness of female Akha entrepreneurs in social networks and in wider economic and political-institutional structures and ask how they deal with the constraints of such structures. Moreover, I explore the strategies Akha migrants employ to become successful entrepreneurs by asking how they obtain and transform different forms of capitals. In order to explore the migrant's agency and mixed embeddedness, I am using participant observation, semi-structured interviews and personal network analysis. Such an approach is able to indicate that ethnic minority entrepreneurs are not entirely controlled by some external structural forces but have shown themselves to be active agents who pursue their own goals and ideas.

Impacts of Destination Image on the Formation of Tourism Space: A Case Study of Ecotourism Development on Yakushima Island in Japan

Fumika Kanetaka (Hiroshima University)

Yakushima Island was registered as World Natural Heritage in 1993. Ecotourism developed in Yakushima; the number of visitors rose to about 400,000 people after the

registration. Although located in the periphery of Japan, Yakushima now is a famous destination as an island richly endowed with nature and tourism has become the most important economic sector. About 200 eco-tour guides are active on the island; 160 mainly small-scale facilities offer accommodation. Many people from other areas of Japan have moved to Yakushima to enjoy life close to nature and make a living in tourism. The purpose of this study about Yakushima is to examine impacts of the destination image widely acknowledged by tourists on the regional development of the destination. We will also discuss the spatial characteristics of the destination image of Yakushima. For this study, interviews were conducted and data collected over a period of three years to analyze the actions of the administrative organs such as Yakushima Town and Kagoshima Prefecture, and the awareness of residents who are involved in the tourism industry such as eco-tour guides and accommodation owners concerning the destination image of Yakushima and problems in its tourism structure. An important key word for the spatial characteristics of the destination image of Yakushima is 'Concentration' and 'Decentralization'. Overuse became a problem as the number of tourists increased, and the negative influence on the natural environment is feared. Especially, tourists' concentration on the Jomonsugi, a cedar tree hidden in the mountains that is the symbol of tourism has aggravated the load on nature. The administrative organs are taking a central role in dealing with this problem and rules for use and the limitation of the number of climbers have been discussed in several committees. Moreover, it is seen as a problem that the ecotourism of Yakushima excludes the culture and the tradition of the island, and recently efforts are made to promote eco-tours in the settlements that use cultural resources. On the other hand, the Jomonsugi is indispensable for the residents to make a living. Many have a negative opinion on the introduction of visitor limitations to the Jomonsugi. However, there are a lot of people who feel a sense of discomfort about the concentration of tourists. Some guides and residents introduce less well known sightseeing spots. It can be said that the destination image of Yakushima has a strong brand power that attracts tourists and has spurred regional development based on tourism. However, it has created spatial patterns of concentration of the tourist's destination, the tourist season and the tourist's attention, and various problems have been caused in the tourism space, so that decentralization is an important issue.

Tourists' perceptions of world heritage destinations: The case of Guimarães

Paula Remoaldo (University of Minho), José Santos (Institute of Accounting and Business - Porto Polytechnic), Laurentina Vareiro (Polytechnic Institute of Cávado and Ave), José Cadima Ribeiro (University of Minho)

Tourism is seen as one of the main drivers of socio-economic progress in both developed and developing regions. Although the evolution of tourism over recent years has been somewhat irregular, domestic and international tourism industries continue to expand in response to growing markets, stimulated by consumers' increased leisure time and relative wealth (UNWTO, 2011). The competition among tourist destinations is fierce due

to the increasing number of cities that envisage attracting international travelers. In this context, destination images are important as they influence people's perceptions of place and can affect their choices and behavior. The city of Guimarães, in the northwest of Portugal, is a world heritage site (UNESCO) since December 2001, and will host the European Capital of Culture (ECOC) in 2012. Taking the opportunity of this important event, the Portuguese organisers of ECOC elicit as one of their main goals to enlarge and reinforce the city image. This exploratory study examines the image of Guimarães as a world heritage tourism destination and the motivations underlying the selection of the city by tourists. Another research objective is to investigate the tourists' satisfaction on the city destination. A quantitative methodology is used making use of the data of a survey implemented. A self-administered structured questionnaire was designed to obtain information on motivations, attitudes and demographic characteristics of tourists that visited Guimarães between December 2010 and August 2011. Given the seasonality of tourism in the city, which also occurs elsewhere in the country, it was decided to apply the questionnaire in three different periods: December 2010 (corresponding to the low season - 90 questionnaires); April 2011 (corresponding to the mid season - 90 questionnaires); and, July and August (corresponding to the high season - 96 questionnaires). A total of 300 questionnaires were filled in, of which 276 were properly completed and provided usable data. The preliminary results suggest that being a world heritage site and the possibility of touring around in the region have a significant effect on tourists' choice of Guimarães. A few particular attributes of the city seem also to shape the image of the destination perceived by tourists.

Characteristics and motivations of backpackers in the Cape Coast-Elmina conurbation, Ghana

Frederick Dayour (University of Cape Coast)

Successful tourist destinations today are seriously engaging in studies to identify new trends in order to build specific tourism product or destination brands. Research has shown that the backpacker market is one of the tourism markets that economically benefit the local community than the mainstream tourist market. The main objective of the study was to assess the characteristics and motivations of backpackers in the Cape Coast-Elmina conurbation. The study was guided by the positivist philosophy of research - quantitative. Questionnaires were used to collect data from 184 backpackers in the Cape Coast-Elmina conurbation, Ghana between the months of September and October, 2011. Factor analysis was used to determine the underlying factors that accounted for backpackers' motivations to Ghana. The independent sample t-test, one way analysis of variance (ANOVA) and chi-square statistic were used to determine differences and relationships. The study revealed that backpackers who visited the Cape Coast-Elmina conurbation were young students who organized their own trips and depended largely on the internet and word of mouth for information on Ghana. They favoured budget accommodation facilities and public transportation systems, and were staying in the

country for more than 1 month. Furthermore, six (6) main orthogonal push-pull related factors (Historical & cultural, heritage, services, ecology, escapism, adventure) were found to have explained backpackers' motivation to Ghana. Moreover, a comparative analysis of backpackers and mainstream tourists average daily expenditure revealed that mainstreamers spent more than backpackers' in the area. Drawing on the findings, it was concluded that backpackers are young independent travellers whose main sources of information are the internet and word of mouth. It was also concluded that backpackers are budget travellers since they mostly used public transport and budget accommodation facilities in the Cape Coast-Elmina conurbation. Though six factors account for backpackers' motivation to Ghana, motivations vary among their background characteristics. The relative long stay of backpackers coupled with the demand for local products suggest they economically benefit the local communities. Therefore, it is recommended that the Ghana Tourism Authority should rigorously market Ghana on the internet by providing sufficient quantity and quality of information about the country. Service quality in the tourism industry may be achieved through education, effective control, effective tracking of visitors complains and provision of incentives to tourism practitioners. Lastly, the Ghana Tourism Authority should formally recognize hostel accommodation facilities, and also regularize monitoring services in these facilities to ensure quality standards.

C08.15-11 - Tourism Mobilities and Urban Space

Chair: Anne-Marie d'Hauteserre, Julie Wilson

Dynamics of the homestay market in the Kumasi Metropolis of Ghana

Elizabeth Agyeiwaah (University of Cape Coast)

Homestay is an emerging phenomenon in Ghana's tourist accommodation. The Kumasi Metropolis has over the last couple of years witnessed its fair share of this market. Using a sample of 151 international guests in the Kumasi Metropolis, dubbed the 'cultural hearth' of Ghana, this paper examined Ghana's homestay market. Specifically, the survey profiled guests of homestay market and their reasons for choosing this type of accommodation. The study found that guests in the homestay market included students, teachers and volunteers and they chose homestay facilities for socio-cultural, economic and security reasons. Similarly, an in-depth interview with 10 host families revealed that socio-cultural, economic and linguistic/educational reasons propelled host families into this business. Although culture shock was a major challenge faced by both guests and host families, the latter described it as educational and insightful experience. Inadequate marketing and promotion by the Ghana Tourism Authority (GTA) and delayed payments by some intermediaries were also challenges faced by homestay operators. As a sustainable tourism development tool, there is the need for the GTA to help market and promote homestay to ensure local participation in the tourism agenda. Moreover, timely payment by intermediaries is critical for a successful homestay operation. Finally, a closer collaboration between GTA and the intermediaries with the view to ensuring quality service delivery will greatly enhance the homestay phenomenon as an addition to the existing tourist accommodation market.

The Cultural Tourist's Consumption of Place: Game or Play?

Dominik Kremer (Universität Bamberg), Christoph Schlieder (University of Bamberg)

Functionally, tourism has been characterized as "a leisure activity which presupposes its opposite, namely regulated and organized work" (Urry, 2002). This is surprisingly close to what cultural scientists beginning with Huizinga in his *Homo Ludens* (1938) have identified as the essence of playing. We ask whether this functional correspondence can be exploited in the geographical study of tourism. From computer game research it is known that the timing of activities has a major impact on the gaming experience (Salen and Zimmerman 2004). The game research pioneer Roger Callois contrasted *ludus* (game) with *paidia* (play). *Ludus* is associated with an external timing of activities implemented by strict rules while *paidia* follows a self-determined temporal scheme. At first sight, among the many forms of touristic activities, the cultural tourist travelling individually or in a small group seems least subject to external timing. On the other hand, there are reasons to

doubt that the activities of cultural tourists are just guided by "improvisation and joy" which according to Callois characterize play. In recent years, close monitoring methods such as self-employed photography or GPS tracking have become increasingly popular in tourism research (e.g. Balomenou and Garrod, 2010). The main focus of these studies has been on places, for instance, on mapping changes in place popularity (Ratti et al. 2008). While time is often recorded as a dependent variable, the issue of the self-determined temporal structuring of a visit has rarely been addressed. We present a data set that consists of interviews and spatial data which we have collected in 2011 from visitors of a classical destination for Western cultural tourism, the Old Town of Bamberg, Germany, a UNESCO world heritage site. In agreement with other studies (e.g. Barten and Isaac, 2010), we found that the visit is structured by phases of activity which alternate with phases of rest. However, because of the high spatial and temporal resolution of the data, we could additionally distinguish phases of spatially focused activities from phases of spatially defocused activities. In our contribution we describe how to identify these in the data set and argue that the former are related to *ludus*, the latter to *paidia*. Our data suggests that after a phase of rest, the spatial activity pattern often changes from focused to defocused. The fact that all tourists in our data set started with spatially focused behavior can be related to the phenomenon which has been described as tourist angst: the fear of missing something. A qualitative analysis of the photographs reveals that there are different levels of visual involvement with a place. Interestingly, low and high levels of involvement occur as well with spatially focused as with spatially defocused activities. It seems that intensive visual experiences are possible in both modes, *ludus* and *paidia*, game and play.

A Critique of Policies to Increase the Attractivity of Urban Areas in New Zealand

Anne-Marie d'Hauteserre (University of Waikato)

The Ministry for the environment in New Zealand had proposed an Urban Design Protocol because New Zealand cities and towns are not world renown as 'visitable places' the way its beautiful natural environment is. The implementation of the protocol should help these urban areas become 'competitive places that thrive economically and facilitate creativity and innovation; liveable places that provide a choice of housing, work and lifestyle options; environmentally responsible places that manage all aspects of the environment sustainably; inclusive places that offer opportunities for all citizens; distinctive places that have a strong identity and sense of place; well-governed places that have a vision and sense of direction'. Considering how the celebration of speed, movement and power has transformed urban places into assemblages of more or less distanced economic relations which have different intensities at different locations and where 'cyborg' men and women walk with a plug in their ear, oblivious to what's around them, can such a protocol truly be implemented to provide competitiveness. Planning is the ideology of how we define and use space, but space is currently dominated by the values

and logic of global capitalism. Societal forces have been geared to maximizing profits and narrowly defined efficiencies, providing competitiveness through 'attractive' consumption spaces. Culture and knowledge have been harnessed to ensure such attractiveness as economies have taken on a cultural and experiential turn. For Purcell (2009: 142), the logic of neoliberalism 'has come more and more to occupy a hegemonic position in urban policy'. The principal preoccupation of planners has been with the branding of cities and the advanced infrastructure required by global capital, to which Auckland and John Key's National government have responded more readily than to the 'good' intentions of the protocol. Innovation and learning are central tenets of economic growth, no matter what the industry or the location. Universities, however, are not included as anchors for clusters of economic development. Cultural industries have received even less attention. The New Zealand Urban Protocol is focused more on design and seems to have missed on the hard turn to the aestheticisation of urban areas at the service of profit. The city of Auckland, however, is creating areas to encourage consumption linked to the Rugby World Cup. The main question then is whether New Zealand can compete internationally, to establish a unique position and relational status for its cities.

The Distribution and Function of Lodging Facilities in Osaka, Japan: Implications for Urban Restructuring and Inbound Policy-making

Yoshihisa Matsumura (Hannan University)

The Japanese government initiated in 2003 a promotion program with a strong focus on inbound tourism. However, in 2011, numerous unfortunate incidents, such as the Great East Japan Earthquake, the resulting nuclear accident in Fukushima and the extremely strong yen, have had a negative impact on inbound tourism. As a result, the Japanese inbound policy now needs to tackle these damages. The Kansai region, where the Kansai International Airport and five world cultural heritages including ancient capitals of Kyoto and Nara are located, is one of major tourist destinations in Japan. As Osaka city is its geographical center, expectations are high for it to become the major base for inbound tourism in Kansai. According to statistics of 2006, there are 838 lodging facilities in Osaka city, with a total capacity of more than 54,000 rooms. This is a much larger capacity compared to those of Kyoto and Nara, providing the main reason why it is widely perceived to have a great potential to boost inbound tourism. However, after having examined the reality of these facilities, it is problematic to uphold this assumption. By analyzing the distribution and function of lodging facilities in Osaka, this paper attempts to explore the various aspects of urban restructuring and to consider the implications for inbound policy-making. Lodging facilities in Osaka are generally divided to five categories, such as "tourist-specialized hotels", "budget hotels" used by tourists and businessmen, "flophouses", "Japanese-style ryokans" and "love hotels". Surprisingly, about 300 lodging facilities in Osaka are de facto love hotels, which are considered unfit to tourists. Nearly 180 budget hotels and flophouses don't have English websites and are reluctant to deal with foreigners, because of communication and cultural barriers. Most of

70 ryokans are very limited in capacity. In total, Osaka's actual situation for receiving foreign tourists is unexpectedly vulnerable. The "Airin district" in Osaka used to be a day-laborer's area until the 1980's, but has since then declined into typical inner city area. Here, in recent years, several flophouses have changed their business into international guesthouses, and have experienced considerable success in attracting foreign budget tourists and backpackers. This case has attracted much social attention as a kind of areal rejuvenation mixed with social inclusion. In Osaka, two large urban redevelopment projects in the "Umeda North Yard Area" and "Abeno Area" are in progress now. Both projects offer optimal access to transportation links and attracting new luxury hotels, and will certainly promote further implementation of urban restructuring. Amid the mounting criticism towards love hotels and illegal lodging facilities, a new wave of urban restructuring is likely to reach their cumulated areas.

C08.15-12 - Transforming Tourism Geographies in the Global South

Chair: Sanette Ferreira, Gustav Visser

The developing business of international business tourism in Africa

Chris Rogerson (University of Johannesburg)

In common with trends in tourism scholarship as a whole, research on business tourism is overwhelmingly 'Northern' biased. In many respects this situation is not surprising as contemporary African tourism research mainly is rural-focused to the oversight of significant questions relating to tourism in cities. One of the most under-researched yet important aspects of African tourism economies relates to the activity of city business tourism. It is often overlooked that business tourism is of critical importance across several African countries. In Ghana 30 percent of inbound international tourists visit for purposes of business, conference or meetings and by 2009 conference tourism was the fastest expanding segment of Kenya's tourism economy with an estimated higher financial impact than leisure tourism. Geographically the industry of business tourism is dominated, however, by South African cities, especially Cape Town, Durban and Johannesburg. New work on business tourism undertaken in Ghana, Kenya, Ethiopia and South Africa points to an important research agenda around the promotion and maximisation of the local impacts of international business tourism in Africa. This urban-focused research agenda requires re-focusing attention on often neglected tourism assets such as hotels and convention/exhibition centres. Using examples from sub-Saharan Africa this paper reviews the emerging agenda for business tourism in the global South and analyses in particular the developing business of international business tourism in South Africa.

Segmentation and the changing geography of the South African hotel sector 1990-2010

Jayne Rogerson (University of Johannesburg)

In many respects the accommodation or lodging sector remains one of the most under-researched aspects of the tourism economy. International research on the lodging sector has focused inter alia, on issues such as the expansion of multinational branded hotel chains, the segmentation of the accommodation sector particularly in North America and Western Europe, hotel investment strategies, and the hotel as property asset class. Within Africa, the development and changing organization of the hotel sector has been a neglected issue in tourism scholarship with the exception of scattered works on Kenya, Mauritius, Rwanda and South Africa. In South Africa there has been some research undertaken on the growth of the country's hotel sector during the apartheid era, the expansion of Southern Sun and Sun International hotel chains, and work which

investigates the historical change in the focus of the country's hotel industry from liquor to leisure. This study addresses the contemporary phase of development of the South African hotel industry. The aim in this paper is to examine the growth, changing organization, segmentation, and spatial dynamics of the South African hotel industry from 1990-2010. It is argued that during the post-apartheid era the hotel industry of South Africa has been radically transformed and re-organised. Key changes have occurred in response to South Africa's re-entry into the international tourism economy. An analysis of the changing hotel sector during 1990-2010 discloses a phase of growth and upgrading in the hotel sector as a whole. In addition, changing geographical patterns of hotel development in the post-apartheid era are recorded. With the award to South Africa of the hosting rights for the 2010 FIFA World Cup, considerable optimism was generated about the potential for tourism development in South Africa. This optimism fed through into a surge of new hotel establishments during the late 2000s. This surge has resulted in a situation that the contemporary hotel economy of South Africa is exhibiting signs that in certain geographical areas and in certain market segments of over-saturation. This paper documents the growth and changing dynamics of the hotel sector in South Africa.

The social impacts of second homes development in rural South Africa

Gustav Visser (University of Free State)

Over the past two decades second home tourism has received considerable research attention in the developed North. In the recent past the investigatory net has been cast wider with second home tourism in the developing world becoming established as a research niche, not least within the South African context. The growing body of research has focused on the economic impacts of second home tourism on host communities and its contribution towards the development of post-productivist countryside. However, no investigations have been undertaken to understand the social impacts of second home tourism on host communities in rural areas. The paper makes a contribution towards addressing this investigatory oversight focusing on the different types of relationships that develop between different host community cohorts and types of second home owners. The paper highlights the complex manner in which second home tourism impacts the social geography of host communities.

Combining Knowledges – Innovative Standards in Tourism as a Mediator in Global Sustainable Production and Consumption

Simone Strambach (Universität Marburg), Annika Surmeier (Universität Marburg)

There is a broad consensus in science and policy regarding the need to develop tourism in a sustainable way. It is still open to discussion as how to achieve sustainability. Although manifold approaches do already exist, research is still needed on how the desired economic development effects can be reached and how possible negative ecological and social effects can be reduced in the long run. This current lack of

knowledge is due to complex regional specific determinants, multi-dimensional tensions, as well as contradicting interest of diverse actors. Recently, the development of standards and certification programs has gained importance on a global level. They are used as tools to guarantee compliance with sustainable business practices and are a means to prevent the so-called greenwashing. Main drivers of these standardization processes are changes in consumer behavior and rising awareness of sustainability in the so-called North. Nevertheless, standards in tourism are hitherto focused to a large part on the ecological dimension of sustainability. Additionally their range is often regionally limited. Until now, there had been only a limited number of standards in place with an explicit focus on the social dimension. Our paper is dealing with 'Fair Trade in Tourism South Africa' (FFTSA), one of the first innovative service standards in this field. We claim that the knowledge dynamics in the creation of this standard is fostering the processes of standard implementation in terms of time and space. The specific way of combining heterogeneous knowledge bases in the development process has had a double-sided effect. Due to the regional embeddedness of this standard, it has fostered the acceptance on the producer's side. Moreover, there is empirical evidence that this facilitates the integration of regional certified service providers into global value chains (GVCs), thus linking previously disadvantaged tourism suppliers to the global tourism industry. These integration processes are due to a high level of trust in the certification scheme starting from the beginning since actors from the North, along the GVC, were asked to bring in their specific knowledge in the process of the standard setting. By using the empirical example of FFTSA, we will analyze the socio-economic impacts at the micro-level of the firms. Furthermore, we will show that standards can act as mediators in global production and consumption networks and, while taking into account the ecological, economical and social dimension, support sustainability.

C08.17

Global Change and Human Mobility

C08.17-01 - Global climate change and human mobility in coastal areas: the SECOA Project 1

Chair: Armando Montanari

SECOA: European comparative analysis in human mobility, 1982-2012

Armando Montanari (Rome University)

In the year 2009 the European FP7 Research Project SECOA have been approved. It will operate in the period 2009-2013. SECOA consider two global issues, climate change and human mobility which overlap in coastal settlements. The coastal zone is a difficult geographical area to manage. Major problems have global origins but have to be managed at local level. Different national and local public bodies, responsible for different aspects of the same physical area and uses of the coastal zone, have also to consider the often competing needs of the numerous stakeholders. Considering the diversity of interest and pressure groups, of stakeholders and authorities, which converge on coastal settlements, conflicts are almost inevitable. SECOA analyses the different typologies of conflicts, the analogies among subjects and variables in order to identify coherences and contribute in this way to the solution of conflicts. Such a complex research project need the cooperation of a large number of disciplines, but geography plays a basic role having the possibility of using the advantages of a solid experience of cooperation which sees the support of physical, human, social and economic geographers. SECOA has also taken the advantages of three decades of intercultural, multinational and multidisciplinary researchers in the field of human mobility. It is not by chance that the IGU Commission on Global Change and Human Mobility (Globility), established in the year 2000, has been the location for the presentation and discussion of the early outputs of SECOA. In the year 1982 the volume "A study of growth and decline" with some the results of the Cost of Urban Growth (CURB) project have been published. This was one of the first European projects, based on the contribution of geographers, which has considered the role of human mobility within metropolitan areas. From CURB to SECOA several other projects have considered urban settlements changes as results of human mobility and vice versa. The oral presentation will try to identify possible methodological continuity within a certain number of European projects, the role of geographers in contributing in the development of the intercultural approach, and the great merit of geography when is able to play a bridging role among disciplines for the advantage of society.

The SECOA Project: Are extreme hydrological events on the rise in South Asia?

Vishwas Kale (University of Pune)

The monsoon rainfall over the Indian sub-continent is often characterized by heavy to extremely heavy rainfall events leading to devastating floods. Such extreme hydrological

events often have severe impact on every sector of the economy and the environment. The exceptionally heavy rainfall (945 mm) in Mumbai on 26th July 2005, the megaflood on the Kosi River in August 2008 and the catastrophic floods on the Indus River in August 2010 have once again brought to the forefront the enormous risk posed by hydrological events in South Asia. In addition to these extraordinary events, several large-magnitude floods have been recorded on many other rivers in the region during the last few decades. Such extreme hydrological events have raised concern that climate change, associated with anthropogenic global warming, is perhaps causing increase in flood frequency and magnitude. It is therefore, important to systematically establish whether monsoon rainfall or flood data provide any evidence of increasing trends during the last few decades. This could be achieved through the analysis of a number of long time-series. In this paper an attempt is made to analyze the long-term trends in monsoon rainfall and large floods in South Asia. The results of this study and studies undertaken by other works indicate that extreme rainfall events have shown an increasing trend over some parts of western and central India as well as the Himalay. An important finding that emerges from the analysis of annual maximum flood series is that the frequency of high-magnitude floods was significantly higher during the post-1950 period.

Coastal ecosystem changes under human impacts

Lan Tran Dinh (Institute of Marine Environment and Resources)

The high diversity in physical environments and socio-economic conditions among European and Asian countries creates various types of coastal ecosystems. Then changing analysis of coastal natural ecosystems will provide a global assessment of natural resources use by human beings. Selecting the same coastal ecosystems for changing assessment is impossible. Therefore, the main criteria were set out to select coastal ecosystems to analyse changes, including the importance of these ecosystems, available information and data enough for analysis. Methods applied for the assessment include the DPSIR (Driving force, Pressure, State, Impact and Response) framework analysis and further employing of sustainability index for ecosystems and the environment. In Belgian case studies, from 2001 to 2007, the use of coastal ecosystems was in unclear changing tendency. Indian case studies with mangroves and marshlands assessed show from 1997 to 2008 the degradation, indicating the increasing tendency of unsustainable use. Israeli coastal ecosystems show a largely unsustainable system further degrading over time from late 1990's to late 2000's. Land use and land cover in coastal ecosystems of case studies in Italy were changing from sustainable use to unsustainable use during 2000 to 2006. Coastal ecosystems in the two Portuguese case studies from 1990's to 2000's were in sustainable use, but showed steady declination. In the United Kingdom currently, all areas have adequate management and implemented measures that will support their sustainability in the short and medium terms. However, the increasing pressure from areas of Medway, Langstone Harbour, Portsmouth Harbour, Thames Estuary, Benfleet and Swale were evident, respectively. In Vietnam case studies,

coastal ecosystem assessed show an absolutely degradation. Generally, three tendencies of coastal ecosystem changes under human impacts are observed. The coastal ecosystems were in degradation, from sustainable use to unsustainable use in case studies of Asian countries. Coastal ecosystems were in sustainable use in most of case studies in European ones and in unclear changing tendency (e.g. changing from sustainable use to unsustainable use with different periods) typically in case studies of Belgium. A general trend is found as the conversion of natural ecosystems into artificial ecosystems and the increasing pressure from human impacts.

C08.17-02 - Global climate change and human mobility in coastal areas: the SECOA Project 2

Chair: Vishwas Kale

Critical analysis of environmental and natural hazards of coastal areas: The case of the coastal area of Rome

Prestininzi Alberto (Rome University)

In frameworks of Work Packages 1 and 2 of European FP7 Secoa Project several Departments of University Sapienza (Rome, Italy), carried out studies about the environmental sustainability of the coastal area of Rome. Regarding the WP2 environmental stresses and the use of resources for sustainable development, an analysis on land use variations affecting the whole roman coastal areas, spanning from Civitavecchia to Anzio, has been performed. An index has been calculated based on artificial, agricultural and natural land use data from Corine Land Cover, for the period between 2000 and 2006. Then, the research focused on the analysis of two environmental local issues: - Coastal water quality in XIII District of Rome The DPSIR study was focused on coastal water quality assessment; sea was assumed as the final receptor of all pollution coming from land, internal channels and Tiber river; the following indicators have been built: fecal coliforms, transparency, pH, balneability; a sustainability index has been then calculated. The most critical aspect for water quality is shown to be the sewer system, as it was initially designed only for dry weather sewage collection, being nowadays also used to convey rainwater and therefore manifestly insufficient; during rain events, the storm overflow at the pumping stations causes a remarkable contamination of the natural system. - Air quality in Municipality of Civitavecchia In the area there are two specific factors of burden concerning air quality: Civitavecchia is an import seaport for goods and passengers, number of cruise ships and passengers has soared over the past ten years; is now the first cruise port of call in Europe and is seat to two thermoelectric power plants, for a total output of 3440 MW. Ambient air quality can be assessed based on the concentration of pollutants; NO₂, SO₂, PM₁₀ have been monitored and indexes have been developed accordingly to national and regional environmental agencies. For framework WP1 - Climate change and natural hazards - an analysis on hazards related to hydraulic and hydrogeological setting has been undertaken by the Research Center CERI and Department of Earth Sciences. The analysis focused on the coastal area of the XIII District of Rome due to its peculiarities, as it is highly urbanized and partially reclaimed. Attention was addressed to the evaluation of effects of the hypothesized sea level rise. The study is divided into three main phases: Setting up of a geodatabase with available data; reconstruction of the present setting (piezometric surface and its relationship with the salt wedge and local hydrography; flooding scenarios; detailed reconstruction of reclamation structures/infrastructures); assessment of variation of hydrological and hydrogeological setting after potential scenarios of sea

level rise (such as areas invaded by marine ingression and/or groundwater rise, implications on flooding scenarios and salt wedge ingression).

Sharing Data in a Multi-National, Inter-Disciplinary Team – The Importance of Metadata

Claire Ellul (University College London)

Metadata (information describing datasets) has long been understood as a fundamental component of any Geographical Information System (GIS) or Spatial Data Infrastructure (SDI, which promote data sharing and reuse). Metadata provides information relating to discovery, evaluation and use of datasets and describes their quality. Having good metadata about a dataset is fundamental to using it correctly and to understanding the implications of issues such as missing data or incorrect attribution on the results obtained for any analysis carried out. Traditionally, spatial data was created by expert users (e.g. national mapping agencies), who also created appropriate metadata. Much of this metadata was standards-based and complex. Increasingly, however, data used in GIS and spatial analysis comes from multiple, less 'official', sources. It could be captured or used by non-expert users - for example academic researchers - many of whom are from non-GIS backgrounds, not familiar with metadata and perhaps working in geographically dispersed teams. This paper examines the applicability of traditional standards-based metadata in an academic context, using a multi-national coastal/environmental project as a case study. SECOA - Solutions for Environmental Contrasts in Coastal Areas seeks to compare and contrast environmental data relating to seventeen Case Study locations in the UK, Italy, Sweden, India, Belgium, Vietnam, Israel and Portugal. Different capture and analysis methods, source dates, completeness, temporal and spatial extents can be identified when examining the data captured and submitted for each Case Study. Metadata is thus fundamental to ensuring that correct scientific comparisons are made across the project. This metadata must be captured by the project teams. The SECOA metadata team has identified three key research themes relating to the use metadata in this multi-national, inter-disciplinary, academic project. Firstly, team members must be introduced to the concept of metadata and helped to understand its importance. Secondly, they must be persuaded to create metadata (a process that is often considered time-consuming and laborious, and left to the end of a project) and thirdly the quality of the metadata must be such that other members of the team can make use of it - in other words, detail and consistency is also required. The paper will describe how each of these themes has been addressed, and successes and issues will be highlighted. The work to date has resulted in a number of suggestions for good practice for Academic SDI, as well as identifying additional research questions. Such research will become increasingly important in future, particularly given the increased levels of data sharing and reuse required by UK and EU funders.

A GIS-Based Approach for Assessing the Costs of Sea Level Rise (SLR) and Extreme Flooding at the Local Level

Michal Lichter (University of Jerusalem), Daniel Felsenstein (University of Jerusalem)

This study presents a systematic framework for assessing the costs of sea level rise (SLR) and extreme flooding at the local level. The method is generic and transferable. It is built on coupling readily-available GIS capabilities with quantitative estimates of the effects of natural hazards. This allows for the ex-ante monetization of the main costs related to different scenarios of permanent inundation and periodic flooding. This approach can be used by coastal zone planners to generate vital information on land use, capital stock and population at risk for jurisdictions of different sizes. The simple mechanics of the method are presented with respect to two examples: one relates to the two largest coastal cities in Israel (Tel Aviv and Haifa) and the other to the Northern Coastal Strip region containing a variety of small towns and rural communities. The paper concludes with implications for coastal zone planning praxis

C08.17-03 - Global climate change and human mobility in coastal areas: the SECOA Project 3

Chair: Lan Tran Dinh

Modeling urban development and environmental conflicts in coastal areas

Maria Caterina Bramati (University of Rome), Flaminia Musella (University of Rome)

The aim of the paper is to propose a conceptual framework for the modeling tasks of the FP7-SECOA project. Modeling is here considered as the statistical formulation of a conceptual model which should help in understanding the links between urban development in all its component related to environment and human activities, and the occurrence of various types of conflicts. The statistical model helps not only in describing the connections between conflicts and urban development, but also for forecasting future conflicts according to various scenarios of environmental and demographic changes.

Climate change adaptation and emerging coastal conflicts in Southern Sweden

Andrea Morf (University of Gothenburg), Per Knutsson (University of Gothenburg)

Sweden, like in many other European states, there is an increasing need to identify and formulate climate change adaptation strategies at national as well as regional and local level. The Swedish 2007 national report by the Commission on Climate and Vulnerability concluded that Sweden have to make a start in climate adaptation through increased responsibility on behalf of the municipalities in adapting physical planning to the risks of climate change and through the key role of the County Administration Boards in coordinating adaptation efforts at the regional level. Since then, municipalities vulnerable to climate change impacts has started to identify and propose adaptation measures (under the coordination and support by the County Administration Boards), and a few municipalities have even started the process of integration adaptation measures into their physical planning. However, the integration of adaptation measures into comprehensive plans is a new and complex task, causing 'new' conflicts of interests to emerge. For example:

- Between the interests to retreat from, defend against or adapt to future climate risks
- Between present and future nature- and human values
- Between existing national and regional regulations of local physical planning and the need for local flexibility in physical planning in responding to uncertain, future climate change risks
- Between national, regional and local interests in relation to climate change adaptation
- Between different social groups (for example between temporary and permanent residents)

Through a case study of the municipality of Vellinge, located in the southwestern part of

Sweden with a population of approximately 30 000, we analyze the potential consequences (in terms of emergence of new conflicts of interests) of the detailed, physical adaptation measures that have been put forward in the draft municipality comprehensive plan of 2010. Furthermore, we discuss potential strategies to mitigate such emerging conflicts.

Resolving Coastal Conflicts in the Context of a New Mode of Regulation and Changing Policy Paradigms

Gidon Jakar (University of Jerusalem), Eran Razin (University of Jerusalem)

The coast in recent years has become a highly disputed zone in the environmental policy and development arenas, and is a focus for environmental conflicts that include an increasing number of stakeholders and decision-makers. These conflicts are related to two main issues: (1) unique coastal attributes and an associated increase in demand for a dwindling supply of coastal land, and (2) changing coastal policy and planning paradigms. A shift from "the coast as a backyard" paradigm, characterizing the industrial era, to "the coast as a front-yard" paradigm of the post-industrial era, has intensified friction of waste, infrastructure, ports and transport facilities with tourism, recreation and waterfront redevelopment serving as a flagship of urban regeneration efforts. Frictions have further intensified with the emergence of a new paradigm - 'environmental sustainability and the coast as a public-domain' - characterized by increasing environmental awareness, rejecting further development that negatively affects natural ecosystems and restricts public access. We first argue that these paradigmatic changes are a major source of coastal conflicts. We then argue that attributes of coastal conflicts in Israel demonstrate the emergence of a new mode of regulation: increasingly complex governance networks accompanied by changing rather than diminishing role of central state agencies. We finally discuss mechanisms for the distribution of cost-burdens associated with resolving coastal conflicts, particularly those resulting from the above changing paradigms, arguing that theses are not fully operational and suitable to the emerging new mode of governance; hence leading to prolonged delays in resolving conflicts. The study begins with a survey of all coastal conflicts in Israel, suggesting a typology and identifying the role of changing paradigms and the involved parties, followed by in-depth analysis of three Israeli case studies: Haifa port, Netanya sandstone cliffs and Palmachim Beach. Results demonstrate the relevance of changing paradigms in triggering conflicts, particularly the challenge of reversing approved plans for tourism development that face new conservation agendas. Conflicts also reveal the emerging new mode of regulation, an increasing influence of NGOs, grassroots activists and the fragmentation of public stakeholders, making top-down conflict-resolution less likely. The lack of fully operational mechanisms for distributing burdens of financing investments and compensations needed to resolve coastal conflicts lead to prolonged delays in reaching final decisions, thwarting any attempts at finalizing solutions. Alternative mechanisms for distributing these cost-burdens will be discussed.

The role of end users in the methodological and practical approach of SECOA project

Francesca Romana Lugerì (ISPRA Institute for Environmental Protection and Research), Nicola Lugerì (ISPRA), Rosanna Augello (ISPRA)

Climate Change (CC) affect the natural balance of our planet in a dramatic way; the awareness of what is happening is now being transferred to the whole society by the research world. However, it is reported a lack of common policies aimed at mitigating the serious effects of CC and the development of new sustainable equilibrium. Human mobility is closely related to the effects of CC: extreme meteorological events, not only cause impoverishment, but also bring about the abandonment of territories, thus rising as a new, fundamental, cause of the increase in migration, until recently mainly due to the dramatic socio-economic-political conditions of many countries of the so-called third world. Paradoxically, the tourism industry provides to these new actors with 'touch and go' package tours, adding nothing, quite the contrary, depriving them of the cultural significance of traveling and making an environmental impact on the destination areas, by operating a chain reaction of transformation (in a negative sense) of the local equilibrium. On the contrary, different kinds of human flows are increasing, showing an opposing trend in the complex scenario of human movement. A relative perfusion of the affluent society in the booming economy countries, inclined new segments of the world population towards the leisure, starting a mass-diffusion of traveling. There is a dichotomy between the power of economy and the requirements of ecology: in this contrast, the research world raises the alarm, analyzing scenarios and creating models in order to find a solution, but still without success in finding answers from the policy makers. A holistic approach which considers environmental and social ecosystem on the whole, is thus imperative. The SECOA project runs this methodological line referring to one of the most sensitive problems of the socio-environmental arrangement. The contrasts in Coastal Environmental Areas are the result of a complex field of forces, that shows even more increasing pressures -consequences of the phenomena described in the introduction- acting on coastal areas, moreover extremely intrinsically sensitive for the geographical location (interface between terrestrial and aquatic environment) and socio-economic (historic land settlements). Particularly, the role of end users helps provide a range of methodological and practical purposes, thus ensuring to the project concrete results, effectiveness in the projections, concrete applicability. In this case, the participation of ISPRA in the SECOA project allows the use and application of geological maps (CARG project) and other GIS based cartographic products, as well as their integration with similar analyses performed by SECOA partners, in order to compare the results of the multi-thematic studies and to suggest new strategies, practicable within the participating countries, aiming to a common solution for the socio-environmental problems.

Environmental Contrasts in Coastal Areas: The Artificial Neural Networks as a strategic method of analysis

Luca Deravignone (La Sapienza), Marco Ramazzotti (La Sapienza), Alessandro Londei (La Sapienza)

The FP7 European project Secoa (Solutions for Environmental Contrasts in Coastal Areas) produced an elevated volume of data formalized in different complex matrices. Using statistical methods is now possible to explore the articulated picture of each data set complex world and hypothesize some tendencies useful to compare macroscopically the analogies and the differences between each area. The Artificial Neural Network methods give now the opportunity of creating a bottom-up model of this complexity that can be explored as a virtual hyper-surface of linear an/or non-linear, symmetrical and/or asymmetrical, regular and/or fuzzy relations between variables. The results of these explorations on the virtual hyper-surface can also be organized and displayed in the geographical space using GIS technology and Graph Theory, in other words the results of these explorations will produce a synthetic interpretation of some tendencies related to selected aspects of the so called SECOA human mobility.

Modelling coastline land use conflicts through GIS-based cellular automata and neural network analysis

Paulo Morgado (CEG/IGOT/UL), Carlos Ferreira (University of Lisbon), Inês Boavida-Portugal (CEG/IGOT/UL)

Trafaria and Costa de Caparica are two coastal parishes of the Almada municipality, located in the River Tagus' mouth (south bank) / coastline. Land use conflicts in this area mainly due to touristic uses (e.g. beach activities and water leisure) and urban pressure related with permanent/seasonal housing growth, facing its environmental assets, namely landscape value and coastline protection. This is a densely populated area of the coast exposed to several natural, technological and environmental hazards. The Trafaria and Costa da Caparica coastal section is subjected to intense coastal erosion due to its sandy soil composition. Often, the effects of coastal erosion - both long term shore line retreat and extreme events - are the destruction of man-made structures and the loss of soil with value to economical and social use. Critical events that triggered conflicts arise from the lack of housing and urban planning and to the urban sprawl with no care for environmental and risk conditions or land uses. Sea retreat cycles from one side, and Tagus estuary mouth silting from the other side, forced the long shore drift to change,

and has been causing significant environmental and touristic impacts. Coastal protection measures became a regular procedure for preventing and mitigating the effects of coastal erosion on human land use. The conflict between human settlement and mobility and the ecosystem services provided in this coastline (e.g. landscape value, preservation of the natural environment and risk prevention) is being tailored both by institutional responsibilities and regulations (or the lack of it), the urbanisation process and the long term action of nature (sometimes with sudden and fierce events). By considering two different scenarios in which coastal defences are lessened or strengthened, we propose a bottom-up, due to the high number of variables and the density of relations between them, approach methodology for modelling land-use conflicts integrating coast-line evolution. The system is based on a probabilistic Cellular Automata (CA) model that divides the study area in a grid, and uses Artificial Neural Network (ANN) to calibrate the weights of the transition rules, so the model could learn from the past and project the future. Finally, we will use Geographical information Systems (GIS) environment, to assemble together different types of data and overlap them in an efficient way, which would be very hard or impossible to do otherwise. Also, once we set on a GIS environment we will be able to test and calibrate our model with some other non-linear spatial analysis methods such as fuzzy logic analysis.

The SECOA model: A proposal for the interpretation of conflicts in coastal areas

Barbara Staniscia (Rome University)

The SECOA model derives from the homonymous Project. This is a logical and interpretative model built on the basis of the analysis of 26 different conflicts taking place in coastal areas of 17 metropolitan areas in 5 European and 3 Asian countries. The analysis is multidimensional and multidisciplinary. Metropolitan areas have been studied taking into account their natural, environmental and socio-economic characteristics. Topics such as urban development, human mobility, regulatory systems and modes of governance have not been neglected. Conflicts were examined with regard to several aspects of their occurrence: objects, type, intensity, duration, parties involved. The disciplines involved, consistent with the approach, were several: geography (physical, human, economic), human ecology, sociology, statistics. The analysis was carried out using approaches distinctive of each discipline; different languages and different methods have, therefore, been used. A first model was imagined at the beginning of the SECOA project and has been used as guideline for the analytical phase. Once that stage was completed, the model has been re-designed starting from the characteristics of metropolitan areas and conflicts, thus generating a new interpretation about their conceptual relationships.

Building on the Seventh Framework Program experience towards HORIZON 2020, the new European Union Framework Program

Riccardo Carelli (Consorzio Sapienza Innovazione)

Consorzio Sapienza Innovazione is a public-private entity created at the moment of the launching of the Seventh Framework Programme, in order to enhance the academic participation to international programs. Since then it has managed, with good results and only from the administrative and financial point of view, several FP7 projects. Those project presented, on the one hand, similar problems, while, on the other hand, each of them had its own peculiarities, which had to be taken into account for a successful management. In particular, the SECOA project, which addresses Global Change and Human Mobility in coastal areas, is particularly challenging from the managerial point of view, because, apart from keeping together 7 partners from 5 European countries and 3 partners from Israel, India and Vietnam, it foresees the active involvement of several end-users, at regional and national level, such as municipalities, environmental agencies, etc., as well as international stakeholders such as UN-HABITAT, the International Housing Federation, etc.. All of them are essential for the early up-take of the results obtained within the project and for reaching the public at large. For this reasons, SECOA is representative of a typical FP7 project and is in itself an interesting case study Those who gained significant experiences with FP7 projects, will now have to face new challenges and opportunities, on the light of the content of the new European Research and Innovation Programme, Horizon 2020, recently presented by the European Commission, which contains several innovations, including: 1) the merging, for the first time, into a single programme all EU investments on research and innovation, with the aim of transforming scientific progresses into products and innovative services able to offer entrepreneurial opportunities as well as to improve people quality of life; 2) the significant increase of the overall budget up to (provisionally) 80 billion Euro for the period 2014-2020; 3) a single set of rules.

Mapping foreign residents in Japan: Its importance and an introduction of maps

Yoshitaka Ishikawa (Kyoto University)

Since Japan's population began to decline in 2005, the reception and settlement of foreigners has attracted great attention. The population decline is one of the country's most serious issues for the 21st century. In contemporary Japan, however, regional differences in spatial distribution have been largely neglected. Nevertheless, since most data on foreigners in public statistics are available as digital files, it is not difficult to map them, suggesting that Japanese geographers can make an atlas of foreign residents to address the above problems. Such an atlas is expected to contribute to the academic research on foreign residents as ethnic minorities and offer a convenient tool to national and local government policy-makers. With these considerations in mind, in March 2011 we published an atlas entitled Mapping Foreign Residents in Japan. It consists of the following chapters: "Postwar chronological table in relation to foreigners," "Explanation of maps," main body, "Definitions of data mapped," and "References." The main body contains six sections: 'Spatial distribution and its changes,' 'Sex, age and nationality,' 'Residence status,' 'Work,' 'Life,' and 'Residential concentration and migration.' Each section consists of a few subsections, including more than one hundred colorful maps on prefecture/municipality scales. Short explanations are added to each subsection, and photos are often inserted. These maps are drawn chiefly from such public statistics as the Population Census of Japan, Statistics on Foreigners Registered in Japan, and the Vital Statistics of Japan. Micro data of the 2005 Population Census are utilized as well. The maps shown in the atlas provide many interesting findings that can be used for confirming the generality of previous results in existing literature, and they are expected to be a point of departure for new, previously unexplored research areas. In this presentation, various maps from the atlas are introduced as examples, and the significance of each is discussed.

Migration, multilocality, and social resilience

Daniel Góler (Bamberg), Zaiga Krisjane (University of Latvia)

The context of globalisation and transition at the beginning of the 21st century entail manifold economic, political and social changes as well as new forms of migration and mobility. This concerns also the labor migration, which tend to intensify the last years. Obvious consequences are mutual interactions between sending and the receiving countries. Therefore we examine the various effects of these interactions on several

scales. Main objective of the research is the study of new social practices and multilocal activities of migrants. We discuss the topic with theoretical evidence and sustain the argument with short empirical sketches taken from the new EU-members and Southeast-European transition countries. The case studies show the ability of migration-subsystems to cope with internal and external caused shocks, to re-organize in this process in a novel and creative manner and, if necessary, to define themselves as a new social system. Main characteristics of this system are a wide-spread multilocal social network led by migration, individual migration experiences, and migration culture. Migrants are in this sense interpreted as agents of societal transformations, which are able to adapt social practices from different economic, social and cultural contexts. Such kind of resilience as a performed social practice is based on creativity, knowledge and other individual and personal skills and capacities of the participants of the network. This approach enables us to introduce the concept of social resilience into an agent-based interpretation of consequences of migratory movements in the sending and the recipient societies.

New trends of mobility in Europe and USA. Evidence from the TIGER Project.

Barbara Staniscia (Rome University)

Migratory and tourist flows represent two of the main vehicles of relations and contamination among countries. Mobile and immobile societies present distinctive characteristics and the effects of more or less intense human mobility are clearly visible in a global context. Mobility - both permanent and temporary - is favoured or discouraged by several factors, widely investigated and discussed by the scholars. The research presented here has been developed in the framework of the TIGER Project, funded under the ESPON Programme. The main purpose of TIGER is to analyze the effects of globalization on the ESPON space highlighting the role it plays in a global context and the relative positions - of strength and weakness - of its regions and its cities. The research relies on three main pillars: (i) the characteristics of spatial structures analyzed in a comparative perspective, (ii) global flows - goods, capital, knowledge, people - and their effects in the re-shaping of national and regional geographies, and (iii) the dynamics of the existing networks of international cooperation among countries. Among the global flows analyzed, human flows have a prominent position. The human mobility perspective - characterized by a double dichotomy: production-led vs. consumption-led mobility, temporary vs. permanent flows - has been adopted. Attention has been focused on the issues of migration (permanent flows linked to production) and tourism (temporary flows associated with the consumption). This presentation aims at presenting some emerging trends of the human mobility - migration and tourism - in the global context, in the last decade, comparing the European and the US spaces. The final goal is highlighting the main differences between those two macro-regions and the main changes with respect to the past.

Classifying the Japanese in London using Geodemographics

Keiji Yano (Ritsumeikan University)

International migrants from advanced countries coming to major world cities such as New York, London and Tokyo greatly contribute towards developing the global economy. The rapid growth in the global economy in the last quarter of a century has involved economic and migratory exchanges between countries with similar levels of economic and social development. The purpose of this paper is to classify Japanese residents in London on the basis of their social and economic characteristics, and reveal their spatial patterns by making best use of the 2001 UK census and geodemographics. Based on official figures it is apparent that in the 1980s there has been a dramatic increase in the number of Japanese residing in the UK. The number grew from 800 to 2,800 in 1970, 10,900 in 1980, 44,400 in 1990, 53,191 in 2005, and peaking at 56,355 in 1993. After 1972, the Japanese register also provides data on gender-specific occupation as well as transient and permanent expatriates. The objective of this paper is to classify the Japanese in London and identify their residence at small area unit. For this we will need to use another data source by smaller area unit. The smallest areas of the UK census geography in 2001 are Output Areas. White and Hurdley (2003) highlight few characteristics of spatial patterns of the Japanese in London, based on a map of the Japanese-born population in 1991 by Ward. Japanese-born people are distributed in a series of disconnected clusters and sectors, and that in certain cases these incorporate both inner city and suburban zones. However due to limited geographical data about disaggregated population at small area units, we cannot find the spatial pattern of the above kind of Japanese residents in London from census data. The geodemographic data source, Mosaic UK, has been applied effectively to clarify the characteristics of these residents. Geodemographics is a typology of residents at small area unit (Sleight, 2004; Harris et al., 2007). The number of Japanese-born people by Mosaic type is estimated by the Output Area in London, using the number of population by Mosaic type at unit postcodes. As a result, it is supposed that these four types of Japanese residents basically correspond to the typical Japanese company mover, as also indicated by White and Hurdley (2003). The paper illustrates the spatial pattern of Japanese residents by Mosaic type at small area units in London. There are several types of Japanese residents in London, for instance the typical Japanese company mover, non-company group, university & college students, and permanent expatriates. It is revealed that although we can identify segregation between the Japanese residents in London, there are different spatial patterns according to the type of Japanese residents. The differences in spatial patterns based on type will be explained on the basis of the location of their work places and some facilities for Japanese.

Career paths of the Latin immigrants in Spain: growth and crisis (2004-2011)

Josefina Domínguez-Mujica (University of Las Palmas), Ramón Díaz-Hernández (University of Las Palmas)

The migratory flow from Latin America and the Caribbean to Spain experienced an unprecedented growth during the last change of century, matching the economic expansion of 1995-2007. Such migrants were different in terms of country of origin, gender, education level and professional career; however they all shared qualities such as endurance and desire of surmounting and a common integration into the local labor market. Further, the late-2000s global recession has affected all working migrants in a similar manner and hence their employment situation and attitude towards a potential return has also been homogenized. The aim of the communication presented hereby is to analyze the common ground and career paths of the Latin and Caribbean migrants through the study of quantitative and qualitative sources. Quantitatively, we have used some innovative data coming from different administrative records, such as the statistical exploitation of the population register, the constant sample of working lives (MCVL in Spanish) and the provisional results of the 2011 population and housing census itself. We have also evaluated other tools such as the national survey of immigrants (ENI in Spanish), a large-scale survey undertaken in 2011 to scrutinize the demographic and social characteristics of the migrant population in Spain. Qualitatively, we have conducted eight in-deep interviews to different migrants following the BNIM (Biographic Narrative Interpretive Method), which have been crucial to understand better their motivations, perceptions and general feelings. Lastly, once this research has been performed, we have set out as working hypothesis, whether this homogeneous and unique behavior of the migrants is due to the demand and structure of the labor market, or it rather comes from the cultural heritage that they share among themselves and also with the local population of Spain.

Socio-geographic factors behind the integration problems of the Roma population in Hungary

István Süli-Zakar (University of Debrecen), Mihály Tömöri (University of Debrecen)

Many researchers believe (including the authors of the present paper) that the integration process of the 600-650 thousand Roma people will be a fundamental question in

Hungary's social, economic and political future. According to the optimistic scenario it is hoped that after the end of the economic crisis, along with an economic upturn, the number of employees (including Romas as well) will rise significantly. However, we should not forget that due to the generally lower educational level and working morale of the Roma population a decrease in the number of unemployed Romas is questionable. Nevertheless, our field studies have proved that Romungros, accounting for two-thirds of the Hungarian Roma population (representing a higher-level of social integration) are willing to work. On the other hand, the work motivation (willingness to work) and the social integration process of the Olahs, accounting for one-third of the Hungarian Roma population, are going to be problematic even if a positive scenario is realized. If a negative scenario is realized a prolonged economic crisis and deepening social and economic problems will have to be taken into account. The slowing integration process of the Roma population may result in strengthening political and criminal problems. It is expected that the demographic boom among Romas can slow down only in the long run. If a negative scenario is realized it is expected that Roma emigration from Hungary will strengthen. This potential Roma emigration from Hungary (along with emigration from other countries such as Romania, Bulgaria, Slovakia, the Czech Republic, etc.) can result in serious social and economic problems in Europe's future. Altogether, it is believed that (no matter which scenario (pessimistic or optimistic) will be realized) the problems of the 10-12 million Roma people have to be addressed at a Pan-European-level. The implementation of the European Roma Strategy, elaborated during the Hungarian EU presidency, can serve as a good starting point to achieve this goal.

The dynamics of residential perception and redistribution in German suburbia

Klaus Friedrich (Martin-Luther-Universität)

Residential suburbanization has shaped significantly the German agglomerations during the post war period. In course of this the former compact central cities expanded by a population and housing sprawl into the urban vicinity. While this process started in West Germany already in the 1960s and continues until today it was significant in the new Länder after reunification in the early 1990s only for a decade. East Germanys residential suburbanization was driven mainly by consolidated family households, originally residing in the socialistic type of prefabricated multi-story housing compounds. Since 2003, however, the central cities experience a slight population growth. Controversial discussions explain this reversal of the spatial population pattern either as indicator of the turnaround in urban shrinkage, or as a tendency towards city renaissance and re-urbanization, respectively. Aim of this presentation is to evaluate the future prospects of the existing suburban residential locations mainly in the light of demographic change both using structural indicators characterizing the living environments and also taking into consideration the perspective of the aging residents. A brief comparison of the settlement structure and population processes in East and West Germany will be joined by the

analysis of space-related behaviors and attitudes of the people living in suburbia. The statements concerning the latter mentioned context are based mainly on the latest results of a major survey currently carried out in the East German Saxony-Anhalt including field studies in about 1.100 suburban sites, where a total of more than 1.000 interviews and 20 in-depth interviews were conducted. The ageing of the relatively homogeneous group of former in-migrants will generate new challenges tackling the timely provision of age-appropriate social infrastructure, especially in non-integrated neighbourhoods. And there are many other uncertainties, in particular concerning the spatial behaviour of suburban residents as well as the residential styles and requirements towards their living environments. A central question of our project is how people perceive indicators like common aging, decreasing demand for and values of residential properties in suburban areas and also, how they react on these challenges. Therefore we have asked for the assessment of the following four dimensions: 1. living environment and infrastructure 2. integration and spatial participation 3. intended transfer of real estate 4. perspective of residential location The mentioned interviews were conducted to validate the inhabitants views concerning the quality of residential areas as crucial factor that affects the identification and satisfaction with the living environment.

Geographies of migration, citizenship and belonging in contemporary Italy: Recent developments at the light of the economic global crisis

Davide Papotti (Università di Parma), Carlo Brusa (Università del Piemonte Orientale)

The most recent analyses of current immigration trends in Italy (ISMU, 2011; Caritas, 2011) show a quite remarkable decrease in the numbers of foreign immigrants entering the country. This decrease, at least partially explainable with the global economic crisis that is striking the country with particular intensity, goes together with an increase in the percentage of people landing on the coasts of Southern Italy and a growing access by immigrants to the Italian citizenship, in spite of a highly restrictive legislation (a country 'with the door only half opened', to use the communicative image used by Etienne Piguët in his study on immigration in Switzerland; 2009). While the first phenomenon can be explained by the political and social instability of the North-African countries that are just across the Mediterranean from Italy, the second one shows evident signs of the growing (request for) stabilization of the immigrants in the Italian society. Drawing from Michael Samer's (2010) recent theoretical contribution to the geographical approach to migration studies, and framing the study of immigration flows within the larger phenomena of 'globility' ('Global change and human mobility'; the effective neologism is also the name of a Commission of the International Geographical Union devoted to the study of these topics), this paper wants to offer an overview of the contemporary immigration trends in Italy focusing on three main issues: the most recent changes in the composition of the immigrant flows (regarding country of origin, sex ratio, age, religion), the processes of acquisition of the Italian citizenship (following the debate started by the President of the Republic who, in November 2011, publicly criticized the current rules related to a *ius sanguinis* legal system that still postpones to the major age the acquisition of the Italian citizenship by the second generations who were born and grown in Italy), and the growing debate on the processes of integration of the immigrant groups in the country. Bibliographic references Caritas Migrantes (2011), Dossier Statistico Immigrazione 2011 - 21° Rapporto, Roma, Idos Fondazione ISMU (2011), XVII Rapporto sulle migrazioni 2011, Milan, FrancoAngeli Etienne Piguët (2009), L'immigration en Suisse - Soixante ans d'entrouverture, Lausanne, Presse polytechniques romandes - Collection "Le Savoir Suisse", 2009 Michael Samers (2010), Migration, London-New York, Routledge <<http://130.54.245.7/geo/globility/index.html> >

The economic crisis and the influence of the feedback mechanisms in the migration flows to Portugal among Brazilians, Ukrainians and Moroccans

Maria Lucinda Fonseca (University of Lisbon), Alina Esteves (Centre for Geographical Studies), Sónia Pereira, Jennifer McGarrigle

After the remarkable migration inflows that occurred during the nineties and the first decade of the 21st century, which altered the position of Portugal in the international migration scene reaffirming its position as a hosting country, the recent economic downturn of the national economy has led many foreign citizens to look for jobs elsewhere in Europe or even in other continents. The news about the poor performance of the Portuguese economy was not only visible in the media, and thus available to potential migrants who might consider this Southern European nation as a possible destination, but was also disseminated by foreign workers already living in Portugal through word of mouth to relatives, friends and acquaintances in the home country, in what is called feedback mechanisms. There is a considerable body of literature on the role of the information transmitted back to the sending regions and the possible effects on future patterns of migration flows in which the authors focus on the transformation of the initial processes and on the change induced over time both in origin and destination areas, namely on positive vs negative feedback, amplification vs counteraction of the decision to migrate and concomitant flows of goods, capital and ideas (Bakewell, de Haas & Kubal, 2011; Mabogunje, 1970; Bilsborrow & Zlotnik, 1995). Using qualitative data from 90 in-depth interviews conducted in the scope of the NORFACE-sponsored THEMIS project, the goal of this paper is to explore the kind of feedback that Brazilian, Ukrainian and Moroccan nationals living in the Lisbon Metropolitan Area and in the Algarve region send to their home places. Particular attention will be given to endogenous feedback mechanisms (networks, remittances, for example) and contextual feedback mechanisms (for example, entrepreneurship, cultural change) - de Haas, 2010 - that may alter the intensity and composition of the flows between origin and destination, set in a macro condition of meltdown of the Portuguese economy. Human mobility, economic crisis and tourism in the Balearic Islands (Spain)

Pere A. Salvà-Tomàs (Universitat de les Illes Balears)

The mass tourism development in the Balearic Islands (Spain) with more than 12 million tourists that consumed more than 110 million overnight stays in 2011 it has impacted in an intensification of the human mobility. The tourism has been a basic factor of a call-effect so much for an economic labour as residential immigration type that globally almost represents 90 percent of the population's growth in the last 15 years. The high immigration index a presence of more than 240.000 foreigners (the 22% of population's resident) that he is defined through a model "New California migration type" in which coexists an and/or entrepreneurial economic immigration and a leisure residential immigration. The dynamism of the economic activity implied the arrival of a high number of economic migrants (labour and /or entrepreneur). But the current economic crisis has implied a decrease of the arrival of tourists, a crisis of the construction sector and a recession of the family expense. This fact has important consequences on the labour market that reduces its work offer and the phenomenon of the unemployment appears, with hypothetical processes of the labour migrants return. On the contrary the economic crisis has not affected from a significant way to the residential immigration (basically German and British people). Of they are deduced it behaviours differed according to the migration typologies and the motivations for migrate to the Balearic Islands. The paper seeks to contribute knowledge on the interrelation among human mobility, economic crisis and tourism.

Toward structural migratory wars?

Stéphane Rosière (Université de Reims)

This presentation aims to consider international migratory flows as the source of a global and structural conflict. This conflict results from the distortion between the neoliberal economy and the demographic evolution of the planet. The neoliberal economic system produces concentration of richness in North and structural underdevelopment in South, at the same time the growing population of South looking for employment, richness and political stability is pushed Northwards. But North countries are closing their borders. The « rebordering of the North » (Andreas and Biersteker, 2003) generates the construction of smart borders and new walls and fences all around the world (part 1). The 'teichopolitics' (Ballif and Rosière, 2009), or politics of territorial closure (esapecially on borders) is developped all over the world. Most of the new border-barriers (often high-tech fences) are erected to prevent illegal migrations (while their role against terrorism or smuggling seems rather marginal). We can analyse the process of border-barriers construction as a paradoxical answer to underdevelopment (Part 2). Beyond this macro-economical and political analysis, we suggest that furthermore contemporary world is now confrontate to a low-intensity structural migratory war. Do we enter a 'new history' characterized by a structural migratory war located at the contact of North/south - According to such creations of Warfare as number of casualties, the up-to-date situation on main

North/South borders can be identified as a War (Singer and Small, 1972). This undeclared War is clearly a consequence of the capitalist development which can not be anymore considered as a peaceful system avoiding crisis and armed conflicts (as expected by 'end of history' and such theories).

Population Flows in Post-Socialist Rural Area: Case of Latvia

Zenija Kruzmetra (Latvia University), Liga Rasnaca (Latvia University)

The current research interest is due to remarkable population changes in rural territories at the beginning of 21st century which is determined by transformations in the Latvian political and economical systems and global processes. The authors' focus to find out regional differences of population flows in post-socialist rural area in Latvia. Latvia is characterized by intensive labor out migration during last two decades in different intensity. The situation is complicated by the negative natural growth. These processes mostly characterize post-socialist Central and Eastern European countries, as opposed to Western Europe and the United States. Authors are interested how these processes could be explained by theory of space of flows in post-socialist countries. The research goal included analysis of connectedness of flows with labor market relations in rural areas. Terry Marsden, professor at the Scottish University of Aberdeen, researcher of rural development apply network theory author's American sociologist Manuel Castells theory of space of flows, underlining the influence of people, capital and knowledge on labor market relations in rural areas. There is a lack of protection mechanisms in rural areas against dangerous influence of space of flows, to allow maintain a local labor market. As a result people in rural areas are unprotected against necessity of out migration. Quantitative and qualitative social research methods were used to describe the population inflows and outflows in different rural areas. One change that has attracted particular attention is the shift in the meaning of rural areas for local residents. During the latter half of the 20th century, people all over the world began to change their human value orientations, and wealthier people began to look for living spaces outside of the city centers - in suburban areas and in closer or more distant rural territories. This process led to a new inflow of residents and, consequently, to an increase in population numbers and substantial changes in population structures. The authors analyzed changes in population numbers between 2005 and 2008 in Latvia and the areas which surround the eight largest cities of Latvia in order to assess the peri-urban territory development situation. The author's analyzed data related to increases in population numbers, including those that can be attributed to migration. The post-socialist features of population in rural areas are expressed as nostalgia for large industrial type enterprises that would employ a large number of the local population. It is expressed repeatedly in the interviews with municipality chairpersons, which could be interpreted as barrier for involvement of new forms of employment and to encourage outflows dimension of rural population. Key worlds: space of flows, population inflows and outflows, regional differences

Booming cities and cross-border migration to rural towns

Birte Nienaber (Saarland University)

Borders can have different characteristics of being. They can be barriers, filters or open spaces (LEZZI 1994). With the Schengen Agreement, the countries which signed this agreement opened their borders for the freedom of movement of people, traffic, capital and goods. Germany is surrounded by nine neighboring countries which have all signed the Schengen Agreement. Schengen as well as other EU regulations have made it possible for each person living in the EU to move to another EU country to live there. This freedom of movement has brought new cross-border arrangements. People e.g. from Luxembourg, the Netherlands (see also van Houtum/Gillies 2006) or Poland are moving to the nearby rural German peripheries where the living costs are comparably low, but still work in their home countries and build up transnational, cross-border societies. Especially the booming cities of Luxembourg and Szczecin lead to a pressure on the rural real estate market on the German side of the borders. This presentation will show the development of cross-border transnational migration systems and possibilities of cross-border governance of this phenomenon along the German borders based on the results different research projects carried out since 2009.

Post-socialist urban population: Commuters and commuting in the Riga metropolitan area

Maris Berzins (University of Latvia), Zaiga Krisjane (University of Latvia), Andris Bauls (University of Latvia), Artjoms Ilevs (University of the West of England)

Recent years have witnessed important changes in geographical mobility of the population in post-Socialist countries. The commuting field of R'ga enlarged due to residential suburbanisation and the intensity of commuting from the suburbs to R'ga increased in the 2000s. Besides, formation of the R'ga metropolitan area (RMA) is associated with specific features of Soviet urbanisation characterised by industrialization, concentration of investments into large cities and immigration. Among in-commuters to R'ga industrial workforce made more than 40% during the Soviet period, but situation changed in the 1990s because of demographic decline, rapid economic restructuring and related adjustments in the labour market. The aforementioned changes over the past decades also affected all aspects of commuter's composition. Therefore the main focus of our study is to contribute to the understanding of post-socialist population mobility. The aim of the current paper is to examine the patterns of commuting in R'ga metropolitan area by identifying different groups of commuters and to identify compositional differences between commuters and non-commuters. The analysis is based on an extensive survey of the R'ga metropolitan area, Latvia. To determine the individual characteristics which affect commuting probability, we estimate binary regression models. The results of the study indicate that people who suburbanised over the past decade were more likely to be commuters than were long time suburban

residents and suburban in-migrants from non-metropolitan regions. Thus, the impact of recent suburbanisation pattern is evident and confirms the previous results that residential suburbanisation, rather than labour-market change, contributed to the increase of commuting in the RMA. Regarding the compositional differences, we found that commuters differ from non-commuters both in R'ga and in the suburbs in regard to most of the demographic and socio-economic variables studied. Similarly, the compositional differences among commuters were found.

Hazard and Risk

C08.18-01 - Earthquake and Tsunami special session

Chair: Shigeko Haruyama

Tsunami impacts on a threatened island ecosystem

Ingo Hahn (Universität Münster)

Tsunamis, like the 2010 tsunami in Chile, have severe impacts on the human life along the coast side. For 3 % of the human population of Robinson Crusoe Island this event was mortal. This Chilean island, although having only an area of 47 km², is the prime conservation hot-spot within the country, e.g. hosting c. 20 % of the endemic bird species. Very little is known in general about the impacts of tsunamis on endangered floras and faunas. On Robinson Crusoe the endemic hummingbird, the Juan Fernandez Firecrown *Sebanoides fernandensis*, showed a total population size of about 1100 individuals. As a nectar feeder it highly depends on flowering plants, and has co-evaluated with an endemic Asteraceae species which is mainly found along the coast side. In this study we investigated how a tsunami functions as an example for a natural catastrophe endangering a critically endangered bird-plant system.

Potential Flooding by Tsunami in Coquimbo, Chile

Jose Novoa (University of la Serena)

As part of the Diagnosis of the Risk Areas in Coastal Cities of Coquimbo Region (MINVU) and the project of Regional Planning for Risks Management of Coquimbo Region (MIDEPLAN, SERPLAC and the Agency of International Cooperation of Japan), presented the map for potential flooding by tsunami in Coquimbo (Chile). Methodologically based on models of the spread of tsunami (model TUNAMI-N) and the historical background (1730, 1922 and 1943 events) that have affected the bay of Coquimbo, are established by tsunami flood elevation and the height of the layer of water flooding above the ground in 3D supported by topobathymetric charts. The results obtained allow determine the most problematic situation from playa Changa southward, reaching the level of the 13 metre curve and a thickness of maximum flooding of 10 meters in the coastline that affects coastal environment that possess an important tourist and residential occupation altogether.

The North Sea Tsunami of June 5, 1858

Juergen Newig (Universität Kiel), Dieter Kellertat (University of Duisburg-Essen)

Tsunamis along passive continental margins are rare, and those in shallow shelf seas mostly unknown. A thorough study of old reports, newspapers and other sources, however, gave a lot of useful hints for a tsunami in the North Sea Basin on June 5th, 1858, culminating in run up values up to 6 m along the southern west coast of Denmark.

The reports from official authorities and eyewitnesses, mostly published directly after the event, contain all phenomena known from ancient and modern tsunamis: single waves approaching with a loud noise, wave groups separated by longer time spans, extremely long wave crests, withdrawal of the sea in front of the first wave, extraordinary wave/run up heights during calm weather and low tide, and much more. The arrival time of the first wave in an area from the southern English Channel to the central west coast of Denmark give hints to a tsunami source in the wider Biscay region or south of it, sending one wave around the British Isles entering the North Sea from the NW, and another one entering from the English Channel and the Straits of Dover. As plenty of wave events are well known from the North Sea region, but nothing similar has happened since the last 150 years and long before 1858, there is no doubt that this extraordinary event was a tsunami and not another kind of wave phenomenon. In detail many questions (e. g. contradictory observations) remain unanswered. With this contribution we are only at the beginning of the study of tsunamis in the North Sea.

Influences of landforms on the extreme tsunami disaster caused by the 2011 off the Pacific coast of Tohoku Earthquake in the lower reaches of the R. Natori and the Sendai Plain, northeast Japan

Hiroshi Shimazu (Rissho University)

The extreme tsunami caused by 'the 2011 off the Pacific coast of Tohoku Earthquake' attacked the east coast of Japan. The Sendai Plain was flooded widely by the tsunami and suffered heavy losses. The strong flood flow also ascended the lower reaches of the R. Natori in the Sendai Plain. Videos and photos which were taken during and after the tsunami event indicated that damages varied as to landforms. This Study aims to reconstruct the geomorphic processes of flood flow and ebb flow caused by the tsunami along the R. Natori and to discuss the influence of landforms on the tsunami disaster in the central part of the Sendai Plain. Firstly analyses on surface sediments, the micro-landforms and type and scale of the damages to the agricultural facilities were performed on the dry riverbed in the lower reaches of the R. Natori. The dry riverbed is separated by artificial dykes from the floodplain and which is used for farmland. Secondly extent of the tsunami flood and a diversity of the tsunami damages in the plain were reconstructed using videos and aerial photographs. And they were compared with the landforms. Height of the tsunami along the coast of the Sendai Plain was estimated over 3 meters. Although the devastating tsunami came into the plain, it was dammed by an elevated motorway which parallels the coast across the plain and is located 2.5 kilometers from the coast. The flow through underpasses of the motorway was weakened and reached an elevation of about 3 meters, 4 kilometers from the coast. The flood flow also went up the R. Natori and reached the points, 9 kilometers upstream from the river mouth along the channel and 6.5 kilometers on the dry riverbed. Both of the points are at an elevation of about 4 meters. In the lowest 2.5 kilometers reaches of the R. Natori the strong flood flow and ebb flow caused erosion on the dry riverbed and the river banks. In the next 1.5

kilometers reaches, although the flood flow was still devastating, there was no sign of the ebb flow. Because sedimentation process was dominant, sandy sediments were deposited. In the reaches between 4 and 5 kilometers from the river mouth, the flood flow went upstream gently on the dry riverbed. Relatively elevated islands surrounded by former channels, were not affected by the flood flow. Around the margin of the tsunami flooding the dry riverbed was inundated and thin tsunami deposits were left on it. In the plain between the coast and the motorway the strong tsunami flood went over the surface relief, such as beach ridges and natural levees, and destroyed most houses and high tunnel greenhouses. Tremendous woody and rubble debris were left on the plain. The weakened flow through the underpasses of the motorway traced former river courses and went up the plain. In this area the houses on natural levee were not damaged. After the tsunami disaster, floodwater widely covered the plain except beach ridges and natural levees within several days.

C08.18-02 - Hazard and risk for future mitigation 1

Chair: Shigeko Haruyama, Victor G. Jetten

Toyooka 2004 flooding and community activities for mitigation

Shigeko Haruyama (Mie University)

It is important that the hydrological infrastructure construction along the river, such as embankment and dam, is planning for natural hazard prevention works, however, the suitable land use planning and its methodology based on geomorphologic view are the most important for disaster mitigation and to make social capital supporting the evacuation activities and expeditious activities for interdependence assistance in each residence under emergency. In this study, the author clarified the flood features of 2004 Flooding in Toyooka City Area, Hyogo pref. in Japan and the community-based activity for disaster response of Toyooka City Area, paying attention to following points, 1) geomorphologic land classification map showing flood vulnerability factors related with flood characteristics of the Maruyama river basin, 2) relationship between land use change and land form should be understood for future sustainable land use planning, 3) local community-based activities for natural disaster reduction, specific flooding reduction. The specific local community in Toyooka City Area for disaster reduction is strongly demonstrating their local characteristics cultivated under their area history between flooding experience and prevention works against flooding. The author will discuss the flood vulnerability assessment of Toyooka City Area along the Maruyama river basin and the local community-based activity for disaster reduction of 2004 flooding in Toyooka City Area.

Locating choke points and mapping land use changes in select river systems of Metro Manila: Historical mapping of constriction and disappearance of waterways in urban settlements

Doracie Zoleta-Nantes (Australian University), Simeona Martinez (University of the Philippines), Rocelyn De Vera (University of the Philippines), Paulo Caparas (Department of Geography), Mart Cyrel Geronia (Department of Geography), Marie Joyce Ilagan (University of the Philippines), Neil Eneri Tingin (University of the Philippines)

A historical mapping of constriction and disappearance, and the land use changes on the banks (20 m easement), of creeks and river systems in five study sites in Metro Manila, Philippines was undertaken during the last quarter of 2011 using GIS and participatory community mapping. The primary objective was to identify the 'choke points' and constricted portions of select waterways due to factors that are associated with unplanned conversions of river banks into concrete spaces due to the rapid urbanization

of Metro Manila and a number of adjoining towns and municipalities in Rizal and Laguna Provinces. These factors had greatly contributed to the widespread flooding that paralyzed human communities in most areas of the metropolis due to the flood events that were brought about by Tropical Storm Ketsana (Typhoon Ondoy - Philippine local name) on the last week of September 2009. A mapping of the flood depths that were experienced by the human populations in the urban settlements that developed in areas adjacent to the river systems was also undertaken. This was done to illustrate the physical-geographical-economic and social contexts of the 2009 flood events that devastated hundreds of communities in Metropolitan Manila area. The resulting maps and data bases are being incorporated into a risk assessment of urban communities in low-lying areas that are adjacent to some select waterways and river systems in the metropolis. The over-all long-term objective is to reduce the vulnerabilities and increase the resilience of prone urban settlements to flood events that are projected to recur more frequently due to the changing patterns of extreme weather events in the Philippines.

Landslide Hazard Zonation

Masood Beheshtirad (Azad University)

Identification of regions having potential for landslide occurrence is one of the basic measures in natural resources management. Different landslide hazard zonation models are proposed based on the environmental condition and goals. In this research landslide hazard zonation map using multiple regression model was provided and applicability of this model is investigated in Bagh Dasht watershed. Dependent variable is landslide inventory map and independent variables consist of information layers as Geology, slope, aspect, distance from river, distance from road, distance from fault and land use. For doing this, existing landslides have been identified and an inventory map made. The landslide hazard zonation map is based on the multiple regression provided. The level of similarity potential hazard classes and figures of this model were compared with the landslide inventory map in the SPSS environments. Results of research showed that there is a significant correlation between the potential hazard classes and figures with the area of landslides. The multiple regression model is suitable for application in the Bagh Dasht Watershed.

Atmospheric droughts over North Eurasia since the middle of 20th century

Andrey Shmakin (Russian Academy of Sciences), Valeria Popova (Russian Academy of Sciences)

Detailed statistical study of atmospheric droughts over North Eurasia is carried out for the period 1950-2011 based on daily meteorological records. Criteria for the atmospheric droughts include both low precipitation and high maximum daily temperature. Regions with high frequency of the atmospheric droughts include south of East European plain, south of Western Siberia, and parts of Eastern Siberia and Far East. Large-scale

atmospheric circulation situations favourable for the atmospheric droughts include combination of anomalous values of West Pacific and some other indices such as North Atlantic Oscillation, Polar-Eurasian, etc. Changes of the atmospheric drought frequency over the North Eurasia during the last decades are explored and mapped. Overall, the frequency of the atmospheric droughts has increased, especially over certain parts of Siberia and Far East, as well as over East European Plain (the latter due to the 2010 event). To a significant extent, increase of the atmospheric drought frequency is related to the changes in the large-scale atmospheric circulation. The statistical relationships between the atmospheric drought frequency and atmospheric circulation indices can vary on the decadal scale. Since the beginning of 1980s, there is a significant trend in some of the circulation indices values, resulting in changes of the atmospheric droughts frequency over North Eurasia.

C08.18-03 - Hazard and risk for future mitigation 2

The Research of the Residents' Experience and Behavior vs. the Local Government's Land Use Strategy under the Influence of Extreme Weather

Robert Y.S. Chen (Kaohsiung University)

The long-term research focuses of geography lies on how people cope with environmental perception and their adaptation to mitigate the impact caused by hazards. Typhoon Morakot invaded Taiwan on August 7, 2009, leading to large scale of hazard, causing death toll of 673 people and 26 people missing, 24,950 people were evacuated as a result. It was also known as the worst flooding ever since the August 7 Flood in 1959. The rainfall hit the worst on August 8, winning itself the reputation of August 8 Flood in Taiwan. This research explores the coastal area of Pingtung County. Due to the blossom of fish farming, this area has been suffering badly from the groundwater extraction for over 30 years. Linbian and Jiadong Township have become the worst locations with the most serious problem of land subsidence. According to the survey the maximum cumulative subsidence has reached up to 3.02 meters, its current altitude is close to the sea level, resulting in habitual flooding during raining season as well as the nightmare of the local residents. While coping with general flooding issue, the residents have developed a series of contingency mechanism to reduce the threat to life and property caused by flooding. Nevertheless, August 8 Flood produced a record-high rainfall of 2500 mm, creating the most devastating hazard in Linbian and Jiadong Township. As to the residents, the power of flooding had gone far beyond any imagination derived from any flooding experiences they have had in the past. Consequently, the hazards derived from coping with current flooding based on their old experience have outweighed any harm before. Qualitative research method is applied to conduct in-depth interviews in an attempt to investigate environmental perception of residents in the research area, hoping to explore the adaptation of residents while coping with environment hazard after August 8 Flood. The preliminary research investigation discovers that the residents have suffered from flooding hazards and developed adaptation behaviors to cope with flooding. While facing the extreme abnormal rainfall in August 8 Flood, either hazard intensity has exceeded residents' imagination. Accordingly, traditional flooding adaptation methods are no longer useful. While being unable to be evacuated, most residents were trapped within the disastrous areas. Key words: Extreme Weather, Environmental Perception, Behaviors, Local Government. [1] This study is supported by the National Science Council of Taiwan. [2] Assistant Professor, Department of Geography, National Kaohsiung Normal University, Taiwan. [3] Professor, Department of Geography, National Kaohsiung Normal University, Taiwan.

Impact of Quaternary Climate Changes on Slope Instability, Case study: Molab Mountain Basin (Zal River), Iran

Manijeh Ghahroudi (Shahid Beheshti University)

Problem statement: Glacial periods in mountainous countries of Middle East same as Iran have several glaciers due to the high altitude mountains of snow-line and also climatic and topographic conditions such as temperature, wind direction, rainfall and slopes which huge volume of their deposits was carried to slope and foothills by ice flow. Dry climate in the interglacial period caused to remain most of these deposits in the slopes and foothills and which causing instability for human activity and settlements. Zal sub-river basin of Molab basin is located in the middle of Zagros Chains (the south of Lorestan province) with an area of 660 square kilometers and its coordinates 32°47'50"N 47°59'50"E to 33°9'10"N 48°25'52"E. Glacial activity has been existed in this Basin especially during glacial periods and works digging of the glaciers are remained as circus and glacial valleys. More than 27 percent of the geological formations of the basin is Asmari limestone and the rest are respectively, Amiran, Gachsaran and Gurpi Formations. These four groups make all of the limestone formations in the sub basin, area of 415.2 square kilometers which is about 63 percent. The amount is sensitive to cryoclastic and it caused to destroy in the cold period. Other glaciers works in the basin are being deposited glacial sediments on the slopes and river beds which causing mass movements. Approach: In the research was determined domain of glacial deposit by using Topographical maps 1:50000, Radar data of Aster Sensor, LISS III and Pancromatic images of IRS Satellite and climatic data during 1985-2005. Fuzzy-Logic analyst was carried out in order to determine zones of instability in Zal sub-basin, because of using different variables, compared their and also coefficients are presented for each of the variables. Sum, Product and Gamma functions were used to assessment slope instability in the sub-basin. Results: The results showed that there is high unstable in Zal sub-basin. High and very high unstable domains are conformity with slopes of cirques and valleys end to cirques. Also the terraces on the edge of river valleys are unstable. Especially the terraces remained at altitude of 1600 meters near the upstream which is formed glacial deposits are the most unstable parts of the area. Fans and terraces of this river basin were exposure drastic changes. Conclusion: The nature of the glacial deposits and irritability of their through human economic activities have created hazardous conditions, so that Land on the terraces is affected by landslides. Several falls has occurred in valleys of the edge roads which during rainfall to dam front of water and with material and a sudden flood waters can threaten roads and bridges.

Planning and Implementation of the Dyke Systems in the Mekong Delta, Vietnam

Cong Huu Pham (Can Tho University)

Floods are a dangerous threat and an implicit risk for farming communities in rural floodplains of the Mekong Delta (MD). The Vietnamese government decided the dyke system construction to control floods and ensure safety for life and livelihood of flood affected communities. The case study of this dissertation refers to Can Tho city, an average floodplain community of the MD, covering also 9 districts. Here a comprehensive dyke system has been constructed to control flood risks. This thesis investigates the existing problems in the dyke system planning and its implementation, dyke impacts on the natural environment and socio-economic development as well as the adaptability of the flood affected farming communities in the protected floodplains. The study used both qualitative and quantitative research methods to collect information and data. Besides Global Positioning System (GPS) and a digital camera were used to identify the location of the most important samples in the field and during the fieldwork. Fieldwork itself was mainly based on the two rural communes of Thanh Thang and Thanh Phu, which are representative for the overall rural situation in Can Tho city and the MD. The study found that the Vietnamese government had made a basically correct decision concerning the necessity of flood risk control by the construction of a dyke system. Dykes have practically guaranteed safety for agricultural livelihoods of the flood affected farming communities and positively contributed to agricultural farming transformation from rice into integrated rice-fish production and rural road improvement. However, a centralized top down approach was strongly applied thus not considering the experiences and all expectations of public organizations and local people. The individuals and local organizations played a very weak role in the whole planning and implementation process. Dyke system construction consequently created conflicts between central planners and local people. In addition, the negative impacts of the dyke system have become a great threat for sustainable development in terms of water pollution, natural fish exhaustion, soil fertility reduction, erosion and in some instances, also due to increasing inundation of the fields. Thus, the dyke system construction and planning as well as implementation strategies need to be studied further to minimize the negative impacts of dyke systems and to ensure a stronger inclusion of local people and their knowledge in further planning approaches. Key words: Dyke planning, implementation strategies, flood control, impact on and adaptability of rural communities

Flood Risk Analysis for the Territory of Russian Federation

Pavel Tersky (Moscow University)

The research is concentrated on creating the system of quantitative evaluation of natural flood risk for the territory of Russian Federation. This system takes into account natural and social preconditions of flood forming. The taxonomical units are the federal subjects because of several reasons: planning of flood reducing activities and its financing,

collecting the hydrological and meteorological information, planning of economic and social activities usually carries out on federal and municipal level. To create the complex system of quantitative evaluation of natural flood risk there were solved two main goals - to define the most important hydrological characteristics (which determine the potential flood) and social-economic indicators (which show economic conditions on the one hand and the estimation of potential finance loss on the other). The main natural hydrological characteristics are: maximal depth of floodplain inundation; probability of water levels of riverside areas flooding; total duration of floodplain inundation; part of inundated area (compared to federal subject area); reach of river channel with the most probable floodplain inundation, which is defined by riverbed process type. The main characteristics of social-economic vulnerability are: population density; part of population which lives on potential floodable territory; human development index; long term assets; anthropogenic conditionality of natural disaster risk. According to expert opinions the most significant factors are the total duration of inundation and the part of population which lives on potential floodable territory. Flood risk is determined by these two groups of factors. Natural flood is multiple-factorial phenomenon and the risk assessment requires multivariate analysis. One of the methods of quantitative non-parametric analysis is PATTERN (Planning Assistance Through Technical Relevance Number). The final result of the research is the typological demarcation of Russian Federation by flood risk, expressed in numerical values for each federal subject. The flood risk is classified into 5 classes - from 'low risk' to 'extremely high risk'. The map of potential flood risk was created according to this typological classification. The typological classification of flood risk was verified on the different data. It corresponds to the list of the most vulnerable regions and regions with the highest flood losses. Also numeric values of natural flood risk and social-economic vulnerability correspond to the prevented damage data (correlation coefficient is 0.68). The highest potential flood risk is typical to Zabaykalsky, Krasnoyarsky kray, Kabardino-Balkaria and Severnaya Osetia republics. The safest regions are Vologodskaya oblast, Karelia and Altay republics.

C08.18-04 - Hazard and risk for future mitigation - Poster session

Chair: Shigeko Haruyama, Victor G. Jetten

Study of rockslide regions in the territory of Republic of Armenia

Marat Grigoryan (Yerevan University)

Modern processes and phenomena, such as rockslides, destructions, rockfalls, settlements, downpour, are wide-spread in the territory of RA, which affect country's economy, as well as became reasons for human victims. Among mentioned processes and phenomena in the Republic of Armenia the rockslides are very dangerous, which by their development, abundance are very dangerous. The wide abundance of rockslides is caused by seismic activity of the territory, geological, hydro-geological structure, slope's tiling, and geo-morphological conditions. The activity of the latter is mostly caused by human activity, wrong construction on slopes, wrong land development for agricultural purposes. In order to eliminate the results of the rockslide enormous means are spent (according to the latest data about 7 billion AMD annually). According to the data of latest studies, about 3500 rockslides are registered in Armenia. The total surface of rockslides is 122 thousand sq. km · Rockslides' phenomena are registered in 233 communities · Road with length of 240 km is damaged by 280 rockslides' Phenomena. A railway with length of about 5 km is damaged by 10 rockslides. In accordance with the data of rockslides' study the direct damage from rockslides' phenomena is about 43 mln USD, and the potential damage is about 54 mln USD. Depending on the level of places' danger in the past, huge engineering-geological, hydro-geological, geo-physical, geo-morphological, drilling, geodesic and other types of work have been performed in the territory of the republic. Today 387 most dangerous rockslide territories of RA consist danger of rockslides phenomena activation and even fall in several regions. Today the issue is raised from the viewpoint of estimation of anti-rockslide arrangements effectiveness as a result of rockslides phenomena study.

Landslide hazard at the flysch-carbonate contact in SW Slovenia

Matija Zorn (Slovenian Academy of Sciences and Arts), Blaž Komac (Slovenian Academy of Sciences and Arts)

In Slovenia flysch rocks occupy app. 6.5% of the territory. They can be found in western and southwestern Slovenia where they are bordered with carbonate Dinaric Mountains. In the Vipava valley this lithological contact is expressed as a thrust between Mesozoic carbonate rocks of the Trnovski gozd high karst plateau and the underlying impermeable Eocene flysch rocks in the Vipava valley. During the Pleistocene, up to 50 metres thick slope debris accumulated on the base of the slopes which extend from 100 m to 900 m a.s.l. The accumulations are mobile due to numerous karst springs which appear on the

surface or below the sediments at the contact between carbonate and flysch rocks. Until now, about 70 landslides have been registered on the slopes above the Vipava valley between the Razdrto village and the town of Nova Gorica at the distance of app. 50 km. Most of the landslides have been registered during a recent motorway construction. Some of the fossil landslides were reactivated due to this construction. Sediments of a large Pleistocene landslide were found near the village of Selo measuring up to 150 million m³. In the last decade some large landslides were triggered due to heavy precipitation. In November 2000 the Slano blato landslide was triggered. The landslide is more than 1300 m long, from 70 to 150 m wide and about 10 m deep with a volume of about 1.000.000 m³. Landsliding at this place has been known there for four centuries at least. The Slano blato landslide did not cause major infrastructural damage but it endangered the village of Lokavec. The cost of major mitigation measures which have been undertaken is almost 10 million euro. After heavy precipitation in autumn of 2010 that caused large floods in Slovenia, another two landslides were triggered in the area. The Stogovce landslide which covers app. 15 ha destroyed the road to the Trnovski gozd high karst plateau and blocked a minor stream. Infrastructure was heavily damaged. Some weeks after several 100.000 m³ of material were moved by the Znosence landslide. The landslides on the carbonate-flysch contact present a constant threat to local population. On one hand, the movements can be accelerated and at least some of the landslides (e.g. Stogovce landslide) may provide mobile material for dangerous debris flows. On the other hand, landslides on steep flysch and rubble slopes constantly damage roads and other infrastructure, such as waterworks and the electric power supply system for the karst Trnovski gozd high karst plateau. In the long run some of the landslides may endanger the motorway of the fifth European transport corridor from Barcelona to Kiev which has been built exactly on the slopes prone to landsliding.

Urban floods in the Arouca village (Portugal): Influence of surface runoff network and land use dynamics

Inês Marafuz (University of Oporto), Alberto Gomes (University of Oporto)

Urban flooding is a phenomenon which reflects the increasing urbanization process of the territory. Although not intensively studied in Portugal, urban flood episodes are growing throughout the country in frequency and affected areas. This type of flooding, assuming in many cases the flash floods characteristics, is the result of water concentration in topographically depressed areas during episodes of intense rainfall over short time. This floods events are enhanced by soil sealing and by malfunction or undersized pluvial rainwater drainage systems. The most critical phase of these events occurs when the capacity of this underground drainage system is exceeded, causing the inversion in flow direction and consequently, its concentration in nodal points and emergence at the surface. To understand the dynamics of the surface runoff in the Arouca urban area (Portugal), it was analysed the role played by each element of the urban grid towards the surface runoff process. For this, it was considered: (1) the slopes that favor the rapid and

intense spread of the flow, (2) the topography and the urban morphology that interfere directly in the surface drainage pattern. By the interpretation of aerial photos and recent orthophotos, it was also analysed the evolution of land use in the last five decades, aiming to understand the effect that gradual sealing promoted in the increase of the superficial flow component. The collected inventory has enabled the identification of the most susceptible areas in the village and the exposed elements to this risk. The most problematic areas corresponds to the lower areas of the village and some streets where occurs a dual concentration of the runoff, i.e., the surface and the pluvial drainage flows. On the other hand, there was an increase of 21% on artificial surfaces, as a consequence of forest and agricultural areas decline between 1958 and 2005. The chosen methodological approach and the obtained results are a contribution to improve the land planning on the Arouca municipality.

Centurial channel and landcover change of the valley floodplain and its implication on flood hazard, Kaoping River, Southern Taiwan

Su-Min Shen (Taiwan University)

The Kaoping River (KPR) is a small mountainous river with a length around 170 km, the area of 3250 km² and a very high sediment yield (11,000 t km⁻¹ yr⁻¹). Its main trunk and major tributaries are characterized by braided channel pattern wherever the valley is wider. As many river valley around the world, its floodplains have experienced significant human modification over the 20th century. In 2009, Typhoon Morakot, with extremely intensive rainfall (> 150-year return period), caused severe flood hazards and has aroused great concern of the floodplain management especially when it is suspect that the frequency of extreme weather events is rising in Taiwan. This study aims to investigate the landcover change of the valley floodplains of KPR's two major tributaries, the Nantszhsien Stream and the Laonon Stream, over a century and its implication on the flood hazard. Landcover and geomorphic interpretation are completed by using historical maps, aerial photographs and orthomaps from early 20th to 2009 (after the typhoon) on a GIS platform. It is found that along with the process of channelization, the former floodplain has been reclaimed, mainly for agricultural purpose. The flooded area induced by Typhoon Morakot was within the former active-channels zone identified from 1948 aerial photos and historical maps published in 1920s for the study area. These pictorial materials together provide a good baseline for delineating the so-called 'fluvial territory' that is wide and continuous enough to guarantee the floodable areas to minimize the risk to the inhabitants. It also contrasts the space of the 'river reservation zone', in which the development is prohibited by law.

Spatial and Social Inequities in Exposure to Flood Hazards: A Case Study in Miami, Florida

Jayajit Chakraborty (University of South Florida), Timothy Collins (University of Texas), Sara Grineski (University of Texas), Marilyn Montgomery (University of South Florida)

Under the rubric of environmental justice (EJ) research, many quantitative studies have focused on investigating whether environmental hazards are distributed evenly across society, or if minority and low-income communities are disproportionately exposed to such hazards. While EJ studies in the U.S. have traditionally focused on the unequal distribution of anthropogenic hazards such as air pollution or hazardous waste facilities, Hurricane Katrina and subsequent government failures in responding to this disaster have prompted researchers to examine the EJ implications of geophysical events such as hurricanes and floods. Our paper contributes to this emerging literature on social vulnerability to natural hazards by analyzing racial/ethnic and socioeconomic inequities in the geographic distribution of flood risk in the Miami metropolitan statistical area (MSA), Florida. With a population of 5.6 million (2010), the Miami MSA is one of the largest coastal metropolitan areas in the U.S. and encompasses the three most populous counties in the state of Florida. Located between the Gulf of Mexico and Atlantic Ocean, Miami is one of the most hurricane-prone urban areas in the world and also one of the most ethnically and socially diverse MSAs in the U.S. The spatial extent of flood exposure is typically measured using 100-year flood hazard zones (areas with a 1% chance of flooding per year) provided by the U.S. Federal Emergency Management Agency (FEMA) Flood Insurance Rate Maps. These 100-year zones serve as the basis for U.S. flood insurance policy and control structures, and have been used in recent studies to assess social vulnerability to flood risk at the neighborhood level. Our study, however, extends this approach to make a meaningful distinction between different types of flood zones, based on the assumption that social characteristics of residents exposed to flood risk depends on the location/nature (coastal vs. inland) and frequency/probability (100-year vs. 500-year) of flooding. This study thus seeks to determine if the significance of various socio-demographic predictors of flood risk differs across relevant flood zone categories in the Miami MSA. Potential flood risk is measured as the proportion of a block group's area within the boundaries of 100-year coastal flood areas, 100-year inland flood areas, 500-year flood areas, and areas outside flood zones. Statistical analyses are based on locally derived spatial autoregressive models that explicitly account for spatial autocorrelation. Preliminary results indicate that racial/ethnic minorities are more likely to reside outside flood zones, but minority residents are significantly overrepresented in inland flood zones compared to coastal zones. Our findings underscore the need to distinguish between

various flood zone categories in future studies on social vulnerability to flood risk. This research is supported by the U.S. National Science Foundation (CMMI 1129984 and 1130191).

Public participation and institutional alignment in river governance: Multi-stakeholder platforms for Tanshui River Basin Management

Sue-Ching Jou (Taiwan University), Yu-Ling Wang (Taiwan University), Yu-Ping Wu (Taiwan University)

The purpose of this paper is to use the concept of "multi-stakeholder platforms (MSPs)" to identify mechanism of institutional alignment for public participation in integrated watershed management in Taiwan. It focuses on examining the role of intermediary organizations in participatory river governance by using Tanshui River Basin Management in the capital region of Taiwan as case study area. In accommodating severe flooding and landslide hazards in the capital region, Taiwan government has allocated huge amount of budget for flood control measures and have also been actively calling for public participation in watershed management since the mid of 2000s. However, this mode of public participation is apparently characterized by and limited in organizational participation. Although this is highly related to the contextual development of democratic governance of Taiwan's environmental management, this form of institutional alignment is worthy of further empirical investigation to reveal the nature of public participation in Taiwan's integrated watershed management. By investigating the activities that civic organizations and NGOs take part in and issues they concern the most for Tanshui River Basin Management since the year 2006 to current dates, this paper tries to summarize the characteristics and modes of participatory river governance in Taiwan. It aims to find out institutional and quasi-institutional platforms that have been exercised as new mode of collaborative governance in watershed management between the state and the civil society in Taiwan.

Reduction of urban flood vulnerability by collaborative modelling

Mariele Evers (Universität Wuppertal), Andreja Jonoski (UNESCO-IHE), Leonie Lange, Aklilu dinkneh Teklesadik, Cedo Maksimovic (Imperial College London), Susana Ochoa Rodriguez (Imperial College London), Vivian Juliette Cortes Arevalo (CNR-National Research Council)

This paper presents an attempt to enhance the role of local stakeholders in dealing with urban floods and reducing flood risk. The concept is based on the DIANE-CM project (Decentralised Integrated Analysis and Enhancement of Awareness through Collaborative Modelling and Management of Flood Risk) of the ERANET CRUE programme. The main objective of the was to develop and test the advanced methodology for enhancing the resilience of the local communities to flooding. Through collaborative modelling together with stakeholders and citizens, a social learning process was initiated which will enhance

the social capacity of the participants and multipliers due to the interaction process. The other aim of the project was to better understand how data from hazard and vulnerability analyses and improved maps, as well as from the near real time flood prediction, can be used to initiate a public dialogue (i.e. collaborative mapping and planning activities) in order to carry out more informed and shared decision making processes and to enhance flood risk awareness. In detail the objectives of the DIANE-CM project were: Development of a shared understanding of current flood risk Development and evaluation of alternatives for FRM Flood risk alternative simulating and testing under different scenarios Support for negotiation and selection of commonly agreed alternatives The concept of collaborative modelling was applied in two case studies: (1) the Roding river/Cranbrook catchment in the UK, with focus on pluvial flooding, and (2) the Alster catchment in Germany, with focus on fluvial flooding

Vulnerability Wiki – A collaborative knowledge platform

Antje Wegner (Karlsruhe Institute of Technology), Bijan Khazai (Center for Disaster Management and Risk Reduction Technology)

The term vulnerability is used in various disciplines and contexts ranging from disaster management and reduction to ecology, public health or climate change and adaptation. Within the last 20 years such a multitude of ideas about how to conceptualize and measure vulnerability was discussed and published that one can hardly keep track with the developments. The challenge for newcomers, practitioners and even experienced researchers to derive appropriate methods, indicators and criteria for a specific vulnerability assessment is broadly acknowledged and described. Vulnerability Wiki (www.vuwiki.org) is a collaborative knowledge platform based on Semantic Media Wiki and provides researchers and other stakeholders in the field of disaster vulnerability assessment helpful tools to structure and access information about vulnerability assessments. In comparison to conventional wikis a semantic wiki enables the organization of content through an ontology, which could be understood as a hierarchical representation of concepts and their interrelations in a certain knowledge domain. The aim is not at 'synthesizing' any kind of holistic and comprehensive model for vulnerability, but to develop a uniform ontology that allows the annotation of key categories and properties of vulnerability studies so that assessments can be made comparable and easily accessible at a glance. The wiki considers vulnerability assessments from four different perspectives: What is the vulnerable system, what are the drivers of vulnerability, which (spatial and temporal) reference framework is set in the assessment and finally, which methods are applied to assess or measure vulnerability? The ontology was elaborated through an iterative participatory process with an interdisciplinary research group at KIT. The semantic structure was validated and revised through 'test-cases' and discussing the 'fit' of the terminological structure to the content which should be organized by it. The ontology is implemented in a semantic wiki through a step-by-step form which allows for capturing structured information on the vulnerability study and

semantically encoding it at the same time. Currently about 50 assessments are populated in the wiki as a 'basic stock'; a number which is expected to increase after the official release of the wiki in December 2011. Like in most taxonomic approaches in vulnerability research or social science in general we will always encounter some difficulties in "classifying" all potential objects by a predefined set of categories and properties. Nevertheless the aim of the project was to provide an initial ontology framework for vulnerability studies and implement this in a collaborative platform. This provides a good starting point for organizing structured discussions regarding the different approaches to vulnerability assessment.

Socio-Economic Dimensions of Vulnerability to Flooding in Selected Communities in Lagos, Nigeria

Adeniyi Gbadegesin (University of Ibadan)

Nigeria is a disaster prone country. The environmental problems associated with uncontrolled expansion and poor management has increased the vulnerability of Nigerian cities to major disasters. The combination of physical development on unsuitable lands such as wetlands, slopes, flood plains and other environmentally sensitive areas, and overcrowding, all exacerbate environmental degradation and vulnerability to environmental hazards in many of these cities especially Lagos. Flooding has become a major problem and a major issue on the political agenda in Lagos in recent years due largely to the increased frequency and intensity of these events. Climate change and anticipated increases in flooding will exacerbate the existing poverty among the urban poor which are in most cases worstly hit. Thus, this study examines the nature of livelihood systems and how these shape victims' perception of floods on one hand, and the implications of the existing patterns of vulnerability created by gender, income and social position including the nature of physical infrastructure on the households' ability to adapt to the effects of flood and coping among victims in Lagos. The study is hinged on a comprehensive conceptual framework and terminology of vulnerability that facilitates the integration of the different research traditions involved in vulnerability and adaptation to climate change research. The study utilized data from both primary and secondary sources. The primary data include questionnaire administration and Focus Group Discussion sessions among the flood victims in the affected areas. The secondary data on the other hand, include data from the Lagos State Emergency Management Agency and the Ministry of environment on flood victims in the State. Questionnaires are drawn to reflect the gender characteristics of respondents. This is to address gender differences in coping practices and adaptation. The result of the study is useful in designing appropriate institutional interventions capable of transiting victims from being painful victims to developing adaptive capacity to live with recurring floods. Key Words: Climate change; Urban vulnerability; Adaptation; Coping mechanisms, Flooding, Nigeria

Persistent resilience and political opportunism: Glimpses of everyday life in Delhi's summer

Chandra Kumar (Aberystwyth University)

Study of resilience has focussed on the inherent capacity of the communities and its ability to devise innovative coping strategies to reduce the impact of any risk. This paper travels further and analyses the entry of political opportunism which encashes the

condition of persistent resilience for political gains and in the process makes the resilience less valuable. In the extreme heat of Delhi's summer, households use various coping strategies to fulfil their daily water requirements. Since centuries, the city residents have developed a rich system of water resilience in the form of cultural practices and behaviours. These practices and behaviours are time-specific and locale specific, and reflect persistent resilience of the communities during extreme summer every year. However in politico-technocratic era of urban water supply system, such cultural norms have been given little space for obvious reasons. It has made Delhi's summer more difficult in terms of water availability for the household and the communities. State has realized it and has started promoting the age-old water practices and behaviours. However, local politics favours the situation of water crisis, in place of water resilient practices, to capture public support. Not only it affects the inherent coping capacity of the communities, but also it devalues the resilience. Using qualitative and quantitative analysis, this paper will argue for better understanding of political use of persistent resilience in the context of urban waters in the global South. Key words: persistent resilience, Delhi, political opportunism, waters, global South

Is vulnerability 'a mere matter of social-physical problem' in urban areas? – A case study in Bantul District – Indonesia

Dyah Rahmawati Hizbaron (Gadjah Mada University), Martin Coy (Universität Innsbruck), Muhammad Baiquni (Gadjah Mada University), Junun Sartohadi (Fachhochschule Koeln), Rijanta Rijanta (Gadjah Mada University)

Scientific endowment has evolved around finding feasible solution towards many urban problems including minimizing vulnerability towards natural disaster. Herein, the vulnerability refers to classic separation between social vulnerability (SV) and physical vulnerability (PV) which address pre-existing condition of being unfavorable due to seismic hazard expressed on a scale from 0 (no loss/damage) - 1 (lethal/full damage) based upon these following criteria, i.e. physical, demographic, social-economic, losses, hazard, and built-up environment. In accordance, this research aims to evaluate whether vulnerability is 'a mere matter of social-physical problem' in urban areas using a case study of vulnerability integration into spatial plan in Bantul District, Indonesia. Bantul has exposed to (1) seismic hazard; (2) rapid land conversion; (3) economic transition and (4) is predominantly inhabited by poor to medium scale households. It experienced 6.2 Mw earthquakes in May 27th, 2006 which caused damages nearly 80% out of the 508 km² total area. The research method covers two phases, (1) generate SV and PV scenarios using spatial multi criteria evaluation (SMCE) based upon weighted criteria and (2) evaluate its integration into spatial plan using semi-structured questionnaire to reveal hidden criteria which contribute to vulnerability. The research findings are twofold. First, SV and PV scenarios have revealed that densely populated and developed areas have exposed to higher vulnerability compared to other areas. Second, the spatial plan has not served as familiar policy direction that assists local people to avoid hazardous areas,

which may increase their vulnerability. Ineffective spatial plan triggers intensive land development in certain nodes which are subjected to seismic hazard, escalates accumulation of people and their assets, and induces vulnerability. In summary, the vulnerability is not 'a mere social-physical problem' however it is embedded within policy making process. Thus, policy formulation, implementation, monitoring and evaluation processes have somehow hold formidable role to determine vulnerability level in the research area.

Vulnerability and resilience: Complementarity, interdependence or subordination?

Iulian Catalin Stanga (University of Iasi)

In the last three decades, vulnerability and resilience have become two basic concepts in risk assessment and crisis management. No scientific study can be realized, no technical measure can be implemented, and no political or administrative decision can be or should be adopted, without having to know the susceptibility of any system to be damaged by a destructive event, its capacity to cope with a crisis or to recover from a disaster. Although in the scientific literature, semantics of vulnerability and resilience is somewhat clear and unitary, many perspectives and distinct points of view can be cited due to very large conceptual sphere and to different fields of application: ecology, social sciences, psychology, economy, health care, risk assessment etc. However, are they complementary, interdependent or subordinated to each other? This article aims to answer this question by creating a conceptual framework, applicable on global, regional or local level and in relation with different categories of hazards. In this purpose, an exhaustive list of factors that influence vulnerability and resilience was created based on literature review and on our own studies. To create a logical scheme, all factors were grouped in several main groups: habitat and technical urban facilities, infrastructure, economical indicators, social and demographical variables, education, health system, environment quality, emergency management etc. A general graph matrix was created to assess the degree of determination or subordination of each factor on a dichotomous query: 'Does factor X affect factor Y?' ('yes'=1; 'no'= 0). This matrix allows calculating the influence score (the number of Y factors influenced by X), dependency score (the number of Y factors that influence X) and the general level of determination applying a mathematical relation. A second matrix allows the identification of correspondence and/or connectivity between vulnerability and resilience factors and to assess the degree of complementarity, interdependency or subordination. Yet, vulnerability can be the attribute of a larger category of systems than resilience is. Moreover, there are four extreme situations: low vulnerability - low resilience; high vulnerability - high resilience; low vulnerability - high resilience; high vulnerability - low resilience. Each case must be analyzed individually or it is possible to set up a model based on scale/level and factor analysis?

Health and Environment

C08.19-01 - Access to Care 1

Chair: Wuyi Wang, Mark Rosenberg, Thomas Krafft

Victims of location: Access to health care in the Lake Bosomtwe Basin of Ghana

Charles Adu-Gyamfi (University of Cape Coast), Albert Abane (University of Cape Coast)

The paper examines the spatial distribution of health care facilities, and factors that determine access to health care facilities in the lake Bosomtwe basin of Ghana. The study employed a descriptive design to examine the effect of the location of health care facilities on access to the facilities. Employing both quantitative and qualitative methods, primary data was generated for the study using interviews, questionnaire and observation. 120 respondents were selected through a simple random sampling technique for the quantitative aspect while 10 health care personnel and 6 chiefs were purposely selected for in-depth interview. Quantitative data were processed using SPSS version 16.0 for windows; the data were analysed using chi-square and simple frequency and findings presented in tables and graphs while qualitative data were categorised into appropriate themes and analysed accordingly. Health care facilities were found to be inadequate and sparsely distributed with only two clinics located in the study area serving residents of 22 towns. Capacity of the health care facilities within the study area was found to be low in terms of infrastructure, staffing and supply of equipment, therefore affecting utilization. The study also reveals that factors such as distance to health care facilities, poor quality of roads, lack of transport to convey sick people, are influential factors in the geographical context of access to health care facilities. The paper concludes with recommendations for interventions such as improvement in the road network and increase in the number of health care facilities in the area as well as ensuring the use of the lake as a means of transport for mobile clinics in the communities along the lake front.

Telemedicine in tropical and subtropical African countries against the backdrop of similar solutions implemented in Asian countries

Izabella Lecka (University of Warsaw)

Telemedicine in tropical and subtropical African countries against the backdrop of similar solutions implemented in Asian countries This paper concerns the use of telemedicine in tropical and subtropical African countries in the years 2000-2009, as well as the comparison of this process with analogical developments in tropical and subtropical Asian countries. Basic information on telemedicine projects come from the MEDLINE database. This is a part of a larger publication, therefore due to the limited time available it has to be abbreviated. This paper includes a definition of telemedicine, together with a

characteristic of the telemedical solutions in Africa and Asia and geographical conditions (referred to as the country-of-origin effect), supporting (or not) introduction of such solutions. In order to carry out a synthetic analysis, it has been suggested to make use of the method referred to as the 'melting pot of forces'.

Migration and health in Nicaragua

Cecilia Gustafsson (Umeå University)

During this session I will present results from my on-going Ph.D- study, which explores interconnections between migration and health in Nicaragua using a mixed methods research design. Migration and health is connected in a multitude of ways. As migration processes are embedded in peoples' lives (as well as in societies as a whole) they naturally affect and are affected by several aspects of human existence, including health and care. In order to understand the enactment of the migration-health nexus in the Nicaraguan setting, this study approaches the topic holistically, and emphasizes the importance of the socio-economic and political contexts in which the nexus takes place. Migration is common in Nicaragua; internal migration flows mostly go from rural to urban areas, and international flows are predominantly directed towards Costa Rica and the United States. The majority migrate in search for job opportunities since these are scarce on the Nicaraguan labour market. Results from my study show that the implications for health and care - for both the migrants and their family members left behind - are complex, multifaceted, and often of both positive and negative character. Migrants may face dangers on the move (especially if they cross borders without legal documents), and they often have to endure tough working and living conditions in new and sometimes hostile environments. Access to health services in the destination country may also be constrained for migrants, especially if they are undocumented. The left-behinds may improve their living conditions (food, housing, education, etc.) if they receive remittances from the migrating family members. Statistics and survey data in this study also show that remittances are used to pay for health care and medicine, thus ameliorating access to health care. This may in fact be a reason behind migration decisions for some, since not all health care services and medicines in Nicaragua are free of charge. The migrants and their family members also go through much psychological stress, particularly due to the separation from their loved ones. The separation between family members also has consequences for care structures, e.g. when parents leave their children in the care of others.

Adherence to Antiretroviral Therapy in Botswana

Fabian Schlatter (Universität Erlangen-Nürnberg)

Botswana is one of the countries which is most affected by the HIV/AIDS epidemic. The Botswana government, with aid of foreign donors, has launched a comprehensive antiretroviral (ARV) program (MASA) with the outcome of now having achieved universal

access to ARVs (according to 2010 WHO ARV-guidelines). Antiretroviral therapy requires a regular and lifelong intake of medicine and thus not only puts a stress on the health care sector which has to attend a great number of patients and which also has to ensure long-term funding. It also puts stress on the people affected by the disease. They not only have to visit the clinics on a regular basis for checkups, but also have to take the medication on a daily basis and have to deal with possible side effects. An adequate adherence to medication is essential not only for the patients, but for the success of the program in total and in result for successfully combating the epidemic. On the other side, non-adherence can lead to therapy failure and cause drug resistance of the virus. Several factors have been identified to influence the adherence of ARV treatment. These include (among others) traveling costs to the clinic, knowledge about HIV/AIDS, stigma, and alcoholism (see Kip et al 2009). Yet, while data that ground these findings were mainly taken from clinical studies, little is known about how people deal with lifelong medication outside the clinical setting in their everyday life in the context of this highly discriminated and stigmatized disease. To better understand how medication is embedded as a daily repeating routine first empirical results from the ongoing study will be presented. The research was conducted in Gaborone, the capital, and in rural settings of Botswana. Some core questions that will be addressed are: How is a lifelong medication regime embedded into daily life and what consequences does this bring on an individual and societal level? How is the perception of HIV/AIDS changing due to the introduction of HIV medication? Where are spaces of adherence; and spaces of risk to non-adherence not only on a physical, but also on a social level? What institutional settings enable or inhibit and structure adherence to anti-retroviral therapy?

C08.19-02 - Access to Care 2

Chair: Wuyi Wang, Mark Rosenberg, Thomas Krafft

The Role of Community-based Health Care Centre on the Health Outcomes of the Elderly: A Lesson to Learn from Indonesia

Evita Hanie Pangaribowo (University of Bonn)

The increasing trend of aging population in Indonesia and other developing countries is not only an indicator of demographic momentum, but it also leads to more consequential matters for socioeconomic condition of elderly people. On the economic aspect, the increasing of elderly means increasing more budgets on social security. In the case of developing countries where social security functions have not been well established and performed optimally, the role of community and extended family is largely significant to maintain the quality of life of the elderly. Using the case of Indonesia, this study examines the role of Posyandu Lansia (Health Care Centre for the Elderly) on the quality of life of the aged. The determinants of elderly participation in Posyandu Lansia are also investigated. This study employs the rich longitudinal data of Indonesian Family Life Survey (IFLS). IFLS collects longitudinal data on household characteristics, the communities in which they live, and the health and education facilities they use. IFLS round 2007 provided a particular section of Posyandu Lansia in the community questionnaire. The results show that education attainment and knowledge on health facility and service increases the probability of participation in the community health care centre. Participation varies across regions. In addition, the presence of health care centre for the elderly in the village has a significant role in enhancing quality of life of elderly people through maintaining physical and mental health of the elderly. Controlling for individual characteristics and socioeconomic variables such as education, income, and access to formal health care facilities, the elder people who participate in the health care centre for the elderly in the village have less sickness period and lower level of depression. Hence, it can be concluded that the health care centre for the elderly in the community might provide informal support for people who have no mean or lack of formal support. The establishment of health care centre for the elderly in Indonesia is an alternative strategy to promote the quality of life of elderly which can be applied in other Asian countries, particularly the developing countries which might experience elderly explosion in the future.

Spatial Justice and Hungarian healthcare policy

Viktor Pál (University of Szeged)

The paper deals with the most important connections between the transformations of the Hungarian health care system, the health care policy, and the spatial aspects of the equal opportunities. The issues related to equal chances and spatial justice are ones of the

most important questions regarding the healthcare policy in postsocialist countries. Before the neoliberal turn of these economies the finance of the welfare systems was manageable. Therefore the spatial justice could play a major role in the organization of healthcare provision. However, the demographic and economic processes and increasing expenses of healthcare caused paradigm shifts and 'western' societies moved further from the principles of equal chances. Effectiveness and financial sustainability became central guiding principles of the territorial organization of healthcare provision. Therefore, the two main (and often conflicting) ideas - equal chances and effectiveness - formed the healthcare policy in the last decades. The aim of the paper is to analyze the role of the concept of spatial justice in Hungarian healthcare policy during the reform processes of the last years. The Hungarian case could contribute to the better understanding of the postsocialist healthcare policy tendencies in general, too. The study is based on the analysis of development documents, regulations, documents related to legislation, articles and media reports on healthcare reform and interviews with key actors of the reforms. The research also seeks to answer the question that whether it is possible to adopt a policy which considers the principles of equality and effectiveness in the same time. Or is it an utopia, and spatial justice is the antagonist of the effective a financially sustainable system?

The Romanian health care system, between crisis and reforms

Liliana Dumitrache (University of Bucharest), Zamfir Daniela (University of Bucharest), Dumbraveanu Daniela (University of Bucharest)

The paper aims to achieve an analysis of Romanian Health Care System during the post socialist period, highlighting the challenges and failures in the process of redesigning the whole approach of healthcare. During socialist period Romanian Health Care System was organised according to the Semashko model: totally centralised, state owned, financed by state budget and coordinated by Ministry of Health; increased costs of medical assistance coupled with reduced budget, low quality of medical services resulted into a crisis of HCS requiring its reform. The reform of the Health Care System has started in 1990, and the main change has occurred at the level of financing the medical services through introducing as mandatory the health social insurances (Bismark-ian model) along with other sources of financing (Health Insurance Law, 1998) administered by National Insurance House that contracts services from providers. Despite good intentions, the reform experienced many difficulties leading the system in numerous situations of crisis; after years of struggling with under financing, (2,9% of GDP in 1990 and 3,6 % of GDP in 2010) Romania has some of the worst health indicators in Europe. The higher demand of medical assistance, the inequitable and inefficient resources allocation, has resulted into depreciated health care services and limited access of population to them while informal payments to the doctors determined the development of a parallel economy of healthcare, expanding the health care inequalities in terms of access and quality. Even if the private health care sector experienced a powerful development after 2004 and it is

perceived as an alternative to the public health care system the accessing is still restricted for particular population categories due to its high costs and location. The population ageing will increase the pressures on health care and consequently the health care expenditure while the migration of health skilled professionals (considered as public employees and affected by numerous wages cuts) towards western European countries is threatening again the system sustainability. These are requiring radical changes within the health care system in order to improve the management of health care services and to increase the costs-efficiency of future health expenditure. The new health care reform will start in 2012 supposing mainly the transfer and the administration of public funds through Private Health Insurance Houses. However, even if many health professionals are well agreeing with the new Health Law (in public inquiry at present) many aspects still remain unclear and population perceives it as a way to transfer some costs directly or indirectly to the patient. The current financial crisis makes even more difficult implementation of health care reforms and their support with numerous essentially correct but producing negative effects on some population categories.

Factors affecting utilization patterns of health care facilities among residents of Lake Bosomtwe basin of Ghana

Charles Adu-Gyamfi (University of Cape Coast)

Accessibility and utilization of health care facilities are important elements which are factored into any policy or programme aimed at improving the health status of citizens of every country especially developing countries. Employing both quantitative and qualitative techniques, the paper examines factors which determine health care utilization patterns of residents of Lake Bosomtwe basin of Ghana. The study used a questionnaire and an interview guide as the main instruments for data collection, and selected 120 household heads for questionnaire administration through a multi-stage sampling procedure; 10 health care personnel and 6 chiefs were also purposively selected for interviews. The study employed the human ecology of disease triangle model to assess how residents utilize health care facilities within and outside the basin. Chi-square tests were run to establish the relationship between independent variables such as age, marital status, place of residence and utilization of health care by residents in the study area. The study found that residents utilize health care facilities both within and outside the study area with the utilization of local health care facilities being low among respondents, a situation which was attributed to the inadequacy of health care facilities, lack of qualified staff and equipment. Place of residence, the role of family members and friends, as well as health insurance policy holding and quality of staff were found to be important determinant factors in one's decision to utilize a particular health facility. Culture was found not to be an influencing factor in the utilization of health care facilities by respondents. The paper recommends that equipping the health care facilities within the basin, posting qualified health care personnel to the area and educating residents on the importance of health insurance will enhance residents' utilization of health care facilities.

C08.19-03 - Access to Care 3

Chair: Wuyi Wang, Mark Rosenberg, Thomas Krafft

Injuries among young people growing up in poverty in Ethiopia, India, Vietnam and Peru

Inka Barnett (University of Oxford), Virginia Morrow (University of Oxford), Daniel Vujcich (University of Oxford)

Globally, unintentional injuries are a leading cause of premature death and disability in children aged between 5 and 18 years. Children from low-and middle income countries and lower socio-economic groups are most vulnerable. Yet the evidence-base for child injuries in developing countries is relatively poor, and the WHO has recently emphasized a need for more research, and (in May 2011) the World Health Assembly adopted a resolution on child injury prevention, the first ever on the topic. This paper aims to use a mixed method approach to get an in-depth understanding of some of the causes, consequences and perceptions of injuries among 15-16 year olds in India, Ethiopia, Vietnam and Peru. It analyses data from Young Lives, a longitudinal study of children growing up in poverty in Ethiopia, India (Andhra Pradesh), Vietnam and Peru. It focuses on the older cohort of children, born in 1994/5, (n=1,000 in each country), and combines quantitative survey data with qualitative in-depth interviews with a sub-sample of children in Ethiopia, India, and Peru (n=25 in each country). Our quantitative analyses suggest country-specific differences in the prevalences as well as the causes of injuries. Most serious injuries happened in India (19 % of all children), followed by Peru (15%), Ethiopia (14%) and Vietnam (8%). While work-related injuries were most common in India and Ethiopia, injuries that happened during play and exercise were most frequent in Peru and Vietnam. Qualitative data give some insight into the history of injuries and some of the longer term consequences. The paper concludes with a discussion of the implications of the findings for injury prevention programmes and policies, which it suggests are not straightforward. We suggest that risks to children need to be understood within the context of their roles and responsibilities within families and communities, as well as beliefs that mean that injuries tend to be interpreted as random events or the result of fate/destiny, and therefore not within people's control.

Aging, Health and Health Care, and Social Deprivation in Canada

Mark Rosenberg (Queen's University), Keltie Gale (Queen's University)

While Canada counts itself among the wealthiest and most developed countries in the world and consistently ranks near the top of the United Nations Human Development Index, social deprivation among the older population remains an issue. This paper reviews the evidence for social deprivation in Canada and what part of the older population is affected by it. A preliminary analysis is then carried out to examine whether

there are any spatial patterns to social deprivation which correlate with health status among older Canadians and their access to health services. We conclude with a discussion of why health geographers should place more emphasis on developing measures of social deprivation and using them in examining health status and health care.

Accessibilité des lieux de don de sang et les communautés ethnoculturelles à Montréal

Gianhi Tran (Institut National de Recherche Scientifique), Marie-Soleil Cloutier (Institut Nationale de la Recherche Scientifique), Johanne Charbonneau (INRS)

Au Canada et au Québec, moins de 4% des personnes admissibles contribuent à la banque de sang chaque année. Avec une population vieillissante, il importe de trouver des solutions afin d'assurer la réserve collective pour satisfaire les besoins futurs. Une des solutions envisagées est de se tourner vers la population immigrante, un bassin de donateurs potentiels considérable. Une population qui demeure toutefois peu nombreuse chez les donateurs, mais importante au Québec et encore davantage à Montréal. Les collectes à Montréal suivent une logique d'organisation particulière qui relève d'un système de collectes mobiles organisées par des associations locales. Cependant, les associations ethnoculturelles ne représentent qu'un pour cent des comités organisateurs au Québec. En effet, le rapport entre la pratique du don de sang et les communautés ethnoculturelles reste relativement méconnu. Afin de favoriser le recrutement des donateurs, il est intéressant de s'attarder davantage sur ces communautés en forte croissance. C'est dans cette optique que ce mémoire propose une étude de l'accessibilité perçue au lieu de don de sang chez les donateurs ethnoculturels dans la région métropolitaine de Montréal. Les collectes mobiles accroissent l'accessibilité physique et offrent un éventail de choix de lieu de proximité. Cependant, la sélection d'un lieu de don de sang est-elle influencée par la distance physique ou plutôt par les facteurs culturels? Cette étude s'appuie principalement sur les données recueillies par une enquête en entretiens semi-dirigés auprès de 29 donateurs et de 46 leaders des communautés ethnoculturelles. En sommes, nous avons constaté que les donateurs ethnoculturels se comportaient généralement de la même manière que tous les autres donateurs. La proximité a été, en effet, un élément déterminant dans le choix du lieu de don. Cependant, certains donateurs interviewés choisissaient un autre endroit en dépit d'une distance plus éloignée. En fait, plusieurs facteurs jouent un rôle dans le choix d'un donateur d'un lieu de don, selon que le donateur soit de première ou deuxième génération, la personnalisation d'une collecte - langue, l'accueil, nourriture, etc. -, pour n'en nommer que quelques-uns. C'est en jonglant avec tous ces éléments que le donateur prend la décision de se rendre à une collecte de proximité géographique ou de proximité culturelle.

C08.19-04 - Global Health and Disease Surveillance

Health risk of disinfection by-products in drinking water of the typical cities in China

Bixiong Ye (CAS), Wang Wuyi, Yang Linsheng, Wei Jianrong

The healthfulness of drinking water is a fundamental human concern. Chlorination is a widely used method of disinfections to protect drinking water against germs and fight disease transmitted through water in China. However, chlorine can also react with natural material in the water to form disinfection by-products (DBPs) such as trihalomethanes and Haloacetic acids. To some extent, these disinfection by-products of drinking water posed a certain threat to the health of local residents, due to their possible adverse health effect on humans. In order to determine the risk of disinfection by-products on human health, and predict the extent and seriousness of the risk of disinfection by-products, a risk assessment of the disinfection by-products in drinking water was carried out in 13 selected cities of different water system in China. The strong spatial variations of the lifetime cancer risk and hazard index of DBPs were observed on the different water systems and typical selected cities. The highest lifetime cancer risk and hazard index of DBPs ($6.05E-05$ and $1.08E-01$) was observed in Tianjin city, followed by Benbu, Zhengzhou and Wuxi city, and the lowest was in Wulumuqi city. Based on geographical information system, the geographical variations of the lifetime cancer risk and hazard index of DBPs in typical selected cities were studied. In the Songhua River system, the total cancer risk of DBPs was higher in Daqing city than in Harbin city. In the Hai River system, the total cancer risk and total hazard index were higher in Tianjin city than in Beijing city. In the Yellow River system, the total cancer risk and total hazard index were higher in Zhenzhou city than in Lanzhou city. In the Yangtze River system, the total cancer risk and total hazard index were higher in Chongqing city than in Changsha city. In the Pearl River system, the total cancer risk and total hazard index were higher in Shenzhen city than in Guangzhou city. In the Huai River system, the total cancer risk was $4.75E-05$ in Benbu city and was almost 50 times higher than the acceptable public risk level of USEPA (10-6). In Wuxi city, a key city of Taihu Lake basin, the total cancer risk was $3.47E-05$. In Wulumuqi the typical inland city, the total cancer risk was lowest and the value was only $2.86E-06$.

The effect of air pollutants on daily number of outpatient for allergic rhinitis in Beijing, China

Wang Wuyi, Zhang Fengying, Thomas Krafft (Maastricht University), Bixiong Ye (CAS), Xu Jin

To investigate the effects of urban air quality change on health, we carried out a time-series analysis of daily general practitioner consultations for allergic rhinitis (AR) in Beijing, China. The objective of this study was to assess the possible effects of air pollutants on outpatient visits caused by AR in Beijing during the period 2009-2010. We considered the lag effects of air pollutants; and also tried to find out the seasonal effects of air pollutants on daily number of outpatient with allergic rhinitis. The results shown that, the largest effect RRs of PM10 were at lag01, lag0, lag01, lag01, lag01 for the total population, male, female, young people (20-60 years age group), old people (more than 60 years age group), respectively. The largest associations of SO2 were observed at lag3, lag5, lag3, lag0 and lag0 for the total population, male, female, young people (20-60 years age group), old people (more than 60 years age group), respectively. The strongest effects of NO2 were found at lag06 for the total population, female and the young people; at lag0 for male and lag03 for elder people. RRs of the three pollutants have shown a decreased order NO2, PM10, SO2. The seasonal effect models shown that PM10, SO2, NO2 had higher risk for AR in warm season than in cold season.

The sustainability analysis on urban life indicators

Hui-Yu Chiu (Chinese Culture University)

Sustainable Cities is the main target of the global development in the 21st century. When urban growth, it must be increase consume and waste. Then, the quality of life will become the first demand. Choosing 5 samples to analysis sustainability and quality of life, including International Urban Sustainability Indicators List, Global Urban Indicators, Urban Taiwan Indicators, Taipei's Sustainable Development Index, Taipei's Sustainable urban Index. The sustainability evaluation divides 4 domains of environment, economic, society and governance. And, the quality of life evaluation divides 4 domains of physical, psychological, social relationships, environment from WHOQOL. Intergrating two rules to analysis 5 samples. The result shows that the sustainability evaluation stress on environment and society aspects. And, the sustainable evaluation system contain quality of life is about 70%. It suggests the sustainable urban system could increase indicators about 3 domains of physical, psychological, and social relationships. Then, the policy-makers could improve the worst way and attain to targets of sustainable urban development.

The restoration of resources for medical tourism landscape: A case of hot springs in Bei Tou, Taiwan

Chung Ling Ouyang (Taiwan University)

Hot Spring resort is one of the classical example where tourism and medical landscape both can be combined. Thus, it is meaningful in today's medical geography to discuss hot springs and its utility as resources. Hot springs were used in curing illness and improving health, long before when people knew their true efficacy. Recently, hot spring business owners in Bei-tou are expecting not only to broaden business, but also to link it up with tourism and leisure industry. This case study takes Bei-tou in Taiwan as an example, to discuss the building and the transformation of the hot spring medical landscape. The development of using Bei-tou hot springs as a business has a history of more than one hundred years (since 1896). The most important reasons are the unique site and tectonic environments that Bei-tou has, and its Japanese legacy. Within the special geological condition and Japanese colonial history, Bei-tou hot springs expanded into large scale hot spring culture and economy. This research analyzes historical documents and literature, interviews government officials related to regional development and the local developers promoting hot spring tourism, and investigate people's perceptions about (using) the hot springs, to understand how the local hot springs of Bei-tou could be transformed into tourism landscape. That includes mechanism and reasons for forming hot spring medical tourism in Bei-tou. The research results show that, during the initial stage while Japanese government colonized Taiwan, hot springs were used mainly in curing illness and improving health, only some for amusement and leisure purposes. In the 1950s, not long after Taiwan restoration from the Japanese government, Bei-tou became a bacchanlic area famous for its red-light district functions. After the 1980s, with rapid economic growth of Taiwan, the local government input much effort to transform back into its original function - health care and leisure. Just recently, local government and residents make special efforts in protecting the hot spring historical monuments and hot spring culture. The owners of hot spring hotels and resorts are also promoting the tourism values of spring resources to the public, so that they could understand the local multi-facet hot springs. Due to the role transformation of Bei-tou hot springs, this area is now enriched by its culture and landscape.

C08.19-05 - Ground truths: Advancing **children's** geographies through including children as researchers 1

Chair: Christina R. Ergler, Wuyi Wang, Thomas Krafft, Robin Kearns

Researching Play, playing researcher: Improving the understanding of children's physical activity

Christina R. Ergler (University of Auckland)

While many children's geographers seek to work with children instead of on their behalf, only a handful of researchers integrate children directly in the research process. In this paper, we address the opportunities and challenges faced when working with children aged 8-10 years old to design and carry out a follow up study. This investigation revisited drawings and GPS travel logs collected earlier as well as including a neighbourhood walk guided by children for non-local children. The paper shows that by going on a neighbourhood walk and discussing elicited drawings and GPS logs the children themselves became de facto researchers and involved in the follow up meeting in different ways. Although this process requires a greater time commitment for the child as well as adult researcher, integrating children into the research process from the beginning is valuable: not only are the interests of the adult researcher on the agenda, but also the curiosities and ideas of the child researcher can be incorporated to shed new light on the original research question. This approach can foster children's well-being in two ways: enjoyment of collaboration on a research project and possible policy implications for children's health gained through a deeper understanding of children's worlds.

How children manage risk in agricultural work in Andhra Pradesh, India

Virginia Morrow (University of Oxford)

This paper explores children's accounts of risks they encounter in agricultural work in Andhra Pradesh, India, drawing on research carried out by Young Lives[1], a longitudinal study of children growing up in Ethiopia, Andhra Pradesh in India, Peru and Vietnam. International and national policies aim to protect children by eliminating all child labour. Previous literature on 'hazardous' child labour tends to focus on single industries or crops, overlooking the variety of activities that children undertake in subsistence farming, often within their families. Very little research has explored children's descriptions of their experiences of risks and how they manage them. The paper is based on analysis of survey data, and qualitative data gathered from young people aged 15-16 years, in group discussions and interviews, using body mapping. The paper describes risks and injuries children experience at work, how they deal with these risks and take measures to protect themselves. The paper also explores children's accounts of perceived benefits of work, and (controversially) what might be lost if they are withdrawn from work. The paper suggests that the most effective form of protection may be to build on existing knowledge

and experience, working with children, families and communities to develop strategies to make work safer. [1] Young Lives is funded by the UK Dept for International Development (DFID) and follows 12,000 children, in two cohorts, over 15 years. A variety of methods are used to collect survey and qualitative data at the individual, household and community level. See www.younglives.org.uk for further details.

Fotonovela as a Collaborative Research Process with Children: Transgressing Research Boundaries through Embodiment and Playful Storytelling

Michael Emme (University of Victoria), Anna Kirova (University of Alberta)

In addressing the issue of adult-designed research on children's experiences (Greene & Hill, 2005; Kellet et al, 2004), this presentation describes an arts-based participatory research method, fotonovela, developed by the researchers in collaboration with children. The method was developed as a negotiation between researchers and participants from diverse epistemological, visual, and cultural traditions. The processes involved collaboratively negotiating research themes, engaging in arts-based inquiry, and developing the photographic narrative format of the fotonovela by combining visual elements, structures and embodied, reflective performance together with written text. Primary consideration of narrative sequence and the body language of lived and observed experience, supported through framing, proximity, point of view, color, and composition, can communicate meanings at the levels of image, sequence and words where each of these layers of representation can be both interdependent and independent. As no one layer of representation can dominate meaning in fotonovela research, the method supports a form of cultural collaboration between the researcher and the participants that offers unusual openings for multiple voices, and results in a product that feeds back and affects the context that it represents. As a vehicle for collaboration on the conceptualization and communication of academic inquiry in response to changing social, pedagogical, technological, and cultural contexts (Voihofer, 2005), it opens possibilities for negotiating authorities in the research process in which 'understanding does not entail agreement, and multiple perspectives are valued' (Clark & Moss, 1996, p. 522). As a research process, fotonovela constructs a hybrid photo-image-text opening new spaces for collaborative dialogue, resistance, and layered representation that simultaneously complicates knowing, saying and seeing, potentially changing the author's and the reader's self-understanding. Based on fotonovela produced by child-collaborators, in this presentation we propose that the visual and the linguistic not only complement each other in capturing children's experiences in school, but allow the reader to engage with the text in multiple ways. As researchers we had access to the 'polyphonic expression' of multiple voices, 'allowing for consensual, dissenting and conflicting perspectives to emerge and exist' (Veale, 2005, p. 269), and the children had opportunities to embody and narrate stories they identified as needing to be told for an audience they identified as needing to see and hear them. The presentation

will examine fotonovela as 'good' arts-based research, highlighting its illuminating effect; its generative quality; its incisive-ness, and its capacity to invoke identifications ranging from the personal to the socially symbolic (Barone & Eisner, 2004)

Negotiating Power and Responsibilities: Ethical and Methodological Issues in Child-Centred Research

Francesca Meloni (McGill University)

This paper aims to explore the ethical concerns of ethnographic research with vulnerable youth. Drawing on fieldwork on undocumented youths and well-being in Montreal, this examination will articulate an ethical framework and propose methodologies for conducting research with these populations, pointing to multiple ethical concerns about both their migratory status and their age. In this respect, I will examine different questions and practices emerging with the new notion of youth and children as social actors and moral agents, so as to say subjects capable of assuming autonomous responsibility for their own actions, and conscious of their moral experiences. In particular, I will identify and discuss three main issues: 1) questions of ethical symmetry and power; 2) informed consent; 3) issues of youths' rights and researchers' responsibilities. Drawing on different disciplines, such as sociology, geography and nursing, and providing with an anthropological approach, my discussion will refer to theoretical discussion and ethical dilemmas that I faced during my fieldwork. Specific methodologies, such as participatory action research and interview methods, will be suggested in order to negotiate power imbalances and navigate researcher's responsibilities in regards to socially marginalized youths.

C08.19-07 - Health Geography and Public Health 1

Spatial distribution of mental retardation in Iran

Ali Goli (Shiraz University)

Medical geography applies the theory, methods and analysis tools of the geography science to the study of human health, disease and health care systems. As the Geographic Information System (GIS) has evolved since the mid twentieth century, it uses spread in geography related knowledge. Medical geography also uses of GIS in study and analysis of health and diseases researches. Mental retardation (MR) is a subset of developmental delay (DD), a broader classification of childhood disability. Spatial analysis is useful for the identification of areas with MR people. Identification of clusters based on MR provides an important tool to investigate risk exposures. However, even though mental retardation (MR) is a substantial public health problem, there are no previous analyses of spatial clustering of MR using individual case data. In this paper, we examine the use of the spatial analysis approach in the analysis of MR clustering. We used data from 2006 census data, in which address number of MR data are available in county level. MR cases with unknown cause were identified in the study population. Local statistic indices used to identify of spatial clusters of MR and its corresponding P-value for each geo-coded location, and the P-value surface was contoured as a heat image to identify the MR clusters. The characteristics of the study population were analyzed using Moran's I value and Getis-Ord Gi statistic and the results confirm that clustering does occur for MR. The shapes of the identified MR clusters were found in counties with high illiteracy percentage. Also MR clusters area was found in counties with high rate of rural residence people.

A spatial-epidemiological approach on mental well-being in Dhaka slums

Oliver Grübner (Universität zu Berlin), Md. Mobarak Hossain Khan (Bielefeld University), Daniel Müller (IAMO), Sven Lautenbach (Helmholtz-Zentrum für Umweltforschung GmbH), Alexander Krämer (Bielefeld University), Tobia Lakes (Universität zu Berlin), Patrick Hostert (HU Berlin)

A spatial-epidemiological approach on mental well-being in Dhaka slums Oliver Gruebner, MMH Khan, S. Lautenbach, D. Müller, A. Krämer, T. Lakes, P. Hostert Urban mental health is of global concern because the majority of the world's population live in urban areas. Mental health problems (e.g. major depression) are particularly prevalent in the rapidly urbanising megacities of developing countries, where a growing number of residents live in slums. Yet, little is known about the spectrum of mental well-being and health promoting socio-physical environments in urban slums. Using a spatial-epidemiological approach, this paper identified factors that contribute to mental well-

being in the slums of Dhaka, the capital of Bangladesh, which currently accommodates an estimated population of more than 14 million, including 3.4 million slum dwellers. The baseline data emanates from a cohort study conducted in early 2009 in nine slums of Dhaka. Data were collected from 1,938 adults (>15 years). The WHO-5 Well-being Index was used as a proxy for self-rated mental well-being. Additional information was obtained from very high-resolution land cover data. We used generalised linear regression and spatial autocorrelation analysis to test for the hypotheses that mental well-being is associated with the socio-physical environment and that it is spatially structured among sub-populations in slums. A WHO-5 scored 13 or above is supposed to be indicative for good mental well-being in higher-income country settings. In our study, good mental well-being was found in 20% of the slum population sample. When controlling for individual factors such as age, gender, and diseases, mental well-being was significantly associated with several features of the natural environment, flood security, good sanitation, and the quality, sufficiency and durability of housing. Population density, job satisfaction, and income generation were further significantly related to mental well-being. Significant spatial clustering of poor and good mental well-being among population subgroups was found. Those spatial clusters were further significantly associated with the most of the above mentioned features from the socio-physical environment. Considering spatial clusters as small-scale neighbourhoods, we can conclude that large inequalities of mental well-being existed in slums and that these inequalities refer to different socio-physical environments in those neighbourhoods. Given that mental well-being is related to physical well-being, our paper provides crucial insights for developing better health care and disease prevention programmes in slum dwellings of the developing world.

Natural-endemic diseases in Russia: Diversity, geography, mapping

Svetlana Malkhazova (Moscow University), Natalia Shartova (Moscow University), Dmitry Orlov (Moscow University)

The aim of this investigation is to determine diversity in the geography of natural-endemic diseases in Russia and elaborate cartographic approaches for its mapping including mathematical-cartographical modeling. More than 20 natural-endemic diseases were selected to carry out the medical-geographical assessment of the natural environment. A characteristic feature of these selected nosological units is that the potential existence of the pathogens, carriers and intermediate hosts of them in an area fully depends on natural conditions, and the realisation of these natural preconditions is related to social and socio-economic circumstances. Besides, these diseases are principal in the population pathology and perform not only a medical but also a socio-economic problem. This typical natural-endemic diseases for Russia are : alveococcosis and echinococcosis, anthrax ,brucellosis, hemorrhagic fever with renal syndrome, hydrophobia (rabies), different leptospirosis, plague, pseudotuberculosis, tick-borne borreliosis, tick-borne encephalitis, tick-borne rickettsiosis, tularaemia, etc. Information about geographical distribution of the natural-endemic diseases and intensity of their development was

acquired from official statistical data, archival materials, literature, field expeditions, etc. for 10-15 last years. Mathematical-cartographical modeling used as a tool of analysis and mapping. Principles and application of medical-geographical assessment of territories including methods of such modeling based on investigations made in Lomonosov Moscow State University are discussed. Concept of medical-geographical atlas of Russia 'Natural-endemic diseases' is proposed. The atlas of such kind is a high priority for Russian Federation. The medical-geographical atlas will be the first experience of compiling and public presentation of diverse and multifaced information about natural-endemic diseases of Russia. General methodology of its elaboration is outlined. Atlas combines maps, graphics, remote sensing materials and the text. They form the basis for identifying the causes of diseases and carrying out preventing measures. Atlas includes seven sections: Introduction, Natural conditions, Demography and Socio-economic situation, Hosts and carriers of natural-endemic diseases, Regional nozogeography, Public health's organizations and preventive measures. The main maps scale for the territory of Russia is 1:20 000 000, for certain regions - 1:4 000 000 and 1: 10 000 000. Atlas is intended for administration, public health services and for the wide public. Its target - to provide an objective assessment of the medical geographical situation in regard to natural-endemic diseases as a part of scientifically based approach to control and emergency response.

Urban health disparities in newly industrializing countries: Perspectives from Pune, India

Mareike Kroll (University of Cologne)

Urban health disparities have gained increasing attention among researchers in the field of health geography. While a lot of research has been done on cities or regions in Western Countries, lack of data in many newly industrializing countries such as India impedes comprehensive studies about differences in health status among different population subgroups. Further, intraurban health disparities have been neglected in India over the last decades due to a long-standing focus on the urban-rural divide. Though, the current rapid urbanization process in India induces multiple changes in the physical and social environment of cities inducing changing disease burdens. In the emerging megacity of Pune, the population has doubled in the last 20 years from 2.6 to 5 million inhabitants, overstretching massively the existing infrastructure. Economic growth is giving rise to an emerging middle class and at the same time to a growing number of slum dwellers through immigration. The increasing social polarization of the urban society causes an unequal distribution of positive (e.g. educational opportunities, access to health care) and negative (e.g. environmental pollution, stress) effects of urbanization within the population. The heterogeneity of the urban society and the steep socioeconomic gradient among different socioeconomic population groups are leading to different epidemiological profiles within the population: infectious and communicable diseases are associated with poverty, inadequate living conditions and lack of basic infrastructure. At the other hand, so called

'lifestyle diseases' such as diabetes and hypertension or cardiovascular problems which are usually linked to the middle and upper class have an increasing share in the overall disease burden. Yet the increasing fragmentation of the urban society and changing urban environments create new vulnerabilities for all socioeconomic strata towards old and new infectious diseases (e.g. tuberculosis and swine flu) but also chronic and degenerative diseases due to environmental pollution, increasing stress levels and changing behavioural patterns. The paper will present results from a doctoral thesis undertaken at the Department of Geography at the University of Cologne, Germany. The work focuses on a holistic view on the disease burden and major health determining factors in different socioeconomic groups using quantitative and qualitative methods. Central tool is a household survey in Pune which has been conducted in three slums and three middle class neighbourhoods in three different parts of the city. Target of the research project is to analyse and explain different epidemiological profiles of different socioeconomic groups in Pune as a deeper understanding of intraurban health disparities is essential to derive appropriate measures to promote and safeguard public health in cities.

C08.19-08 - Health Geography and Public Health 2

Chair: Helmut Brand, Dr Sarah Lovell, Wuyi Wang, Thomas Krafft

Analysis of environmental health condition at Algarve region, Portugal: A method using quantitative indicators and opinion-based measures

Daniel Canavese (University of Paraná), Margarida Queirós (University of Lisbon), Neli Regina Siqueira Ortega (University of São Paulo)

Geography and Public Health domains have examined the relationship between health and environment in an interdisciplinary way in the last few decades. Both research areas are contributing to the knowledge of the intense socio-environmental changes, as those ones that arise from demographic growth, tourism and urbanization and that have been establishing different situations regarding the quality of life. This research aimed to investigate the environmental health condition of Algarve, in the Southern part of Portugal. The objective was to analyze the environmental health condition of Algarve using quantitative indicators and opinion-based measures. A linguistic model based on quantitative indicators and experts' opinions was designed to examine the environmental health condition of Algarve's cities in Portugal. A wide range of quantitative indicators frequently used by local Ministry of Health agency was selected. Four Ministry of Health professionals, have constituted the panel of experts whom have provided some opinion-based classifications about the quantitative indicators. Using some principles of Complex Theory, Fuzzy Logic and specific software, the linguistic model was designed in order to give a synthetic measure about the condition of environmental health of each city. Results demonstrate two patterns in the regional reality of environmental health. Although Algarve, in general, has a developed condition in environmental health it also shows important specificities. The best condition of environmental health was registered in the majority of cities located in the center part of the region and in the east part by the border of Spain. In these areas the seasonal tourism is more frequent and could explain investments previously made that now reflect better standards of health and environment. On the other hand, the worst condition is located in the west and interior parts of the region where some cities have no coastline and have been facing population decrease in the last decade. This study reveals inequalities in an apparent homogenous region. The understanding of unequal patterns is important for the development of plans focusing on public policies to improve the referred conditions.

Socio-spatial distribution of airborne exposures in Berlin

Annegret Kindler (Helmholtz Centre for Environmental Research), Ulrich Franck (Helmholtz Centre for Environmental Research)

Air pollution is one of the serious environmental problems in urban agglomerations impairing human health. But, human exposure varies within one city. Therefore, the

question arises about relations between environmental exposure and social situation of population aiming at minimization of health risks and enhancement of the quality of life and well-being. Particulate matter (PM) and nitrogen dioxide are significant air pollutants in urban areas. Particulate matter is often categorised according to its aerodynamic diameter into the following size groups: PM10 (<10µm, inhalable), PM2.5 (<2.5µm, respirable). Environmental epidemiological studies indicate that even small amounts of particulate matter impair human health. This means that there is no known threshold value below which no effects are to be expected. Besides the studies showed that nitrogen oxides (NOx) in the air can also damage health.. Especially in urban areas, traffic is a significant source of both airborne pollutants. In most northern and western European cities, traffic is a dominant source of air pollution. On the example of Berlin the spatial distribution of airborne exposures of PM10, PM2.5, NOx and NO2 was determined for the 447 planning areas (PLA) each characterized by about 7500 inhabitants, unique structure of buildings, types of roads, and rather homogeneous social structure. PM10 and NOx concentrations, additional reference data for selected monitoring stations and for street sections were used to calculate the area weighted annual average values for all planning areas. PM2.5 and NO2 air pollution was determined from the PM10 and NOx values. Traffic sources have been taken into account as an additional contribution to background concentrations. In order to investigate socio-spatial distribution of PM2.5 and NO2 at the PLA level the air pollution was statistically and spatially correlated with the development index of the Social Urban Development Monitoring. In addition, the number of people was determined exposed to different levels of air pollution in relation to PLA and social status. The assessment of combined exposure by PM2.5 and NO2 shows increased frequencies of highly or very highly affected PLA within the low emission zone and adjoining PLA to the west, southwest and north. Air pollution decreases from the centre towards the outskirts of the city. Assessing the combined exposure, 15% of the PLA are lowly, 59% medium, 12% highly and 14% very highly polluted. About 10% of Berlin's population live in PLA with a very low or low development index and with very high or high air pollution levels and thus are discriminated twice. The lower the development index in a PLA, the higher is the share of population with high air pollution.

Environmental impact on the quality of life (on the experience of the central regions of Russia)

Tatiana Trifonova (Moscow University), Natalia Mishchenko (Vladimir University), Alexey Krasnoshchekov (Vladimir University)

Nowadays the rate of environmental conditions is changing so fast that people does not manage to adapt to the subject. In this respect it is principally important to establish the relationship between varied environmental factors and level of human health in order to provide the preventive activity in the field of health protection. We suggest to assess the habitation comfort factors according to three groups of parameters: nature-anthropogenic, social and medico-ecological one. Vladimir region, located in the central

part of Russia, has been chosen as a investigated object. We offer to study the factors at the regional level by using the GIS- technologies. To estimate the comfort level for population we introduce the integrated database for Vladimir region. The researched area zoning has been performed according to the population habitation comfort indices in various territories. The most favorable items for that have been defined, i.e. the higher comfort level is determined by the better socio-economic and medico-ecological conditions, that is obviously determined by the vicinity of major economically developed megapolises like Moscow and Nizhniy Novgorod. The territories of the lowest comfort level have been revealed, as well, being basically connected with the worst nature-anthropogenic and socio-economic conditions. Medico-ecological ranking of Vladimir region has been carried out by approach on the basis of typical population sickness rate regarding the principal nosologies. Environmental impact on the regional population health has been studied in connection with air pollution and anthropogenic activity load. Developed approach is the universal and can be applied to any territory.

Modern Tendency of Population Mortality of Far East of Russia

Tatiana Komarova (ICARP FEB RAS), Efim Frisman (ICARP FEB RASc)

Our investigation is aimed at the study of economic and social factors influence on mortality and health of the population in the Russian Far East. The prevailing reasons for the mortality and morbidity increase are identical anywhere in the world representing lowering of living standards, poverty, unhealthy nutrition, health services system degradation, contamination of the environment. Strengthening these reasons is the economic crises in Russia that has stimulated a further deterioration of the situation in the Russian Far East. The population death rate has been steadily growing since 1993. A crude death rate in Russia had increased 1.3 times for the period of 1990 -2008 (accounted per 1000 heads), in the Far East this showing being 1.6. It should be pointed out that until the above-mentioned period average showings of mortality over Russia had exceeded those in the Russian Far East, the age structure of the population being younger in this region, as compared to the rest of the country. But during the period of 1990- 2008 mortality had increased 30.3% in Russia (calculated per 1000 heads), and in the Russian Far East - 65.8%, while in most countries of Europe it had decreased (16% in Austria, 19% in Great Britain). Among the socially stipulated factors of increase in male mortality a leading place belongs to unhealthy life style, first and foremost to alcoholism with the men of able-bodied age. It actually takes 100% in the structure of mortality caused by mental frustration (psychoses and poisoning). In 1995 the showing was much lower taking only 19.7%. Life expectancy is one of the overwhelmingly important demographic categories, representing a kind of generalizing characteristics of human mortality. The mortality crises growing in the Russian Far East, during the period of 1998-2006 average life expectancy of its citizens had reduced for 2.77 years, while over Russia this showing was 2 years. However, there is a striking difference in absolute values of life expectancy: 65.07 years, as average Russia parameters, and only 62.42 years - in the

Far East. Since 2006 it has been observed some growth of life expectancy in both Russia and the Far East, but still there remains a gap of about 12 years between male and female life expectancy. To reveal basis factors affecting mortality of the population in the Russian Far East, the coefficients of correlation between life expectancy, mortality and separate showings of living standards were calculated. As a result, it has been revealed that the greatest influence on the population death rate in the region is exerted by the level of living wage ($r = + 0,82$), income of the population ($r = + 0,8$). The inverse correlation between mortality and housing conditions is less vividly expressed.

C08.19-09 - Health Geography, Vulnerability and Global Risk

Influence of regional road network and mobility on spatial diffusion of dengue fever between Brazilian counties

Marcos Ferreira (UNICAMP)

The aim of this research is to evaluate the influence of road network structure and mobility on dengue fever outbreaks sprawl at regional scale. The methodology is based on cartographic modeling of spatial diffusion of dengue fever epidemics, using network analysis techniques and GIS. Data from 109 counties, organized in epidemiological weeks related to a dengue fever epidemic that occurred in 2001 in northwestern Sao Paulo state, were used to map the spatial diffusion of cases. The methodological procedure is structured in five phases: the phases one to four join exact objects and continuous fields models with single and multiple times slices sequences. The phase five is based on network analysis of connections between counties. At the last phase, urban node connections are spatially analyzed using road network analysis techniques, to map potential for contagion between counties and the path of spread of dengue fever over the region as a whole. The results show the spatial diffusion of dengue fever is most efficient in major highway corridors, where the daily trips are more frequent, and where has no impedance to the circulation of commodities and people. Analyzing the maps, one perceives the existence of indications of spatial contiguity in the concentration of cases, associated with the alignment of the cities that continue to present more occurrences over time. As the climatic conditions in the region are practically homogeneous, other factors have increased the potential for the diffusion of the epidemic. Since man is one of the vectors for dengue fever, the circulation of people becomes an important factor in the propagation of the disease. The mobility of the population is governed by the regional economy, where some cities act as centers of agglomeration of people due to the concentration of services and employment. The daily migration and the circulation of merchandise and services are very important factors in the spatial diffusion of the disease in this region preferential alignment of diffusion between municipalities, forming corridors of great susceptibility to contagion. It was also found that a large majority of cities where new cases appear are contiguous to cities with reports of past cases. However, this contagion occurs with greater intensity along regional corridors with more traffic. The higher incidence of cases and average velocity of contagion, occur in cities with higher nodality index values (a great number of roads cross the city) and with greater and faster accessibility to the regional highway network. These regional centers have the highest rate of demographic growth, the fastest rate of change in urban land use, and high population density in poor neighborhoods. These factors are fundamental to the

transmission of the virus by the population that migrates daily from smaller cities to these larger regional centers.

Changement climatique et maladies réémergentes en Tunisie: Exemple de la LCZ dans la région de Sidi Bouzid

Habib Ben Boubaker (Université de Manouba), Mohamed Kouni Chahed (Observatoire National des Nouvelles Maladies Emergentes)

La Tunisie subit un changement climatique qui se manifeste déjà par une élévation des températures, une régression des pluies, le décalage des saisons climatiques?. Les répercussions sont déjà perceptibles, notamment dans le domaine de la santé. En effet, le pays connaît la réémergence de certaines pathologies dont le cycle biologique est fortement lié à des facteurs bioclimatiques. C'est le cas de la leishmaniose cutanée zoonotique (LCZ) qui enregistre, depuis 1982, une réémergence épidémique dans certaines régions de la Tunisie Centrale, comme celle de Sidi Bouzid. Il s'agit d'une zoonose à transmission vectorielle due à un parasite du genre *Leishmania* appelé *leishmania major*. Le parasite responsable est hébergé par des rongeurs réservoirs (*Psammomys obesus* et *Meriones shawi*) et se transmet de l'animal réservoir à l'homme par l'intermédiaire d'un moucheron de la famille des phlébotomes, de type *phlebotomus papatasi* engendrant des lésions cutanées à type de croûtes ou d'ulcérations touchant les parties découvertes du corps. La présente étude a pour objectif d'analyser la relation entre l'évolution des facteurs climatiques et la réémergence de la maladie dans la région. Elle est fondée sur les statistiques relatives au nombre de cas de LCZ enregistrés d'une part et sur les indicateurs bioclimatiques d'autre part, observés dans le gouvernorat de Sidi Bouzid entre 1968 et 2011. Les résultats préliminaires mettent en évidence 2 constats majeurs: - Une réémergence de la LCZ datant du début des années 1980, parallèlement à une augmentation des températures et une multiplication et intensification des épisodes caniculaires, attestant vraisemblablement l'effet récent du réchauffement climatique en Tunisie. - Une périodicité quinquennale des pics épidémiques de LCZ qui semble être corrélée avec la variabilité constatée du régime de pluies et du décalage progressif des saisons. D'autant plus, les années où les pluies de fin de saison prennent de l'importance, les sebkhas abritant les rongeurs réservoirs connaissent l'abondance d'une végétation, à base de petits arbustes de la famille de chénopodiacées, qui constitue l'alimentation exclusive des rongeurs réservoirs. Ces conditions sont également favorables à l'explosion des populations des vecteurs.

Integrated assessment of vulnerability to heat stress in urban areas. The example London

Tanja Wolf (Kings College London)

Increasing mortality and morbidity related to periods of hot weather and heatwaves are a direct health impact from a warming and more variable climate. They are also the

consequence of demographic processes leading to an ageing population and of urbanisation which enhances the urban heat island effect. It is a challenge for public health, urban planning and risk management to protect citizens from these threats. This paper proposes the development of an index to assess the vulnerability to heat stress in urban areas. The method combines risk indicators of heat stress as identified from international literature into a vulnerability index using Principal Component Analysis. The vulnerability index is applied to Greater London to show a very heterogeneous vulnerability landscape. To test the performance of the vulnerability index, daily data on temperature from London Weather Centre and spatial data on daily mortality and ambulance callout are used. Testing methods show that it is possible to model where hot spots of vulnerability, in terms of increased mortality and a higher number of ambulance callouts, are occurring. The results encourage further research on hot spot analysis to better target intervention measures that preserve the health of the most vulnerable in a cost-effective and efficient way. At the same time, the results lead to questions on science and policy interaction that are the driving forces of decision-making.

Place, electromagnetic fields and health risk – a case study in the northwest of Portugal

Paula Remoaldo (University of Minho), Helena Nogueira (University of Coimbra)

The electromagnetic pollution is a type of pollution that continues to grow nowadays. This invisible pollution can have adverse effects on the health of populations, especially at the level of chronic degenerative diseases (e.g., cancers and more specifically, childhood leukemia). However, there is no clear evidence about this influence and few research on this topic has been carried out at Portuguese, and even, international level. In this paper we try to understand the impact of electric sites and cables of very high voltage on population health. Our main concern was getting an answer to the following question: to what extent proximity (until 50 meters) of the cables of high and very high voltage can affect the health and well-being of individuals? A cross-sectional study of 173 individuals living in Serzedelo, Guimarães, in the northwest of Portugal, was performed in 2010. Serzedelo is one of the 69 parishes that composed the municipality of Guimarães and it was selected because of the high density of this kind of electric sites and cables at national level it is endowed with. 96 women and 77 men were observed. They were classified into two groups given the location of their residence according the electric sites and cables of very high voltage they were exposed to: one group included those who lived nearby, up to 50 meters; and another included those who lived at 250 meters and more far from those sites or cables. Semi-structured interviews were made, giving us information about individuals' sex, age, education, occupation, tobacco consumption, physical activity, years of residence in Serzedelo, years of residence in current home, time spent at home, use of mobile phone, health status, symptoms, diseases, number of physician visits and reason to. We used a logistic regression models to analyze the associations between the incidence of the reported diseases, life styles and factors

related to residence place. Considering cancer incidence, results pointed to a significant influence of two predictors: years of residence in Serzedelo and number of physician visits. Odds of having a cancer disease increase with increasing time of residence in Serzedelo (OR = 2,495; $p < 0.05$) and with increasing number of physicians visits (OR = 1,89; $p < 0.05$). Considering CVD, we found a significant influence of age, education and number of physician visits: the likely of having a CVD increased with age (OR = 1,78; $p < 0.1$) and number of physicians visits (OR = 1,4; $p < 0.05$) and decreased with higher education level (OR = 0,64; $p < 0.05$). Considering endocrine diseases, we found a negative association with education (OR = 0,45, $p < 0.05$) and a positive association with number of physicians visits (OR = 1,77; $p < 0.01$). Evidence on cancer incidence highlights the need of developing deeper studies on this topic, as well as the urgent taken of action plans for sensitive residential areas, as Serzedelo.

Chair: Bruno Schelhaas, Jacobo García-Álvarez

Semantic reduction of the concept of nature in geography

Witold Wilczynski (University of Cracow)

Geography is a field that does not have a defined, generally accepted object of study. Nature is a concept that often appears in the definitions of geography since the time of Strabo and throughout the classical period. The situation changed radically only in the twentieth century, when nature has been reduced in meaning, and then displaced from the geographic literature by other terms, such as the environment. Although the representatives of classical geography, especially the Alexander von Humboldt, considered themselves to be naturalists, their understanding of nature (and Earth) does not have much in common with contemporary meanings of these terms. Dichotomy of man and nature, which now seems to be something obvious, was not a classic feature of geography in the period of its development. The classical nature of geography is not just that part of reality, which remains after deducting the man and his creations. Alexander von Humboldt saying, "Nature," he meant the entire reality, including man and his creations. The reality of the classical period was divided into two autonomous and distinct in the metaphysical sense spheres: the natural and the supernatural. During the Enlightenment the supernatural was excluded from scientific considerations, while the nature in a broader sense began to divide into two categories: the nature in a narrow sense of wildlife and the man (culture, society). This now forgotten fact contributes to the perpetuation of dualism in the geographical literature and the organizational structure of science. Moreover, this semantic reduction of nature have affected the evolution of environmental ideas. Today, they probably would look different if modern geography was not formed under the influence of the disseminated opposition of nature and man.

The time has come for a new concept of (geography's) nature

Barbara Zahnen (Humboldt-Universität Berlin)

Due to their work, historians develop a good feel for the fact that what seems to be "new" often is not really "new" at all, but rather old wine in new bottles. Nevertheless, historians also know that times can change indeed, and that new ways to see things and to be in the world can emerge. Both aspects, of course, also apply in the field of geography, and to the way geographers address "nature" and/or relations between human beings and nature. In my paper, I want to introduce a novel way of conceptualizing nature in and for geography, and I want to reveal why the time has come for this novel conceptualization. Thereby, it should firstly become clear that the novel way of conceptualizing (geography's) nature is not just another way of interpreting "nature" in addition to the sum

of interpretations that one runs across in "contemporary" geography, but that it rather touches the issue of (geography's) nature -- and the relation between human beings and nature -- in a deeper and more comprehensive way. Secondly, and at the same time, it should become clear that the possibility of the novel conceptualization is already "given" in the materials of the geographic tradition, as well as in practices of (physical) geographers, so that it comes along with understanding new possibilities of doing geography.

Le rapport homme-nature dans les magazines grand public de géographie

Guilhem Labinal (CNRS, Paris)

Les préoccupations environnementales ont été devancées ou relayées dans les magazines grand public de géographie qui s'attachent à décrire l'environnement naturel des hommes. Les publications que l'on peut rattacher à la géographie par leur titre, leur origine, leur usage ou une sorte de catégorisation du sens commun sont nombreuses. L'importance de leur diffusion est connue : Geo bénéficiait d'une audience de plus de 4.5 millions de lecteurs en 2010 et les différentes versions du National Geographic étaient, à cette date, diffusées à plus de 8 millions d'exemplaires dans le monde. Le contenu de ces publications a été analysé aux Etats-Unis (T.Y. Rothenberg, S. L. Hawkins) et en Europe où les géographes se sont intéressés à leur dimension idéologique, à leurs discours iconologiques et textuels[1] mais aussi à la nature des représentations qu'ils donnent des territoires nationaux, telle l'Espagne (J. García Álvarez, coord. : recherches en cours). Dans la continuité de ces travaux, notre communication propose d'interroger le regard proposé au public sur l'environnement à l'appui d'exemples puisés sur les dix dernières années (ceux d'Ushuaia magazine notamment). Quel rapport à la nature les magazines proposent-ils et quelles distinctions peut-on établir entre eux - En quoi les choix effectués sont-ils emblématiques d'une vision particulière de la nature et du rapport que les hommes entretiennent avec elle? Pour esquisser des réponses à ces interrogations, nous examinerons les lignes éditoriales des magazines, certains d'entre eux s'inscrivant dans un discours écologique qui sacralise l'environnement. Nous analyserons également les supports (les illustrations, les titres, etc.) parce qu'ils témoignent de la façon dont le rapport homme-nature est conçu. Au terme de cette réflexion, nous aurons relevé l'aspect sélectif des représentations et montré les valeurs dont les lieux sont dotés. L'environnement n'est-il pas idéalisé à des fins militantes ou réenchanté pour satisfaire le désir d'évasion du public - L'impact des magazines est tel que les géographes ne peuvent éluder ces questions. [1] Labinal, G. (2009), La géographie des médias. Une analyse iconologique et textuelle des magazines, Thèse de doctorat de géographie, Université Paris 1. 503 p.

Evolution of view in geography

Musa Saikhanov (Russian Academy of Sciences), Zulfira Gagaeva (Russian Academy of Sciences)

Geography is associated with a variety of disciplines. During many years the earth's surface is the object of research and vital people interests. Society necessities and modes of production have made correction into the subject, content and objectives of geography. The development of the philosophical views of the first centuries AD was marked by attitudes to nature as a single whole consisting from the parts (elements). Philosophical ideas of Spinoza (1632-1677), Leibniz (1646-1716), Kant (1724-1804) and others are passed the thought about that the essence of complexly organized objects is not limited by simple set of elements. By the middle of the XIX century in the natural sciences there was the lack of the knowledge about complex systems that could not be research only by expanding of the nature to elementary particles. By the end of the 'I'th and early 'II'th century the scientists realized the necessity of approach to solving scientific and economic problems from the positions of the nature wholeness, based on general connections of phenomena. Gradually accumulating research experience in different geography areas and non-uniformly scaled complex researches allowed to say about existence of the regular territorial combinations of natural components. Thus, the whole previous course of geography has prepared the base for the formation of representations of the landscape as a "new" object of study. The study about geographical sphere and biosphere (Grigoriev, Vernadsky) has enriched the understanding of landscape in the 1st half of the XXth century. The theory of the self-development and self-regulation of landscape and the views to the landscape as an irreducible element of geographic reality, landscape-brick of the earth nature are appeared in the middle of the XXth century (Armand, 1988; Preobrazhensky, 1981) The important role played the general systems theory (Bertalanffy, 1969). A. Humboldt (1866), Ritter (1864) and Dokuchaev (1948) are some of the firsts that recognized the necessity of the common theory for the research of the complex objects and diversity of nature in its unity. The systems approach predetermined the views on the landscape as a complex object. There is the integration of a set of geographically relevant elements and relations in space and time (V. Gokhman, ?, 1971; E. Neef, 1974; V. Sochava, 1975 and others). The research methods in the geography (J. Hanvell. M. Newson, 1977) has developed. I. Prigogine's (1986) and H. Haken's (1991) ideas associated with a "new dialogue with nature" and macroscopic approach to complex systems also make a meaningful object of study of geography. The concept of sustainable development, as well as W. Ebeling (1979, 2001) "covenants" allow to estimate the necessity for understanding of views on the object of research in geography.

The traces of ice: Albrecht Penck (1858-1945) and the emergence of geographical fieldwork in the context of the German continental ice controversy, 1875-1885

Norman Henniges (Leibniz-Institut für Länderkunde)

The presentation aims to examine the socio-cultural practice of geological fieldwork during the German continental ice controversy from 1875 to 1885. Dealing with the main question, how the controversy shaped a new disciplinary self-understanding, it will be discussed how conflicts in everyday mapping practices provided the basis for the formation of the new discipline of geomorphology. This will be linked to a special biographical view on the early years of the geographer Albrecht Penck who began his career as assistant geologist for the Geological Surveys of Saxony and Bavaria. By drawing on unpublished archival sources (field maps, letters, field reports etc.), we can shed further light on this debate. Which complications and situational irritations occurred against the backdrop of the controversy during the geological mapping of Saxony? How did the practice of fieldwork change as the problems increasingly went beyond the fixed geological mapping and taxonomic rules of the surveys - while quaternary phenomena more and more appeared as a fundamental research problem? Which role did the growing transnational and transdisciplinary integration of scientists play, the various thought styles and worldwide availability of observational data? What was the impact of different, colliding styles of practice and thought, as well as conflicting epistemic ideals and moral values in dealing with research objects of different scales? And finally, what consequences did all these changes have for the emergence of German geomorphology as part of geography?

Edmund Naumann as Geographer: Neglected Aspects of the German Father of Japanese Geology

Toshiyuki Shimazu (Wakayama University)

This paper focuses on the way that a German geologist acquainted with geographical and cultural features of Japan acted also as geographer in several European journals and geographical societies in late 19th century. By unveiling these neglected aspects, I intend to shed some light on another dimension of the inseparable relationship between geology and geography within the context of the gradual institutionalization of geography and related sciences. Edmund Naumann (1854-1927) is hardly known in contemporary German academia, although he has been famous among Japanese geologists as 'father

of Japanese geology'. After gaining a doctorate at the University of Munich in 1874, Naumann was invited to Japan in 1875 as one of the technological and academic professionals requested to promote Japan's industrial and cultural modernization. He taught geology, mineralogy and paleontology at the University of Tokyo as professor, and then directed systematic geological surveys all over Japan except Hokkaido and compiled geological maps as de facto director of a governmental geological survey office. He wrote a lot of scientific papers, two of which appeared in Dr. A. Petermanns Mitteilungen and one of which in Verhandlungen der Gesellschaft für Erdkunde zu Berlin, and he trained his Japanese successors until his return to Germany in 1885. In contrast to this brilliant career path in Japan, Naumann's post-return academic life was not a rewarded one. While he habilitated as Privatdozent of geology and physical geography at the University of Munich in 1887, he remained in this unstable position until his resignation in 1899. He then worked for a Frankfurt-based metalworking company as mining engineer and never came back to academic life, which accounts for a relatively small portion of his post-return practices. From 1885, Naumann gave lectures on the geological and geographical features of Japan at the meetings of several European geographical societies including those in Vienna, Dresden and Berlin. He was honorary corresponding member of the Royal Geographical Society and corresponding member of the geographical societies in Leipzig and Dresden. He also read papers at the 6th Deutscher Geographentag in Dresden in 1886 and at the 6th International Geographical Congress in London in 1895, which he attended as delegate from the Geographische Gesellschaft in München and as one of the vice-presidents of the congress. Naumann as geographer wrote substantial papers in journals and proceedings including Proceedings of the Royal Geographical Society, and he became the single author of Dr. A. Petermanns Mitteilungen Ergänzungsheft Nr.108 entitled 'Neue Beiträge zur Geologie und Geographie Japans' in 1893. Naumann's trajectory suggests that he clearly recognized the interrelationships between geological structures and surface landscape features and that geology was apt to be subsumed in the broad category of 'geography' in his times.

The Idea of Autarky: Leo Waibel's Economic Geographical Positioning Against Blood-and-Soil Ideology

Simon Runkel (University of Bonn)

The work of Leo Waibel (1888-1951) yet awaits its fully contextualisation. Waibels contribution to economic geography has been acknowledged by few scholars (Schätzl, Bathelt & Glückler), but his impact on German geography, American geography and Brazilian geography is not fully conceptualised yet. Due to the Jewish background of Waibels wife, he was forced out of his professorship in Bonn 1937 by Nazi laws and decided to leave Germany two years later. The geographic inquiry of Waibel was focussed on economic and agricultural aspects with a main regard on subtropical and tropical regions. Convinced by the necessity of an unified discipline ('the geographical experiment') Waibel strived for the development of a consistent vocabulary and set of

principles to understand economic geographies. Waibel was an outstanding thinker and his knowledge of theories and works in economics and in agricultural science as well as his background in physical geography enabled him to develop a consistent theoretical system. In facing increasing objection within the discipline, Waibel remained completely unaffected by the progressing amalgamation of geographic inquiry and Nazi ideology. Through his clear intellect and his personal concernment he looked through the creeping appropriation of Geography through Nazism. The idea of autarky was propagated by national socialist agrarian politics. These policies were based on the blood-and-soil ideology and Neo-Lamarckism (Darré). Waibel built a case against this ideology just before his emigration in 1937. His monography on 'Rohstoffgebiete des tropischen Afrikas' can be analyzed as an opposition to the moral discourses within the discipline. Waibel's interest was mainly concerned with the practical application and empirical work in the tropics and sub-tropics. His political idea was loosely connected to List's cosmopolitan division of labour, and colonisation was seen by him as European task. He was opposed to colonial hegemony and favored balance in international trade. The paper will contextualize Waibel's position against the effects of blood-and-soil more closely. Against the background of Waibel's academic work and his impugment within the discipline, the paper will help to reveal the conditions and geographical imaginations of geographic inquiry during the 1930s in Germany. It will give a clue about how Geography was steeped with Nazi ideology and it will honour Waibel's merits for the discipline.

Nature and Landscape in the sailing instructions of Ahmad ibn Majid (15th century)

Marina Tolmacheva (Washington University)

Nature and Landscape in the sailing instructions of Ahmad ibn Majid (15th century) The famous 15th-century navigator of the Indian Ocean Ahmad ibn Majid al-Najdi was a contemporary of Vasco da Gama and a witness to the Portuguese arrival in the Indian Ocean. One of the few Arab sailors of the pre-modern era to leave written instructions for the monsoon routes of the eastern and western parts of the ocean, he composed poetry and prose and was learned in formal as well as practical aspects of navigation, astronomy, and geography. Continuing interest in Indian ocean studies brings Ahmad ibn Majid firmly within the orbit of historians of regional and indigenous geography. His writings, some of which have been translated into European languages, allow s to explore the interaction of practical, popular, and scientific knowledge of geography and nature. In the more formal of his works, Ahmad ibn Majid drew on established authorities ranging from Ptolemy to Abu'l-Fida and Ulugh-Beg. But the nautical instructions, composed in rhyme for easier memorization, highlight the practical information required for guidance to sailors needing expert advice in navigation and less familiar with the wide-ranging destinations along the numerous sailing routes of the ocean. This paper will focus on the famous 'Sufaliya' poem (urjuza), so named for the city of Sofala in Mozambique and containing instructions for sailing from northwest India to southeast Africa. The long

Arabic text allows for sustained narrative and contains information about a diverse and extended, yet geographically and climatically somewhat uniform coastal area. The paper will address Ibn Majid's ideas about nature and landscape as they are present in the text and integrated into his record, consciously adapted for transmission to the next generation of learners. Examples will be drawn illustrating Ibn Majid's use of scientific knowledge of geography and astronomy, his acceptance and promotion of the regionally-specific practice, and finally, his knowledge and opinion of the indigenous knowledge of the landmarks on the coastal route.

Simion Mehedin'ti, a predecessor of global thinking in Romanian Geography

Dan Balteanu (Romanian Academy)

Simion Mehedin'ti, a predecessor of global thinking in Romanian Geography This year Romanian geographers are commemorating 50 years since Simion Mehedin'ti (1868-1962), the founder of modern Romanian Geography, passed away. After having completed his studies in Paris, Berlin and Leipzig with Paul Vidal de la Blache, Ferdinand von Richthofen and Friederich Ratzel, Mehedin'ti was nominated Professor of Geography at the University of Bucharest in 1900. In his fundamental work written in Romanian - Terra. Introduction in Geography as Science (1930) and in other of his writings the Earth is viewed as a complex system within which the four planetary covers are interacting both in terms of static's (spatial distribution) and dynamics. The complex relationships established between the four geospheres are reflected in such planetary circuits as regularly winds and Ocean currents. Man is considered to be one of the most active agents increasingly more involved in changing the relationships among the geospheres, thereby radically influencing the evolution of the Earth System. The paper analyses several significant aspects for the current development of Geography, namely, global human pressure on the environment, the impact of human activity on the biosphere and hydrosphere, global degradation of the biosphere and the relationships between the Earth's covers.

Géographie et Naturphilosophie au 19e siècle: quelles relations dans l'aire francophone?

Federico Ferretti (équipe EHGO Epistémologie et Histoire de la Géographie)

Dans l'histoire de la géographie, on retrouve de nombreuses traces de l'influence de la Naturphilosophie allemande sur la formation intellectuelle des géographes européens du 19e siècle. Entre les auteurs qui ont le plus retenu l'attention des géographes on peut citer Friedrich Schelling et Lorenz Oken. Plusieurs auteurs contemporains remarquent l'adhésion de Carl Ritter à la dialectique binaire de Schelling dans sa représentation du rapport dynamique Homme-Nature, alors que d'autres reconnaissent la stricte solidarité entre les Naturphilosophen et Alexandre de Humboldt. Comme l'influence de Ritter et Humboldt sur toute la géographie européenne est universellement reconnue, il nous semble important d'analyser l'utilisation, chez les géographes, des concepts produits par cette école philosophique, à une époque où la géographie se construit comme discipline scientifique. Nous aborderons ici l'aire francophone, où plusieurs auteurs sortent directement du magistère ritterien, comme Édouard Desor, Arnold Guyot et Élisée

Reclus. Concernant ce dernier, sa lecture directe d'auteurs comme Schelling, Oken et Steffens est ponctuellement documentée par ses biographies et ses archives. On parle pour l'instant de « aire francophone » parce que cela nous permet d'aborder des auteurs suisses comme Guyot, et d'assumer l'importance des traductions françaises de Ritter et Humboldt dans ce transfert. Entre les principales questions à éclaircir, quelle a été l'importance de la Naturphilosophie pour les géographes francophones et pour la formation de leur démarche scientifique? Quels sont les concepts principaux qui marquent cette influence - Par quelles voies et par quels ouvrages passe-t-elle - Quel est, enfin, le point de rupture après lequel on peut considérer définitivement affaiblie l'influence, directe et indirecte, des Naturphilosophen sur les géographes - Nous essaierons de répondre en interrogeant les ouvrages et les archives des géographes cités, à l'aide de la littérature critique disponible et des textes principaux des philosophes de la nature. Nous remonterons chronologiquement le courant du 19e siècle jusqu'aux premières années de carrière du père de la géographie humaine, Paul Vidal de la Blache, auteur qui s'est nourri à son tour de la tradition allemande, pour évaluer ce qui restait de la Naturphilosophie au moment de la naissance de l'école française de géographie.

Russian representations of the Caucasus between the XVIIIth and the XXth centuries

Marina Frolova (University of Granada)

The Caucasus evokes in the European imagery an ensemble of clichés: first of all, that ones connected to Greek and biblical legends; than the images of the XVIIIth and XIXth centuries of a strategic region, an exuberant and rich "Orient"; that one of the end of the XIXth and of the XXth century of emblematic space for research and tourism, up to most recent representations of a marginal and divided space characterized by persistent ethnic and territorial conflicts and tensions. Since the end of the XIXth century the Caucasus has been presented in Russia as a "transcontinental", rich and exotic mountain with virgin nature. The naturalist, pragmatic and imperialist representation dominated in Russian and Soviet geography and served as a scientific archetype for interpretation of other mountains. The aim of this paper is to show, within the context of production of landscape visions in the specific geographical, historical and cultural conditions of the Caucasus, the relativity of scientific interpretation of environment and its relation with social and cultural representations circulating in Russia between the XVIIIth and the XXth centuries.

Les relations Homme-Nature en Argentine d'après Malte-Brun en 1845

Gloria Zamorano (University of Cuyo)

L'objectif de ce travail est celui de caractériser les relations Homme-Nature au milieu du dix-neuvième siècle, à partir de l'analyse d'un texte de Malte-Brun qui décrit l'Argentine, publié en 1845. La méthodologie consiste, d'un côté, à l'analyse sémiotique du discours

sur l'Argentine extrait du "Précis de la Géographie Universelle ou Description de toutes les parties du monde sur un plan nouveau". Dans cette oeuvre Malte-Brun traite les territoires qui comprennent l'Argentine dans deux livres du sixième tome, intitulé "Description des deux Amériques. Océanie. Table générale", en particulier sur une partie du livre cent quatre-vingt-douzième, où il s'occupe de la description des terres argentines mises en valeur à l'époque, et dans le livre cent quatre-vingt-treizième, où il fait référence aux espaces n'appartenant pas à l'époque à la Confédération Argentine, soit à ce qu'il appelle l'Araucanie, la Patagonie et les Terres Magellaniques. De l'autre côté, pour traiter la relation Homme-Nature en premier lieu nous employons l'approche hypothético-déductive que nous permet de faire une classification de la position des entités urbaines selon trois critères d'analyse des propriétés spatiales employées dès la fin du dix-huitième siècle, suivant Marie Vic Ozouf-Marignier : les critères esthétique, hygiéniste et fonctionnaliste, en les combinant avec des visions optimiste ou pessimiste (Ozouf-Marignier, 1992). Secondement, nous traitons les caractères naturels du milieu et ethnologiques des tribus qui habitaient au nord et au sud de la Confédération Argentine à l'époque, ainsi que les caractéristiques des terres désertes de la Patagonie et de l'Antarctide, d'où nous pouvons inférer des sujets typiques de l'époque, tels le dualisme civilisation-sauvagerie. Parmi les résultats, nous constatons que le texte de Malte-Brun met en relief les relations Homme-Nature avec des connotations propres à la géographie inventaire du dix-neuvième siècle. En effet, dans le discours scientifique positiviste alternant la description littéraire et la narration historique, nous apercevons non seulement l'influence du déterminisme environnemental mais aussi celle de la vision culturaliste de l'époque.

Nature and landscape seen through the eyes of 19th-century Mexican novelists

Luz Tamayo (Universidad de Mexico)

Nature and landscape seen through the eyes of some 19th-century Mexican novelists. The path to wards consolidation and recognition of Mexico as an independent and autonomous nation was tortuous. In the nineteenth century its territory was invaded, maimed and again invaded by foreign powers. In this climate of war and despair some Mexican intellectuals wrote novels that portrayed the landscape, customs and problems that surrounded them expressed through the plot of a romance or adventure story. Some 19th-century novelists described nature and landscape in particular detail, showing a nationalist fervour that was perhaps fanned by the fear and menace that hung over the land and liberty of the Mexican people. The present study analyzes descriptions of nature and landscape by 19th-century Mexican intellectuals.

Critical inquiry into national environmentalism in modern Japan

Koji Nakashima (Kanazawa University)

One of the features of the studies on Japanese culture in modern Japan is an emphasis on the close link between nature and nation in Japan. As suggested in famous Japanese ethicist Tetsuro Watsuji (1935)'s "Fudo (Climate and culture)," a masterpiece of Japanese culture study, a tendency to understand Japanese nationality with focusing on specific linkages of people and nature in Japan is quite popular among various scholars including geographers in the early modern era. Especially during the wartime of the 1930s and 1940s, natural scientists such as physicist, meteorologist, geologist and forestry experts, as well as human-social scientists such as philosopher, historian, ethnologist, referred to the uniqueness of Japanese culture by stressing the uniqueness of Japanese nature. What motivates this understanding is a certain desire to differentiate Japan as an independent subject from the West. While the former is characterized by its close link with nature, the latter is characterized by its separation from nature. We can find out a similar type of discourses in some of contemporary Japanese culture studies which stress the uniqueness or superiority of Japanese culture and thought in contemporary world confronted with serious environmental problems. This paper calls such type of discourses "national environmentalism" which (re)produces the desire for "Japan" on the basis of specific articulation between nature and nation. This paper critically examines some representative texts of national environmentalism including geographers' works published in modern era and attempts to elucidate a structure of the texts which

unconsciously directs their attitude toward nature and environment. Conclusion is summarized in following four points. 1) Nature is used for material foundation of nationality, and the identity of Japanese nation is considered to be rooted in the uniqueness of nature in Japan. 2) Modern national identity of Japan is projected onto the history of relationship between people and nature since the ancient times. 3) The legitimacy of Japanese nationality is understood to depend on the scientific analyses of nature, in other words, Japanese nationality is scientifically confirmed by scientific analysis of nature. 4) Japanese national identity is made visible by producing scenic beauty of natural landscape of Japan. Discourses of national environmentalism stir the desire for "Japan" under a neutral banner of nature and raise a geographical question "what is Japanese nature?" instead of unanswerable political question "what is Japan?" An invisible subject of "Japan" appears by answering this geographical question.

Institutionalization of landscape in Japan: Between academism and social institutions

Tamami Fukuda (Osaka University)

"Landscape" a key concept in geography, is translated in Japanese as "keikan." While landscape itself is a multivocal concept, the word "keikan" is more problematic because of the complicated processes through which it was translated and introduced into Japan. This paper focuses on the introduction of the term "landscape" into Japanese society and explores the institutionalization of "keikan" in modern times. The first person who translated the term "landscape" into Japanese and made it a part of Japanese academic fields was a botanist, Manabu Miyoshi (1862-1939), an important researcher who is inevitably mentioned when the history of the study of "keikan" is discussed. For Miyoshi, "keikan" was a translation of the German word "Landschaft" and meant the physiognomy of the plant community. It is noteworthy that he committed himself to the conservation of natural resources and introduced the national park system. In other words, for Miyoshi, the concept of "keikan" was inextricably related to social practices such as natural conservation. Following Miyoshi's works, Taro Tsujimura (1890-1983) promoted "keikan" as a central concept in human geography. In the 1930s, Tsujimura, a geographer and topographer, published books and articles that included "keikan" in their titles. He also explored the scientific study of "keikan" on the basis of the landscape tradition in German geography. Thus, his approach toward "keikan" has influenced Japanese geography. In contrast, landscape architects focused more on the practical aspects of "keikan" that is, in the design of gardens and parks?. The same is true for a field of engineering called architectonics, in which "keikan" is considered a manipulated object, that is, something artificially produced. Moreover, in civil engineering, "keikan" is strongly related to laws and regulations. Thus, the concept of "keikan" has been defined, studied, and institutionalized in different academic fields and for different purposes since its introduction. Geographers, if they studied it within the discipline, did not directly encounter the diversified concepts of "keikan" in other fields. All that was needed was an awareness of the current trends in

which the concept of landscape was reconsidered in sociocultural geography. However, a new category of national cultural properties, "cultural landscape," which was introduced in 2005, forced us to theorize "keikan" in chaotic circumstances. In the light of the problems that stemmed from "cultural landscape," this paper examines the relationships between academic practices in different fields and the institutionalization of "keikan."

The History of Understanding of China in Western Maps for More Than 2000 Years

Liankang Yang (Ministry of Land and Resources China)

The relationship between China and the West has evolved over 2000 years. Both accurate and inaccurate perceptions flourished during this period. In terms of historical cartography, early Western maps misrepresented China and Africa, and suggested they were contiguous.'C. Ptolemy, 90-168 A.D, see< Ptolomaeus Cosmographia Ulm 1482 >) In the Middle Ages, many European maps did not include China.(For example, <Die Ebstorfer Weltkarte>, circa 1235 AD.) Some maps depicted a large peninsula, larger than the Indian Peninsula and Indo-China Peninsula, jutting off the coast of southern China.'H. Martellus, Nurenberg, circa 1490 AD and F. Rosselli, Florence, 1492-1493 AD; even after Columbus' discovery, 1506, 1507-1508 AD. etc)'Other maps linked China and N. America. (G. M. Contarini , 1506 and J. Ruysch, 1507-1508; B. Columbus' manuscript 1506. O. Fine, 1534-36) China has been producing maps for >2000 years and has employed a systematic approach for much of that period. Towards the end of the Middle Ages, increased interaction between China and the West resulted in more accurate depictions of China in Western cartography. It is now apparent that since this period aspects of Chinese map making have been incorporated into western cartography. In 1375, A. Cresques' Catalan Atlas contained a map of China, possibly borrowed from Yu Di Tu(Song Dynasty map), created circa 1270. Two other early Western maps that included China - M. Ricci's World Map (1602) and M. Martini's Novus Atlas Sinensis (1655) - were both based on Luo Hongxian's Guang Yu Tu (1555). M. Martini's maps were widely copied in western world maps. Another example, D'Anville's "Nouvelle Atlas de la Chine (1737)", appears to be copied directly from Kangxi Huang Yu Quan Lan Tu (1718). Although these maps were incomplete and sometimes inaccurate in their rendering, subsequent depictions of China in western cartography were far more accurate. 2000 years of history tells us: contacts need maps. And, maps also promote communication, mapping must rely on technology, but we can take the initiative to adopt new technology to create new maps. In the future, exchange of information between east and west may continue to erode inaccuracies in our perception of eachother. This could also have benefits for sharing new map making technology. For example ,to unify the main data in World Maps (such as world river's lengths, YangLiankang ,Seoul ,IGU,2000). To create new kinds of maps(such as changing the geographic content of maps according to time to show how continents and oceans have changed eachother over

geological periods), and even ,hopefully, ordinary citizens will be able to participate and contribute to the map making process.

Nature et surnature, Gondwana et Lémurie: une géographie du sacré à Madagascar

Mialy Ratrimoarivony (Antananarivo University)

Résultant de l'étude de différents sites sacrés naturels et des populations autochtones à Madagascar, on remarque que la compréhension des relations qui régissent l'espace et le sacré dépasse la simple construction mentale pour être en définitive, le résultat d'une expérience de vie bien ancrée dans une réalité multidimensionnelle. A Madagascar, les esprits de la nature-ancêtres appelés Kalanoro, Zazavavindrano et Vazimba, peuplent et préservent multiples espaces naturels terrestres, forestiers et aquatiques. Leur nature divine et spirituelle définit la sacralité de leur site d'implantation, indépendamment de tout sentiments ou actions humains. Quand une population humaine est présente sur leur territoire, ils se révèlent à elle de diverses manières et lui dictent les règles de vie qui régissent ce territoire. Dans ce cas, la sacralité d'un site naturel lui est intrinsèque. Les échanges humains, rituels et culturels qui s'opèrent au sein du site sacré naturel, dévoilent alors un espace bidimensionnel composé : d'un espace visible qu'est la nature, et d'un espace invisible mais sensible de la surnature, qui sont en connexion permanente. C'est ainsi que nous relierons le continent « Gondwana » des Sciences de la Terre, au continent « Lémurie » des Sciences ésotériques, continents auxquels Madagascar est rattachée. Une autre approche de la géographie du sacré se dessine.

Poetics of signs: Reading "feng-shui"(geomancy) landscapes in Ryukyu-Okinawa islands

Naoki Oshiro (Kobe University)

Poetics of signs: reading feng-shui (??, geomancy) landscapes in Ryukyu-Okinawa islands In Ryukyu-Okinawa region, south-west part of Japan, we can find many strong influences of 'feng-shui' thought as a method of reading landscape or a tool of land assessment like in other regions of East Asia. Reception of 'feng-shui' thought in the Ryukyu kingdom was track back to 1667 when the first foreign student 'Shu Koku Shun' was sent to 'Fuzhou' for learning it systematically. Before the modern era, 'feng-shui' thought was recognized as highly professional knowledge and government administrated it exclusively. Administrators who were called 'Chiri-shi' or 'Funshi-mi' applied this thought to settlement management, river and road improvement, or mountain forest management. This aspect shows very a form of knowledge-power relation. In fact, 'Saion' (1682-1762), a famous administrator who advanced his career to the top of

officialdom (Sanshikan), was a geomancer, and he made the survey of castle, tomb, and mausoleum of the dynasty and gave a favorable blessing of their location in the authentic history, 'Kyuyo(s)'. After the inclusion in 1879, the kingdom of Ryukyu became a prefecture of Japan. But its legal systems had been continued until 1903 for the stage of preserving old customs, and pre-modern ways of life were carried through those ages in Ryukyu-Okinawa islands. Although these conditions were carried on, however, it is important to recognize that modernization had advanced in the aspects of education or police system, and that class system was broken down, then that what was former privileged knowledge or genre de vie had been appropriated into common people during this quarter of century. The knowledge of 'feng-shui' had thus diffused from capital city and privileged class to local villages and ordinary people in late 19th century. But there were some differences between urban area and countryside in modalities of reception more than a little. Still, the vernacular folk knowledge had been strongly-rooted in countryside. There had been also discrepancies between the sophisticated knowledge of 'feng-shui' and vernacular acceptance of it. In this paper, I would present some aspects of articulation of 'feng-shui' knowledge as highly professional knowledge with vernacular folk geographies in Okinawa by investigating 'feng-shui' maps and landscapes.

The Holy Land in Germany's Cultural Landscape: Religion, Pilgrimage, and Science

Haim Goren (Tel-Hai College)

From the time of the Crusades, and even much earlier, a great number and variety of links and relations developed between the German countries and the Holy Land. These ties were initiated by individuals or groups who, for religious, military, commercial, political, missionary, artistic or scientific reasons traveled to the East, and, on their return, either brought with them existing relicts and artifacts of remembrance from their travels, or tried in various ways to reconstruct their voyages and retain their impressions and recollections through various processes of 'memory-building'. Other 'points of memory' originated in the 'religious zeal' which derived from intensive preoccupation with the Bible. Naturally, religious motives played a major part in these cultural connections, but one should also add, depending on the period, scientific, political, geo-political (sometimes even colonial or imperial) and commercial motivations. All of these led to the fact that the map of Germany, the current one which presents the contemporary 'cultural landscape', the landscape shaped by people into a landscape representing 'the combined work of nature and of man', is dotted with numerous 'Topoi' (single: Topos) or manifestations depicting and commemorating the Holy Land, or even more so - the relatively long-lasting and changing German connections to that land on the eastern shores of the Mediterranean. Although always affected by a wide variety of 'outer' and 'inner' processes, by the changing international climate and geo-political interests, by the changing rulers in the Holy Land and their attitudes towards Western Christianity as well as processes within the European Christian churches themselves, these ties between

East and West never seemed to be totally broken. The connections were expressed in various ways, and many of them will be studied in the following paper, demonstrated through existing or vanished relics, of different forms, in today's Germany.

Beautiful Plains and Rocky Range. Nature Representation in the Map of the Holy Land.

Jutta Faehndrich (Leibniz Institute for Regional Geography)

In 1858, the Gotha publishing house of Justus Perthes produced a 'Map of the Holy Land'. The author and cartographer of this large-scale topographical map of Palestine was Charles William Meredith van de Velde (1818-1898), former cartographer of the Dutch Royal Navy, landscape painter, and devoted protestant. Van de Velde was a typical representative of 19th century scientific cartography: 'Many of [the existing maps] are filled up with cities and places laid down merely according to fancy', he wrote and claimed to have made a complete, up-to-date, no-nonsense map of the region, based only on reliable, first-hand information. He had even travelled to Palestine himself to survey regions formerly neglected by cartographers and explorers. And indeed, until the advent of the triangulation-based map of the Palestine Exploration Fund in the 1880s, van de Velde's map held as the region's most reliable cartographic representation. Yet a map necessarily reduces our experience of the world - in this case to a two-dimensional, black-and-white set of lines and shades. The result is a discrepancy: between the cartographer's desire to capture the world in its entirety, and the limited ability of his medium. If we have a closer look at the 'Map of the Holy Land', we find a plethora of details that van de Velde used to breach this gap. Perhaps the most charming of these is the inscription 'beautiful plain' in a valley close to the river Jordan - apparently the cartographer found no other means to express his admiration for Palestine's beautiful nature. Others include remarks like 'rocky range' (terrain/ landscape), 'wandering Arabs' (population), 'reeds' (vegetation) or 'quarantine' (information for travellers). The most frequent textual comment though is 'not examined'. So at first glance, these extras seem to be slips of the cartographer's tongue. Yet they really draw our attention to the strengths and weaknesses of the medium. Where pre-modern fancy filled gaps by 'hic sunt leones', the enlightened 19th century cartographer admitted his lack of knowledge. Ultimately, these comments help us understand why for van de Velde, a map was not enough to express his views on the Holy Land. Very much like van de Velde's 'Map of the Holy Land', maps never come as single, detached products. Thus apart from analysing the depiction of nature in the 'Map of the Holy Land', this talk will also argue in favor of reading maps together with the contexts they were published in.

Modern ideas of nature – negotiating nature in the context of the international city of Tangier (Morocco)

Valerie Viehoff (Universität zu Köln)

In Harrouda, a novel by the Moroccan author Tahar Ben Jelloun set in Tangier and Fez, one of the narrating voices mocks the glorification of the ‘naturalness’ of Morocco and the Moroccans by the French painter Eugène Delacroix. In his letters written in the 1830s, Delacroix lauded not only the beautiful light and colours of Morocco, but also the simplicity of the inhabitants of Barbary, whom he praised for being so “close to nature in a thousand ways” (Delacroix, 28th April 1831; cited in Ben Jelloun, 1973: 137). His praise for the “simple life of the barbarians” combined ancient prejudices against “barbarians” as those people perceived to be less or un-civilized, with a European fascination for the Orient that developed out of an Enlightenment admiration for the “noble savage” stereotyped as thoroughly good and uncorrupted. The world, in the 19th and early 20th century was a “world of crisis, confusions, and contradictory processes and experiences” (Ogborn, 1998: 2). A world where people were experiencing a maelstrom of rapid change, scientific discoveries, new modes of production, shifting social relationships. A world marked by the struggle of modernity. This paper traces the fundamental changes that occurred in Tangier and Morocco in the later 19th and at the beginning of the 20th century, especially the construction of Tangier’s first “modern” urban water supply system. The key factor was the extension of a colonial, capitalist, economic system under French colonial rule, allowing private ownership of natural resources, such as water, making it possible for a private (French) water company to acquire a contract for distributing and selling water in Tangier. The new water supply system is often lauded as the beginning of modernity in Tangier. The paper discusses the different implications that these developments in engineering had with regards to ideas of nature, its values and its uses.

Andrew Clark and the interpretation of changing landscapes

Michael Roche (Massey University)

Andrew Hill Clark (1911-1976) an influential figure in North American historical geography in the mid 20th century spent 1941-1942 in New Zealand teaching at Canterbury University College and completing the research for his Berkeley PhD, later published under the title of *The Invasion of New Zealand by People Plants and Animals* (1949). This paper considers his writings on New Zealand particularly as they relate to understanding

changing landscapes. This was a subsidiary but not insignificant thread of Clark’s early writing.

The landscape of Toledo (Spain) from Los Cigarrales: Cultural and symbolic interpretations of a natural site

Carlos Cornejo (University of Madrid), Juan Vázquez-Navarro (UAM)

This paper examines the cultural and symbolic interpretations of a natural area facing the old town of Toledo known as Los Cigarrales, and the transformations that have undergone in recent years. Geological and geomorphological features of these open spaces, whose cultural appreciation has constantly been a topic in history, have held a strong attraction throughout the ages. In recent decades, this tradition has been trivialized due to tourism business, whose marketing processes have entailed profound changes that has led this cultural landscape to lose its own identity. The southern natural outskirts of Toledo is home to a mixed space of sixteenth-century cottages (named also cigarrales), gardens and forest area called Los Cigarrales. Here country estates are located on the southern slopes of the gorge of river Tagus. They have historical and cultural origin as recreational and gathering country houses for Renaissance humanists. The value of this area lies in the visual scope towards the ancient downtown, which motivated the location of these cottages in the 16th century. This site with its views contributed to the significance of the cultural heritage of the town itself. During the early twentieth century an intellectual recovery of the historic use of cigarrales was carried out by means of literature and art. Some writers and artists close to the so-called 98 Generation, such as Azorín, Pérez Galdós and Beruete, reinvigorated the cultural tradition of these cottages and its original intention with regards to the oldtown scenery. By focusing on the panoramic view of Toledo they conceptualized a powerful symbolic image of the decadent Spanish reality. Cigarrales cultural landscape has undergone physiognomic and discursive changes throughout its history. Since mid-twentieth century to nowadays, this site has been intensely commercialized, thus losing its geographical and cultural logic, carrying deep changes that have distorted their *raison d’être*. Nonetheless, it has also been the subject of some legal protection and it still remains the main point from which the oldtown is depicted. This is done nowadays through the advertising language of tourism industry to convey this image to the public. In this paper, geographical and territorial features, cultural appraisals, and recent changes of the use of the area will be problematized.

The relationship between bio-resources and cultural tradition on Austronesian islands – the cases of Orchid Island and Easter Island

Flora Sheng-hua Cheng (Chinese Culture University), Yi-Ju Lee (Chinese Culture University)

A large portion of the Pacific Austronesians live on oceanic islands, which are formed from volcanic eruption on the floor of oceanic tectonic plates. Many of the islands, such as the Hawaiian Islands, were formed from hot spots; others, such as Easter Island, from oceanic ridge; and still others, such as Orchid Island, from island arc effect. Among the three types, the hot spots islands are often arranged as a linear and closer archipelago, while the other two types of island often appear in remote and isolated location. This study will explore the latter two types of isolated islands, focusing on the relationship between their bio-resources and traditional culture. Because of their isolation in the ocean, the living space of those solitary islanders is small and closed. The resources for Islanders' livelihood cannot be separated from the marine resources, especially in exploiting animal protein. There is usually a seasonal or annual cycle of gathering these precious substances, and that developed a material-based unique culture rooted in long-term interaction with the environment. Two islands, Orchid Island and Easter Island, are selected for studying the relationship between their bio-resources and development of culture tradition. They, distant 15,000 km from each other at the two extremes of Pacific Ocean, have both similarities and differences in natural and human geographies. Both are of the Pacific high volcanic island. Both peoples are all Austronesian. (They are called "Tao" on Orchid Island, and "Rapanui" on Easter Island.) And both have about 3,000 residents who have developed their major beliefs and rituals within a span of 200 to 400 years. The differences are also striking. With a tropical climate, Orchid Island in spring and summer each year is supported by the Kuroshio Current which brings in a wealth of fishes. So prominent among the bounty is the flying fish group that the seasonal activities related to its catching (*Cheilopogon* spp.) have developed unique types of cultural ceremonies, tribal fishing organization, related buildings, shipbuilding techniques, and arts and sculptures. Easter Island is in a subtropical maritime climate, visited in each spring by the terns, they breed on offshore islets and provide islanders with egg proteins. The Sooty Tern (*Sterna fuscata*) and the Grey-backed Tern (*Onychoprion lunatus*) are collectively known as manutara. The

manutara has developed the tangata manu ("bird, man") ritual, related buildings, the rules of allocating the bio-resources, as well as the form of stone art. Each of the unique cultural tradition of the two Islands can be traced to its original bio-resource. Keywords : Austronesians, oceanic islands, bio-resource, traditional culture, Orchid Island, Easter Island

Hurricane Resilience in Grenada from a Complexity Theory Perspective

Arnd Holschlag (University of Hamburg)

In the context of increasing natural or man-made hazards and global environmental change, the study of uncertainty, vulnerability and resilience of social-ecological systems represent core areas of human-environmental geography. Extreme geophysical events coupled with the social construction and production of risks and vulnerabilities, viewed as hazards, raise questions about the limits of knowledge, creating long-term social uncertainty that has to be acknowledged as such. Small islands sharing "isla effects" or "insularity" are exceedingly vulnerable to external shocks and the impacts of the social-ecological interplay. Therefore, the study of islands is extremely insightful in order to analyze and understand hazards as socio-ecological constructions which require human induced resilience capacity. In the Caribbean, tropical storms and hurricanes in particular can lead to abrupt change and disturbance. In 2004 the 344 km² small island state of Grenada was hit by category 3 Hurricane Ivan. The effects were responsible for 37 deaths, over 90 % of the country's housing stock was impacted, significant losses of livelihoods took place, especially in rural communities. Valuable ecosystem services were affected, too. In this paper, Grenada is regarded as a complex social-ecological system. I intend to link the weather system of tropical storms and hurricanes with the social system of disaster preparedness and management. The ecological and social vulnerability to such disturbances and disasters is influenced by the buildup or erosion of resilience. Concepts of resilience generally focus on the capacity of the system to absorb shocks whilst still remaining functional, as well as the system's capacity of adaptation, renewal and development when coping with change and crisis. One resilience perspective that has emerged in ecology (C.S. Holling) is embedded in theories of complex adaptive systems. I draw on the heuristic models of the "adaptive renewal cycle" and "panarchy" as approaches for social-ecological system analysis. Hurricane resilience is a local and long-term issue which requires constant institutional learning. Persistent risk communication challenges include the consideration of diverse needs and priorities as well as diverging mental models. In this paper, pre-disaster, disaster and post-disaster management structures, agents and practices in Grenada are examined, taking into account various systems of knowledge generation and communication, forms of organization and networks on different spatio-temporal scales (panarchy). The aim is to understand better the principles of system (or adaptive renewal cycle) dynamics and to find out potentials to enhance hazard resilience. Such lessons can be useful for application to other cases dealing with hazards.

Discursive Constructions of Danger, Resilience, Connection, and Difference: Insights from Seas of Islands and Mediterranean Seas

Phil Steinberg (University of London)

Culture is often associated with adaptation, and the Mediterranean is classically labeled a hearth of culture, a region where coastal and island dwellers, reacting to a mix of separation and connection, developed a rich and historically robust set of cultural norms for coping with an environment that, while broadly conducive to human existence and interaction, also posed a number of hazards. One of the less frequently noted aspects of Mediterranean culture, however, is how the idea of a Mediterranean culture - a culture specifically responding to the geographic structure of an inland sea punctuated by fragmented coastal and island communities - has spread to other parts of the world. This paper draws on fieldwork conducted in the Gulf of Mexico/Caribbean and the Arctic to explore how Mediterraneanist tropes are used in these two regions. On the one hand, this paper confirms the general perspective of the Mediterraneanist ideal: appeals to maritime connections and island 'bridges' are used throughout the world to discursively reframe borderlands as spaces of crossing. On the other hand, however, the comparative perspective afforded by this research reveals that the application of Mediterraneanist tropes is much stronger during times of hegemonic expansion (the early 20th century in the Gulf/Mediterranean and the early 21st century in the Arctic). This suggests that the application of the metaphor has a tactical-geopolitical component not often highlighted and that the entire idea of a Mediterranean system of resilience may need to be placed within a more explicitly political context.

of far-reaching colonial intrusion and impacts. Our purpose is to highlight the role of local knowledge in building community resilience, and the role of resistance in the resilience of local knowledge.

Local knowledge, resilience and resistance on Pongso no Tau

Huei-Min Tsai (Taiwan University), Eric Clark (Lund University)

There is increasing interest in relating local knowledge and resource management practices to the construction of social and ecological resilience. The aim of this paper is to contribute to this emerging field of research, focusing on how resistance plays into these dynamic relations, and drawing on an empirical case study of a small Pacific island, Pongso no Tau. The Tau people of Pongso no Tau (literally, 'Home of Humans', a small northern outlier of the Batanes Islands southeast of Taiwan) have for centuries exercised highly egalitarian resource management practices, largely in isolation prior to being subjected to two waves of colonial oppression by Japan (1896-1945) and Taiwan (since 1945). Japanese dominance brought police, formal schooling (for 'savage children'), currency and trade. Colonial influence escalated with Taiwanese dispossession of land, establishing farms and labor camp prisons, topocide of traditional villages replaced with low quality housing, imposing Mandarin as primary language, exploitative tourism, extraction of timber and replacement with alien fast-growth species, over-fishing, dumping nuclear waste, and increasing material dependence. This paper analyses social-ecological resilience of Pongso no Tau, primarily from the perspective of reproduction of local knowledge and traditional livelihood. Tau culture has proven itself resilient in the face

C08.22-02 - Human/Nature-Interaction on small islands – an integrative geography perspective. 2 Co-supported by the IGBP/IHDP core project LOICZ which explores coastal vulnerability and sustainability in the context of global change and human dimensions

Impact of sea-level rise on atoll island states: A bleak future for Tuvalu and the Maldives?

Roger McLean (University of New South Wales)

The low-lying atoll states of Tuvalu (central Pacific Ocean) and the Maldives (central Indian Ocean) have been identified as extreme examples of the potential negative impacts of climate change and sea-level rise. Key impacts of the latter include: accelerated coastal erosion; saline intrusion into fresh-water lenses; increased inundation and sea flooding; and, the destruction of settlements and infrastructure from the higher reach of storm surges and king tides. Some authors suggest such impacts will result in the islands becoming uninhabitable. Island abandonment, is increasingly seen as a climate change adaptation option with an exodus of islanders as so-called environmental 'refugees'. Indeed, the long-term viability of these island states is in doubt. What is the basis for such views? How vulnerable are Tuvalu and the Maldives to climate change and sea-level rise in reality? How fragile are atoll islands? What will the likely impacts of climate change be over the next few decades? Is the outlook that bleak? This paper addresses these questions from the perspective of three decades of geomorphic and environmental research undertaken in both archipelagos to assess the linkages between sea-level rise and reef island morphodynamics. Specifically, it has involved reef drilling and island coring; archival map, air photo and satellite-image interpretation; and repeated plan and profile surveying to determine how reefs and islands have responded to: (1) the mid-late Holocene rise in sea level; (2) global sea-level rise during the last 100 years or so; (3) temporarily elevated water-levels associated with recent tsunami and storm surges; and (4) exceptionally high sea levels, deep ocean swells and king tides. Results from these geological and contemporary analogues (of the response of atoll islands to rises in sea levels) suggest that the future situation may be less bleak than some advocates, media, and governments make out. The results also suggest that little modified atoll islands are quite robust in the face of changing external conditions, especially where natural processes of sediment production, erosion and deposition are allowed to proceed with minimal human intervention. Where this is not the case, and where there has been substantial modification and 'development' of reefs, lagoons, shorelines and islands, the future is rather more bleak.

The Ecological Footprint as a tool for small island sustainability promotion

Jan Petzold (University of Hamburg)

For island societies major issues of environmental management result from limitation of space. Depending on island and population size, geographical isolation and consumption patterns, small islands have very different circumstances which intensify their limitation of productive space and make sustainable development more difficult. These differences are even more evident in contrast to continental regions, as e.g. high energy costs and emissions from transportation are often inevitable on small islands. Nonetheless, the land required for imported energy and goods is not evident on the island itself but rather abstract. For this reason a first step to develop sustainable management strategies is the assessment of current land use and consumption patterns. A comprehensive way to achieve this goal is by means of an indicator which offers the opportunity to account for and compare islands' actual land use and quantify their progress towards sustainability. In this paper I intend to present the Ecological Footprint concept with its potentials and opportunities as a sustainability indicator from the perspective of integrative geography, which focuses on human-nature interaction. The 'Ecological Footprint of Islands' project discusses the concept's role for the management of sustainability in the special case of small islands. It assesses whether high food consumption, energy generation, built-up land or rather transportation is the major cause for a high footprint. In this way the impact a society is leaving on the island's ecosystem is reflected in a quantified way: the Ecological Footprint, measured in hectares. This paper, moreover, presents the results of the project and shows how certain consumption and land use patterns influence an island's Ecological Footprint in different ways. Furthermore, an indicator such as the Ecological Footprint is suitable to support a cross-island network for small island sustainability promotion and allows for benchmarking among islands across the globe.

Human-nature interactions on Soqatra Island (Yemen) in the past and against a background of political uncertainty

Dana Pietsch (Universität Tübingen), Lisa Banfield (Al Ain Zoo), Miranda Morris (University of St. Andrews), Kay Van Damme (Jinan University), Uwe Zajonz (Senckenberg Research Institute BiK-F)

Inhabited dry tropical islands are seen principally as vulnerable socio-ecological systems, especially if their inhabitants have limited access to arable land, fresh water and crop seeds. On Soqatra Island/Yemen, well known for its unique biodiversity and therefore declared a World Heritage Site in 2008, the exploitation of natural resources, i.e. those related to provisioning ecosystem services, plays an increasing and important role in the rural economy. Looking at both the terrestrial and the marine resources, the most critical questions are: Which traditional and which modern approaches in the exploitation of natural resources do we find in the Soqatra Archipelago? Which of those practices are sustainable, i.e. are preventing overexploitation, ensuring generation equity and

conserving biodiversity? On the other hand, what kinds of land degradation occur? How does the current political situation in Yemen, with ongoing poverty, and lack of effective central or regional government, affect conservation efforts and resource management, both regarding biodiversity, and natural resources in general? Which priorities could be suggested for the future? After a brief overview of the landscape, economy and people of the main island of the archipelago, this paper will give insight into the use of resources such as rock and soils, fresh water, arable land for pastures for grazing livestock and home-gardening, but also into the importance of medicinal and other plants, terrestrial wildlife, and into the living and non-living marine resources for subsistence and marketing. Based on the long-term-experience of each contributor, suggestions towards a sustainable future for Soqatra will be projected, to serve as a case study for the discussion on human-nature interactions on islands. Vulnerabilities and opportunities: There is nothing new in the island realm

Stephen Royle (Queen's University)

The abstract for this session organized by CO 8.22 Islands contains the phrase 'Are small islands in a position to turn their windows of vulnerability into windows of opportunity'? This paper attempts to develop this concept, taking 'vulnerability' to apply to socio-economic and political stresses as well as to climate change and natural hazards, whilst 'opportunities' builds on another phrase from the abstract, the 'resiliences of island societies'. In sum: islands display vulnerability but from this can come opportunity, which may be seized upon by resilient islanders. The 'nothing new in the island realm' phrase from the paper's title points to its identification of such processes in the past as well as the present. The example from the past comes from new research the author is undertaking into Port Hamilton. This was the name given to what is now Geomundo or Komundo, a small archipelago off southern Korea, which was annexed by the British in the late 1880s for potential development as a military base and coaling station. That the island could be taken in this way displayed its vulnerability. The presence of the British

navy however, was an opportunity for the resilient islanders, who whatever resentment they may have felt at their home being invaded by representatives of the 'big queen', soon were profiting from selling land, labour and produce to the foreigners whose barracks and buildings were anyway erected on an islet which they did not occupy. An enterprising man even set up what the archives coyly do not call a brothel; one desperate marine was drowned whilst attempting to swim to it. After two years the British decided that Port Hamilton would be too costly to defend (vulnerability) and left. In the present day one can point to islands such as the Falklands now profiting from tourism to battle sites from the 1982 Conflict, vulnerability developing into opportunity; to island residents working with their small scale and remoteness to market niche products; to perhaps the most profound potential change to take place to a small island in the near future, the building of an airport on St Helena. Here is an island whose economy proved terribly vulnerable to external shock - the demise of its flax industry in the late 1960s was a blow from which it never recovered. In recent years there has been massive emigration and population decline, the one last hope of positive change and opportunity is the plan to build an airport, which has finally been approved. Tourism numbers are estimated to increase from 800 to 50,000 p.a. Let us hope that the islanders are indeed resilient.

Coastal change of wetland, Taijiang National Park

Jiun-Chuan Lin (Taiwan University)

This study is mainly focus on coastal change of Taijiang National Park. Taijiang National Park was designated as the eighth national park of Taiwan in September 2009. As this national park is famous for its wetland, it is necessary to know more about the evolution of coastal change for the purpose of management and sustainable development. This study carried research efforts by analysis of archive maps, field work and analyzing more than 200 references regarding its geographical and cultural landscape, environmental background information, biological resources, historical resources and past management practices. Conservation goals, future research and conservation work are suggested according to the above findings. The results show that it is important to ensure sustainable development and integrity of Taijiang national park's natural, historical, and industrial features, baseline studies, monitoring and conservation work, together with the formation of a systematic database framework are suggested as the major foci at the early phase of Taijiang national park's establishment. According to this study, the vulnerable wetland in south-western Taiwan has changed dramatically due to human activities, dam construction, coastal erosion by typhoon, currents. It is necessary keep monitoring and documentation on this dynamic coast. Keywords: coastal change, long-term monitoring, Taijiang National Park, Taiwan

Islands as Refuges of Rare Species

Tatiana Dikareva (Moscow University)

In our research we examined the role of marginal (ecoton) ecosystems in the formation of biodiversity of islands or isolated territories which could be considered as "islands". The goal was to evaluate the ecological-coenotic composition of the flora of coastal or marginal vegetation communities and to identify the strategy of flora conservation on the islands. The investigations were made in the Chinese island Hainan and mountain forests of southern Kazakhstan (Karkaralinskie mountains) isolated from other forests by vast territories of steppe zone. Research works were made in 2008-2010 years. For each type of island we identified the sites more favorable as retreats for plants and studied the border communities of the whole island. For Kazakhstan mountain forests we showed

that ecoton communities are more diverse than inner communities as for ecological-coenotic groups and in floristic composition. For coastal communities of Hainan island we showed that floristic composition is poor and flora of coastal communities is composed by pioneer or ruderal plants common for most coastal communities of tropical islands. For all island and "island" communities we showed that certain habitats, such as springs, banks of small brooks, valleys of temporal currents, lakesides, quagmires, bogs, cracks in the mountain blocks, submontane niches are favorable for preservation of rare species. For each type of island we revealed the rare species. For Kazakhstan mountain forests they are such species as *Althaea officinalis*, *Berberis karkaralensis*, *Anemone coerulea*, *Neottia camtschatea*, *Gymnocarpium robertianum*, *Gymnocarpium dryopteris*, *Lonicera pallasii*, *Hypericum perforatum*, *Dracocephalum peregrinum*, *Saxifraga sibirica*, *Nymphaea candida*, *Papaver tennelum*, *Epipogium aphyllum*, *Moneses uniflora*, *Artemisia glabella*, *Coridalis schanginii*, *Dictamnus angustifolius*, *Dactylorhiza fuchsii*. For Hainan island some rare species are *Liquidambar formosana*, *Kleinhovia hospida*, *Spondias pinnata*, *Tillia hainanensis*, *Meyna hainanensis*, *Hopea hainanensis*. Thus, islands can provide habitats for conservation of rare plant species while marginal or ecoton communities can serve as buffer zone between these refuges and surrounding ecosystems. The results of this work can be used for organization of natural reserves on the islands or isolated territories.

Facing the crisis from an island perspective. The case of Menorca (Balearic Islands) between recession and opportunity.

Federica Letizia Cavallo (Università Venice)

The financial and economic crisis, risen between 2008 and 2011 is lately involving with special seriousness the countries of Mediterranean Europe. Most of these countries (Greece, Italy and Spain) have a well established tradition of seaside insular tourism, involving big islands, such as Sardinia, as well as small (e.g. Menorca) and very small ones like the islands of Greek archipelagos. This situation arises some questions: Does the crisis hit small Mediterranean European islands in specific terms? Which are the major economical, social and environmental effects of the crisis on small islands? Besides, considering that those islands have in seaside tourism their major economic activity, how the insular tourist sector is affected by the crisis? If the crisis of an economic system, including a touristic one, rebounds on the socio-environmental system, this is particularly noticeable within small island, characterized by reduced resources and limited territory. But any crisis implies the need to re-think strategies and goals, as well as to shape a different vision of the future: could this transformed in an opportunity? Are small Mediterranean islands able to face the crisis for good? How the so-called (from a classical development perspective) weaknesses of insularity, could be transformed in chances in a critical juncture? In the last decades the island of Menorca, in spite of being an Unesco Mab Biosphere Reserve from 1993, largely continued to found his tourist development on a Sea, Sun & Sand model, with a particular stress on two kinds of

accommodation: resorts and holiday homes. This tourism model is questioned by the crisis of Europe and Spain: some evident signs can be found in the closing of bars, restaurants and shops, as well as in the 'shrinking' of the tourist season. But the strongest setback lies in holiday homes' trend, with severe consequences on development companies and real estate agencies; that has also to be framed in the national situation, since the crisis in Spain is closely linked to the previous pumping and the subsequent collapsing of construction sector. This all for Menorca means unemployment, insecurity, emigration. The tour operators' managed 'all inclusive' low cost tourism seems to be much less affected by crisis: but its economic fall-out on the island is weak and the competition of other destinations grows. Another sector less affected is ecotourism and agritourism, which is island based and environmentally compatible. Considering this general picture, from the crisis could result a reduction of a tourist strategy based on high land consumption, as well as on high water and energy demand (unreasonable in a small island context). It could also emerge a strengthening of sustainable tourism, characterized by local management and gains, more rooted in island society, based on environmental quality and, therefore, more in line with the purposes of a Biosphere Reserve.

Les politiques de développement durable dans les îles de l'océan indien: le cas de la Réunion

Ulrich Maillot (Institut de Recherche pour le Développement), Gilbert David (Institut de Recherche pour le Développement)

La conférence de la Barbade, qui a suivi le sommet de Rio en 1994, était consacrée à la mise en place du développement durable dans les petits Etats et territoires insulaires. L'accent a été mis sur les contraintes qu'impose l'insularité dans ce domaine. Vingt ans après le sommet de Rio, cette communication traite des politiques publiques de développement durable à la Réunion. Quatre acteurs, l'Etat, le Département, la Région Réunion et Réunion Economique, sont à l'origine de ces politiques. La Région Réunion a été la première à se lancer avec la mise en oeuvre en 2002 d'un agenda 21 basé sur l'autonomie énergétique. En matière de gouvernance, il visait à décliner le développement durable à l'échelle du citoyen dans le cadre d'une démarche participative. Cette démarche a été reprise au niveau local par le Département avec la mise en place du Schéma Départemental d'Aménagement et de Développement Durable en 2005. En 2006, constatant que l'agenda 21 n'avait pas le succès escompté, la Région Réunion est revenue à une conception moins participative du développement durable avec pour objectif l'indépendance énergétique de l'île d'ici 2030. A côté de ce volet énergie, des Domaines d'Activités Stratégiques (DAS) ont été identifiés et intégrés à la nouvelle politique de développement durable régionale, le Plan Réunionnais de Développement Durable. La Réunion Economique a aussi proposé sa démarche, Réunion Île Verte 2030. En 2007, à l'issue du Grenelle de l'environnement, l'Etat s'est emparé du développement durable sur l'île en créant un programme ambitieux, Green Energy Revolution Réunion

Island. Il souhaite faire de la Réunion un modèle de développement durable à l'échelle des outre-mer français et des régions ultrapériphériques européennes. En 2009, un groupement d'intérêt public est élaboré et lance enfin le projet sur l'île. Cependant, ce projet élaboré par l'Etat rencontre de difficultés et c'est la mise en place du développement durable sur l'île qui est ralentie. Comment est-on passé d'une volonté régionale à un projet piloté par l'Etat? Quels sont les freins du développement durable de l'île de la Réunion? Que reste-t-il des politiques menées sur le territoire réunionnais?

Karst

C08.23-01 - Human impacts and environmental changes in karst

Chair: Ilona Bárány-Kevei

Human impact to the karst of the Franconian Alb, Germany

Martin Trappe (University Eichstaett), Sebastian Wagner (University Eichstaett)

The Franconian Alb, located in southeastern Germany, consists of karstified limestones and dolomites of Jurassic Age. It is partly covered by Cretaceous and Miocene deposits and a clayey to loamy overburden. Hydrogeologically, it is separated into a shallow and a deep karst zone. Humans using the different natural framework requirements formed the actual cultural landscape of the area. Depending on the spatial distribution of limestones, dolomites and cover deposits the surface is used by agriculture and forestry. Caused by different percentages of these aspects in the catchment areas karst springs exhibit different chemical compositions with respect to chloride, nitrate, phosphate and other substances. Especially the shallow karst and transitional zone to deep karst show such characteristics. Since a long time the Franconian Alb was affected by exploiting of the natural resources. Mining of iron ore ended twenty years ago in the eastern part of the Franconian Alb. For most of the karst area this human impact has been overcome in the natural scenery and mining remains only as a local touristic aspect. Nowadays the pit and quarry industry exert a large influence to the karst area and locally it is the main branch of the economy. The natural stones were extracted since several hundred years within several quarries to use them for different purposes (e.g. staircases, window sills, wall claddings, building stones). Several parts of the Franconian Alb were declared to natural parks and they are subject to special environmental regulations. Nevertheless the industrial and agricultural use of the landscape persists but it is liable to a number of restrictions. Additionally, different large-scale projects affected the area in the last twenty-five years. The construction of the Rhine-Danube canal, extension of several highways and the construction of high-speed train routes were the main impacts.

Slovak karst – land cover, exploitation of the karst landscape and its transformation

Alena Petrvalská (Institute of Geography, Faculty of Natural Sciences), Zdenko Hochmuth (University of Pavol Jozef Šafárik)

There is the evidence of a human being 15 thousand years ago in the Slovak karst, when they began occupying the area that was mainly forested. What most affected the land was deforestation and exploitation of pastures at the turn of second and first centuries B.C. The largely deforested areas were nearby castles, castle hills to the present time are covered by meadow vegetation. Generally, due to exposition, there were primary

deforested south slopes with formation of karst heathland and xerophyte communities. Forest was preserved only in depressions of deeper dolines and steepest north slopes of valleys. The primary reason for distinct changes in the use of the karst landscape over the last 50 years is establishing the institutionally protected natural area, the national park and biosphere reservation. At the same time, there were considerable changes in social situation of inhabitants (rising average age, emigration?), what resulted into the absence of agriculture in the major area of this region. Nowadays, the transformation of the protected karst area is a very topical and interesting issue, mainly in considering the relationship between nature protection and landscape 'degradation' because of many legislative restrictions (in agriculture, construction activities, commercial forestry, sport activities, hiking etc.). There were following changes established: Artificial afforestation - typical for a period 1970-1975. European black pine (*Pinus nigra*) and South European Flowering Ash (*Fraxinus ornus*) as not original species. Natural succession. When the forest is spreading, the shrub and undergrowth plants are retreating, parallelly with this process the number of species is decreasing in this area, but some new are forming. Slopes of karst plateaus were typical of herbaceous associations, today there are shrubs. This effect is caused by the extinction of pasturing on the ground due to collectivization of agricultural land. But the question 'what means natural' can be raised. Urban, demographic changes and ecological loads - relate with the Roma people who settled in this area and constructed their settlements without any plans, devastation of forests and illegal dumps. These factors have affected the quality of life, water and soil resources, aesthetics of landscape. The worst impact to the karst landscape is the existence of the four huge limestone quarries. When evaluating the positive and negative effects it is necessary to think about vulnerability of the karst landscape. Humans and their activities are changing the whole character of country, character of vegetation, soil situation and microclimate. By the soil erosion an originated karren were destroyed, in cave humans left damaged decoration, inscriptions and objects. It is difficult to say, if all these processes are either positive or negative, but from the long-time view, it slowly comes to reversibility of derivative processes.

Implication for Karst Rocky Desertification by $\delta^{13}\text{C}$ in New Carbonates from Caves

Ziqi Liu (Southwest University)

In order to study the implications for karst rocky desertification by new carbonate from caves, cave deposits in central-western Guizhou Province of China were sampled for analyzing their $\delta^{13}\text{C}$. Vegetations and soils on the top of the caves were also sampled for analyzing the organic $\delta^{13}\text{C}$. It was found that $\delta^{13}\text{C}$ average value of new carbonate of Shijiangjun Cave (SJJ) in Anshun > Zhijin Cave (ZJD) in Zhijin > Houzi Cave (HZ) in Shuicheng > Jiangjun Cave (JJ) in Qinzhen. It can be seen that $\delta^{13}\text{C}$ of cave deposits can be used to reflect the vegetation situations of the time; from the old time till now, the vegetation is in a trend of decreasing. The average organic $\delta^{13}\text{C}_{\text{VPDB}}$ in the vegetation

and soils of HZ is -32.75‰ and that of SJJ is -24.33‰ . For the $\delta^{13}\text{C}_{\text{VPDB}}$ in new carbonate, it is -5.21‰ and -0.87‰ respectively in HZ and SJJ. It means that C3 plants predominate in HZ while C4 plants predominate in SJJ. Through the comparative analysis of different grades of rocky desertification surface with the $\delta^{13}\text{C}$ of cave deposits, it was found that the more severe the rocky desertification is, the heavier the $\delta^{13}\text{C}$ of cave deposits will be. Therefore, although factors affecting $\delta^{13}\text{C}$ of cave deposits are very complicated, it basically reflects the changes of vegetation on the surface and organic $\delta^{13}\text{C}$ of soils; vegetation coverage rate and vegetation types are significant factors affecting $\delta^{13}\text{C}$ of cave deposits; the average $\delta^{13}\text{C}$ also varies with the different grades of rocky desertification on the surface. Thus, $\delta^{13}\text{C}$ recorded in cave deposits can be used to study rocky desertification evolution processes.

C08.23-02 - Management and conservation of karst landscapes 1

Chair: Elena Trofimova

The significance of landscape ecological research in the 21st century

Ilona Bárány-Kevei (University of Szeged)

The assessment of the environmental stress and strong anthropogenic impact on karsts came to prominence in international research in the 1990-ies. First, the "Study Group on Man and Impact in Karst" IGU Commission (Paris 1984), and the "Conservation and Environmental Changes in Karst Areas" (1989) IGU Commission was formed. Karst ecological research has started from that time (Gams 1987; Jakucs 1987; Bárány-Kevei 1987, 1996; Dreybrodt 1988; Gillieson - Smith 1989; Pfeffer 1990; Williams 1993; Uruishibara Yoshino 1995; Day 1996; Urich 2002; Urich - Day - Lynagh 2001; Simon 2007). Karst ecosystems are vulnerable to anthropogenic impacts like land use and climate change. Climate change in space and time determines the movement of karst water, but also affects soil and vegetation. Understanding the ecological consequences of such changes and the prediction of the adverse effects is one of the most important issues of karst research today. It is very important for both ecosystem protection and management. The proper understanding of the hot spots and hot times of ecosystem functions and the recognition of the factors of the system's driving forces are very important issues for the future. One of the most common forms of land use on karsts is forest management. Sustainable forest management manages forest products as well as protective and recreational functions in such a way that their continued existence is ensured for a long time (Tanács - Samu - Bárány-Kevei, I. 2007). The agricultural use of land for grazing may also cause damage (erosion by trampling) to slope steppes, and the presence of livestock affects the chemistry of the soil and the infiltrating waters. Accelerated eutrophication processes (Samu, A., Bárány-Kevei, I., 2010) in the karst lakes also lead to changes in the karst system. Urbanization and the management of the urban environment puts a significant pressure on the karsts, through the acidifying effect of the infiltrating contaminated water. Quarried rock material causes a shortage of material, which indirectly has a landscape deforming effect, the same as waste disposal. Karst water pollution is increasing, and often water abstraction is damaging to the system. The task of karst landscape ecological research is to examine landscape changes due to land use. In order to work out future landscape management the current state should be assessed and different use proposed if needed. The proposal should include possible methods for the sustainable development and conservation of karsts. Plans should be drawn for both landscape use and management. This requires the knowledge of the mechanisms that characterize the functioning of the karst ecosystem. The presentation gives some international examples of current changes in land management.

Proposed Criteria for Karst Ecosystem Deterioration of Indonesian Karst

Eko Haryono (Gadjah Mada University)

Indonesia in 2009 enacted revised act on Environment Protection and Management (Act number 32). The act stipulates that Environment Ministry must provide criteria and guideline for ecosystem deterioration of which one of the guideline is for karst ecosystem. The guideline is already drafted with three principles, i.e. simple and objective, easy to apply, and data availability. The guideline is divided in two criteria. The first criteria are for karst region and the second are for specific object in karst region. For the karst region, the criteria are percentage of vegetation coverage and outcrops/bare land. Specific object in karst area which is included in the guideline are cave, spring, doline pond, karst hills. Parameters for karst deterioration are speleothem condition, cave sediment condition, and the existence of bats. Parameters for spring deterioration are water quality and discharge fluctuation. Parameters for doline pond deterioration are the period of inundation. Parameters for karst hills deterioration are percentage of vegetation coverage, outcrop coverage, and volume of quarried limestone. Keywords: Karst Management, Karst Environment Deterioration

A micromorphological approach to deterioration of speleothem of show cave

Jie Zhang (Nanjing University)

With spectacular speleothems, karst caves often become tourist destination in China. Yaolin Cave is one of them, which was developed as a show cave in 1980s and once had become one of hotspot of tourist destination in China those years. However, as soon as a cave opened to public activities, the cave environment has been largely changed, and causes artificial deterioration and changes of surface color of speleothems on the one hand, and also changes of original condition of calcite precipitation on surface of speleothem. In this paper, a micro morphological approach to surface processes and types of micromorphology of weathering or deterioration, especially the biodeterioration is carried on with observation and statistics of characteristics under both OPM (optical microscope) and SEM (Scanning electronic microscope). In situ observation and sample collection include choosing typical comparable geomorphic or illuminative position as sample collection sites, recording related hydrologic condition and hand sample description. Lab observation and statistics include Optical microscope (OPM) observation and Scanning Electronic Microscope Observation. A series of criterion of micromorphology were developed for the statistics with systematic observation on surface features of samples, occurrence frequency of the characteristic features on surface were quantified in percent of area coverage. The surface erosional features can be classified under OPM into three types of the crystal-based type of surface erosional features, i.e., round fresh solusional features with patch, roughly solutinal feature with micro pinacles, and polished round solutinal surface with densely calcite crystal. Types of micromorphology of speleothems under SEM can be classified into several groups of

criterion as follows: unweathered Original features with 3 subtypes, Physical weathering features with 4 subtypes, Chemical corrosional features with two subtypes, Biokarst erosional features, with 4 subtypes, Biomats and Primary precipitation features with 3 subtypes. Our observation with statistics according to such focused on subjects as follows: Surface features and mechanism of corrosion of speleothems, Precipitation on speleothems, Show cave environment and related bioeffects, Deterioration of speleothem and the possible mechanism, Micro morphology of speleothems. It is concluded that cave deterioration of speleothems might be reflected and observed in terms of micromorphology with a series of characteristic features as indices, to depict . In this case sample cave, i.e., Yaolin, China, there is certain deterioration of speleothem as the cave opened to public tourist with artificial illumination and subordinate growing of algae, which calls for a better management of cave tourism.

Cold karst of Natural Park “Lena Pillars” (Yakutiya, Russia)

Elena Trofimova (RAS)

Natural Park 'Lena Pillars' is located in the latitudinal part of the valley of great Siberian River Lena. Orographically region explored belongs to Prilensko'e Plateau raised at 300-600 m a.s.l., dissected by the valleys of Lena and Boutama Rivers. Climate of the territory is Sub-arctic extreme continental and dry: average annual temperature of the air is '9,8°C at the annual temperature amplitudes to 98°C. Average annual precipitations doesn't exceed 249 mm. There is the area of continuous permafrost up to 300 - 500 m thickness, the thickness of active layer is 2,12-2,36 cm. Lower Cambrian limestones and dolomites with a thickness 400-500 m outcrop represent the karst rocks. In spite of the insignificant quantity of the precipitations falling on the territory of NP Lena Pillars, karst processes are widespread here. One the one hand, the additional receipt of the water is supplied by the processes of condensation, occurred both from the air, and in consequence of the condensation water on the lower part of active layer: because of the big gradients between earth temperature and lower situated perennially cryotic rocks. On the other hand, according to L. Jakucs, the solubility of CO₂ in the water decreases with the increase of temperature of the solution: at temperature 0°C the coefficient of absorbing of CO₂ is 1,713 and at temperature 30°C - only 0,665. Thus, cold waters of permafrost's regions, saturated by CO₂, are characterized by the considerable aggressivity in respect to karstifying rocks. Additionally, the infiltration of summer precipitations along the deep fissures of carbonate rocks, the condensation, as well as the considerable snow accumulation, have the warming impact on the cryolithozone and condition the formation of supra- and intra-permafrost taliks. Three main morphogenetic types of the karst are developed on the Prilensko'e Plateau: naked, covered and soddy one. Karst sinkholes, ponors, dry channels, disappearances of the rivers, karstholes, karren, etc. represent the classic superficial and underground karst. Solutional denudation rates for the territory researched were estimated by three methods and showed the following figures: 9,43mm/ ka by J. Corbel, 11,7 - by M. Pulina and 12,9 mm/

ka by F. Gombert (maximum potential dissolution of the limestones). Whimsical and picturesque karst pillars - Lena Pillars are the emblems of Natural Park. On-going development of the pillars is controlled considerably by the following geomorphologic processes: frosty and cryohydration weathering, karst, gravitational-slope and fluvial processes. Cold karst of Natural Park 'Lena Pillars' is being of outstanding value internationally and nationally.

Stable isotope analyses of freshwater tufa sites and karst springs in the Mecsek Mountains (Southern Hungary)

Gabriella Koltai (University of Szeged), Sándor Kele (Hungarian Academy of Sciences), Ilona Bárány-Kevei (University of Szeged)

Annually laminated freshwater carbonates are of particular importance in paleoenvironmental studies since they are considered to be suitable for high-resolution analyses. The present study focuses on freshwater tufa sites located in the Mecsek Mts (Southern Hungary) as possible sources for paleoclimatic research. Water samples have been collected for ^{18}O and ^2D analysis on a regular basis and basic physicochemical parameters such as water temperature, pH and conductivity have been measured monthly in situ since September 2011. Stable-isotope analyses of the investigated karst springs revealed unambiguous differences between the Eastern and Western Mecsek. The possible cause of this difference could be the so-called 'altitude effect', which is stronger concerning the higher Eastern Mecsek, than the lower Western Mecsek. At some springs (e.g. Anyák-kútja) monthly differences can be observed in the isotope composition of the karst water, reflecting seasonal changes in precipitation. The ^2D and ^{18}O data of the investigated springs from the Mecsek Mts fit to the Global Meteoric Water Line, indicating their meteoric origin. Recently deposited riverine tufa samples were also collected for ^{18}O and ^{13}C measurements; furthermore core drillings were carried out at four tufa sites for future investigations. Comparing our stable isotope data with the database established by Andrews et al. (1997), the samples from Mecsek Mountains are similar to the tufas collected in Poland and in the Dinaric Karst concerning ^{18}O values, reflecting the effect of continentality compared to the tufas collected from Western-Europe (Andrews 2006). The ^{13}C values of our tufa samples are isotopically light and fluctuate between -9.0 - (VPDB) and -11.6 - with a mean value of -10.3 ‰, suggesting strong soil-zone CO_2 contribution. An investigation of land cover patterns in Hungarian karst areas between 1990 and 2010 with special regard to forests

Eszter Tanács (University of Szeged), Ilona Bárány-Kevei (University of Szeged)

The most important forms of economic activity in karst areas are usually agriculture, forestry, water management, limestone extraction, and tourism (Watson et al. 1997). Agriculture, forestry and to a lesser extent quarrying strongly affect the karstic landscape and thereby tourism; they also influence both the quality and quantity of the water supplies. Their major changes are well reflected in the land cover making it possible to retrace changes over time. The aim of the present research was to investigate land cover patterns in Hungarian karst areas after the democratic transformation in 1989 with special regard to forests. First, CORINE land cover maps from all available dates (1990, 2000 and 2006) were used in order to investigate tendencies of change at the landscape level in the land cover. A time series of vegetation indices (NDVI, NDMI) calculated from LANDSAT TM and ETM+ imagery were used for local change detection in the forest cover in two of these areas, Aggtelek Karst in North-Hungary and Mecsek Mts. in Southwest-Hungary. Temperate deciduous forests indeed play an important role in Hungarian karstic landscapes; the studied areas all have at least 75% forest cover. Thus forestry policy, wood prices and demand may have a fast and direct effect on our karst areas, also leading to regional differences. Between 1990 and 2000 the total land cover change in the karst areas was ~7%, most of which consisted of reforestation following the abandonment of former agricultural areas and the conversion of arable land to meadows. Between 2000 and 2006 changes were even less significant, only 2.8% of the total area, mostly related to the cycles of traditional forest management operating with clear-cuts. However the forestry law of 1996 limited the maximum area of clear-cuts in mountainous areas to 5 hectares, so while locally they still influence the karstic environment, they would not often appear on large-scale land cover maps. The welcome shift in paradigm towards continuous forest cover may result in an apparent lack of change in the land cover at the landscape level while hiding important dynamics at the local level. The two highlighted areas are very differently affected by forest management; the interests of conservation are much better observed if not challenged by short-term economic interests. Investigation of soils on the slopes of sinkholes in nature reserves

Maria Smirnova (Moscow University), Alexander Gennadiyev (Moscow University)

Karst landscapes are widely spread all over the world and some of them are negatively impacted by human activities such as agriculture, mining, industry and so on. For successful management, conservation of karst landscapes and estimation of human

impact on such fragile ecosystem it is important to study components of these landscapes in nature reserves. The problem addressed in our work is related to the research of soil catenas on the slopes of subsidence sinkholes in natural reserves. It is based on field research of 24 soil catenas in the north and south of taiga zone, broad-leaved forest and steppe zone in European Russia. Our work is devoted to the comprehensive analyzes of soil formation on the slopes, changes in morphological, physical and chemical soil properties from top to bottom of sinkholes and the assessment of contrast among soils within soil catenas. We studied soil erosion within the slopes of sinkholes beneath the forest and steppe vegetation by the method of magnetic tracer. The main feature of soil cover in karst landscapes is a considerable variety of soils within relatively small areas and their high complexity. Soil development in these landscapes is affected by an ancient and modern denudation processes. Current research showed that the thickness of humus horizon increases and the content of organic matter decreases from top to bottom of sinkhole slope. Textural metamorphic and calcic horizons lose their morphological properties such as structure and texture from top to bottom of sinkhole slope. Soils from the bottom of the slopes have more in common rather than soils from the top of the slopes regardless of landscape and morphological properties of sinkholes. Soils in sandy soil catenas are more contrast among each other than soils in loamy and clay soil catenas. Water-filled sinkholes bottoms lead to the increased soil contrast within soil catena in comparison with other sinkholes.

Global Environmental Change, economic globalization and increasing social vulnerability of local communities in Atacama Desert

Hugo Romero (Universidad de Chile), Magaly Mendonca (Universidade de Santa Catarina), Pamela Smith (Universidad de Chile), Manuel Méndez (Universidad de Chile)

Global climate change and economic globalization are both together threatening rural and indigenous people local communities living in Atacama Desert Andean highlands, i.e. Chilean mountains and plateaus located between 18 and 27°S and above 3.000 heights. Global Circulation Models predict important reductions in precipitation and increments in temperatures, especially in some specific and meaningful water source areas such as freshwater and salty lakes, lagoons and groundwater bodies. Desertification trends should be added to large interannual precipitation variability that are, in turn, a complex and dynamic result of spatial interactions among South American Monsoon, El Niño-Southern Oscillation, the Pacific Decadal Oscillation and the Antarctic Oscillation. It is expected a crisis of water availability and an increasing hard competence between mining, agriculture, nature conservation and urban uses. Public policies and integrated watershed management practices are being urgently required in these landscapes. Global economy, on the other hand, is meaning the investment of more than 80.000 million US dollars in export oriented copper, gold, lithium and other mineral ores only at the current decade. Water requirements of such mining installations are meaning outstanding decisions in terms of social vulnerability of local communities. Mining companies are particularly interested in a water re-allocation process that based on an accentuation of privatization and commodification of water rights; finally replace domestic farming and grasslands for more economic efficient uses. For the government and national and foreign mining companies decertification of natural conservation areas is another important goal to ensure water availability. In spite of critical situation of water resources in Atacama Desert there are not explicit public policies nor did management instruments that could control social vulnerability and avoid natural and social collapses that can be anticipate everywhere.

The significance of land use on ecosystem health and soil organic carbon in Iceland

Guðrún Gísladóttir (University of Iceland), Egill Erlendsson (University of Iceland), Rattan Lal (University of Iceland and Ohio University)

The Icelandic natural environment is highly dynamic, and the climate has been the principal control of ecosystem variability prior to the Norse colonisation around AD 874. During the post-settlement era, drastic change in Iceland's ecosystem has been influenced primarily by human activities. Healthy ecosystem, soil and vegetation, is not only an important resource to meet human demands but also a prominent sink of atmospheric CO₂. In contrast, soil erosion and land degradation are major sources of atmospheric CO₂. This paper discusses the impact of climate change and human activities on vegetation, soil erosion, and soil organic carbon (SOC) in some soils of Iceland. Analyses conducted include pollen in Histosols and lake sediments, soil properties, soil accumulation, SOC in Histosols and Andosols, and terrestrially-derived SOC in lake sediments. The pre-settlement landscape was not entirely stable, and relatively small differences in climate may have caused subtle changes to the terrestrial environment. However, the Norse colonists and subsequent occupants caused drastic alternations in the environment and exacerbated environmental deterioration, and the magnitude of alteration was spatially variable. The farmed lowlands were largely deforested during the early Norse colonisation, which reduced an important habitat for fragile biota and caused degradation of soils. The late-Medieval climatic change put further stress on the terrestrial environments, to beyond the threshold of ecosystem resilience. The vegetation denudation accelerated soil erosion, with attendant redistribution of soil over the landscape, and decline in its quality. Vegetated areas became important sinks for wind-transported soils, as evidenced by increase in deposition and bulk density, increase in susceptibility to soil erosion, and decline in SOC content. Despite decrease in SOC content, the high sedimentation rate and elevated bulk weight resulted in higher SOC sequestration at these sites, even though soil quality declined. The potential soil C sequestration in adjacent sparsely or devegetated soils were highly impaired and along with soil mass losses these areas became important sources of anthropogenic CO₂. The analyses of lake sediment show an increase in C fluxes during the periods of major landscape instability in the post-settlement era. These trends indicate that the surrounding organic soil was being eroded and transported into the lake. Barren sites lost soil cover and SOC pool, resulting in net loss of soil resource and SOC reserves.

Understanding the Endogenous Dynamics of Environmental Degradation in Northern Togo

Bernhard Martin (University Halle-Wittenberg)

Since three decades in northern Togo various processes of environmental degradation could be observed, in particular the sharp decline in tree vegetation and soil degradation. The reasons for that are complex: Successful attempts of agricultural modernisation led to the introduction of ox-plowing, cotton and hybrid maize and to an increased use of chemical fertilisers. The new techniques led to the give up of former, ecologically more sound farming practices and to deforestation. The lucrative growing of cotton created new consumer needs. The cultivation of maize led to new food habits. However, these changes were heavily disputed between younger and elder people. Thus the agricultural modernisation involved also local conflicts regarding modernity and concepts of life. In addition new consumer needs of rural young people, urban energy needs and profit interests of local traders caused the expansion of firefuel and charcoal production. These contribution wants to sensibilise to the social backgrounds of the processes of environmental degradation in peripheral rural African areas.

The use of soil chrono-sequences in studies of ecological succession under changing climatic conditions

Aaron Yair (University of Jerusalem)

Chronosequences of soil characteristics represent an important tool in the reconstruction of past climatic changes over millennial time-scales. They are sometimes used for studying temporal dynamics of plant communities under changing climate and soil conditions. The northern Negev desert offers unique conditions for the study of the environmental effects of loess deposition, during a wet climatic phase. The loess mantle was deposited directly on rocky hillslopes devoid of soil cover. The loess mantle buried a preexisting well developed drainage network. A comparative study of the environmental characteristics of a dry rocky area with a wetter loess covered area, allow us to describe and analyze the environmental effects of loess deposition. Average annual rainfall in the rocky area is ~ 90 mm; while in the loess covered area it is ~175 mm. Pedological, botanical and zoological data clearly indicate that the loess covered, wetter, area is more arid than the drier rocky area. The explanation proposed for the desertification effect of the loess deposition, during a wet climatic phase is as follows. Most rainstorms in the study area are characterized by their low rain intensity and very short duration of most rain-showers. Under such conditions the loess mantle; rich in fine grained particles, is able to absorb all rainwater at most rainstorms. The high water absorption of the loess results in shallow water penetration. Infiltrated waters are afterwards lost by the high evaporation losses during the lengthy intervals between successive rainstorms. An opposite effect is characteristic of rocky areas. The quick hydrological response to rainfall of rocky hillslopes results in the concentration of runoff water from extensive contributing

rocky areas into a limited adjoining collecting soil-covered area the process of water concentration leads to deeper water penetration and water preservation, beyond that allowed by direct rainfall, limiting thus evaporation losses.

Principles of spatio-temporal evaluation and the cause-and-effect relations of desertification in Republic of Armenia (RA)

Ashot Khoetsyan (Yerevan University), Susanna Khachatryan (Yerevan University)

The cause-and-effect relations of global climate change, decreasing biodiversity and the enlargement of the desertification habitat have been central issues in geographical studies from the second half of the XX century. Desertification can be attributed to a number of local and global natural and socioeconomic factors. Especially intensive desertification can be observed in tropical and subtropical regions of the planet, where the arid mountainous territory of Armenia is located. Main natural and socioeconomic factors resulting in environmental degradation and desertification in the territory of RA have been explored in the present study. Analysis has identified the following findings: The Republic of Armenia is geographically located in a high desertification risk zone. This is underpinned by contemporary socioeconomic conditions and the faulty system of nature management. Desertification is especially intensive in the arid and sub-arid landscapes of RA, located between 400-1500 m. Given the vertical (mountainous) nature of the landscape, environmental degradation freely progresses from one zone to another. While modeling the desertification processes in RA, numerous natural and socioeconomic factors have been identified. Nonetheless, a few dominant factors are responsible for the environmental vulnerability: aridity coefficient, atmospheric moistening coefficient, draught frequency, number of rainless decades, nature management culture, public awareness, etc. Main factors of the spatio-temporal dynamics of main desertification factors have been identified utilizing contemporary objective graphical-analytical methods (correlations, regressions, dynamic aridity spectrums, probability calculations, modeling, chronoisopleths, hydroclimatological analysis of the formation of surface water drains, evolutionary analysis of landscape formation, development of synthetic and assessment draught maps, desertification risk, etc.). The effect of contemporary socioeconomic and political situation in the country on the desertification process has been assessed (hasty privatization of land, the level of ecological degradation of land, imperfections in nature management legislation, military action, transportation blockade, strong migration trends, etc.). Not only technical, but humanitarian sciences have to take part in the fight against one of the central issues of sustainable human development, desertification. This ultimately requires higher nature management culture, stronger 'bottom-up' public motivation in the fight against desertification. Recommendations are provided for most

efficient forms and technologies of decreasing the vulnerability of the territory of RA against desertification. Those can serve as a basis for a state anti-desertification program.

Land Degradation in Semi-arid Region: Assessing Wasteland Distribution and Reclamation in Dhaulpur District, Rajasthan, India

Rama Prasad (University of Rajasthan), Rani Singh (Kanoria PG Mahavidyalaya)

Land degradation will remain an important global issue for the 21st century because of its adverse impact on agronomic productivity, the environment and its effect on food security and the quality of life, which ultimately has resulted in wastelands. Land on India suffers from varying degrees and types of degradation, stemming mainly from unstable use and inappropriate management practice. It manifest chiefly in the form of water erosion followed by wind erosion, bio-physical and chemical deterioration. In India vast tracks of lands (20.17% of total geographical area) exists as wastelands. In Thar Desert of region of Rajasthan, in India land degradation is occurring at an increasing rate. The region contains more than 2lacs sq. kms of arid land has a fast growing human population and increasing livestock number, all of which accelerate damage to fragile arid landscape. The present study juxtaposes the view of land degradation with the increase in wasteland in eastern most part of Rajasthan where whole economy is dependent on agriculture. Here, land degradation is a dominant problem. Over 40% area is affected by various categories of wasteland. Gully and ravine erosion is severe problem along the river Chambal (only perennial river in state), which has a calamitous effect on the agro-economical activities of the area. Overgrazing and salinity are other problems causing degradation of land. Prevailing of semi -arid climate, the area is renowned for its badland topography. Objectives are to evaluate the Tehsilwise distribution, trend and characteristics of 10 years interval, to identify the various environmental and anthropogenic factors responsible for land degradation,

Estimate of the structural stability using the pedotransfert functions: Application to Cheliff soils (Algeria)

Hamel Zineb (Hassiba Ben Bouali University)

The physical properties of soil have been the objective of many studies in recent decades. These properties are difficult to measure because of the requirements in terms of date of sampling, sample storage, heaviness of the protocols and the cost of measurement. Early studies have been designed to establish relationships to estimate the structural stability of soils from the characteristics of the soil more easily accessible. These relationships, or pedotransfer functions (PTF) as they are called in recent years are in fact a heterogeneous soil properties that tell us about the behavior of soils under rain or irrigation. These pedotransfer functions were determined on groups of soils from different stratifications. The PTF selected by various stratifications are applied to land in the Lower

Cheliff (Algeria). The results show that the soils in Cheliff (Algeria) are very diverse they belong to the group of stable, unstable soil. Their behavior towards the action of water is clearly different.

Estimation of water resources in the high-mountainous regions of Georgia on the background of the climatic change

Besik Kalandadze (Iv. Javachischvili Tbilisi Universitaet), Vazha Trapaidze (University Georgia)

Georgia is a high-mountainous country, with 54% of its territory (approximately 37.000 km²) located over 1000 m hypsometrical altitude above the sea level. The mountainous type of the territory of the country and abundant atmospheric precipitations result in the height of flow layer of 757 mm per square kilometer. With this indicator, Georgia ranks first in the world. The high mountainous region of Georgia is rich in underground waters and their reserve amounts to 15 km³. There are about 1000 mineral sources with the daily output of over 100 mln. l. registered on the territory. There are 30.000 mln. m³ ice accumulated in the glaciers of the high-mountainous regions, with 5% of the given mass contributing to the feeding the rivers. Numerous rivers of the regions are typical high-mountainous rivers well characterized by the factor most important for high power potential - great fall per length unit. If considering that the strength of the river water current is proportional to the product of the river fall and water discharge, the great resources of the high-mountainous rivers of Georgia are clear. Due to the climatic change in recent twenty years, the flow of the rivers and intensity of the glaciers melting will have different reactions and therefore, their hydrological regimes have changed evidenced by sharp variation of the peaks of maximum and minimum levels and water discharge in different seasons. Large-scale evaluation of the water resources and elements of the regime of flow of the rivers in the high-mountainous region of Georgia is of a great importance to ensure the sustainable development of the eco-systems in the mountainous regions.

Concepts of soil erosion by shallow flowing water – deconstructing the models

Manuel Seeger (Trier University), Stefan Wirtz (Trier University), Mazhar Ali (Wageningen University)

Physically or process based soil erosion models describe sediment detachment and transport by flowing water as the interaction of the soils' resistivity to be eroded, the force of the water to entrain particles and its capacity to transport them in suspension. This has led to concepts in which hydraulic parameters as flow velocity and composite parameters such as shear stress, stream power etc. are set into a direct relation. Soils' resistivity to erosion is in general represented as a threshold problem, in which a critical value is trespassed and the following increase of erosion is considered a soil constant. Despite considerable efforts, the process based model concepts have not been able to produce more reliable and accurate reproduction and forecast of soil erosion than 'simple' empirical models such as the USLE and its derivatives. Therefore, there still remain some unanswered fundamental questions about soil erosion modelling: 1) What are the main parameters of soils and flowing water influencing soil erosion?, 2) What relationship do these parameters have with the intensity and different types of soil erosion?, 3) Are the present concepts suitable to describe and quantify soil erosion accurately? To elucidate the influence of basic parameters as grain size, slope, discharge and flow velocity on sediment transport by shallow flowing water laboratory experiments were performed in a flume. Variable flow was applied under different slopes on mobile beds of non-coherent substrates. Field experiments were designed to quantify the hydraulic and erosive effects of small rills in the field. Here, small existing rills were flushed with defined flows, and flow velocity as well as transported sediments was quantified. The laboratory flume experiments clearly show a strong influence of flow velocity on sediment transport, depending this at the same time on the size of the transported grains, and the sediment concentration. It is also shown that hydraulic parameters are not able to predict the combination of sediment detachment and transport. Moreover, the relationship between flowing water and sediment transport is shown to be complex, depending on the morphological evolution of the bed. The field experiments confirm these results, and also show that under variable conditions higher transport rates than those predicted by different model concepts are possible. Soil erosion by flowing water is much more complex than reflected in model concepts: they neither reflect the process variability nor the interaction between the different dynamic parameters of flow and soils. We conclude that mechanistic concepts, in which simple or composite predictors define the dynamics of soil erosion, can not succeed in soil erosion modelling.

Prioritization of sub-watersheds using extracted Cartosat-1 DEM derived morphometric and natural parameters by AHP

Akanksha Balha (TERI University)

Soil erosion is a kind of land degradation process. Categorizing a watershed on the basis of its soil erosion response and prioritizing it correspondingly at the level of sub-watershed helps the decision makers and planners to decide and implement their plans accordingly. Catchment area of proposed Bhugad Reservoir in Damanganga Basin, Maharashtra state, India, covering an area of 710 sq km and having an elevation range of 38m to 866m is chosen as the study area. Physiographically, the study area has a rugged and hilly terrain. Twelve ground control points and twenty seven tie points have been taken on four stereo-pairs of Cartosat-1 satellite to extract a Cartosat-1 DEM at 10m resolution using high resolution Carto-DEM and orthoimages at an RMSE of 0.32 pixels. The extracted Cartosat-1 DEM has been used for hydrological analysis to delineate eleven sub-watersheds with area varying from 42 sq km to 96 sq km. The origin of all hydrological and geomorphological phenomenon is a watershed, hence it has been considered as the basic unit for the study. To study the behavior and the hydrological processes within a watershed, morphometric analysis of the basin has been done. Various morphometric parameters of the watershed are calculated, analyzed and all the eleven sub-watersheds are prioritized on the basis of their soil erosion response towards morphometric parameters using AHP. AHP is a decision making method which quantifies the comparative priorities for a given set of parameters on a ratio scale and puts stress on the significance of judgement and knowledge of decision makers. Another methodology of prioritizing sub-watersheds on the basis of their soil erosion response towards natural factors like vegetation, soil characteristics, slope and etc using AHP has been done. Then a comparison between the two methodologies has been made and respective interpretations are made. The study would help in taking up suitable soil conservation measures resulting in suitable planning and sustainable watershed management.

Gully Erosion and Land Degradation in Semi-arid Environments – Monitoring, Quantification and Assessment

Johannes Ries (Trier University), Irene Marzolf (Johann Wolfgang Goethe Universität), Manuel Seeger (Trier University)

Gully erosion is considered one of the most important soil erosion processes, but its contribution to the total soil loss needs to be discussed. If gullies, and not interrill and rill erosion processes are the most effective source for the siltation problems in reservoirs in semiarid landscapes, strategies to combat land degradation need to be changed significantly. Despite the efforts made to understand the occurrence and development of gullies, there is still a lack of knowledge in spatio-temporal dynamics, on the range of headcut and sidewall retreat, on the factors leading to gully formation and growth as well

as on the influence of human activity, causing misinterpretation of volume rates. This paper presents results of several research projects on gully monitoring between 1995 and 2011 which employed large-scale aerial photography taken from remote controlled platforms. The resulting high-resolution images (pixel sizes < 10 cm) are used for photogrammetric and GIS analysis in order to quantify gully development with linear, areal and volumetric measurements at various sites in small to medium-scale catchments in semi-arid landscapes of Spain and Morocco. The monitoring results from high-resolution aerial photography are combined with the characterisation of the gully catchments (mapping of soil surface types and geomorphology) and the analysis of the relationship between runoff patterns and infiltration behaviour (rainfall simulations). Natural rainfall characteristics and catchment sizes are included. Additionally this study investigates how medium-term gully-development data (7-13 y) differ from short-term (1-2 y) and long-term data (20-50 y). The results show an extremely high spatial and temporal variability of gully development in an order of more than two magnitudes, being almost independent from the size of the contributing catchment and rainfall characteristics. Gully area loss varies by a factor of 25 and gully volume loss by a factor of 200. For these, sidewall erosion may play a considerable part. The short-term gully volume changes observed at the individual gullies show very high variability: on average (median of all gullies), the maximum headcut change observed in 7-13 years was 14.3 times larger than the minimum change, but the degree of fluctuation varies strongly between the gullies. The varying negative and positive influence of land use and human activities - especially on connectivity of surface flow to the headcut - appears to play a dominant role, both for short-term variability and medium-term difference in gully development. The study proves the value of capturing spatially continuous, high-resolution 3D data using small-format aerial photography for detailed gully monitoring. In particular, human activity on varying time scales and its positive or negative effects on runoff production and connectivity need to be considered as an important factor for gully-erosion variability.

Terrestrial laser scanning for detailed topographic analysis of slopes affected by large tsunamis

Takashi Oguchi (University of Tokyo), Yuichi S. Hayakawa (University of Tokyo), Hitoshi Saito (University of Tokyo), Akitoshi Kobayashi (University of Tokyo)

A massive earthquake of $M = 9.0$ occurred on Friday 11 March, 2011, off the Pacific coast of northeastern Honshu, Japan. This has been the largest earthquake ever recorded in Japan. The earthquake triggered destructive tsunami waves that struck the Pacific side of Japan, traveling up to 10 km inland. The total number of dead and missing people due to this disaster is about 19,000, and more than 125,000 buildings were damaged or destroyed. The damage caused by the tsunami waves was much greater than that by ground motion due to the large earthquake. We investigated the impact of the huge tsunami on landforms in the coastal area. The tsunami waves destructed numerous buildings and other artificial objects, and they contained sandy and muddy

grains transported from the sea bed. However, erosion and deposition on flat lowlands and valley bottoms were unexpectedly limited. In contrast, side-slopes of valleys along a ria-type coast often underwent erosion including the removal of vegetation, soil, and regolith, and even bedrock may also have been modified due to strong wave action. To understand the characteristics of landforms affected by such erosion, we conducted field surveys in some valleys and collected high-resolution 3D topographic data using a terrestrial laser scanner (TLS). The targets of scanning include both relatively broad valley-side slopes and specific landslides caused by tsunami waves. One of them is the valley of Aneyoshi, where the maximum tsunami run-up height was measured (38.9 m). The results indicate some differences of the surveyed slopes from usual slopes. For example, nearly vertical segments often occur at lower slopes although they are almost free from erosion by normal coastal waves and rivers. Historical and sedimentological records indicate that the study area experienced multiple large tsunamis in the late Holocene. Erosion by the repeated tsunamis seems to be responsible for the observed unique slope shapes. In other words, topographic characteristics of slopes may be used to identify areas with high risk of large tsunamis.

Chair: Guðrún Gísladóttir, Paul F. Hudson

Soil development within late Holocene glacial chronosequence of Skaftafellsjökull glacier, SE-Iceland

Guðrún Gísladóttir (University of Iceland), Olga Vilmundardóttir (University of Iceland), Rattan Lal (University of Iceland and Ohio University)

Worldwide glaciers are melting due to a warmer climate, exposing surfaces where weathering and new soil formation commences. Since the end of the Little Ice-Age, Icelandic glaciers have been retreating after reaching their maximum extent in 1890, leaving behind deposits of glacial till of basaltic rock fragments mixed with tephra. The presence of end moraines mark the location of the glaciers' terminus, and a chronosequence can be established along proglacial areas. In a chronosequence, it is hypothesized, that except time, all other soil forming factors (climate, parent material, biota, and topography) remain unchanged. Thus, it is possible to assess the role of time on the rate of pedologic processes. As soils develop, organic carbon accumulates in the soil. In fact soils encompass the largest terrestrial carbon pool containing ~1500 Pg of organic carbon in the upper 100 cm. Sequestering carbon in soil is an option of mitigating climate change. Thus, the aim of this research was to investigate how the soil develops over time, determine the rate at which carbon is sequestered in the soil under natural circumstances, and to study the relationship among soil properties, landscape and vegetation. The research was conducted at Skaftafellsjökull glacier, SE-Iceland. Soils in different stages of development were sampled along three moraines representing surfaces of ~ 8, 65 and 120 years. Several parameters were analysed to investigate early stage soil formation and its relation with time; formation of A-horizon, bulk density, organic matter, organic carbon and nitrogen, soil reaction (pH), and clay content. To compare the properties under a mature ecosystem, which may develop on the glacial moraines in the future, soils were also sampled in the birch forest on the Skaftafellsheiði heathland adjacent to the glacial moraines. The data indicate that after 120 years of development, the proglacial soils are still young compared with the older soil under the birch forest. Bulk density decreased with time as did the soil pH, and these changes were more evident in the 0-10 cm than 10-20 cm depth. The formation of A-horizon and the proportion of organic matter and soil organic carbon increased over time. After 120 years, the A-horizon was 8 cm thick and the soil contained 19.6 Kg C m⁻³ of organic carbon. When compared to the organic carbon of 29.7 Kg C m⁻³ under the forest soil, it was apparent that the soil had not yet reached its climax carbon sequestering capacity. Further, the young soils contained a substantial amount of secondary clay minerals characteristic of soils of volcanic origin, but the increase in the concentration with age was not clear. The research is funded by the University of Iceland doctoral fund, the

Landsvirkjun's Energy Research Fund, and Targeted Investment in Excellence, Climate, Water and Carbon Project, C-MASC, OSU, Columbus, OH, USA.

Complexity and local-scale variability in floodplain geomorphology along a heavily managed fluvial system: A lowlands perspective from the Nederrijn-Lek River (Rhine), Netherlands

Paul F. Hudson (University of Texas/ University of Amsterdam)

Flood management alters fundamental fluvial processes that have consequences to rivers and floodplains. This paper examines overbank sedimentary deposits and floodplain morphology of the Lek-Nederrijn River, the second largest tributary of the modern Rhine delta. Historic and modern geomorphic, hydrologic, and sedimentary data from field and archival activities are examined in relation to different types of historic floodplain uses and management approaches. In view of the modern system representing a mosaic of different human impacts superimposed upon a dynamic system, this study addresses the degree to which the modern system is disrupted. Specifically, the study quantifies the magnitude of disruption of sedimentary deposits from natural or theoretical patterns. The sediment size channel banks displays considerable spatial variability, but lacks an overall downstream fining trend. Although lateral fining trends are observed, they vary from typical natural levee patterns because of the influence of engineering works. Despite having ample time for natural levees to form, the morphologic expression largely lacks the pattern observed in natural systems. The results have implications to floodplain rehabilitation, which should consider the sedimentary and morphologic framework in which floodplain restoration occurs.

Influence of landform and land use on soil properties of the Sikkimese Himalayan piedmont in India

Pawel Prokop (Polish Academy of Sciences), Dominik Ploskonka (Polish Academy of Sciences)

Quaternary piedmont deposits of Sikkimese Himalaya built a system of fans decreasing in elevation from 200 m a.s.l. at the mountain front to about 100 m a.s.l. within a distance of 10 km. The alluvial surface is dissected by the braided mountain rivers and forms several extensive terraces. The higher elevated terraces are stable landforms, while lowest ones are frequently flooded in effect of heavy monsoon rains reaching 4000-6000 mm annually. The piedmont zone was under natural forest up to the second half of the 19th century when the foundation of tea plantations and laborers migration caused rapid deforestation. As a result, higher elevated terraces were taken under cultivation of tea, while active floodplains were converted to paddy rice fields. Fifteen soil profiles representing main landforms and dominant land use - forest as reference sites, tea plantations and paddy rice cultivation were elaborated within an area of 170 km² in piedmont zone. The morphological and physico-chemical characteristics of soils from

higher terraces and active floodplains revealed two distinct stages of pedogenic development: A-(Bw)-C and A-C with soil classified as Inceptisols (Dystrudepts) and Entisols (Fluvaquents) respectively. Old, stable landforms, good drainage conditions of Inceptisols result in rapid leaching and enhancement of the weathering process, giving rise to thick humus horizon, thereby lowering the pH (4-5) and development structural Cambic horizon. However, maintained tea garden soils are characterized by thinner A horizon and lower organic matter content in comparison to forest soils. Entisols of active floodplains, imperfectly drained, without any diagnostic horizon except ochric epipedon, show little alteration of the original deposits and higher pH (5-6), because they receive new sediments faster than the assimilation of previous material into the genetic horizons. Textural stratifications are the effect of fluvial genesis. Along with the increase of the distance from river bed, and continuous soil tillage operations on paddy rice fields they result in organic matter depletion in comparison to forest soils. Topography of the land along with the time factor and nature of parent material played a main role in the genesis of piedmont soils. About 130 years of monoculture cultivation of tea and rice significantly modified morphological and physico-chemical soil properties within different landforms.

Environmental and socioeconomic consequences of gully erosion in agricultural areas (Lublin Upland, East Poland)

Wojciech Zglobicki (Sklodowska University), Bogusława Baran-Zglobicka (Sklodowska University), Leszek Gawrysiak (Sklodowska University)

The Lublin Upland is an important agricultural region in eastern Poland owing to the occurrence of Luvisols and Cambisols. At the same time, the natural conditions and long-lasting agricultural activity have led to the formation of a dense network of permanent gullies. In some places, their density exceeds 11 km/km². The total length of gully forms in individual gully systems can exceed 15 km. The largest gullies are 20-25 m deep; their width is similar. The formation of gullies entails several environmental and socio-economic consequences. Most of the socioeconomic consequences are unfavourable from the human perspective. Gully erosion processes can thus be regarded as a land degradation factor. Gullies reduce the size of land that can be used for agricultural purposes, impact the conditions of agricultural production (changes in hydrologic conditions, difficult access to the fields), and increase the frequency of local floods. This study investigated 43 rural districts in loess-covered areas in the Lublin Upland. The permanent gullies in the study area cover a total of 61 km². An attempt was made to assess the correlation of the selected indicators reflecting the state of the environment and the socio-economic development of the rural districts with the size of the area covered by the gullies within the territory under study. The indicators analysed included: forest cover, area of arable land, size of agricultural holdings, revenues of the districts, population density, and balance of migration etc. The project has been financed by Narodowe Centrum Nauki - the National Science Centre (project no. NN305 262840).

The effects of gully erosion and land use changes on environment and socio-economic status of Lower Chambal Valley India

Padmini Pani (Jawaharlal Nehru University)

The natural environment of an area has always a certain degree of influence on society. Land degradation due to gully erosion is one of the key environmental challenges which affect the sustainability of the ecosystem. In the present paper an attempt has been made to study the effects of gully erosion and land use changes on the environment and its impact on the socio-economic status of Lower Chambal Valley of India. The lower Chambal Valley of India is considered as an ecologically fragile region over the years due to the vast ravenous tracts along the river Chambal. The selected study area is a part of

Morena district of Lower Chambal Basin India. The striking feature of the area is the ravines in the form of dissected landscape which are difficult to cross and unsuitable for cultivation. The formation gullies in the area causes not only the loss of fertile soils but also shifting of agricultural lands due to the advancement of gullies. The mechanism and rate of gully development has been studied in the region for several years. Areal extent of gully erosion was measured using Indian Remote Sensing satellite images. The land use changes due to gully erosion have severe impact not only on the agricultural productivity but also on the poverty. The decade-long history of land use change has been recorded from the time-series digital satellite images. The study comprises in two steps. Firstly the land use changes have been estimated along with the intensity of the ravines and secondly the affects of these changes on socio-economic status have been investigated. The relationship between gully erosion and land use change has also been considered and its effect on society has been discussed. One of the major indicators of the impact on society is the development of the villages. The villages found within the ravenous zone are comparatively less developed than the villages out side the ravines. It is inferred that the local people are also aware of the processes of land degradation. Loss of agricultural land due to spreading of the ravines along the marginal lands has long been considered as a major threat to the local farmers. It was found that people surviving mainly on the agricultural resources of this area have developed a range of coping strategies to cope up with the impacts of land degradation. These strategies ranged from collective action at the community level to micro-level coping strategies at the level of the households or the individual. The pattern of gullies has also an impact on the development of marginal lands which ultimately effects the agriculture production. The results reported in the study suggest that natural environment certainly play a key role in the development of the society. Key Words : gully erosion, land degradation, ravines, marginal lands

Pyrogenic polycyclic aromatic hydrocarbons in soils

Anna Tsibart (Moscow University), Alexander Gennadiyev (Moscow University)

Polycyclic aromatic hydrocarbons (PAHs) are priority organic pollutants composed of fused benzene rings. Natural and anthropogenic processes generate PAHs during the incomplete combustion of all types of organic matter. But the connection between combustion conditions (temperature, oxygen amount and scattering of combustion products), type of burning material and PAHs accumulation in soils is not covered in literature. One of the most important combustion properties is scattering of combustion products. Intense scattering of combustion products takes place during wildfires. The PAHs accumulation in soils was studied in three different Russian natural reserves (Norskii, Khakasskii, Polistovskii natural reserves) affected by forest, steppe and peat fires. Conditions of limited scattering of combustion products appear during domestic wood combustion. For studying PAHs accumulation under these conditions we chose a site with stove heating (village Verchnie Dachi, Moscow Region). Weak scattering of combustion products is observed during processes of coal dump combustion. We

investigated burning gangue dumps of Kuznetskii coal field (Kemerovo Region). Soil samples were analyzed for 12 compounds: fluorene, naphthalene, phenanthrene, chrysene, pyrene, anthracene, benz(a)anthracene, benz(a)pyrene, benz(ghi)perylene, retene, coronene, benz(e)pyrene. Identification and quantification was carried out by high resolution Shpol'skii spectrofluorometry. Under conditions of intense scattering of combustion products during wildfires PAHs accumulation in soils was low. The difference of PAHs concentrations in affected and background soils did not exceed 10 times. Type of burnt vegetation had an effect on pollutants amount in soils. Wildfires in coniferous forests and peat bogs tended to give higher absolute PAHs concentrations in soils (to 100-150 ng/g) than steppe wildfires (to 30-40 ng/g). PAHs distribution in fire-affected soils also depended on soil type. Mineral soils had maximum of concentration in surface horizon and in peat soils the highest concentrations of pollutants were detected at depths of 5-10 and 10-20 cm. Limited scattering of combustion products during wood heating favoured intense PAH accumulation in upper soil horizons (to 1000 ng/g). Under conditions of weak scattering of combustion products derived from coal dumps PAHs accumulated across the soil profile (to 500 ng/g). Soils subjected to forest fires contained higher concentrations of chrysene, benz(a)anthracene, retene, phenanthrene, benz(ghi)perylene. Peat-fire affected soils showed prevalence of pyrene, naphthalene, benz(a)anthracene, phenanthrene, chrysene, benz(a)pyrene. Grass combustion during fires favoured the accumulation of low weight PAHs (fluorene, naphthalene) in soils. Combustion of coal particles in gangue dumps gave naphthalene, phenanthrene, retene, fluorene.

Ep-seated landslides and accretionary prism with reference to Kii Mountains, Japan

Hiroshi Suwa (University of Tokyo)

Typhoon Talas in 2011 brought about heavy rainfall of more than 1000 mm in a few days at many gauging stations in Kii Peninsula, Japan. The rainstorm triggered many deep-seated landslides. The landslide closed river flows at more than 18 places to form landslide-dam reservoir. Then water level was artificially reduced to avoid secondary hazards from breach of landslide dam at 4 unsteady dams. The same area in Kii Mountains had experienced a severe landslide hazards also in 1889 which was triggered by heavy rainstorm of a typhoon whose trajectory was almost same as that of typhoon Talas. The 1889 hazard formed 53 landslide dams, most of which breached in less than a few days and brought about secondary dam-breach flood hazards to the villages along the rivers below the dams. The local government of Uchi-Yoshinogun County published a survey report of the hazard consisting of 11 volumes in 1891. The report records and explains the features in detail concerning the rainfalls, landslides, flash floods, loss of peoples, loss of properties, evacuation of local peoples, rescue activities, emigration of local peoples to a northern island: Hokkaido after the disaster during the 1889 winter and so on. Discussion combining the study of the 1891 report and field studies of the 1889

landslides and other 5 recent hazards including the 2011 typhoon Talas rainstorm hazard indicates the major incipient causes for deep-seated landslides at geologic belts of accretionary prism as follows. (1) Slopes consist of dip slope. The dip slope originates from a structure of accretionary prism. Otherwise it faces syncline axis. (2) The slope has break line on its mid position. The upper slopes including break lines are candidates for a next slide. This occurs due to large uplift rate due to a tectonically active movement of accretionary prism. (3) The slopes on outer side of winding. They are kept unstable by successive undercutting. (4) Both geomorphic indexes: drainage density and slope angle are large. This condition is equivalent to high frequency in steep and long slopes. (5) High infiltration capacity of the slope, which contributes slope instability under rain storm.

Land Classification Based on Sediment Yield Production (Case Study: Eyvanakey Watershed- Iran)

Mohammad Hassanzadeh Nafooti (Azad University), Moslem Chabok Boldaje

Sedimentation due to erosion in watersheds is regarded as environmental pollution which always incurs considerable damage to hydroelectric facility and rivers' recreational value. By land classification based on sediment yield production it is possible to provide priority in order to correctional action and sedimentation control. Thus Eyvanakey watershed which is consisted of marl deposits sensitive to erosion is selected. Marl deposits have higher sediment production due to structural nature such as destructive particles (silt and clay) and chemicals (calcium carbonate' Gypsum' Anhydrite and salt). In this research, a portable rainfall simulator was used in order to measure sedimentation in marl units. Then sedimentation level of each unit is analyzed by SAS software. Groups' difference was significant in levels 1 and 5%. marl units were divided into four main groups by Duncan's average comparison method : A (including OLs unit), B (including M3 unit), C (including M1 , M2 units) and D (including O-M, OLg units) in terms of sediment yield production where this susceptibility decreases from A to D.

Assessment of Land Degradation in Al-Bathina Region, Oman

Ali Al-Buloshi (Sultan Qaboos University), Yassine Charabi (Sultan Qaboos University)

The Batinah region is situated along the sea of Oman. This coastal plain is approximately 25km wide and lies at the foot of the Western Hajar Mountains. After Muscat the capital of Oman, it is the most densely inhabited area in Oman. The problem of salinity in this region started in the mid 1990 due to the extensive agriculture activities, coupled with increasing population, through the use of lands for farming and overdraws of fresh groundwater to a degree of causing seawater intrusion. This region is also characterized by low amount of annual rainfall (less than 100mm) and high evaporation ration. These factors contributed in increasing the area of salinity and causing abandoning of productive farms. For the assessment of the land degradation in this region during the last decade a GIS database was designed and compiled with different spatial attributes (salinity, crop. Built-up area, ground water etc). The fuzzy logic and multi-criteria analysis into GIS environment was used to classify the land suitability index. The unsuitable lands represent 40% and 48% of the total Land of the region in 2005 and 2010 respectively.

This paper shows that the land suitability index is a good index to retrieve the spatio-temporal dynamic of the land degradation.

Land Evaluation for its Optimum Use in the Kendujhar District, Orissa

Punyatoya Patra (Aditi Mahavidyalaya)

Endowed with rich natural resources such as different types of forest and high-grade minerals, the Kendujhar District contributes a major share in state's economy. The rich forest as well as fertile agricultural land is sacrificed for extraction of minerals and development of various types of industries. The rich farmers who have very big and fertile agricultural land are unable to take care of it, grow valuable sal and teak which needs little care and gives high return in long run. On the other hand landless tribal people grow crops on the marginal uneven/ sloppy land for their basic needs. So there is drastic change in land use pattern, which is not sustainable in long run. Keeping all these problems in view the purpose of the study is of three-folds: (i) evaluation and classification of land of the Kendujhar District for its optimum use; (ii) deviation of actual land use from its optimum use and the reasons behind it; and (iii) suggestion for possible land use changes for sustainable development. To obtain the results, the secondary data on land and soil variables have been collected from Survey of India toposheet on 1:50,000 scale; National Bureau of Soil Survey and Land Use Planning, Nagpur; and Orissa Space Application Centre. The land and soil variables are: slope, texture, pH class, depth, drainage, soil erosion, stoniness, groundwater condition etc. These variables have been evaluated one by one and land of the study area has been classified for its optimum use following USDA land capability classification keeping local conditions in view. Then the deviation of actual land use from its optimum use has been found by overlying the map prepared for optimum use and the map showing existing land use pattern. All these data have been processed by using GIS software (ARC/VIEW 3.2 version). The primary data in sample locations have also been collected in the field by interviewing local villagers, forest and revenue department staffs to suggest possibilities of changes in existing land use pattern wherever required. Eight types of land for optimum utilization have been delineated. They are: Type I- suitable for double crops; Type II- suitable for single crop; Type III- suitable for plantation; Type IV- suitable for pasture; Type V- suitable for mixed farming; Type VI- suitable for forest; Type VII- suitable for sanctuary; Type VIII- suitable for other. In 35 percent area, the actual land use deviates from optimum land use. Most of the type IV, V and VI lands are used for agricultural purpose. In many places type I and II lands are used for plantation purpose. Lastly it was found that in many places there is possibilities of land use change for sustainable development which need cooperation among government officials, social workers and local people.

Forest fires in the southern Russia steppe forests

Maria Martynova (Southern University)

Southern Russia forests are extrazonal, the forested area is very small. It varies from 0.01% in deserts up to 20% or more in Caucasus foothills. The especially low humidity, intensive rainfalls, droughts (relative humidity is below 30%), sharp winter temperature fluctuations (from +10°C to -40°C), extremely hot summers (up to +40°C), dried eastern winds, dust storms, etc restrict the development of woody vegetation. In Rostov region (forested area - 2.5%) one may see a big variety of steppes. Mainly, the natural vegetation is converted to agricultural landscapes. Southern Russia forests are both natural (valley-glens, floodplains, sand) and anthropogenic (more than 50% of the area). Mainly, mono-breed arrays of *Pinus sylvestris*, *Quercus robur* L. and *Robinia pseudoacacia*, large areas of *Ulmaceae*, are represented, especially along gullies and floodplains. Young trees and middle-grades ages dominate. The forest geosystems are not viable in the arid steppe. Now, the forest plantations start growing old. The bad sanitary conditions cause the death of forest landscapes due to pests, diseases and fires. The predominance of the 2nd and 3rd class forest fires risks is the result of dry steppe soils, dense road network and "wild" tourism. During the fire risk season both lower and crowning fires are possible. In this sense, the large arrays consisting of *Pinus sylvestris* and planted in 1950-1970 are the most risky. The frequent dry winds and poor sanitation conditions lead to incensement of the number of fires. However, a downward trend in the forest fires events, as well as one of the covered areas is observed during the last 2 decades. The peak-years are 1994 (4269 ha burned), 1995 (5876), 1998 (2321), 2001 (4685 ha) when the middle-age forests playing the most important ecological role have been lost. Recently, the big fires have been observed in 2002, 2004, 2007 and 2010. The local fires become more frequent. Our group has been observing the forest fires during the last 5 years. The investigations include area surveys and profiling of the damaged areas. The landscape maps and vertical profiles have been constructed and succession series have been described. Usually, the fires in the southern region are line, distributed along the roads, rivers and edges of fields. The forest fire region activity zonation has been carried out. One can see seven distinct areas, where the species and age of trees, sanitary status, forest fires frequency during past 15 years, the crowning fires proportion, fire areas and burned wood volumes have been studied. The high proportion of crowning fires (more than 40%) is very dangerous since the traditionally grown steppe arboreal species are hardly fire adapted and regeneration of natural steppe forests is almost impossible. The lower steppe forest fires are also destructive; they lead to the abrupt change of region landscapes.

C08.25

Land Use and Land Cover Change

C08.25-01 - Session on Land Use and Land Cover Change – Global Change 1

Chair: Ivan Bicik

Land Use/Cover Change: Global challenges – local solutions

Elena Milanova (Moscow University)

Climate change and biodiversity degradation are very vital contemporary issues of global concern. Between the natural factors that shape the land cover and biodiversity in Russia, climate is the most important one. The five different Global Circulation Models (GCMs) were used for three pre-set time periods: 2020s, 2050s, and 2080s. Land use/cover change (LUCC) is a complex process, driven by both natural and anthropogenic factors. LUCC transformations under human activities are threatened to the sustainability of environment and people life-support systems. One of the important issues is how to balance land cover capability and land use practice with anthropogenic stress. Russia is distinguished by a graphic share of such problems, and one of them is the elaboration of sustainable land use policy that is especially important during current land use restructuring connected with many geopolitical, economic and social problems. The territory of Russia has huge landscape diversity of main land biomes. At the same time, the country's economy developed under the conditions of strong centralization, lack of the normal market and isolation from the most of the global system. Agriculture is one of the major driver of land cover and biodiversity change in Russia where more than 220 mln ha (13 % of the total country territory) are designated for agricultural use. Integrated approach on the base of landscape methodology was used to map and to assess land use/cover change. Present-day landscape was chosen as the core unit of LUCC classification, because it comprises various aspects of natural and socio-economic environment. The landscapes' applications and mapping were done at global, country and regional scales using remote sensing data. This methodology helped to provide understandable presentation of geographical distribution of areas with different LUCC trends and degree of land cover transformation; to identify territories with similar land cover status in order to replicate more advanced environmental management experience and to reveal the territorial extent of areas with the most heavily transformed lands that may need prompt rehabilitation actions. The ecologically sound land use systems should help to reconcile human activity needs with the requirements of the environment and to avoid the unfavorable consequences of land and biodiversity degradation. The agrolandscapes' applications were done at macroregional, regional and local scales on the base of cartographic, remote in-field data. The ecologically sound agriculture development should help to reconcile social needs with the requirements of the environment and to avoid the unfavorable consequences of land degradation.

Land use systems in the Brazilian Amazon

Gilvan Guedes (Vale do Rio Doce University), Alisson Barbieri (University of Minas Gerais), Eduardo Brondizio (Indiana University), Bernardo Queiroz (University of Minas Gerais)

This paper aims to analyze the impact of household and lot life cycles, as well as integration into markets on smallholders' land use systems from a mixed-method perspective. Research on land use/land cover change in agricultural frontiers worldwide usually applies traditional LULC classes to define agropastoral strategies among smallholders (Caldas et al. 2007; Perz 2002; VanWey et al. 2007), yielding mixed evidence about how the demographic and temporal dimensions of frontier occupation impact the landscape (VanWey et al. 2007; Perz 2002; Walker et al. 2002). Based on the conceptual framework developed by the Food and Agricultural Organization (FAO 2003), other studies applied cluster and fuzzy methodologies in order to incorporate smallholders' joint decisions when choosing a specific land use system (Brandtberg 2002; Walker et al. 2002). This work builds on the participatory spatial research perspective (D'Antona et al. 2008), and advances the study of land use systems by combining a fuzzy method (Grade of Membership) with qualitative spatial instruments (participatory sketch maps) to create multidimensional profiles of land use systems. These previous techniques combined with in-depth interviews and multivariate regressions were applied to a representative longitudinal dataset of 402 smallholders along the TransAmazon Highway, in the Brazilian Amazon. In-depth interviews with landowners from each type of the four land use systems found (pasture with cattle, pasture and annuals, perennials and pasture, perennials) help to better understand the relation between demographics, place-specific capital, market stimulæ and land use choice. We found that proximity to markets and life cycles have significant effects on system choice, but in a non-linear fashion: landowners adjust their land use systems based on market stimulus (e.g., increasing perennials when cocoa price increases), constrained by the viability of the type of soil. At the same time, labor constraint is overcome by informal exchange of days of labor. These findings probe universalistic approaches that explain how local actors interact with their immediate environment. The increasing time on the frontier expand smallholders' ability to process exogenous sources of information, such as price changes in national and international markets, yielding efficient choices under labor and biophysical constraints. While the latter is harder to overcome, the former is mediated by informal labor arrangements. As smallholders respond rationally to change in market stimulæ, government intervention might focus on ecobalanced reduction in transportation costs (expanding existing road networks) coupled with fiscal incentives on sustainable crops. These actions promote both social and ecological benefits, by reducing pressure on the remaining standing forest, as well as improving smallholders' livelihoods.

Global Cropland and Agricultural Systems AD1000 - AD2000

Mats Widgren (Stockholm University)

Climate change models can be improved by incorporating past human landscape transformations. Accurate maps of global agricultural history are critical in this regard. The existing datasets, widely used and quoted, are all based on backcasting from 20th century land cover data using historical population estimates. This method tends to overemphasise European and colonial agriculture and reflect to a large degree Eurocentric and environmentally deterministic assumptions rather than historical, archaeological and palaeoecological evidence. The paper presented here reports on a collaborative project based in US and Sweden and carried out by economic historians and historical geographers with the aim to present in global maps the most recent knowledge of the agricultural systems of the world for AD 1000, AD 1500, and AD 1800 with discussion of 19th and 20th century agricultural developments. Changes during the past millennium occurred suddenly, in great leaps, not in a slow and continuous manner. Qualitative changes within existing agricultural systems -- intensification -- were as important as quantitative changes -- expansion -- of previously established patterns of land use. Moreover, abandonment and collapse was part of the development, especially in the Americas. The maps presented provide input to an alternative dataset of land cover change during the last millennium. The paper is coauthored with William E. Doolittle, University of Texas-Austin, Ulf Jonsson, Stockholm University, Janken Myrdal, Swedish University of Agricultural Sciences, William I. Woods, University of Kansas.

Assessment of Geosystems Transformation Using Time of Succession Processes

Vladimir Karakin (Pacific Geographical Institute)

One of the basic processes which are studied by geography is anthropogenic transformation of natural environment considered in various borders (geosystems, ecosystems, landscapes, or administrative and historical units). The main problem here is to find proper metrics of assessment of the object's transformation degree. There were developed many scales, in verbal or scorecard shapes, to assess a degree of transformation of the object by its contemporary state (from badlands and urban landscapes, then to agricultural landscapes and to weakly transformed forest and wetland objects). Most of the used methods assess the contemporary state of the geographical object but not the process of its transformation from initial state to the contemporary one. From our point of view, the transformation process is more informative since the different processes can lead to the similar results. For instance, the modern intensive agro-landscape with high share of arable lands can appear in result of transformation of initial forests, steppe areas, and wetlands that demands for methods of assessment of its transformation. We developed and apply the method of the geosystems transformation assessment according to duration of time needed for

hypothetical recovering of the existing type of anthropogenic landscape to the initial state. This method focuses on duration of recovery process, and a degree of transformation is measured by objective time units (years, centuries). These measures characterizing separate sites (field, forest area, etc.) can be 'weighted' and used to characterize areas of any larger dimension (landscape, country, etc.) then. The method was approbated through scale systematization of accumulated regional data according to duration of succession processes under various base conditions.

Results and Comparison between CORINE and SIOSE in the Land of València (Spain)

Joan Carles Membrado (Universitat de València), Emilio Iranzo Garcia (Universitat de València)

The land of València (officially Comunitat Valenciana) is a 23.000 km² territory in eastern Spain inhabited by five million people, traditionally known abroad because of the oranges it produces, and nowadays as a remarkable tourist destination as well. The author of this paper was the person in charge of photointerpretation for the CORINE (2000 and 2006) and SIOSE (2005-2006) projects in the land of València, being then a member of the Institut Cartogràfic Valencià (Cartographic Institute of València). As regards CORINE, we can see that artificial surfaces almost double between 1990 and 2006, and the class that grows the most in those years is Discontinuous Urban Fabric. In 2008, the collapse of the Spanish property bubble put an end to this huge growth of artificial surfaces, as the next CORINE will no doubt show. As for SIOSE, this is a Spanish acronym standing for Sistema de Información de Ocupación del Suelo en España (Spain's Land Cover Information System), a GIS promoted and coordinated by the Spanish Instituto Geográfico Nacional. It is the most detailed geographic information system ever created in Spain on land cover and land use. For example, whereas photointerpretation allowed CORINE to identify 8.541 different polygons in València, SIOSE identified more than 157.000 polygons for the same territory. The reason for such a wide gap between the two systems' figures is that CORINE has a minimum mapping unit of 25 hectares, whereas SIOSE's minimum is 2 hectares (in forests and agricultural land), 1 hectare (in urban land) or even ½ hectare (in humid and water-covered areas). Thanks to this, a huge quantity of researches can be derived from SIOSE, especially on a local level, since SIOSE's information is very detailed and precise. Nonetheless, on a regional or a national level, it is better to use CORINE land cover, since SIOSE's detail would be excessive in this case, as it would make it impossible to compare the differences and coincidences between Spanish or European regions. In this paper we will compare CORINE and SIOSE in order to identify the main technical differences between them, and also the differences regarding their València land cover results, which are remarkable because of the different photointerpretation mapping units employed in each case.

Tracking dynamic land use change using Spatial-Markov model based on spatial analysis techniques

Xiyong Hou (Chinese Academy of Sciences), Li Wu (Nanjing University), Xianghong Di (Chinese Academy of Sciences)

Land use change has become one of the main research subjects of global environmental change and sustainable development. It's fundamental works to develop modeling techniques in order to understand land use change precisely and imagine future land use scenarios visually. In the past few years, scientists have developed lots of models of land use/cover change (LUCC). In this paper, Spatial-Markov model, a model based on the theory of Markov chain process and spatial analysis techniques was presented and evaluated by comparing it with Logistic-CA'Markov model. The spatial-Markov model was applied in Jiaodong peninsular, China to simulate the spatio-temporal process of land use change from 2005 to 2010 at 500m spatial resolution. The error matrix and kappa index were used to evaluate the simulation results, and the disagreement due to location and disagreement due to quantity were also analyzed in order to get more information about how to improve the model. The results show that: (1) The overall accuracy of Spatial-Markov model was higher than that of Spatial-Markov model by 1.2 percent, and the Kappa index of the former was also higher than the latter by 1.91 percent. (2). The disagreement due to location of the Spatial-Markov model is lower than that of the Logistic-CA'Markov model, whereas the disagreement due to quantity was higher than that of the Logistic-CA model slightly. That is to say, the Spatial-Markov model outperformed the Logistic-CA'Markov model in the aspect of location, but underperformed it in the aspect of quantity.

Global long term energy and CO² emissions scenarios under land use constraints

Francois Cattier (EDF R&D), Prabodh Pourouchottamin (EDF R&D), Jean-David Sta (EDF R&D), Jerome Wirth (EDF R&D)

ContextCurrent trends are leading us to an unsustainable world: between now and 2050, energy needs and associated CO₂ emissions are expected to double [IEA, 2010] - Food demand would increase by 70% [EC-SCAR, 2011]. At the same time fossil fuel resources scarcity will increase, especially for oil since conventional oil resources have already reached their production peak [IEA, 2011]. These driving forces will drastically increase the pressure on land use in order to: - Respond to the food challenge - Develop bioenergy and biofuels in order to compensate at least partly the expected decline of oil resources - Preserve some areas for CO₂ sequestration or for biodiversity - Support urbanization and development in emerging countries This raises several questions on the availability of land and on the interactions between the different demands. Land use is a central concern with multi dimensions which are rarely taken into account in long-term energy studies. ObjectivesThe objectives of this paper are to: - provide a global picture of

the energy world in 2050 - evaluate the potential for bioenergy, taking into account land use constraints - estimate the impacts on CO₂ emissions. In this paper we have compared the results of different scenarios combining food and energy trends. We have assessed their implications on land use, CO₂ emissions and provided some insights on possible resulting tensions. The scenarios and variants in this paper are based on the 'Mescalito' Model [Cattier, Wirth, 2010] which simulates global long-term energy supply and demand trends. Developed by EDF R&D, Mescalito is based on the estimation of possible supply on one hand and desired demand on the other hand, taking into account fossil and fissile fuel resources availability, political, economical or industrial constraints. Mescalito also estimates CO₂ concentration in the atmosphere with a simple carbon-cycle model. The model has been enhanced in order to: - Take into account land potential for different uses - Explore their interactions especially between food and energy - Make a first evaluation of CO₂ implications of land use changes. The carbon sequestration and dynamics of soil respiration in post-agrogenic ecosystems of Russia

Dmitry Lyuri (Russian Academy of Sciences), Sergey Goryachkin (Russian Academy of Sciences), Dmitry Karelin (Moscow University)

The goal of this research is to reveal tendencies and factors of the abandonment of agricultural lands in Russia in XX century and to describe the role of fallows in the processes induced the carbon balance. The major objectives of the work are: - to analyze the long-term dynamics of agricultural areas in Russian regions in the 20th century; - to calculate the area of abandoned agricultural lands and fallows in different Russian ecoregions; - to study the sequestration of carbon in soil and plant covers in the course of postagrogenic successions in different ecoregions of Russia. - to investigate the dynamics of soil respiration in process of post-agrogenic self-restoration of ecosystems. Abandoning of agricultural lands began in some regions of Russia since the end of the 19th century. Our calculation shows, that the total area of abandoned lands since that time (1897-2007 yrs.) in Russia is approximately 71 mln ha. And almost at 65 mln ha of them (fallows) the process of the self-restoration of natural post-agrogenic ecosystems is very active. The largest part of Russian fallows locates in southern taiga (23.1 mln. ha), steppe (13.9) and forest-steppe (7.3) zones. The old (>50 years old) and medium-aged (50-20 yrs.) pre-crisis fallow lands occupy a significant part of the southern taiga and forest-steppe zones. On the other hand, the fallows of steppe zone are the young fallows (<20 yrs.), forming during the last Russian crises (1991-2000). The accumulation of

carbon in them (soil + vegetation) increases from north to south, reaches the maximum value in the zone of hardwood forests, and decreases again to a minimum level in the semidesert zone. The fallows presently accumulate about 64 million tons carbon annually (first of all in south taiga - 34 mln tons), which is more than 25% of the total current industrial emission of carbon in Russia. The processes of carbon sequestration are different in forest and steppe zones. Post-agrogenic ecosystems in forest zones, which having been manured while in use, in first 20-25 years of succession emit carbon, and only after this period begin to sequester it. Post-agrogenic ecosystems in steppe and forest-steppe zones haven't this emission period. Measurements of soil respiration at different stages of post-agrogenic succession in southern taiga confirm the existence of this emission period. The initial stages of succession (5-20 years) have the most intensive emission. Then the soil respiration decrease and increase only in final (spruce forest) stages of succession, first of all, because of litter soil horizon. So, post-agrogenic ecosystems actively sequester carbon, especially in forest ecoregions, and they play a very important role in carbon balance.

Chair: Ivan Bicik

Opportunities and Threats of Artificial Reforestation in Steppe Zone of Eurasia

Oxana Klimanova (Moscow University)

The steppe zone of Eurasia includes several types of landscapes with different degree of transformation by anthropogenic impact. In various part of steppe zone there are well preserved natural areas, pastures of extensive use, great farmlands, mining areas and also big cities and rural settlements. Russian steppes are the most changed landscape zone in the country. 80 per cent of steppes in European part of Russia are arable lands. In others countries such type of ecosystems plays also the most important role in food security. The absence of natural vegetation, strongly dissected relief, high wind activity are the main factors of wind erosion which is the most dangerous process of degradation of the steppe landscapes changed by human impact. There were intensive deflation, increase in frequency of dusty storms, decrease in soil fertility and transformation of the big areas of arable lands into badlands among its consequences. Reforestation in peripheral parts of arable lands was one of means of struggle against intensive erosion in steppe zone during about one and a half centuries that contributes to improvement of water balance in soil, microclimate stabilization and decrease of erosion. That way of ecological rehabilitation of arable lands was an extended measure on areas under intensive agricultural use. The economic changes, which have mentioned in agriculture of Russia, Kazakhstan and Mongolia last two decades of twentieth century, have led to change of character of land tenure in steppe zone, for example, to area compression of non-irrigated lands in arid areas (Mongolia, Kazakhstan, Siberia) till ecologically and economically optimum sizes, and also to decrease in intensity of actions for the device of forest shelter belts. At the same time, other tendency was also outlined. So, in steppe zone of Russia several regional programs directed to increase amount of forest of regions are accepted. Their basic direction is creation of forest plantations on the former agricultural lands. The cultivation of «Kyoto forests», which is provided on the lands never occupied earlier with wood, can also become the possible mechanism of increase of forest. At the same time, artificial reforestation without taking in account local features of climate and applied tree species can cause negative effects, e.g. fire danger strengthening, reduction of biodiversity of steppe ecosystems because of reforestation of territories served refuge for native steppe kinds of plants and animals. In that case, increase of forest can turn back destruction of remained steppe and other grassy and shrubby ecosystems.

CA Markov modeling of dynamics of land use land cover and sensitivity analysis to identify sensitive parameter(s)

M. Surabuddin Mondal (Indian Institute of Technology, Roorkee), Nayan Sharma (Indian Institute of Technology), Martin Kappas (University of Goettingen), P k Garg (Indian Institute of Technology, Roorkee)

An attempt has been made to explore and evaluate the Cellular Automata (CA) Markov chain modeling to monitor and predict the future land use land cover pattern scenario in a part of Brahmaputra River Basin, India, using land use land cover map derived from multi-temporal satellite images. CA Markov is a combined Cellular Automata / Markov Chain / Multi-Criteria / Multi-Objective Land Allocation (MOLA) land use land cover prediction procedure that adds an element of spatial contiguity as well as knowledge of the likely spatial distribution of transitions to Markov chain analysis. In this study, evidence likelihood map were used for as knowledge of the likely spatial procedure in CA MARKOV model. This study also establishes the validity of the CA Markov process for projecting future land use and cover changes in the study area. The validation calculates various Kappa Indices of Agreement (KIA or Kstandard) which indicate how well the comparison map agrees and disagrees with the reference map. The validation shows Kstandard is 0.7928. Sensitivity analysis has been also carried out to identify the LULC parameter(s), which have the highest, lowest or intermediate influence on predicted results. The results shows that the land with or without scrub appeared to be most sensitive parameter as it has highest influences on predicted results of LULC of 2007. The second most sensitive parameter was lakes / reservoirs / ponds to predict LULC of 2007, followed by river, agricultural crop land, plantation, open land, marshy / swampy, sandy area, aquatic vegetation, built up land, dense forest, degraded forest, waterlogged area and agricultural fallow land. The least sensitive parameter is agricultural fallow land, which has minimum influence on predicted results of LULC of 2007.

The Methods for Extracting Changing Information of Coastal

Yan Gu (Nanjing University), Ying Zhang (Nanjing University), Zhengjun Wang (Nanjing University)

The offshore tidal current forces attribute to the changes of Coastal. These changes occur frequently especially in the region of the silty mud coasts. So the study of the methods how to extract the information of estuary accretion erosion changes from satellite images is of great importance for the coast and tide flat development and the ecological environment protection. In this paper, the Wang gang River in Yan cheng, Jiangsu Province is chosen as the study area, and the satellite images with the spatial resolution of 10m and 2.5m of 2006, 2008, and 2009 as the data source. It is purposed to study the method how to extract the artificial seawall, the average high tide line and the average low tide line from the satellite images and this will be taken to analyze the evolving characteristics of tidal flat on both sides of Wang gang River. Research has revealed that: Firstly, compared with

traditional remote sensing images, high resolution images can be extracted more subtle features, so it can extract the average high tide line by the characteristics of surface features which are left on sea and land boundaries after high tide; Secondly, on the basis of the extracted average high tide line and water edge and through the tide date of the image for the day, the average low tide line can be worked out in accordance with the linear relationship among the average high tide line, instantaneous water edges and average low tide line; Thirdly, the average high tide line is in deposition, and deposition every year, and the rate is increasing after 2006, The average low-water line of the region is in homeostasis. The average low-water line in 2008 to 2009 has eroded 840 m, and change is very obvious.

Land use/land cover changes along the Romanian Danube Valley in the postcommunist period

Dan Balteanu (Romanian Academy), Monica Dumitrascu (Romanian Academy), Ana Popovici (Romanian Academy)

Land use/land cover changes along the Romanian Danube Valley in the post-communist period After crossing the Carpathians, the Danube Valley runs along around 1,000 km on Romanian territory over a fertile plain area which, together with a large floodplain, are used mostly as arable land. The paper presents land-use dynamics in the post-communist period, based on Corine Land Cover data-base (1990, 2000, 2006), Agricultural Farm Survey (2005), General Agricultural Census (2002, 2010) and many additional data obtained from field surveys. Structural changes in land use are discussed, with highlight on the transition from excessive concentration of terrains into collective farms and state farms to marked fragmentation of land into small individual farms. Following Romania's EU membership status in 2007, terrains tended to be amassed into large and medium-sized farms, with some abandoned lands from the Danube floodplain and terraces being integrated into agricultural production. The occurrence of ever severer droughts and desertification phenomena, as well as intervals of low Danube levels or overflows and the destruction of irrigation systems and dykes with direct impact on land use are being analysed within the context of global environmental change.

Natural and human impact on land use change of the Eastern Himalayan piedmont, India

Pawel Prokop (Polish Academy of Sciences), Subir Sarkar (University of North Bengal)

The piedmont of the Eastern Himalaya in India, receiving 4000-6000 mm rainfall annually, forms a system of fans dissected by dense river network. The overloaded rivers carrying heavy bed load are liable to shift their braided courses and cause the land use changes. Such natural land use changes often overlaps with the accelerated human activities along the tea plantations and human migration to the piedmont zone at the end of the 19th century. As a result, extensive forest areas were replaced by tea gardens and floodplains were taken under crop cultivation. Simultaneously, a number of large blocks of natural forest became protected and forestry stayed an important contributor to the economy of the piedmont. A hydrologic and geomorphic approach was employed to delineate three key areas (about 300 km²) along river courses on alluvial fans stretching 10 km from the

mountain front. The changes in land use were derived from topographic maps supported by detailed tea garden plan, satellite images from Corona project and Google Earth for the year 1930, 1970 and 2010. Six land use categories were defined: forest, grassland, tea plantation, crop cultivation, built up area and river. Logical rules in GIS were used for determination where areas has the same land use class in each time period (stable), locations where there had been one point of change (stepped), areas where frequent change has occurred between two categories (cycle) and a high turnover between many different classes (dynamic). The major processes of land use change between 1930 and 2010 are deforestation (10-17% of each key area) and expansion of the tea plantation (4-12% of each key area). The changes of grassland and cultivated land, situated within floodplain does not show clear tendency because their area depends on flood events. The stable land, consists of large blocks of reserved forest, tea garden and settlement, covers more than 50% of each studied key area. About 30% of land in each key area undergone stepped changes. These are conversion of forest and grassland to tea bushes and natural shifting of river courses or widening river beds as result of extreme floods. Cyclic changes occur only in places within floodplains of the larger rivers. Land undergoing dynamic changes is scattered within river beds where sand bars are frequently degraded and built up by flowing water. A result of anthropogenic impact is the gradual increase of the land use stability through the increase of areas with monoculture cultivation of tea and rice. The rivers are still the most dynamic factor of land use changes.

Catchment hydrologic response to changing land system in Kashmir Himalayas

Shakil Romshoo (University of Kashmir)

Hydrological response is an integrated indicator of catchment conditions and significant changes in the land system may affect the overall health and function of a catchment, as it modifies and alters many other inter-related processes. It has been observed that the changes in the land cover types in a catchment substantially affect the hydrological response including surface runoff. Such changes in runoff patterns in turn result in severe environmental implications like increased erosion, sedimentation and nutrient loadings of the water bodies particularly fresh water ecosystems and disrupt their ecological stability and functioning. The current study was carried out in the Dal Lake Catchment, Kashmir Himalayas to assess the impacts of the changing land cover from 1992-2005 on the hydrology and nutrient loadings. In order to accomplish the study, the Generalized Watershed Loading Function (GWLF) Model, considered to be a combined distributed/lumped parameter watershed model was used. The GWLF model simulates surface runoff using the SCS-CN approach with daily weather (temperature and precipitation) inputs. Erosion and sediment yield are estimated using monthly erosion calculations based on the USLE algorithm (with monthly rainfall-runoff coefficients) and a monthly composite of KLSCP values for each source area. The datasets used include

multi-date satellite data, digital elevation model, soil, stream, catchment, weather and field data. The LU/LC information was generated through the digital image analysis of Landsat ETM (Sept. 1992) & IRS LISS III (Sept. 2005) satellite data using supervised Maximum Likelihood Classifier (MLC). Images were classified into 17 LU/LC types viz, built up, agriculture, fallow, horticulture, coniferous forest, deciduous forest, sparse forest, grasslands, scrubland, plantation, aquatic vegetation, bare land, bare exposed rocks, water bodies, water channel area, snow and golf course/turf. The results of change detection showed that significant changes in the LU/LC of the catchment have taken place from 1992 to 2005. The vegetation cover in the catchment has declined, with coniferous forests decreasing by 5.67 km², deciduous forest by 1.8 km², grasslands by 7.89 km², and plantation by 12.9 km². During the same time period, impervious surfaces like the built up increased by 12.8 Km², bare land by 4.44 km² and scrubland by 11.97 km². The model simulations showed that the average annual runoff increased from 329.07 mm/yr to 341.34 mm/yr under the changed LU/LC conditions with impervious surfaces contributing the maximum to it. Strong correlations were observed between the increased runoff rates and the erosion and sediment loadings which increased respectively by 651.37 and 122.2 tons under the altered land system conditions. The results confirmed that the altered land system is one of the main reasons for the increased surface runoff, erosion and sediment loadings from the catchment into the Dal Lake.

The role of courts in open space conservation

Tseira Maruani (Bar-Ilan University)

Under conditions of proceeding urbanization and expanding development the issue of open space conservation is becoming more complex and controversial. This is manifested, among others, by the growing body of research dedicated to various aspects of the issue and the factors that affect it. However, research so far has quite neglected one of these factors, namely, the significant role that courts may play in monitoring planning decisions relating to conservation. The present paper wishes to draw attention to this role of courts and to the constraints that frame their potential impact on the consequent spatial layout of open spaces. The paper provides evidence from a recent study of Israeli court rulings that were concerned with issues of conservation and planning decisions, and offers practical suggestions for immediate implementation as well as directions for further research. Among others, it reveals the important part that environmental non-governmental organizations play in this arena.

Spatial Analysis of Farmers Attitude in Defending Agricultural Land within Land Conversion at Sleman Regency-Indonesia

Rika Harini (Gadjah Mada University)

Increasing number of people will directly impact on land resources to meet the necessities of life. As resources are limited and cannot be updated in terms of quantity then the existence of land need more attention, especially agricultural land. Conversion of agricultural land due to the increase in population cannot be avoided. If it is allowed to be continued, this problem will lead to uncontrolled land conversion. The impact threatens food security in addition to other possibilities is the occurrence of environmental damage. The attitude of farmers to maintain agricultural land is an interesting study to be assessed. Considering the incessant development outside the agricultural sector, it shifts the agricultural activities, especially in areas close to centers of economic growth. The research was done in Sleman which will be divided into three zones namely zone 1, which are regions with high conversion, the conversion zone 2, which are areas with moderate and low conversion which are named zone 3 area. Survey method conducted in this study through interviews with owners of agricultural land of farmers. Descriptive analysis and statistical tests with binary logistic models and Seemingly Unrelated Regression (SUR) is displayed in the form of tables and maps. The results showed variation in the area of "land conversion in Sleman Regency. Internally the location of land and land prices significantly affects the conversion of land in all zones, which are zone 1, 2 and 3. Externally the population and prevention of land conversion regulations significantly affects the level of land conversion of all regions in Sleman Regency. The test results in the attitude of farmers to maintain agricultural land shows that the variables age and educational level did not significantly affect the attitudes of farmers to maintain agricultural land. Based on SUR test results, the variation in attitudes of farmers to maintain agricultural land happened in wetland, dry land, or yard. Key words: Spatial Analysis, Farmers Attitudes, Defending Agricultural Land

Assessment of soil erosion changes in the small arable catchment of Kursk region based on different-age tracers methods

Evgenia Shamshurina (Moscow University), Andrey Zhidkin (Moscow University), Valentin Golosov (Moscow University), Aleksandr Gennadiev (Moscow University)

To assess the rate of soil erosion'accumulation processes during different time intervals was used the method of different-age tracers, based on simultaneously use of spheric magnetic particles (SMPs) and technogenic radionuclide ^{137}Cs as tracers of the soil erosion. The analysis of the radioactive isotope distribution in the sloped soils allows characterize rates of the soil loss and accumulation during the last 25-year-long period from the Chernobyl fallout in 1986 to the moment of the soil sampling. ^{137}Cs is used as a tracer of erosion because of its ability of being rapidly and strongly sorbed by soil particles and transferred with them. The magnetic tracer method can provide data on the mean rates of the soil erosion and accumulation during the period since the beginning of the exploitation of steam locomotives on the nearest railroads (the last 130-150 years). SMPs have the same weight and size ($10\text{-}50 \times 10\text{-}3\text{ m}$) as the soil particles and are very stable in soil material. Within local areas, SMPs relatively uniformly arrive from the atmosphere into the soil; therefore, the changes in their concentrations in the soil cover result from their redistribution due to the erosion'accumulation of soil material. The assessment of the erosion or accumulation processes is studied on proportional calibration model based on the direct relationship between the changes in the tracers reserves in the sloped soils against the initial (reference) values on geomorphologically stable plots, where there is almost no removal of soil material or input of sediments from the adjacent areas. Small catchment in Kursk region with total area 1.98 km^2 was chosen for detailed study. The catchment occupies area with typical and leached chernozem soils formed mostly on loess deposits. Catchment topography is characterized by gradually rolling interfluvial areas and predominance of convex slopes with maximum gradients up to $5\text{-}10^\circ$. Most of the catchment area has been cultivated (71 % of total area - 141 ha) in 1986 (before the Chernobyl accident). For our research has been selected three transects on the slope of southern and northern exposition, as well as additional transect on the slope with soil conservation practices of western exposition. The low rates of soil erosion ($<4\text{ t/ha}$ per year) observed on the northern exposition slope during the studied period (since 1869 and 1986). The high rates of soil erosion ($>10\text{ t/ha}$ per year) were obtained on the southern exposition slope using SMP tracers. The rates of soil erosion have decreased by 5 times since 1986. Probably, the rate of soil erosion declined because of reduced agricultural loads. The situation is similar to the western exposition slope - the soil erosion rate since 1986 significantly decreased. Using the method of different-age tracers revealed to study the reduction of the soil erosion rate since 1986 compared to the average rate since 1869 in small catchment in Kursk region.

Major societal driving forces of agricultural development in Czechia and LUCC 1845–1948: From differential rent I to differential rent II

Leos Jelecek (University Prague)

The paper gives general characteristics of major SDFs (economic, technological, political, geopolitical, social, etc.) and events in the history of Czechia, which basically influenced the development of capitalism in agriculture and consequently of LUCC. The different influences of the Industrial Revolution, and the agricultural revolution, followed at the end of 19th century by the technological-scientific revolution in agriculture etc. on LUCC are characterized and analyzed. Their periodization, phase shifts, and definitions of those basic SDF, not only technological historical innovations, are provided. Some of these processes led to both extensive and intensive modes of productions in agriculture and LUCC. The impact of chief milestones in political history defining new geopolitical and geoeconomic positions for Czechia and fundamentally influencing LUCC is also documented and evaluated. The explanation of the different influence of capitalism's developmental phases and modes of production in agriculture on LUCC is based on analysis of LUCC documented by a number of tables and cartograms. Cartograms show LUCC on the entire territory of Czechia divided into about 9,000 territorial units comparable in time and area. The paper provides clear evidence that in the 2nd half of the 19th century the necessary increase in agricultural production caused by the Industrial Revolution was made possible to secure by LU extensive changes predominantly influenced by differential rent I generation (i.e. mainly by the large increase of arable land area). Within the last two decades of the 19th century the transition to DR II is documented by small changes in LU. Then during the 1st half of the 20th century further necessary increase of agricultural production was enabled by LU changes resulting from the impact of the differential rent in its intensive form, notably DR II, i.e. by intensification of production by investing capital in more fertile plots of land with relatively better position to market.

Accuracy Assessment of Multi-source data sets in Landcover Analyses in Southwestern Nigeria

Adebayo Ojo (African Regional Centre for Space Science &Tech. Education)

Remote sensing has moved beyond its traditional role of mapping natural resources, environment, and infrastructure and hazard zonation, to making geo-spatial data infrastructure and services one important pillar supporting the information society. The study aimed to assess the relative accuracy of feature definitions on the imageries; and examines the potentials and constraints of data seaming for complimentary usage of spatial data. The study revealed that significant and positive correlated occurred within the visible bands in NigeriaSat- 1 ($r=0.95$; $p < 0.05$) and SPOT ($r= 0.98$; $p < 0.05$) while it was lower in Landsat TM imagery ($r =0.3$; $p < 0.05$) on the other hand the objects in the Near Infrared (NIR) correlated significantly with the red band (visible band) only in SPOT

($r= 0.98$; $p < 0.05$) Landsat TM imageries ($r = 0.98$; $p < 0.05$). In addition, the percentage accuracy of the classified area was highest in NigeriaSat-1 for built- up area (97.3%) and lowest in SPOT imagery (81.98%). On the other hands, while bare rocks (89%) were classified with the highest accuracy in SPOT, other land uses such as farmland (88.1%), secondary forest regrowth (78.3 %) were more accurately classified in NigeriaSat-1 ($k = 0.97$; $p < 0.05$). waterbody was however most accurately classified in SPOT imageries (85.5%; $k = 1.0$; $p < 0.05$). Furthermore, the results of the accuracy assessment of the seamed set of the imageries showed that a merge of SPOT + NigeriaSat -1 correlation was however yielded higher 81.2% ($k = 0.98$) than other combination (i.e. Landsat TM + NigeriaSat-1 seamed was however yielded higher level accuracy for built up area (>96%) and were more defined than other landuse classes. The study showed that both SPOT and NigeriaSat-1 imageries are likely to be useful within acceptable accuracy for land use/ land cover in urban area in southwestern Nigeria. The study concluded that integrating more than one medium resolution imageries could provide better accuracy than a singular image for land use/ land cover study in the southern Nigeria.

Chair: Ivan Bicik

Fifty years of land use change in the Swartland, Western Cape, South Africa

Michael Meadows (University of Cape Town), Gator Halpern (Pomona College)

The Swartland is a largely agricultural region situated to the north of the greater Cape Town Metropolitan Area in the Western Cape, South Africa, and is known to have been subject to significant land use changes over many decades. This fertile land lies within the winter rainfall region of the Western Cape and has been used intensively for agriculture since European colonial occupation from mid-17th century onwards. Historically, the most prominent land use in the region has been grain, typically winter wheat and, while this remains the case, throughout the past half-century, however, there has been a substantial shift among many commercial farms in the region towards wine grapes. There are, nevertheless, relatively few quantitative assessments of the nature and extent of such changes, their underlying causal factors or, indeed, their environmental and economic impacts. This study presents an extension and re-evaluation of previous work in the region that considered land use change and its environmental implications (Meadows et al. 2006) with the aim of providing a more detailed description of land use change in the Swartland during the period 1960 to 2010 and to explore the possible causes and implications of the observed changes. The methodology involves the analysis of five comparable sets of sequential aerial photographs for the Philadelphia area that may be considered representative of the broader Swartland landscape. The resultant series of land use maps is analyzed employing GIS and statistical techniques. The results show a marked recent shift from grain to grape, as well as a general increase in urbanization. The underlying structural causes of such trends are discussed and their possible environmental consequences explored.

The growth of traffic areas in Slovenia in the last 200 years

Matej Gabrovec (ZRC SAZU), David Bole (ZRC SAZU)

In the past investigations on the land use and land cover changes in Slovenia the emphasis was laid on the changes in farming areas. Among Slovenian investigators the interest for lands below built structures was much lesser, and they were mainly discussed in relation to the building up of farming lands. In spite of the fact that among the lands below built structures traffic areas occupy the largest portion, nobody has analysed the changes in these areas in Slovenia yet. The lands used by traffic have not aroused interest so far, not even among transport geographers. The ever greater mobility of the population also exerts intense impact on land use. Due to the increase in motorized forms of transport, traffic land use is increasing, in suburbanized areas in particular where the

daily mobility of workers and school-children is the most intense. We believe that the growth of transport infrastructure is directly related to certain social groups; therefore, the growth of traffic land use is more rapid in newer suburbanized settlements while the growth of transport infrastructure in traditional environs is closer to sustainable models. The first part of the research analyzes the size of traffic areas in the time of traditional agrarian society in the first half of the 19th century. Next, the paper presents the degree of growth of traffic areas in different types of settlements in the following 200 years. However, not only the degree of growth of traffic areas is important, but also the changing relation between traffic areas and other built-up areas, or the relation between traffic areas and the number of inhabitants. On the basis of the performed analyses of changes in traffic areas we will be able to assess how far individual settling patterns in Slovenia meet the standards of sustainable development.

Great Disasters and Land Use/Cover Changes – Some Lessons of Great East Japan Disaster

Yukio Himiyama (Hokkaido University)

Land use/cover change was highlighted as an important theme of global change research in 1996, when LUCC (Land Use and Land Cover Change Programme) was jointly established by IGBP and IHDP, and IGU-LUCC (IGU Commission on Land Use/Cover Change) was launched in order to support it. Despite their wide-ranging research activities, LUCC and its successor GLP (Global Land Project), as well as IGU-LUCC, have not addressed great disasters as their priority research theme. However, the increase of great disasters in the recent years is becoming a major threat to sustainable land use world-wide, and there are enough reasons for GLP/IGU-LUCC to include it in their research mission. The presentation discusses these reasons and the related research issues that should be given high priority based on the case study related with Great East Japan Disaster of 2011.

Specific methods applied in investigation of the long term land use development in Czechia

Ivan Bicik (University Prague)

Bicik, I., Janousek, Z., Stych, P: Specific methods applied in investigation of the long term land use development in Czechia. In the beginning of 21st century was finished special database of land use development in Czechia based on cadastral units and 8 903 comparable basic territorial units= BTU (1845 - 2010). We derived some special methods applied on evaluation of this database. There are: coefficient of concentration and triangle graphs. Coefficient of concentration gives information about extent of the Czech republic territory in which was observed directly half (also quarters) evaluated category (arable, grasslands, forest areas etc.). Basic territorial units (BTU) must be ordered from point of view of biggest share of observed category (arable, grasslands, forest etc.) in the BTU

and then summarized. When sum of ordered BTU will rich just half of size this category in Czechia we will rich more concentrated half. These results are given on the cartograms from different time horizons and evaluated. Differentiation of compared cartograms from two time horizons gives information about changes of observed category concentration in the observed territory (of all Czechia). Second method is based on possibility to show structure composed from three parts by point(s) in triangle graph, development between two time horizons by vector(s). For this method we can use simplified structure showing only three categories: agricultural land, forest areas and the rest (inland water bodies + built up + other areas). We could compare results using different specific geographical units in different order (regions, microregions and BTU). Results are clear. Using smaller geographical units their differentiation (shown as a location in triangle graphs) is wider and wider. Triangle graphs show also specific types of development in land use structure in observed units.

C08.25-07 - Session on Land Use and Land Cover Change – Society and Environment 2

Chair: Ivan Bicik

Multi-temporal analysis of land use transition considering lifetime

Chiaki Mizutani (University of Tsukuba)

The monitoring of the latest status of land use and the analysis of transition trends is increasing in importance. It is important to analyze continuity of land use attributes by high temporal resolution data sets. However, many time series land use data sets have five timestamps in five years or more temporal resolution in maximum. Enrichment of the temporal resolution of land use has accumulated many issues (e.g., data development and up-dating budget, methodological consistency of data development). For this reason, many land use studies have emphasized the spatial aspect of land use transition processes (e.g., increase and decrease of total number of different of land uses, distribution pattern of land uses) rather than the temporal aspect of land use transition. This indicates the lack of understanding of temporal aspect of land use transition. This study aims to understanding temporal and spatial aspects of land use transition processes through multi-temporal analysis of land use transition processes. The study area that was selected to apply multi-temporal analysis is a central part of Tsukuba City, Ibaraki, Japan. The study period covered a total of 3565 days from February 25, 2000, to November 29, 2009, with eleven timestamps. Firstly, spatial distribution of land use changed area was mapped to analyze adjacency of polygons. Secondly, survival time analysis was conducted. As results show, polygons, adjacent to those that have frequently changed have also changed the land use type frequently. Conversely, the surroundings of polygons with a low frequency of land use changes have not experienced land use change at all or have changed once to twice at maximum. This indicates the existence of local variability in land use. Survival analysis executed on both the number of polygons and the area of each lifetime clarified the differences of variability for each land-use type. Focusing on lifetime, the analysis highlighted the turning point of the transition by comparison in both the number of polygons and the area. Generally, the input data of survival analysis, such as the statements of patients and products are assumed to exist individually and independently. On the other hand, land use has spatially interactive relationships between each polygon (e.g., neighborhood effect, spatial adjoints). Considering the spatial relationship, future analysis requires the application of a semi-non-parametric model or parametric model considering spatial attributes in survival analysis. However, it is a step forward to deepen spatiotemporal analysis with representation of the continuity of land use by lifetime and survival probability.

Dynamics of Landuse/Landcover Change in a Sub-catchment of Pohru Catchment using Remote Sensing and GIS

Syed Mohd. Rashid (Jamia Millia University), Pervez Ahmed (University of Kashmir)

The Landuse/Landcover change is a global phenomenon and intensity and the magnitude varies from one part of the globe to other. This change has wider ramifications in our part of the world as in majority of the cases it is unplanned and primarily governed by personal interests. This change in ecologically fragile mountainous areas has future consequences, which can prove to be quite disastrous. The present study reveals that in the study area, the Landuse/Landcover change is discernible and importantly, the drivers of this change are physical and economic factors. The change is unplanned and can be detrimental to the health of the soil. The study used multi temporal remote sensing data for two time periods viz-a viz 1974-75 and 2008. The change detection was performed in GIS environment followed by subsequent analysis for examining the factors responsible for change.

Classification and landscape mapping of the Russian part of Amur River basin

Kirill Ganzei (Pacific Geographical Institute), Ermoshin Victor (Pacific Institute of Geography)

In connection with great attention to geopolitical and to environmental problems of Amur River basin the number of the works devoted to research of questions of economic development, the decision of water-environmental problems, estimations of ground resources, tendencies of economic interaction between Far East of Russia and North-East of China. The further researches and development of this region demand not only more detailed, but also more homogeneous information about natural components. In the Information-Cartographical Center of Pacific Geographical Institute FEB RAS within the limits of performance of works under the project of the International Scientific and Technical Center «Environmental Criteria and Restrictions in the Programs for Sustainable Nature Management in the Amur River Basin» are begun works on landscape mapping of the Russian part of Amur River basin in scale 1:2500000. The main goal of the present project is definition of the priority, possible and forbidden types of wildlife management for planning land use activity in Amur River basin. The landscape analysis of territory will allow to classify landscapes on sensitivity degree to anthropogenous influences within various areas. This data is correlated with existing and potential ecological risks. Works on electronic map «Landscape structure of Amur River basin» are conducted on the basis of synthesis thematic information layers. The structural-genetic classification is put in a basis of landscape classification. Now are defined taxones of following levels: classes of landscapes (horizontal and mountain), subclasses (peculiarities of geomorphologic structure), types (39 classes of vegetative formations and 45 types of soils), a sort (relief

genesis and a lithology of superficial adjournment - 10 generalized types). At present the classification matrix includes 171 sorts of landscapes. On the basis of the developed variant of landscapes classification landscape mapping of the Russian part of an AmurRiver basin are carried out. During the work gathering of remote sensing dates Landsat TM is carried out, construction of digital models of a relief is executed. With using of software package ArcMap overlays-operations with the branch thematic maps translated in an electronic kind also are made. The electron layer of landscape in which have found reflection about 5500 polygons is generated. According to methodology of GIS-technologies for a layer the attribute table in which for everyone polygon characteristics of vegetation, relief, soils, and geology are resulted is constructed. The layer of landscapes will form information base for zoning territory on types of economic use with consideration of ecological risks and prospects of social and economic development of the South of the Far East of Russia. Work was carried out under the support of ISTC Project 4008.

Spatio-temporal Land Use/Land Cover Dynamics and its Environmental Implications in the Highlands of Ethiopia: The Case Study of Lake Alemaya Watershed

Berhan Gessesse Awoke (University of Erlangen- Nürnberg)

The study of LU/LC changes and its implications on the environment is an essential strategy for sound policy decisions to enhance natural resource conservation and management options. In this paper, long term LU/LC dynamics (between 1965 and 2007) analysis was carried out. The objectives of this study are intended to examine the magnitude, rate and patterns of spatio-temporal LU/LC dynamics processes and analyze its implications on soil and water degradation. Remotely sensed datasets (Panchromatic aerial photographs and SPOT image) and topographic maps were the principal data sources of this study and post-classification comparison change detection algorithm was employed using the integrated techniques of geo-information technologies. Eventually, a serious and rapid LU/LC changes were observed in the study watershed during the past 42 years. Specifically, aquatic vegetation cover, urban land use and intensively cultivated lands have considerably expanded. Conversely, forest cover, grassland, open water (mainly Lake Alemaya) and shrub land covers deceased in size. Based on the 1965 aerial photograph interpretation, about 925 rural dwellings are identified and a total gully length of 93.88 kms measured. Moreover, in the year 1996 the number of rural dwellings was reached at 1390 and the size of gully length advanced to 109.52kms. On the other hand, 154.38 kms gully length is measured and the size of rural dwellings along with intensively cultivated lands extremely surpassing in the year 2007. The expansion of cultivated land increases along steep slope areas whereas the areal coverage of forest, grass and shrub lands decreased along steep gradient. On top of this, the size of gully density is expanded from time to time in the entire watershed mainly along with the intensively cultivated land areas and steep slope site. These settings had implication on land

degradation in the form of soil erosion, siltation, water quality as well as quantity which intern the complete drying-up of Lake Alemaya (since 2003) in the study watershed. To ameliorate these problems, sound land-use plan development and implementation as well as soil and water conservation methods is needed in the studied watershed. Keywords: Change detection; GIS; Gully developments; Lake Alemaya Watershed; Ethiopia

Spatio-Temporal analysis of Land Use Land Cover in the Muni-Pomadzi Ramsar site, Ghana

Gerald Atampugre (University of Cape Coast)

Land Use Land Cover (LULC) dynamics in wetland catchments is poorly understood Ghana albeit its importance as an indicator of wetlands' ecological integrity. The study aimed at detecting and quantifying LULC changes at the Muni-Pomadze Ramsar site in Ghana. The objective was to produce LULC maps for the area, assess the LULC dynamics during a ten year period, and establish statistical relationship between the major LULC changes and biophysical factors that influence human decisions. Using image processing techniques, an aerial photograph of January 2005, Landsat Thematic Mapper (TM) and Enhanced Thematic Mapper (ETM) data of December 1990 and February 2000 respectively were analysed to produce LULC maps for the Muni-Pomadze wetland catchment. The image analysis produced an overall accuracy of 85% and a kappa coefficient of 81%. The post classification technique involving overlay operation was applied to produce LULC change map and matrix which aided the analysis of LULC dynamics in the area. Two LULC maps were produced with LULC units such as farm fields, rangeland, built-up, barren-land closed forest, open forest, and water. The dynamics of LULC within the Muni-Pomadzi could be said to be complex since counter transfers were detected. Using logistic regression in SYSTAT, it was established that altitude, distance to roads, rivers, and settlement were significant in explaining deforestation and afforestation which culminated in the reduction of the physical extent of the wetland.

The impact of land use and land cover change on stream discharge and suspended sediment loading on Mt. Elgon

Yazidhi Bamutaze (Makerere University), Bob Nakileza, Gorret Kitutu, Paul Mukwaya

Although land use and land cover changes are believed to be taking place on Mt. Elgon, their patterns as well as impacts on water resources are not well understood. In this paper, we present preliminary results on trajectories (1960-2010) of land use and land cover change and associated fluxes in stream water flow and suspended sediment loading on from key rivers on Mt. Elgon in Eastern Uganda, namely Manafwa, Simu, Sipi and Namatala. Trajectories of land use and land cover were assessed using Aerial Photo Interpretation (API) for the period prior to 1970. For 1970 to 2010, landsat satellite images

of 30 meter resolution were interpreted and classified using supervised classification techniques in IDRISI Taiga software and subsequently ground-truthed in the field. Historical and current data on discharge and Total Suspended Solids (TSS) were obtained from the Directorate of Water Resources Management of Uganda, which has gauging stations along the target streams. Preliminary results indicate that land use and land cover changes on Mt. Elgon have entailed largely conversion of forestland (from 52.4% in 1960 to 7.7% in 2003) to arable land thus increasing the magnitude and severity of environmental degradation. Significantly, woodlands and forests have given way to annual and perennial cropping. Discharge patterns were varied among the studied streams ranging from 2m³ s⁻¹ to 24m³ s⁻¹ between 1960 to 2010. Critically, the streams depict a changing trend in discharge in 2007 with Namatala and Simu showing a declining trend, while Sipi shows an increasing trend. Results also indicate changing spatial and temporal stream loading dynamics, with river Manafwa currently heavily laden with silt to the magnitude of 43.7 mg/l and transporting over 35 tons/day. A preliminary analysis strongly implicates land use change although anecdotal evidence also links the increasing intensity of footpaths and roads on Mt. Elgon to changes in stream discharge and sediment loading. Further analysis and modelling are being undertaken to quantify the land use impacts as well as other key parameters including climatic factors.

Short-interval Monitoring of Land Cover Change Using RADARSAT-2 Polarimetric SAR Imagery

Zhixin Qi (University of Hong Kong), Anthony Yeh

Many illegal land development schemes are emerging in some of China's rapidly developing regions. Some illegal land development projects have caused irreversible environmental problems. Short-interval monitoring of land cover changes is important for preventing and controlling illegal land development at an early stage. Remote sensing data obtained from different optical sensors have been commonly used to characterize and quantify land cover information. However, conventional optical remote sensing is limited by weather conditions. Difficulties are encountered in collecting timely land cover information in tropical regions that are characterized by frequent cloud cover. Radar remote sensing, which is not affected by clouds, is therefore an effective tool for extracting timely land cover information. The objective of this study is to implement short-interval monitoring of land cover change by using RADARSAT-2 PolSAR imagery. Since the repeat cycle of RADARSAT-2 is 24 days, monthly land cover change information can be extracted by using RADARSAT-2 imagery. In this study, land cover change detection was conducted based on the comparison of two repeat-pass RADARSAT-2 images. Change Vector Analysis (CVA) was used to extract land cover change areas. The image channels used in CVA were selected using decision tree algorithms based on training samples. The change types were determined based on the post-classification of the RADARSAT-2 images. A novel algorithm that integrates polarimetric decomposition, PolSAR interferometry, object-oriented image analysis, decision tree algorithms, and

support vector machines (SVMs) was used to implement the classification. Polarimetric decomposition and PolSAR interferometry can be used to extract polarimetric and interferometric information to support the classification of PolSAR data. The main purposes of object-oriented image analysis are delineating image objects, as well as extracting various textural and spatial features from image objects to improve classification accuracy. Decision tree algorithm and SVMs provide an efficient way to select features and implement classification. The results of this study show that RADARSAT-2 PolSAR imagery can achieve very satisfactory accuracy for identifying land cover changes from vegetation to barren land and barren land to urban/built-up areas. This type of land cover change is mainly related to construction activities and therefore can provide important information for identifying illegal land development schemes. The results indicate that RADARSAT-2 PolSAR imagery are very promising for short-interval monitoring of illegal land development and can provide accurate and timely information to prevent and control illegal land development.

Agricultural land use change in the Jaman North District of Ghana: Implications for land tenure, women's rights and food security

Simon Mariwah (University of Cape Coast)

The recent agricultural land use change from the production of food crops to the growing of cashew in Ghana raises a number of concerns. The study therefore sought to explore the causes and implications of such a change. Employing an exploratory design, the study used interviews and FGDs to collect data from purposively selected opinion leaders in a randomly selected village in the Jaman North District. The study found that the major causes of the change are decreasing food crops yields, resulting from decreased soil fertility, infrequent rainfall (climate change), and the increasing demand for cashew nuts. It was also found that the change has altered the land tenure regime, reduced women's access to land, and has the potential to threaten food security in the village within a short time. It is recommended that the Jaman North District Assembly should engage in diversified sensitization programme to avert the already threatened food security in the district.

Changes of artificial surfaces in Slovakia 2000-2006

Jan Feranec (Slovak Academy of Sciences), Monika Kopecka (Slovak Academy of Sciences), Jan Otahel (Slovak Academy of Sciences), Jozef Novacek (Slovak Academy of Sciences)

Landscape changes resulting from human activities are associated with building of infrastructure (dwellings, production, sports, etc.) and communications (roads, railways, parking lots, etc.). As these processes are systemic and they irreversibly cover the areas of agricultural and forest landscape, their effects (degradation) on land, soil especially, are analysed and assessed by multiple approaches. Among them, the most frequently used, are the identification and assessment of soil sealing. Aerial and satellite images or data derived from them (e.g. CORINE land cover - CLC data) but also data obtained by the conventional national statistics (statistics of plots using) are important data sources. The aim of the paper is to demonstrate on example of Slovakia: - Possibilities of the use of CLC data for observation of the building process with stress on the analysis of CLC classes 11 (urban fabric), 12 (industrial, commercial and transport units), 13 (mine, dump and construction sites) and 14 (artificial, non-agricultural vegetation areas); - Possibilities of the use of national statistic data for observation of the building process; - Results of comparison of the conventional national statistical data concerning the building process in Slovakia (the area of building was 219,340 ha and 227,092 ha in 2000 and in 2006 respectively; enlargement amounted to 7,752 ha) with CLC data (areas of classes CLC 11 and 12 were 256,040 and 257,895 ha in 2000 and 2006 respectively; enlargement amounted to 1,855 ha) and their map presentation; - Identification and analysis of differences along with assessment of causes and spatial aspects characterizing enlargement of artificial surfaces.

Contact zones of the Amur River basin: Anthropogenic influence, Land cover and Landscape structure

Ermoshin Victor (Pacific Institute of Geography)

An emergence of new natural-anthropogenic and anthropogenic boundary systems - contact geozones (tension geozones) with different spatial scales - with the specific features, structures and stabilities is the object of wide speculation. The contact tension geozones are transitional, boundary spaces between different natural systems, between natural and anthropogenic systems. Their occurrence is huge and roles are quite substantial. A considerable increase in the areas of boundary contact formations related

to diverse anthropogenic activities is noted. The contact structures are characterized by the increased intensity in exchange of matter and energy. At that, a fast development of destructive processes, negative effects and local environmental conflicts and crises is characteristic of them. Our study is concerned with the contact territories - transitional zones from plains to mountain areas in the Amur River basin within the range of elevations of about 250-500 meters. The plain territories are most developed and more than 90% of populated localities and industrial centers, about 80% of agricultural lands and more than 70% of road network are concentrated there. These areas have their impact on the adjoining contact territories which extend it on the mountain regions. From that matter, the contact territories realize, in a greater degree, the buffer function. The environmental health of the mountain territories will depend on their response to the anthropogenic impact and transfer and transformation by them of this impact. The landscape mapping of the Amur River basin territory carried out earlier has served as the information base for analyzing the landscape structure, identifying the contact (tension) zones themselves and making their functional zoning. The functional zoning assumed a preparation of the special electronic map with identification of major groups of landscapes exercising different functions. The landscapes of reserves and wetland ones fulfill the environment-oriented function with maximum restriction of the economic activities. The landscapes of waterlogged larch and Korean pine-broad-leaved forests in the hill countries and low-hill terrains perform the protective function with the limited economic exploitation. The most part of the forest landscapes of different types was assigned to the regulated use. For the specific post-fire landscapes of bushes and thin forests, the recovery function is recommended. The agricultural zone was also identified. Further, it is supposed to correct the boundaries of identified zones and to redefine the landscape functions in accordance with additional environmental restrictions and balance ecologic-economic model. The works performed provide the information base for planning of the nature management within the transboundary basin. The work was carried out with financial support by the ISTC Project 4008.

Land use changes in the peri-urban agriculture of the Belgrade region during the transition period

Mikica Sibinović (Belgrade University), Mirko Grcic (Belgrade University)

LAND USE CHANGES IN THE PERI-URBAN AGRICULTURE OF THE BELGRADE REGION DURING THE TRANSITION PERIOD The Belgrade region is comprised of 17 municipalities with a total of 166 settlements and with about 1.6 million inhabitants. Peri-urban agricultural production is organized to meet the needs of the population. Over time the agricultural system in the rural areas of the Belgrade has transformed from traditional agriculture to the agricultural production for the market. Standardization, vertical integration, and globalization have resulted in land use changes in the agricultural system. In peri-urban areas these changes are most pronounced because of the pressure of urbanization and rural-urban conflicts. The development, distribution and structure of

agricultural production depends on environmental and social conditions. Social factors are strongly reflected by the agricultural population, agricultural structure, the achieved level of agricultural technology, access to markets and the industrialization of agriculture. The needs of Belgrade influences agricultural production and land use changes in the peri-urban areas. This research investigates the nature and intensity of this relationship in terms of the functional aspects of agricultural production, rural-urban conflicts, and future trajectories of agriculture. Results suggest possible directions for the sustainable development of agriculture and optimization of land use in the Belgrade region. Keywords: Belgrade, peri-urban agriculture, land use changes, rural-urban conflicts

Suburbanization as a driving force of land cover change in Prague metropolitan area

Lucie Kupkova (University Prague), Ivan Bicik (University Prague), Martin Ourednicek (University Prague)

Before the "Velvet Revolution" in 1989, cities in the Czech Republic expanded to the surrounding land in a very limited extent, due to many factors that characterized the socialist system. As there was no market economy, a market for land and private property did not exist; efforts to reduce regional differences were high and laws for land preservation were strict. Since the beginning of the economic transition after the fall of communist regime in the Czech Republic in the early 1990s a new stage of urban development of Prague metropolitan area has become. The rapid suburban area development is reflected in extensive changes of selected types of land cover categories. Based on aerial photos and QuickBird imagery an analysis of land cover changes in Prague suburban area in the period 1990 - 2007 using modified CORINE legend and manual vectorization was carried out. The results proved an extreme increase of typical suburban land cover types, especially of areas of commercial and residential buildings, impervious areas, bare areas (construction sites), road network and gardens. We were able to distinguish areas of typical residential suburbanization - for example relative change of residential urban fabric in Kvetnice municipality was 368% while the count of family houses increased from 82 to 447 in this period. Commercial suburbanization caused an extreme increase of impervious areas in many municipalities situated around the main roads. Impervious surfaces have spread over 5% (41 ha) of the Jirny municipality total area. It is serious problem because often the most fertile soils are exploited for the purpose of these constructions. Spatial planning failed in the Prague suburban area, urban sprawl is very serious problem and our research outputs are important indicators that will be used at the level of the Ministry of the Environment for the further control and prevention. Acknowledgement: The research is carried out thanks to the support of the Czech Science Foundation project no. 205/09/0995 Regional differentiation and possible risks of land use as a reflection of functional changes of landscape in Czechia 1990-2010 and to the support of the Ministry of the Environment of the Czech Republic project no. SP/4i5/212/07 Suburban Development, Suburbanisation

and Urban Sprawl in the Czech Republic: Tackling the Negative Impacts on the Environment

Chair: Ivan Bicik

Land use and land cover changes in the Oresund region

Mariola Ferenc (Polish Academy of Sciences)

The Oresund Region is a cross-border area located in Denmark and Sweden on both sides of the strait of Sund. With 3,7 million inhabitants, it is the most densely populated region in the Nordic countries. Changes in land use and land cover in the Oresund Region are the results of both demographic and economic factors, as well as local and regional law. Based on the Corine Land Cover 2000 and 2006, observations and interviews conducted in the region during the implementation of case studies, the EU-LUPA program (European Land Use Patterns) drew conclusions about the dynamics and scope of change. Changes in land use extend on multiple levels: both between sectors, as well as within administrative boundaries. One example might be the impact of construction of the Oresund Bridge, which created the conditions for development, especially settlement, on both sides of the strait. In 2010 more than 20 000 people crossed the bridge every day. The Oresund region is very interesting in the aspect of land use and land cover typologies because of the increasing importance of multifunctionality in this area. Denmark and southern Sweden, was for many years characterized by intensive, trademark agricultural. But nowadays farming has become more organic and focused on producing good quality food. Two additional functions that have appeared in the rural areas in recent years are recreation and the production of bioenergy. More and more farms are offering accommodation and entertainment, for example horse riding or fishing. Farmers produce biomass, which unfortunately contributes to the devastation of the landscape by vast fields of energy crops. Tourists also interfere with wind farms, which increasingly appear in the landscape of the coast. To prevent the devastation of the landscape and inconvenient noise, producers move farms to the sea. Changes in land use structure is influenced in majority not only by the agricultural situation, but also by strong pressure of new investments of agglomeration development, especially new settlements. Additionally, knowledge industries and research activities are moving to rural or coastal areas, because people prefer to work in nice landscape and clean conditions. The most important result is that the functional changes of land use in rural areas are far stronger than changes in land cover structure. Also we should say, that the changes are greater in semiurban areas than in cities and in rural areas.

The assessment of urban sprawl effect with emphasis for land use change using multi-temporal satellite imagery (Case study Urmia city 1984-2011)

Mina Farokhi (Zanjan University), Shahrivar Rostaei (Zanjan University), Mohsen Ahadnejad Reveshty (Zanjan University)

This paper assessment of characteristics, causes and effects of urban sprawl development pattern with emphasis on land use changes. The sprawl is external growth without control and imbalance at around of urban area that caused of destruction green space, increase traffic, loss of agricultural land and changes it's to built-up area. Sprawl use more land in comparing with compact development and it's a global phenomenon that is not only developing countries but developed countries also were involved by this phenomenon. This study was investigated to urban sprawl assessment and land use change in Urmia city and it's around with use of Landsat TM5 images for 27-year period. In order to detect and evaluate land use changes, image differencing, principal component analyses and Fuzzy ARTMAP classification method were applied. The result of this study shows that economic, social and environmental effects of sprawl caused that change in agriculture land to built-up area, density and transportation system in Urmia city in 1984-2011 during. In this research after detection of land use changes in case study area with use of other countries experimental and attention to case study area conditions the strategies in order to smart growth were developed that could improve Status quo and prevent further sprawl in the future.

Object-based LULC classification of urban and peri-urban areas

Luka Valozic (University of Zagreb)

During the last decade significant attention has been paid to object-based image analysis (or object-oriented image analysis) methods as the means for the land cover and land use classification of data acquired by remote sensing. This paper will present object-based LULC classification performed on multispectral remote sensing imagery of urban and peri-urban areas. Emphasis in the classification process will be placed on the mapping of the impervious surfaces as opposed to vegetation, soil, and water surfaces because that land cover class is made out of the most noticeable features of urban spaces: buildings and transportation network. Impervious surfaces, or more specifically their quantity and spatial pattern, are the ones that define the human settlements' morphology and structure most clearly and have undeniable influence on the water and energy flux in the environment. Remote sensing data used for this research will be RapidEye satellite imagery that comes in 5 spectral bands (red, green, blue, Red Edge, NIR) with the spatial resolution of 5 m and with the 16-bit radiometric resolution. Error matrix will be produced by comparison of the classification results and very high spatial resolution remote sensing imagery (available through services such as GoogleEarth) that will serve as the ground truth data. Software used for the object based image analysis and most of the other tasks will be Trimble eCognition Developer 8 and ESRI ArcGIS Desktop 9.3.1 (ArcInfo).

Modelling Spatio-Temporal Urban Land Cover Growth Dynamics: A Case Study of Khulna City, Bangladesh

Bayes Ahmed

The primary objective of this paper is to predict and analyze the future urban growth of Khulna City using the Landsat satellite images of 1989, 1999 and 2009. Khulna City Corporation (KCC) and its surrounding impact areas have been selected as the study area. At the beginning, a fisher supervised classification method has been applied to prepare the base maps with five broad land cover classes. In the next stage, three different models have been implemented to simulate the land cover map of Khulna City of 2009. These are named as 'Stochastic Markov (St_Markov)' model, 'Cellular Automata Markov (CA_Markov)' model and 'Multi Layer Perceptron Markov (MLP_Markov)' model. Then the best-fitted model has been selected based on various Kappa statistics values. This is how the 'Multi Layer Perceptron Markov (MLP_Markov)' model has been qualified as the most suitable model for this research. Later, using the MLP_Markov model, the land cover map of 2019 has been predicted. The MLP_Markov model shows that 33.33% of the total study area will be converted into builtup area cover type in 2019.

C08.25-11 - Session on Land Use and Land Cover Change – Urbanisation and Demographic Change 3

Chair: Ivan Bicik

Ivan Bicik et al.: Results and conclusions of the long – term land use development studies in Czechia (1845 - 1896 - 1948 - 1990 - 2010).

Ivan Bicik (University Prague)

Ivan Bicik et al.: Results and conclusions of the long - term land use development studies in Czechia (1845 - 1896 - 1948 - 1990 - 2010). One of the most progressive investigation not only in geography in the last two or three decades is landscape change. Faculty of Science at Charles university has some experience in this type of topics, as from geoecological as from social points of view. The second one was realized using statistical data from archives as data up to date on the base of cadastral units. All territory of Czechia covered 8 903 basic territorial units (= BTU - comparable as in time as from point of view of land use structure in 8 observed categories) and created database is fully located on the website (www.lucc.ic.cz). This database gave us possibility to study size of observed 8 categories and also to study land use structure and its development in different periods in specific natural and social economic conditions. Main results: bigger typological regions of similar land use structure were created step by step. Their inner structure is similar looking on land use structure of BTU, but there are big differences in comparison among created typological regions (metropolitan, suburban, lowlands with intensive agriculture, afforested mountain areas, second homes and recreational areas etc.). The same specific characteristics we can observed in long term development of land use in these specific regions. Completely different development of land use structure in four observed periods was defined. We will show specific methods suitable for similar databases in other countries (index of change, coefficient of anthropogenic influence, typology of macrostructural development of land use, main landscape processes etc.). This topic will be presented with many specific charts and tables explaining main results of this specific investigation. We can also compare rich results based on the statistical data and results obtained by overlaying detailed maps created for specific time horizons.

Investigation of urbanization in relation to accessibility of urban green space in Kunming, China

Jialing Wang (University of Pennsylvania)

Urban green space is an important component of urban ecosystem and contributes to the quality of life. This project takes Kunming of China as a case study and uses GIS and remote sensing techniques to analyze the linkage between rapid urbanization and the accessibility of urban green space. Situated on the northern shore of Lake Dian,

surrounded by mountains to the north, west, and east, Kunming is the capital city of Yunnan Province in southwestern China and is well known as 'Spring City'. During the last three decades, Kunming has experienced rapid urban growth that has led to tremendous landscape changes in the city and its surrounding area. This research is designed to include three major parts: (1) to map land use and cover, particularly, to map built-up land and urban green space of Kunming in different periods, based on Landsat images acquired between 1976 and 2010; (2) to measure the accessibility of urban green space in different years; and (3) to analyze the factors in the urbanization process of Kunming that have effects on the accessibility of urban green space. This study will add our understanding of urbanization as a major force driving the urban ecosystem changes and the research outcomes will be beneficial to make Kunming a modern eco-city in the near future.

Change detection of green cover areas, Greater Cairo, Egypt

Ahmed Abdelhalim Hassan (Münster University)

KEY WORDS: Greater Cairo; green cover; horizontal and vertical classifications; change detection analysis. **ABSTRACT:** The fertile land in Greater Cairo Metropolis is suffering from loss and misuse, since urban encroachment, high population growth rate, and poverty lead to exert pressure on fertile land. Therefore, this paper examines the transformation of green cover in the Greater Cairo; further evaluate the impact of rapid development on agricultural landscape and urban green areas. Multi temporal and multi resolution remotely sensed data (Landsat and Spot images) and field observations were used to apply horizontal and vertical conceptual classification and analysis to reveal green cover patterns and changes. Both positive and negative changes were detected and analysed in different levels and scales. Thus the green cover was decreased dramatically in the contact zone between the agriculture fields and settlements (hot spots) and increased in new metro areas. This approach could be contributed to the sustainability of fertile land in the future spatial planning in Greater Cairo.

Local Development

C08.26-01 - Regional Development: Planning and Disparities

Chair: Michael Sofer

Problems of Local Development: Impact of Population Distribution and Urban Agglomerations in Sabah, Malaysia

Shuang-Yann Wong (National Institute of Education)

In the early stage of local development, geographical asymmetries have often resulted in unequal development that tends to benefit the strategically located places in a country. The locational advantages of strategic regions are further reinforced with the extension of internationally connected and world standard transport and communication systems. Space economies are interdependent and agglomeration in one region may reduce the occurrence of agglomeration in another, especially when there are limited resources for development. Biased policies may worsen existing regional disparities. Using Sabah as a case study, this paper aims to show that the presence of too many sparsely distributed small urban centres and the absence of a strong urban agglomeration may retard the development of a remotely located region like Sabah in Malaysia. The assertion is that without the economies of scale and scope, the region will continue to function as a resource frontier, deepening its dependence on the more developed regions and precluding any opportunity of potential constructive local development. The spatial pattern of the region's population growth and distribution, the evolution of the urban landscape and related development problems and constraints over the last forty years including the social and political issues will be reviewed and analysed to provide the empirical evidence for the explanation of the suppositions made.

An Introduction to Regional Planning and Regional Policies in China with a Special Attention to the Main Functional Zoning

Weidong Liu (CAS), Hui Liu (CAS)

China is widely applauded for its rapid economic growth in the last three decades. However, along with such rapid growth, the Chinese society has witnessed a high cost in natural environment and social justice. Regional disparity and environmental degradation are two major issues faced by the Chinese government for achieving sustainable development. To alleviate the social and natural tensions, since 2000, the Chinese government has announced and implemented a number of major regional policies and made specific planning of major regions. One of the new measures in recent years is the Main Functional Zoning (MFZ), which has been included in the Twelfth Five-Year-Planning. The paper will introduce why and how to make the MFZ against the general

political and institutional background of China and analyze the role of the MFZ in achieving balanced regional development in China.

Potential of industrial heritage for regional development – case study of Brno city

Libor Lnenicka (Masaryk Universität)

The Brno city, centre of South Moravia region and also of the whole Moravia passed in terms of economic activities and their spatial localization after 1989 significant change. The industrial city became a post-industrial city with dominant administrative function. Location of areas intended for the production underwent a complete change in localization patterns, structure of employment and also other factors impacting economics of locality and whole South Moravian region changed (e.g. FDI inflows, innovation, businesses networks or R & D, etc.). The aim of this paper is to outline the current post-industrial development of the Brno city, with emphasis on the largest industrial zones - one along the Svitava River, the second zone on 'ernovice terrace'. The article also tries to analyze new trends in manufacturing location, industry structure and industrial heritage (brownfields).

C08.26-02 - Local Development in the Rural Space 1

Chair: Anthony Sorensen

The Regional Council as a Local development Agent: An Israeli Case Study

Michael Sofer (Bar-Ilan University), Levya Applebaum (Bar-Ilan University)

During the last three decades the rural space in Israel has gone through a process of economic, social and visual restructuring - from a productive farming space to a multifunctional space. This paper is concerned with one aspect of this process - the growing role of the regional councils, the local government bodies of the rural sector, as the leading actors in the transformation and development of the rural space. In addition to their statutory roles as administrators of the regions under their jurisdiction and representation of their residents vis-à-vis the national authorities, the councils have assumed responsibility for the physical, demographic, economic and social development of their regions. There are, however, considerable differences among the regional councils regarding their development priorities on the one hand and their organizational and economic capacity to implement their development plans on the other hand. The focus of this paper is upon the regional councils' ability to adjust to the changing conditions at the national, regional and local levels and to cope with the development challenges and their residents' expectations, in view of the available resources, the array of local opportunities, the options of institutional support, and the pressures of competing local and external interests. The underlying assumptions of the research are first, that some of the regional councils lack the professional capacity to make use of supporting programs and resources offered by national authorities, and second, that some of the support programs do not take into account the differences in the needs and priorities of regional councils. The result is a mismatch between the needs and possible solutions. The research is based on three inter-related components: analysis of policy papers; interviews with chairmen and officials of regional councils; and analysis of development plans submitted by the regional councils to the Ministry of Agriculture and Rural Development.

Local Development and Demographic Change – How the Region “Der Selfkant” (North Rhine-Westphalia, Germany) Meets the Challenge of Ensuring the Local Quality of Life

Sandra Opitz (RWTH Aachen)

Demographic change is one of the major challenges many developed nations are facing today. This is also the case in Germany where the population is expected to decline and age in the coming decades. These changes not only affect all aspects of society, but also all levels of administration. While there is a necessity for national and federal state governments to adapt legislation in order to manage this new situation, it is up to the

local authorities in the communities to deal with its effects by implementing federal state and national laws. In the light of this it becomes even more challenging for sparsely populated rural areas, which are already facing difficulties today, to provide an adequate level of public services and infrastructure in order to sustain the local quality of life. Research on this particular topic has up to now mainly been focusing on former East Germany where most rural areas are already dealing with or are going to have to cope with a shrinking as well as ageing population. Comparatively little is known however on the challenges awaiting West German rural areas. One of these rural areas with an ageing, if not yet shrinking population, is the region 'Der Selfkant' located in the district of Heinsberg in the West of North Rhine-Westphalia. With the financial support of the European Agricultural Fund for Rural Development (EAFRD) a group of local stakeholders and members from the communities' administrations in the region started to work out a long-term strategy to enhance and ensure the local quality of life. This strategy aims at making life in the region easier and more comfortable for an ageing population. It also strives to prevent the possibility of a large number of people moving to urban centers in the future. In a first step the most significant factors that contribute and affect the quality of life in the communities were determined. Realizing that future local development has to take greater account of the people's needs, the second step was to find out how the quality of life in the region is perceived by the local population. For this purpose, a large-scale citizen survey was carried out in 2009 by the Cultural Geography work group of RWTH Aachen University. It resulted in 1,600 residents aged 35 and older providing information and data. Selected findings of this survey will be presented in this talk and discussed keeping the question in mind as to how the local quality of life can be sustained and enhanced in view of an ageing population and tight municipal budgets.

The Role of Migration Networks on Rural Development in Iran

Seyed Ali Badri (University of Tehran), Hassan Izady (Shiraz University), Seyed Abbas Rajaei

Remittance has become a crucial source of income for households in rural areas of developing countries and migrants' networks have a significant role in the path it to the development projects in some societies. Using a cross-sectional dataset from two rural districts in Iran along with techniques of questionnaire and interview, the paper tests the relative significance of organized remittance and the other determinants of remittance behavior. The use of an improved statistical methodology enables corrections for potential NGOs in existing studies of remittance motives. The empirical results suggest that remittance appears to be driven by NGOs interested motives for provenance and hometown development. Interest and bias toward the hometown development is the effective factor that shape migration networks and NGOs in some Iranian metropolis same as Tehran lead to increase benefits of migration as well social capital. Keywords: Migration; Rural-Urban migration; Social capital; Migration networks, Rural areas of Iran.

Landscape at a rural-urban fringe

Milada Šastná (Mendel University in Brno), Iva Kenovská (University in Brno)

Local studies are mainly carried out at the outer part of the urban fringe; however this paper will present an overview of a research that is emphasizing the specific character of changing landscape at the rural-urban fringe in the South Moravia Region. This Region is distinguished by its diverse location, natural, economic and social potential for a further development. Growing emphasis will stay on the quality of the environment, a small and large scale landscape and an environmental conservation. Such a trend may lead not only to the improvement of the community life, but also disproportions in a regional development. Growing amount of leisure time of economically active people and pensioners in particular will play an important role in forming the landscape to satisfy their activities. The potential of the countryside at the rural-urban fringe as a place for a quality relaxation and recreation will come into consideration.

Cultivating a Culture of Business Innovation: Sustaining Rural Communities in Outback Australia

Anthony Sorensen (University of New England), Bernice Kotey (University of New England)

Australia's large number of small and remotely located rural service centres often struggle for survival under the weight of new technologies, rising agricultural efficiency, demographic restructuring, constantly shifting patterns of accessibility, and skeletal regional development strategies. We start by sketching the implications of this dynamic and sometimes lethal operating environment for the survival of local small businesses in country towns. Secondly we consider alternative antidotes to the stresses faced by small business, focusing especially on their need to acquire a culture of constant and rapid innovation. This is not an easy goal for either individual enterprises, as revealed by our recent work for Australia's Cotton Catchment Communities Cooperative Research Centre, or for communities as a whole observed during our current piece of action research. Our task in the latter research was to help develop strategies and institutions enabling enduring culture of innovation and entrepreneurship in the two small rural communities of Moree (in Northern New south Wales) and St. George (across the state border in Southern Queensland). We document the problems and successes we encountered along the way in our two chosen service centres and draw out themes of potential relevance to public policy and community action.

Spatial analysis of models of knowledge transfer in agriculture – first results

Konrad Czapiewski (Polish Academy of Sciences)

In the article will be presented the first results of the four-year project entitled 'Models of knowledge transfer in agriculture and its influence on agricultural productivity - spatial analysis' financed by the Polish National Science Centre. In view of the spatial differentiation occurring in Poland, it can be asserted that the issues concerning the overall level of education in a society are strictly related to the old-established two-dimensional division of the country (east-west, centres-peripheries). Also it is believed to be an indubitable truth that the magnitude of knowledge resources (differently quantified) has an immense effect on productivity, on economic results of the entire economy as well as on particular areas and firms. However, there are no in-depth analyses examining spatial differentiation from a perspective of people employed in agriculture that could allow for modelling of processes of knowledge transfer into agriculture. It should be stated that the available analyses concerning the effect of level of education, as well as of knowledge resources, on productivity and on other results of agricultural activity are not

sufficient enough to program the growth of that production factor. The whole project has a theoretical, cognitive and applicative character. A theoretical goal is related primarily to description and carrying out a spatial typology of agricultural farms, taking into consideration the dominant model of knowledge transfer. The cognitive task is going to be encapsulated at every stage of the project. In addition, along with development of models the conditions of their effectiveness will be established. The basic task of the project is to develop models of knowledge transfer in agriculture in a spatial dimension. Three particular goals that can facilitate achieving the main goal are: Analysis of significance of and accessibility to various knowledge sources that are available to farmers (secondary schools and higher education institutions, agricultural consultancy services, manufacturers of materials and equipment used in agriculture, information-communication technology, governmental agencies and private firms, EU projects and others). Analysis of changes in spatial diversity of the level of farmers' education (directional and general) in the years 1988-2010. Determining the effect of various forms of knowledge and education on economic results obtained in different types of farms.

Policies for local development in sparsely populated areas: Comparative analysis of three rural Spanish regions

Carmen Vazquez (University of Castilla-La Mancha), José M. Martinez (University of Castilla-La Mancha)

In the Green Paper on Territorial cohesion published by the European Commission in 2008, the "Sparsely Populated Areas" have been identified as "Regions with specific geographical qualities", which should be given particular attention within the EU cohesion policy. These are not only identified by criteria of population density, but also by the extent of the potential population (calculated for the resident population from a point and specific perimeter) in order to emphasize the relationship between the phenomena of scarcity and dispersal of population and the potential socio-economic consequences. The green paper identifies 18 sparsely populated areas in the EU, three of which are located at Spain (the provinces of Cuenca, Soria and Teruel articulated on the same mountain ridge, the Sistema Ibérico). The main challenge for these regions according to the green paper is "low density, peripheral situation and structural weakness, as well as dependence on the primary sector, which represents a substantial barrier to development". The LEADER European initiative has been consolidated in their different calls as a laboratory of socio-political experimentation which has enabled the financing of rural development programmes in most of Spain's regions and the renewal of the working methods of territorial actors in this field, becoming a useful tool for the acquisition of operational skills both for local action groups and public administrations. We insight the overlap and interaction between European, regional and local policies and criteria has led to processes and dynamics differentiated in each of the three provinces analyzed, fact that we will try to demonstrate in the development of our contribution. In order to address the development of this contribution we will begin presenting the structure and

characteristics of the three territories selected, characterised by remarkably similar ecological structures, based on statistical data and mapping which allow us to analyse diachronically the regressive evolution thereof. We will analyse the peculiarities of the territorial organization of development in each province through local action groups which have been developed its work since the 90s of last century to the present day to immediately pass to scrutinize the programs and projects managed and financed as well as their impact on local-rural development. Finally, we will study the policies and actions of regional and/or local initiative and its interaction with the regional policies of territorial cohesion animated from the European Union.

Development of Handicraft Industry for Rural Industrialisation: Case study of Sheetalpati (Reed-mat) in Cooch Behar District, India

Suman Sao (University of North Bengal)

Handicrafts are mostly defined as items made by hand, often with the use of simple tools, and are generally artistic and/or traditional in nature. They are also objects of utility and objects of decoration. The handicraft Industry stands a unique place among all other industries in India. It represents the rich culture, tradition and heritage of India. However, handicraft Industry has the status of cottage industry and it is one of the most important segments of decentralized sector in India. Most of the part of industry operates in rural and semi urban areas throughout the country but it has shown promising growth and has evolved as one of the major revenue generator over the years. It has shown continuous growth at the rate of 15-20% over the years and has large potential in Indian & International market. Handicraft Industry includes wide range of products because of country's diversified culture, traditions and heritage and provides ample opportunities for employment to people belonging to backward and weaker classes of society. Although the development of the rural economy in India will still be largely determined by the development of the rural-agricultural sector, however, the development of the non-agricultural sector, particularly handicraft industries is of equally crucial importance in leading towards a more effective and significantly integrated rural development. Handicraft Industry may be expected to absorb part of the underemployed rural population and to divert the rural work-force away from the overcrowded agricultural sector. Thus, rural industrialization could be seen as an important strategy in the programme of integrated rural development designed to remedy the problems of the rural sector. The main purpose of this study is to identify the constraints and potentials faced by Sheetalpati (Reed-mat) handicraft industry in a peripheral and underdeveloped region of the district of Cooch Behar in the State of West Bengal, India, and targeted the entrepreneurs and workers in the Sheetalpati handicraft enterprises. The study is based upon both qualitative and quantitative analyses of materials derived from field-work in several villages in the study area. It seeks to place handicrafts production within the broader theoretical context of rural industrialization and the development of traditional and peripheral rural areas of Cooch Behar. The analysis exhibits that though the sector in the

study area attracts skilled artisans and continues the industry's tradition moderately, units suffer from the problems like low productivity, monopoly of middlemen in marketing system, low level of investment, lack of credit facilities, slow growth in volume of production and no diversification in production system. Present study attempts to formulate constructive guidelines for the eradication of the inherent problems so that maximum utilization of the potentials of the sector is ensured.

C08.26-04 - Local Development in the Urban Space

Chair: Suman Sao

Effects of counter-urbanisation on the metropolitan areas of Romania

Liliana Guran-Nica (Spiru Haret University), Mihaela Frasineanu (Spiru Haret University), Dragos Frasineanu (Spiru Haret University)

Counter-urbanisation, the process by which people and employment leave the large urban areas moving into the countryside, is a continuous trend beginning with the 1960s. This process of decentralisation spread out from the most developed areas to the developing ones and it is present nowadays in the majority of the European countries. Romania has also experienced the process during the last decade as the result of the socio-economic changes issued from the political turnover in 1989. Counter-urbanisation affected mainly the rural-urban fringes but spectacular transformations occurred in the metropolitan areas. There are 9 such areas officially defined in Romania that are characterised by important demographic and socio-economic changes under the impact of urban-rural migration. The causes and the effects of this process are the main subject of the paper. The large diversity of settlements in these areas implies a complex set of determinants and responses, resulting in a number of behavioural types. Each metropolitan area is analysed based on a representative set of indicators, the results being the supporting information for the comparative study indicating the evolution tendencies for the next period.

Creation of social capital in the context of festivals and local development

Leena Hagsmo (Karstads University)

Keywords: local development, place, social and cultural impacts, social capital, festivals. In the context of local and regional development there is an ongoing discussion about the role of culture. One cultural phenomenon is festivals of different kind which can be important for local development especially in smaller places. In this discussion I will focus on the social and cultural impacts that a festival have on its host community, and if and how this in turn can have significant effects for local development. Soft factors as spirit of community, cooperation, happiness and confidence may be important for the wellbeing on a place and may affect its development. The essence in my discussion is the meaning of social capital and how significant this can be in the context of festivals and local development. When I am using the concept of social capital it is about trust and reciprocity between people, both within a special group but also between different groupings. The question is if those soft components, which may be strengthened in a festival contexts, in return can create benefits for the place and become important for the local development. Can the presence of social capital, which in turn can lead to a stronger confidence, affect the local development positively? Sometimes people need to cooperate

and act together to get things happen, so their creativity will be able to function. Festivals are such an arena where this is possible. A lot of work and engagement are required from the people within the festival organization; these people also spend a lot of time together in this group which may strengthen the social capital. In this context I am thinking about the social capital from an individual perspective and the potential individuals that benefit of social capital. If you as an individual are included in the "right" kind of social network you can hold a rich social capital, which may create some advantages for the individual in different ways. Networking and contacts are important aspects in a person's life. And I want to discuss how the engagement in a festival may have meaning for these people and in turn have meaning for the place. It is also necessary for the festival organization to create contacts with actors both within the local community as well as outside the community. Perhaps links can be created between groups and individuals, links and contacts that may be able to remain and survive outside the festival, meetings that otherwise would not occur. In terms of annual festivals, this can create lasting networks, which in turn can be positive for the local society.

Innovation potential of Polish cities

Piotr Sika (Polish Academy of Science)

Themes of innovation have gained importance in recent years, both in scientific discussions and practice, where the concept of innovation has become a key issue used in the development of enterprises. The popularity of this theme, however, contributed to the ambiguity of many basic concepts and the difficulties in the emergence of a uniform methodology. Synthetic description of the models of the innovation processes which are most common presented by Philimore and Marinova (2003). On the basis of subsequent models the concept of innovation systems was created, where existing term innovation potential which is the main subject of study in the presented paper. The main aim of this study is to identify the innovation potential of selected Polish cities and its relationship with the characteristics of the analyzed economic development in urban centers. There will be also structure of innovation potential presented. Spatial range of the study is 65 cities with county rights and the time span covers the years: 2000, 2004 and 2008. According to review of the literature and available statistic indicators five basic components of the innovation potential were identified. Those five components are: science, research and development, supporting institutions, industrial enterprises, enterprises structure. In total there were 21 indicators taken into account. In the first stage of analysis cities were divided into three groups (metropolitan centers, regional and sub-regional) to make greater transparency of the presented results and also to come forward with additional analytical findings. The second step of the analysis was to create a synthetic indicator of innovation potential. At the beginning there was made standardisation by Z-score of data. Next they were checked in terms of variability and separation demands. Calculation of the partial indicators (five basic components) was done by the method of distance from the model. Synthetic indicator of innovation

potential based on the method for the classification of multi-feature objects. In the third stage using the correlation coefficient Spearmana and Pearsona an analysis of relationships between the potential for innovation and economic growth was made. The last stage was factor analysis which based on 21 variables used also in construction synthetic indicator of innovation potential. The results presented data of innovation potential for each group of cities, showing how the individual centers change their potential for innovation in the subsequent time points. It also describes the relationship between the potential for innovation and the characteristics of urban economic development, which indicates a moderate correlation essentially static. On the basis of factor analysis there where identify three basic dimensions in structure of innovation potential.

Does FDI help local industries in Japan to survive? A case study of two local industries in Shikoku

Atsushi Taira (Kagawa University)

This study aims to explain the relations between overseas operations and the locality of the local industries through a case study of glove- and towel-related industries in Shikoku, Japan. Local industries ("jiba sangyo" in Japanese) have been struggling to survive rapidly increasing globalization particularly since the 1980s. For a long time, over a century in many cases, these local industries have played crucial roles in the regional economies. Some local firms began to internationalize their operations starting in the 1970s due to mainly labor shortages at first and then because of soaring production costs. The glove- and towel-related industries in Shikoku, Japan, are good examples of this phenomenon; both consist of small and medium-sized firms, and both have a domestic share over 60 percent. However, the significant percentages of their products are now produced in their foreign affiliates, especially in those in China. Along with the growth of overseas production and sophistication of product quality, the home regions in Shikoku are trying to redefine their positions and functions in their 'glocal' networks. A paper by Japan's Small and Medium Enterprise Agency reported that the number of domestic employees of small and medium-sized firms in Japan starting FDI first declined sharply, but later grew steadily, while the number of those not performing FDI kept dwindling. Is this also the case with the glove- and towel-related industries in Shikoku? What are their challenges? This study tries to provide answers of those questions.

C08.26-05 - Assessment of Local Development Projects and Initiatives

Chair: Ayda Eraydin

Participatory assessment of development in Ghana and Burkina Faso

Ton Dietz (African Studies Centre)

Between 2008 and 2012 in Northern Ghana and Southern Burkina Faso nine workshops took place in which a method was tested and improved to assist local populations to write their own local development histories and to assess and value the many development initiatives that came to their areas, partly initiated by the central and local governments, partly by non-governmental agencies, churches and mosques, and partly by private commercial agencies. A vlot of it was funded or sponsored by foreign donor agencies and well-wishers. In this paper I will highlight the geographical differentiation in 'development density', on the basis of the information gathered in all nine workshops, and the impact of these differences in 'density of development initiatives' on peoples' perception of development and change. The research was funded by three Dutch development NGOs (ICCO, Woord en Daad and Prisma) and undertaken by a consortium of Dutch, Ghanaian and Burkinabe partners: in the Netherlands these were the University of Amsterdam, the African Studies Centre and the Royal Tropical Institute; in Ghana the University for Development Studies in Tamale and in Burkina Faso the Expertise pour le Developpement du Sahel. Research took place in Ghana's Upper East Region (Sandema), Upper West Region (Nandom and Lasia Toulou), Northern Region (Langbensi, Wulensi and Daboya) and in Burkina Faso's Southern region (To, Silly, and Niabouri). Reports and a guidebook can be found on www.padev.nl. Ton Dietz, December 2011

Economic Resilience: Adapting to and Benefiting from the Volatile Conditions Imposed by Globalisation

Ayda Eraydin (Middle East Technical University)

Economic Resilience: Adapting to and Benefiting from the Volatile Conditions Imposed by Globalisation Studies into the impacts of globalisation have emphasised its positive effects on metropolitan economies, firstly by enhancing the appeal of such places for international capital; secondly, by enabling local agents to export their products and services all over the world; and thirdly, by allowing benefit to be drawn from the spillover effects of globally circulating knowledge, information and technologies. The common key word in all these debates is 'competitiveness,' which has become a way of discussing the relative economic performance of territories in their achievements in the generation of income, employment and new enterprises. However, the recent debates following the economic and ecological crisis experienced in the last decade, the concept of economic resilience received increasing attention not only by academics but also by policymakers

(Hudson, 2010). As Hill, Wial and Wolman (2008) emphasise despite the growing importance of the idea of economic resilience it has not been carefully defined or measured. This paper aims to define the attributes of economic resilience and operationalise the concept with the help of case studies that explore and compare the characteristics regional economies and strategies of the different stakeholders of the regional economies that are successfully adapted to the crisis and even benefited from the volatilities and the ones not. REFERENCES Hill, E., Wial, H and Wolman, H. (2008) Exploring Regional Economic Resilience, IURD Working Paper Series, Institute of Urban and Regional Development, UC Berkeley Hudson, R. (2010) Resilient regions in an uncertain world: wishful thinking or a practical reality? Cambridge Journal of Regions, Economy and Society 2010, 3, 11'25

Rebuilding Babel: Finding Common Development Solutions Using Cross-Contextual Comparisons of Multidimensional Well-being

Gilvan Guedes (Vale do Rio Doce University), James Hull (Brown University)

We build on the theoretical tradition of livelihood strategies and capital portfolios to empirically assess wellbeing among rural households, with an eye to comparison across contexts. First, we estimate a multidimensional measure of poverty based on fuzzy logic, for two rural frontiers: Nang Rong, Thailand and Altamira, Brazil. To enable cross-contextual comparison, we calculate a second estimate using a subset of shared measures. We find that the pattern of response over the range of many key variables - for example education, income, and demographic dependency ratio - is robust to model specification, suggesting that comparative generalizations, useful in formulating cost-effective policy interventions across contexts, could be satisfactorily identified in many instances. More generally, our approach provides researchers and policymakers with a framework for understanding the interaction of context and the subjective construction of wellbeing that is useful for distinguishing stable corollaries of poverty from those that are volatile across contexts.

C08.27

Marginalization, Globalization, and Regional and Local Responses

C08.27-01 - Interpretations of Marginality 1

Chair: Etienne Nel, Walter Leimgruber

From merge to place: Pewenche's case

Hugo Capella Miterique (Universidad de Chile)

Nowadays, Pewenche's territory is split in the Andes, between Argentina and Chile, but in the past, it was seen as a unity based on the adaption of a transhumance mountain society, related to the Andes. Present marginality and poverty discourses in that area, are based on the difficulty to live in the Andes, according to physical determinism discourses that hide the real historical and cultural marginalization process, under national identity interests. The present article focuses on one hand to prove how a cultural marginalization in the split Pewenche's territory has been hidden behind natural causes and on the other hand, we deep into the need to study the area as a whole unity, to encourage a new glance to this land and its own development ways. The new glance on Pewenche's unity would be a useful answer to regional development, close to ecological sustainability principles and at the same time a way to recognize the Pewenche's marginalized identity, after years of Argentinian and Chilean National rules dominions.

The colonias populares of Mexico City: Spaces of marginality?

Antonine Ribardiere (Université Paris), Jean François Valette (Paris)

This paper aims to examine the pertinence of the concept of marginality (GURUNG G.S., KOLLMAR M., 2005) in understanding the specific characteristics and the evolutionary dynamics of the lower-class neighbourhoods that lie on the outskirts of Mexico City. Our analysis is centred on three aspects of marginality. The first of these is social, and characterizes the resident population according to its standard of living as well as its access to basic services and decent housing conditions. It relates to the definition of marginación urbana that has been adopted by the Consejo Nacional de Población for establishing official economic and social development programmes (CONAPO, 2009). The index based on this definition is specifically intended for the colonias populares, large built-up areas on the fringes of the city proper that became urbanized through the settling of the local residents, despite them not possessing any title deeds. These areas are also characterized by two other forms of marginality. One of these is spatial, and concerns their peripheral location at the time of their urbanization as well as their poor connection to networks. The other is property related, and reflects the irregular status of their occupancy of the land. This land tenure insecurity assumes a strong political dimension for two reasons: first, without title deeds, the residents may potentially be deprived of civil rights, and second, land and physical regularization processes require the involvement of clientalist games at different levels. We propose to examine the relationships between these three aspects of marginality. To what extent does the illegality into which these

lower-class neighbourhoods are born operate as a determinism, imprisoning them and their residents in their marginal status? Is it possible to establish a link between progress in land and physical regularization and changes in the indicators of social marginality? A diachronic study of the socio-demographic indicators of vulnerability will serve to demonstrate how such lower-class neighbourhoods may be identified as sites of social marginality. Several subtleties will be taken into account in this interpretation: we will show that social marginality is also associated with other types of areas, and that the colonias populares take on a wide variety of forms and encompass various degrees of social marginality. Most notably, today, the earliest generations of colonias populares are largely integrated into the city proper. Yet, the simplistic relationship between regularization and social and urban integration should be examined. Thus, we will compare progress in regularization with changes in the social profiles within a sample comprising four recent peripheral areas, which sprang up some twenty years ago, in order to reveal the complex and changing relationships between the social, spatial and property-related aspects of marginality.

Spatial reproduction of floating population: Social geographical perspective

Yao Huasong (Guangzhou University)

Social space of floating population is a reproductive space impersonated of their natures and activities based on urban roots. Firstly, this paper inducted the forms of spatial reproduction, which included physical space, behavioral space and cognitive space (differentiated space, segmented space, space under fordism and information age, compressed space, flexible space, space of flows, problematic space, suppressed space, representational space). Second, tapping event history analysis, discussed the construction process of social space of floating population. It is found that social space of floating population is indicative of marginalized space, which resulted from socialization of their natures, social discrimination of related regimes, ne-liberalism of urban governance, fierce competition for urban space, profits-seeking of entrepreneurs, exclusion of local citizens. Spatial reproduction is also the process of reproduction of original production relations. Lastly, facing pressures from other groups, they tend to alter their spatial adaptability, pushing forward their relations with cities where they live.

The Rural - Urban Topological Space of Finnskogen: Conveying Marginality to the Marginal?

Camilla Berglund (Karlstad University)

The forest landscape of Finnskogen, in the county of Värmland in Sweden, has faced a dramatic depopulation and hence a loss or decline in provision of public services - due to institutional and livelihood changes. These changes could probably be said mainly to have started when the forests became of interest in different phases of the industrial development. If the pre industrial forest landscape offered a diversified livelihood related

to the shifting seasons and practices associated with these, and meant a life in a relatively time and space compression, the post industrial forest landscape could perhaps be said to once again offer diverse way of living, in a time and space compression out of mobility. In the traces of depopulation houses are sold to people from mostly urban areas in Sweden, Norway and northern Europe, and become second homes. For those individuals with longer roots in the area, still living there, this leads to (new) meetings in values and knowledge of the forest landscape and practices related to it. Who or what is being marginalized becomes of relatively blurring boundaries even though the area of Finnskogen as such is considered one of economic and geographical marginality. The area of Finnskogen is just a geographical entity, defined and valued by its users and consumers, and what is considered marginal by who seems to differ, especially when marginality becomes of a value as such. The history of decline in Finnskogen could almost be described as a prerequisite for the development of a marginality in the meaning of rareness (i.e. silence, freedom, authenticity) desired today by many urban dwellers. It is interesting here to reflect on the topology as an alternative to the concept of relational - of rural and urban space and time connected through the mobility of people and their views and values. The purpose of the paper is to discuss some theoretical ideas and considerations grounded in for instance literature about marginality: How are the concepts of decline, development and marginalization articulated and used by different settlers in Finnskogen and what kind of multiple landscapes will come out of this? The theorization will be discussed and illustrated from field studies, participant observation and interviews carried out in the area during the years of 2010-2011.

C08.27-02 - Interpretations of Marginality 2

Chair: Etienne Nel, Walter Leimgruber

The global food issue in the marginality context

Walter Leimgruber (University of Fribourg)

The problem of food supply and nutrition have been the objects of discussion ever since Malthus wrote his famous essay. Usually, the roots of and the solutions to this problem are exclusively sought in environmental and technical fields: harvest failures due to meteorological and climatic reasons, inadequate food distribution channels, food prices and so on are quoted - in other words, the approach has been dominated by quantitative arguments. While these factors doubtlessly play an important role, they are not the only reasons for the fact that about one billion people on our Planet suffer from hunger and/or malnutrition. This paper proposes a number of reflections on the superficial and on the deeper reasons for the food problem. It argues that we are confronted with a much more complex situation that is linked to the intimate relationship between environmental and societal problems. Agriculture (the food provider) is not only dependent on physical conditions (soil, water, weather etc.) but is anchored in cultural practices. Besides, the lust for power and the greed for material profit all along the food chain have transformed this entire field into a political and neoliberal playing field with dire consequences for the underprivileged and the poor. The answer to the global food crisis lies therefore not only with the many solutions technology seems to offer but to an even greater degree in the attitude humans across the globe manifest towards food and nutrition. Keywords: world hunger, food, nutrition, energy, value systems

Does English marginalize other scientific languages – the case of Slovenian Geography?

Stanko Pelc (University of Primorska)

»English as a lingua franca« undoubtedly became a mean of communication between speakers of different first languages. It is widely used in international contacts in politics, business and tourism as well as in science. Internationalization and globalization of research carried out at universities and research institutes strengthens the dominating role of English as a scientific language. It became the current most significant publication language. The slogan long present in academic society 'Publish or perish' has therefore been changed into 'Publish in English or perish'. As we are forced to publish internationally and usually in English we no longer do our research work with respect for local problems and needs. On the contrary, we are selecting the topics that can be interesting for international audience and are therefore internationally publishable. Slovenian universities and Slovenian Research Agency are all encouraging (forcing) researchers to publish internationally through evaluation of their work that is based on

numbers of bibliographical units published in scientific journals with higher impact factors included into indexed databases such as SCI, SSCI, A&H and ERIH. As the number of citations is also very important for researchers that want to be successful at national level have to publish about the topics that are relevant for larger number of researchers (on the international 'research market'). This redirects the focus of research away from many nationally important topics. Furthermore it impoverishes the national scientific language. In case of Slovenian geography its Slovenian geographical scientific language. National terminology cannot develop if researchers that are using it are doing so predominantly in foreign (English) language. From this point of view in today's globalized science the Slovenian geographical scientific language may be considered as marginalised (similar as many others) and the scope of our paper is to give some evidence of this fact and to discuss the present and expected consequences of it.

Changing Livelihood Strategies and Practices of a Marginal Community of Bhutan

Raghubir Chand (Kumaun University)

Bhutan is a country of diverse and rich ecosystems and being increasingly looked upon as a model for nature conservation by other countries. Bhutanese live in close proximity to nature and derive their livelihood from natural resources from centuries. The subsistence farming, livestock rearing and forest based activities are the major components of traditional livelihood practices. Bhutan's rugged mountain terrain and cold climate exhibit a crucial challenge for the growth of agriculture and dependence on itself. People have thus developed local arrangements and use of time and space factors to evolve various indigenous strategies to balance their livelihood systems. For last few decades a lot of developmental initiatives are taken to improve the living of Bhutanese population. As Bhutan has evolved into a new era of democracy in the year 2008, the issue of people's living has gained significant momentum. It is in this perspective that the present paper addresses the existing and changing livelihood strategies of a very remotely located Shingkhari-Lauri region of Bhutan. Lauri gewog (block) of Samdrup Jongkhari dzongkhag (district) is one of the remotest gewog of far-east Bhutan. The gewog is three days walking distance from Jomotsangkha (previously known as Diagam) dzongkhag (a sub divisional administrative unit) and a border town at the foot hill adjoining the plain of Assam, India. Village Lauri is selected for livelihood strategy survey conducted in January 2009. The data gathered from 100 households suggest that a majority of 77 households derive their main income from non-agricultural pursuits such as wage labour and porter charges, manufacturing of local traditional goods, carpentry and masonry works, collection of wild medicinal herbs, weaving and painting and performing rituals by local priest called gomchens etc. It is also observed that labour and porter charges are common source of income for all households along with all other means of livelihood. There are two ways in which the wage labour is practiced by the village people. One is more immediate which absorbs them in transporting food grains and other essentials

including raw material required by the on going community development schemes. The second and more important is the labour migration as part of seasonal move to low lying warmer valleys during winter. Jomotshangkha is the main destination of Lauri people where a majority of 62 households were found working followed by 39 households in Langchenphu at the time of survey. People also move across in to Arunachal Pradesh of India in search of jobs. This paper thus presents an overview of selected livelihood components in the changing environmental context.

Spatial Representation in the Marginality

Antonie Schmiz (Universität zu Berlin)

Migration is predominantly taking place into cities. While there is a national responsibility for migration management, the communal level deals with migrants' daily and practical hurdles and challenges in the settlement process. Since large parts of the former Vietnamese contract worker community in Berlin nowadays live in Berlin's marginal districts of Lichtenberg and Marzahn-Hellersdorf, this group is hardly visible in the central parts of the city while it does not command a spatial representation of its economic activities. As a reaction on this absent spatial representation, Berlin's communal politicians repeatedly tried to establish a Chinatown to accommodate Asian entrepreneurs at one site. The self-evident but unconsidered lack of a common identity of Asian migrants in Berlin, the randomly chosen local sites, as well as the top-down approach contradicted the grown structures of the multi-layered Vietnamese community in Berlin. Hence, these projects were never realised. Using the example of the Dong Xuan Centre (DXC) in Berlin, it will be demonstrated how a 'Vietnamtown' grew on a marginal site in a bottom-up process. Currently, this centre receives growing attention by tourists, scientists, artists and the administrative urban planning units. The DXC, as a developing, prosperous project newly takes the global brand of Chinatowns as a role model. Its endogenous development is based on reciprocity and a mutual trust between the wholesale traders and the Vietnamese management. Its vision of a holistic development with a residential zone, a TCM-medical centre, a building for cultural events and a hotel contradicts the administrative planning restrictions. Thus, the centre's management is in an ongoing conflict with the district of Lichtenberg's administrative planning units. On the one hand the districts administrative planning follows Berlin's interest to establish the DXC as a Chinatown to gain a spatial representation for Asian entrepreneurial communities in Berlin and for an official marketing in tourist guides and on touristy websites. The marketing of this place further targets the development of a cosmopolitan urban concept as a soft locational advantage for the settlement of knowledge based and creative industries. On the other hand, the district obliges a planning tool which has been generated to protect retail trade in stated urban centres. Following this tool, retail trade and the provision of services, which is currently taking place in the DXC informally, shall be prohibited. The paper discusses the further development of an endogenously grown place as a possibility to avoid conflicts of former related projects while it already enjoys

the acceptance of the Vietnamese community. Thereby it provides an example of a marginal group contesting on a marginal site which is hidden by processes taking place in many regions of the globalised world.

C08.27-03 - Marginality in a Globalizing World

Chair: Etienne Nel, Walter Leimgruber

Östmark, Marginalized in a Globalized World – Some Future Possibilities

Gerhard Gustafsson (Department of Geography and Tourism)

By the help of experiences from a case study, the Östmark area in Värmland, Sweden, globalization may be treated as both a problem and an advantage - a problem because of the economic force that can be seen as promoting urban growth and that makes different areas in the world look more alike and an advantage because the process brings people closer to each other due to different kinds of communication and this implicate that different areas have much in common. In this presentation there is a try to see how marginality in this situation can be seen as something positive in the sense that areas like Östmark represent a social structure that represent more of a society that can survive in a future society more adapted to the threats from 'climate change'. The presentation consists of both empirical examples of changes in the area, between global and local constructions, and more philosophical ideas about changes in society. All together the presentation is based on a discussion of different ways of develop marginal areas as well as other areas in the future. The conclusion is that development in marginal areas can be seen as a total social change strategy and is no longer marginal, but central.

The local-global interaction in the Uco Valley (Mendoza, Argentina): overcoming marginality or increasing heterogeneity?

Margarita Schmidt (Universidad de Cuyo)

In a previous case study about the Uco valley in the province of Mendoza (Argentina), we referred to the local transformations in the agro-industrial activities in a mountainous area under the influence of globalization. Based on the results of that study, presented in a former meeting of the Commission of Marginality, we reconsider one of the problems of the area, to deepen its analysis. In that opportunity, we stated that the recent developments of the last twenty years 'constituted essentially by the incorporation of large non-local and often foreign viti- and viniculture enterprises- have allowed to overcome some conditions of insufficient integration and of lower development level that characterized the area. Nevertheless, one of the negative consequences of these transformations is represented by an increasing structural heterogeneity. This deeper contrast between globalized actors and traditional actors represents the marginality characteristic that is being accentuated. In the present study, those conclusions are reconsidered with the aim of deepening in the problem of the divergent development of different agents and activities in the Uco valley. Lately, we can realize the coexistence of a globalized world and a traditional world that goes beyond the viticultural activity, and progressively acquires manifestations in other areas. The launching of new undertakings

belonging to diverse areas, like entertainment, tourism, gastronomy, sports, residence, among others, is added to the large and modern wineries of high technological level with their respective vineyards. All these activities are oriented towards a very selective public, of high income, non-regional and frequently foreign origin and with interests that are very far away from those of the locally rooted population. Although these developments are still incipient, they already show some evident territorial effects. In this sense, an objective vision of these transformations is presented. They include the new undertakings and their consequences in the traditional ambit. Between these last ones, the abandonment of agricultural activities, the sale of properties to non-regional investors, the change in the size of the parcels of land, the reconversion and the change of activities can be mentioned. The perception of the positive and negative effects of these new undertakings and activities that have the diverse involved actors is also examined. The valuation of the integration degree they reach in the context of the local community is finally considered. In this way, the integration, complementation, coexistence or confrontation between territorial actors with deeply different productive and activity profiles is analysed from diverse complementary perspectives. Herewith, we try to evaluate the results of this local-global interaction and its influence on the marginality conditions of the region, particularly the heterogeneity between the different groups.

Local development through tourism and new localism

Yasutaka Matsuo (Senshu University)

This research aims to explore the indigenous sustainability of rural areas. The center of interest is the formation of localism through tourism. In the vast depopulated areas in Japan, a few local habitats are competent enough to live a stable life through the prosperity of tourism. Local development has been attained in the substantiation process as the tourist spots. In the first place, the following is investigated. What kind of special natural resources or social conditions has made the local development possible? Whether some common characteristics are recognized or not among the flourishing tourist spots? Next, the research deals with the tourist spots where the inbound tourism has become prosperous. The inbound tourism means the tourism of the foreigners into Japan. As Japan is characterized by its ethnic homogeneity, the introduction of the inbound tourism was rather a big decision for the rural local residents. Its success probably had a widespread influence upon the locality. This suggests that the formation of the new localism is potentially under way in the inbound tourist spots. It is examined whether and how the new localism is manifested in the phases of land management, landscape care, social structure and psychology, local networks and so on.

Getting even more marginal: Global economic crisis and regional disparities in Romania

Raularian Rusu (University of Cluj-Napoca)

Global economic crisis has severely hit Eastern European countries, and Romania made no exception. Since 2009, the crisis has determined the government to make a financial agreement with the IMF, which led to budgetary cuts, including a 25% reduction of wages of all public sector employees, the cancellation of almost all bonuses and an increase of VAT from 19% to 24%. These measures resulted in lower living standards and an overall reduction of consumption. In addition, higher taxes and especially the compulsory tax for all companies, regardless of their profit, led to a general collapse of the microeconomic sector, resulting in the bankruptcy of thousands of SMEs and increasing unemployment rates. While these facts point out to the economic and social decline at national level and the increasing marginal position of Romania in the European Union, there is a growing differentiation within the Romanian society as well. The dissolution of hundreds of schools in the rural areas and the closing of hospitals in small towns enlarged the existing gaps between central regions and large cities, on the one hand, and rural and marginal areas, on the other hand. The concentration of investments in or around the large cities and along the main development axes is also in favor of centralization. In contrast, the scarcity of subsidies for the primary sector determined many farmers to abandon their activities. Therefore subsistence agriculture is still the main economic activity in the countryside, producing next to nothing for the national economy as it has almost no connection to the market. The decommissioning of many mining sites and heavy industry plants also had a high impact in formerly developed regions, especially in mountain areas, where unemployment rates reached maximal levels. The strategies of highlighting the tourism attractions of these areas and to change the focus of their development to service provision (mainly tourism) proved partially unsuccessful. The analysis of regional disparities at the regional and county level shows ever increasing imbalances and inequalities between the developed and underdeveloped areas. While the hierarchy remains largely the same, with Bucharest and Ilfov County still way ahead of the other regions, the largely rural counties are getting even more marginal.

Formalizing Urban Agriculture and Practice an Response to Economic Marginalization: Evidence from Zambia's Copperbelt

Etienne Nel (University of Otago), Tony Binns (University of Otago), Jessie Smart (University of Otago)

Urban agriculture is now widely recognized as a both an inevitable and a legitimate response to the lack of economic opportunities available to the residents of the burgeoning cities of the Global South. Unfortunately many government's still adopt a negative response to the growing of crops and the keeping of animals in urban areas, leading to the destruction of crops and enhanced suffering on the part of the poor. One area of the Global South which has been particularly hard-hit by economic change is the once thriving Copperbelt of Zambia where the collapse of once prosperous mines and industries from the 1990s has forced the majority of the population into a reliance on informal livelihood strategies and urban agriculture. Partially in response to the scale of economic loss, the City Council of Ndola, in a move which is virtually unique in Africa, has decided to overtly support urban agriculture through policy support, collaboration with key stakeholders, including the Ministry of Agriculture and efforts to leverage infrastructural and financial support. This presentation is based on extensive fieldwork in the area undertaken over a 3 years period. An overview of the scale of the economic loss the area has experienced is provided, the key role which urban agriculture now plays in people's livelihoods is outlined and emphasis is placed on an assessment of the impact of policy support. The latter leads into a discussion on what else the city still needs to do and the broader implications of such support for cities elsewhere in Africa.

Intégration des régions montagneuses d'Asie du Sud-Est continentale, 1960-2010: entre adaptation et marginalisation

Steve Déry (Université Laval)

L'adaptation des sociétés humaines aux transformations profondes de l'économie mondiale, et plus généralement de l'environnement dans lequel nous vivons, constitue un défi pour les humains du XXI^e siècle. Les régions montagneuses d'Asie du Sud-Est constituent un terrain fertile pour étudier ce processus. Les États modernes centralisés y reconstruisent une nouvelle territorialité dont la légitimité repose en partie sur l'organisation politique et économique mondiale. L'intégration au reste du monde s'est accélérée et intensifiée depuis les indépendances et les années 1970, déclenchant des processus d'adaptation mais aussi, une marginalisation de plusieurs populations

affectées. Dans ce contexte, cette communication vise à faire un premier bilan des processus d'intégration de cette région aux systèmes socioéconomiques et politiques nationaux et internationaux. Qui sont les acteurs? À quel niveau se situe leur action et sur quel terme temporel? Qui sont les populations visées? Quelles transformations sont induites? Le cas spécifique du Vietnam sera examiné plus précisément. Mots-clés: Asie du Sud-Est continentale, Vietnam, État, niveaux géographiques, intégration, marginalisation

Impact of rural restructuring on the time-space behavioural patterns in marginal area

Vladimir Ira (Slovak Academy of Sciences)

The contemporary era of rural restructuring in marginal regions of Slovakia is set by earlier changes in the rural world and by the pace and persistence of change in transition period as experienced during the last decade of the twentieth and early twenty-first centuries. The characteristics express the way in which recent rural change has been driven by processes of transformation (modernization, post-communist transition, marginalization, and globalization). The contribution sought to analyse recent and contemporary rural restructuring by examining time-space behaviour of people living in marginal mountainous municipality of Lom nad Rimavicou in Central Slovakia. Several time-geography concepts applied in the study are presented and results from three surveys (based on time-space budgets) conducted in the years 1986, 1997 and 2011 are analysed. The processes of rural restructuring and their time-space consequences in individual's behaviour might lead us to re-think the way in which we approach the changes in rural life.

Demographic and Economic Change in Small Towns in New Zealand

Etienne Nel (University of Otago)

Small towns are widely regarded as 'under-researched' elements in the urban systems of most countries. Contrary to conventional wisdom in the 20th Century which argued that in most OECD countries small towns were broadly in a phase on long-term decline, recent evidence indicates a reversal in the fortunes of many, but not all, small towns. Counter-urbanization, globalization, the retirement of the 'baby-boomers', tourism, new forms of rural enterprise in a 'post-productivist' or an increasingly 'multi-functional' reality have helped small towns in many areas to experience what has been referred to as the 'second modernity'. Such change is not however universal as it is apparent that some towns are either better located to benefit from change or have greater capacity to initiate endogenous development processes. This paper provides a comprehensive overview of what has been happening in New Zealand's small town system since the early years of the 20th century. While initial emphasis is placed on demographic shifts and associated small town growth and decline, the focus then shifts to examine economic change. Activities associated with the 'second modernity' clearly are having an impact, however a key question which need to be assessed is whether such processes can reverse population loss and economic decline in all centres. Evidence from places which have 'reinvented' themselves are contrasted with places which have failed to do so in order to arrive at the paper's key conclusions.

Development, Marginalization and Problems of Identity: The Post-Liberalization Scenario in West Bengal

Lakshminarayan Satpati (University of Calcutta)

West Bengal, as a state of the Indian Union, holds a unique position in regard to historical, political, economic and cultural aspects of the country. During the British period the then Bengal Province used to play key roles in the administrative affairs also, as Kolkata was the capital till 1911. Taking several physical and human factors as advantages for development, there was tremendous industrial-economic growth along the Hooghly River leading to excessive concentration of wealth and population within and around Kolkata, which became a megacity during the recent past. Even after the shift of India's capital to Delhi, the Kolkata-centric growth continued through Independence. Although the State Governments of West Bengal successively tried to establish a few industrial-economic growth centres at Asansol-Durgapur, Siliguri and Haldia areas, the rural agrarian economy could not find any significant achievement to curb unemployment,

poverty and selective migration from rural to urban areas. The influx of population from countryside and also from the bordering Bangladesh became an important issue that was responsible not only for the change, so some extent, of demographic character of the state, but also became one of the crucial political regulator, especially during the 1970s when the Left Front Government replaced the Congress-led government. Owing to liberalization in 1990s, West Bengal had to face drastic change in economic policy of the Indian Government. The ideological conflict, at least theoretically, between the Left and Non-left parties came into the forefront; but in reality market became the key player. Subsidized education, shift towards ICT- based industries, substantial increase in the incomes of the high middle-class people with corresponding rise of purchasing power favoured the emergence of a new type of consumer-society. The developments again led to accumulation of wealth in Kolkata conurbation, and the rural areas became more impoverished and marginalized. The political and administrative decisions continued to be centralized and a sense of deprivation among the rural poor became imminent. As the prevailing education system does not have much relevance to job and income, the educated youth of the remote areas wanted to proclaim their identity and a series of socio-political crises having economic root took prominence. The disturbances in so-called Jungle Mahal, Darjeeling Hills and among a section of the minority communities cannot be resolved without addressing the issues. This paper is an attempt to analyze the socio-political crises of post-liberalized West Bengal taking into consideration the historical as well as regional contexts of development in the state.

Modeling Geographical Systems

C08.28-01 - Geocomputations and Applications

Chair: Therese Steenberghen, Stewart Fotheringham

Progress on shape metrics for edge analysis

Steven Roberts (Wilfrid Laurier University)

Shape is the property of a geometric figure that is invariant under translation, rotation and scaling. Earlier efforts to use shape metrics to analyse polygonal boundaries in landscape spatial data utilized Kendall coordinates (Roberts et al., 2000). This works well for shapes that have well defined landmarks. We demonstrated at the Canadian Association of Geographers Conference 2007 how to use statistical shape analysis tools for the automatic parsing of morphological features from GPS tracking points of Grizzly bears and also shape metrics as a way to formulate an alternative stopping criteria for the Douglas-Poiker line generalization algorithm. However, the lack of a canonical dimension for the metric is a significant drawback for studying landscape boundaries that often lack unambiguous landmarks. The metric of Small and Le (2002) avoids this problem of lack of landmarks via a parametric representation. However, the shape representation introduced creates a problem for the use of this metric with geographic spatial data as there is no apparent canonical way to parameterize a closed curve. In this paper we demonstrate the use of a shape metric to analyse the structure of landscape feature edges specifically by partitioning a set of boundaries between different landscape feature types into classes based only on shape as defined above. The partitioning is via a pruning algorithm operating on an Minimum Spanning Tree of shape distances between the set of boundary edges. We also introduce a solution to the problem of calculating unambiguous shape distances for closed curves when using the Small-Le shape metric. S. A. Roberts, G. B. Hall and P. H. Calamai, Shape-based Properties of the Boundaries between Landscape Feature Types, in P. Forer, A.G.O. Yeh and J. He (Eds.), Proceedings of the 9th International Symposium on Spatial Data Handling, Beijing, 1b.27-50, 2000 (Aug). C.G. Small and H. Le, The statistical analysis of dynamic curves and sections, Pattern Recognition, 35: 1597-1609, 2002.

Temporal assessment of land use and occupation of the city of Conde, Brazil

Maria Emanuella Firmino Barbosa (UFPB/IFPB), Nathália de Alcântara Rodrigues Alves (Ciência e tecnologia da Paraíba), Denize Monteiro dos Anjos (Ciência e tecnologia da Paraíba), Michelly Gomes de Araújo (Ciência e tecnologia da Paraíba), Michele Beppler (Ciência e tecnologia da Paraíba)

The municipality of Conde is located in the metropolitan area of João Pessoa, Paraíba State, Brazil. Is between the geographical coordinates of 7 ° 11 '48 "and 7 ° 23'49" south latitude, 34 ° 47' 35 "and 34 ° 57 '25" west longitude and occupies an area of 174 km².

The cited above municipality, located in the coastal region has a great importance in the tourism sector due to the presence of natural beauty, attracting investors, particularly land property, hospitality, and tourists to the site, generating income for its inhabitants. This paper aims to show the advancement of the use and occupation of land in the last decades through the preparation of thematic maps (land use and occupation, vegetation, slope, hypsometric and geomorphologic). The Cartographic Base to be used in this study, still has in the Geodetic Reference System SAD69. However this study also aims to update the cartographic base for the Geodetic Reference System SIRGAS2000, through the development of an application in the Java language. The information to generate the base map of the project will come from satellite images CBERS 2B, aerial photographs and topographic charts of the area. All data processing and generation of thematic maps will be done with the help of the software SPRING 5.1.7. During the research will be necessary field visits for data acquisition and verification of information acquired. The results to be achieved with this research project is the creation of a geographic database with information about the locations of irregular occupation and deforested areas in the municipality of Conde, providing a database for those who seek to information about the municipality.

Site Selection for Ecotourism with Emphasis Red List (IUCN), Case Study: Miankaleh Peninsula (Iran)

Manijeh Ghahroudi (Shahid Beheshti University), Seyed Hasan Sadugh (Shahid Beheshti University), Mohammad Ali Nezammahalleh (Shahid Beheshti University)

In Miankaleh Peninsula, ecotourism is in its incipient stage of expansion. As the political and economic circumstances of the developing countries, rapid global growth in the industry and the national situation of the area, penetrating and establishing of ecotourism facilities in the near future will be inevitable in the area. Therefore, it is essential to identify suitable sites for development of the facilities in the area as the objective of the research. To select the most eligible sites for this objective, three sets of environmental, economic, and geodata criteria are essential. Maps, satellite images, available researches, statistics, and questionnaire data were used to define 17 criteria and weight them. We devised some novel methods, in addition to common methods, for assigning within subject weights to these criteria. The red list categories of IUCN present a method based on which it is possible to identify the plant and animal species that in the near future will be in danger of extinction. Therefore, the 8 categories of the list in a new method are used as a tool to determine within subject weights in both plant and animal habitats as two environmental criteria for site selection of the study. We conducted two stages of field work survey, on 1 year distance, including for observation and collecting data and then to try on the produced results and understand the analysis accuracy. In the first stage, some data gathered to measure dune vulnerability index parameters and check the boundaries resulted from image classification as well as collecting questionnaire data.

Data on position and dimensions of the active sand dunes, on vegetation densities and dune particle sizes were gathered and stored in predesigned sheets. From these data we attempted to determine within subject weights for some criteria. The values of individual criteria that are in different ranges and calculated in different units must be normalized into a standard scale to integrate in the final analysis. In normalization each given point that is assigned a grade of membership using Fuzzy membership functions, assumes a degree of suitability for the purpose of site selection for sustainable ecotourism facilities development. The AHP method, readily applicable in spreadsheet program, was used to determine appropriate weights for layers. In the method the decision making problem is decomposed into a hierarchy of sub-problems and the relative importance of the elements can be evaluated in a pairing standard comparison way, for between subject weights, with respect to the main goal above that hierarchy. Multi-Criteria Evaluation (MCE) method help us to integrate the conflict criteria and goals. The results indicate that the sites qualify the included criteria conditions and that the decisions with conflict goals can accurately be made prior to any action to conserve the environment.

Analysis of the solution effectiveness of visibility search techniques in multiple observers siting problem

Young-Hoon Kim (Korea University), Evans Andy (University of Leeds)

This paper demonstrates a set of solution techniques for multiple observers siting to maximise their visible areas whereas the observers has no overlapped visible areas on gridded terrain surface. As this problem reflects multi-objective function (i.e. maxmin problem), visibility modified spatial heuristics are discussed for which greedy search techniques, swap algorithm and genetic algorithm are explored. As topographic features that show candidate solution for the spatial heuristics, peak, pass, pit, valley, and ridge features are extracted from DEM data in South Korea. A benchmark test is undertaken to compare the solution quality and computing time of the solution techniques - i.e. visible area sizes, CPU time. The summaries of the analysis are as follows: First, it shows that the relationship between high elevation positions and their visibility is not highly correlated. It also suggests that highly elevated observers are not necessarily better visible areas and they are not suitable for search for largest visible areas. Secondly, the positions that can see large visible areas are highly correlated with their elevation and are distributed within a certain range which has small deviation of their correlation between visibility and elevation. This means that, when selecting potential observers, geographical dispersion is also important, and it is necessary to employ the positions located at relatively high elevation area. Thirdly, the visibility results of the topographic features are compared with the results from a whole surface area. It is identified that the topographic features show similar or better visibility results for the DEM data, which can guarantee optimal candidate sites for visible large areas. Finally, as practical purposes, visibility assessment of current watch towers for detecting forest fires are carried out in order to determine their visibility performance. Then, searching for a set of best watch towers

location that satisfy the multi-objective visibility function is undertaken by employing algorithm testing environment: spatial heuristics, topographic features using greedy search technique, and using genetic algorithm. As topographic features based search, distance buffering methods are explored, and their results are compared with those of spatial heuristics in terms of the solution quality (i.e. visible area size). Finally, this paper found that the GA method is outperforming to search the optimal sites, compensating large computing time than the swap algorithm and the topographic features based distance methods. The swap algorithm technique is also generating optimal solution with reasonable computing performance. The experiment also indicates that the proposed topographic features based method shows much better computing performance than the genetic algorithm and the swap algorithm if other extra computational processes are undertaken.

C08.28-02 - Modeling Human and Physical Processes 1

Chair: Pavlos Kanaroglou, Jinfeng Wang

Modeling the Effects of Endogenously Triggered Changes on Dynamic Repertoires of Activity-Travel Behavior

Ifigenia Psarra (Eindhoven University), Harry Timmermans (Eindhoven University)

Modeling the dynamics of activity-travel behavior is high on the research agenda of activity-based analysis. The conceptual framework of modeling the effects of endogenously triggered dynamics on activity-travel behavior is presented in this paper. Endogenous dynamics are caused by factors internal to the individual, rather than imposed by reasons beyond an individual's control. Conceptually, we consider both a top-down (life trajectory affecting daily activity agenda) and a bottom-up process (problems with daily rescheduling inducing changes even in long-term time horizon). The first approach is related to the exogenous changes, as it focuses on an individual's reaction and adaptation to external factors/policies. Conversely, the bottom-up chain of influence concerns the endogenous changes, as it examines how people learn from their behavior and reconsider their activity schedule. Some cases when an endogenous change is induced are the following: First, when traveling, people will see new locations, which they may decide to explore. This may result in changes in the current activity patterns, as reinforcement of beliefs and update of the memory trace may take place. Second, people may be passively exposed to advertisements or other information sources. Third, information exchange and adjustments of the aspiration values may occur, through social contacts. A person's desire to comply with the behavioral patterns of a social network can lead to exploration of new options. Finally, as the environment is non-stationary, it is realized that differences usually exist between preference (an ideal state) and choice (an actual state). These discrepancies can be called stress and give rise to emotions that can trigger choice change. Most people's behavior is characterized by inertia, as they avoid making perpetual, marginal adaptations to their choice behavior, in order to keep themselves at their optimal (utility-maximizing) state. Thus, stress can be regarded as a disutility. However, if accumulated stress goes beyond some threshold, individuals will be actively engaged in trying to reduce it. This may involve short-run changes, drastic changes (in order to enhance the prospect of exploring new alternatives) or even more dramatic decisions (e.g. moving house or finding another job). To sum up, in the suggested framework, endogenously triggered dynamics are examined through the prism of dynamic choice sets formation, stress and aspiration values. Of course, it is taken into account that the validation of any dynamic model of activity-travel patterns cannot be similar to the validation of a static model. There is a need to broaden the methodological horizons and we should be satisfied with a partly estimated and expert-knowledge based model. Currently, numerical simulations are conducted in order to

assess the performance of the model. Thereafter, the model will be calibrated with empirical data.

Simulating Spatial Growth Patterns in Developing Countries: An Agent Based Modelling Approach

Justice Inkoom (University of Cape Coast)

In Sub-Saharan Africa, rapid urban growth is characterized by prolific expansion of unplanned (informal) structures, and unguided spatial expansion. These unguided expansions by human agents have outstripped the regulatory capacities of central and local government. Governmental institutions in their bid to find solutions to the unguided expansion in unplanned use of land need to invest in the modelling process of what influences the spatial decision and role of human agents in the growth of informal settlement. The objective of the study is to simulate spatial growth pattern of settlements in the Shama district using an agent-based model. The study was conducted within a framework of NetLogo. The NetLogo assisted to incorporate and simulate driving forces that affect location decision-making by households and the growth of informal settlement. A preliminary survey was conducted to obtain household location decision preferences. The development of unplanned settlement has been a function of land price, proximity to economic centre's, household economic potential, and the location decision-making patterns of households. The exploratory analysis found particularly that majority of spontaneous development took place on areas liable to floods suggesting that some structures fall outside the required building regulations. The application of the proposed model indicates its potential to improve urban planning policies and decision-making processes in emerging cities of developing countries. Also, the result of the simulation suggests potential preferential location for residential development. The research justifies an approach in the area of simulating urban dynamics with agent-based models.

Gully Erosion Mapping Using Remote Sensing Techniques in the Capricorn District Municipality, Limpopo Province, South Africa

Nthaduleni Samuel Nethengwe (University of Venda), Ndifelani Mararakanye (Department of Agriculture, Forestry and Fisheries)

Gully erosion is a major global environmental problem confronting land and water resources. In order to address it, the spatial extent of the problem has to be established and monitored. Recently in South Africa, gullies have been mapped using manual digitizing. However, this process is time consuming and laborious, as such it will be expensive to repeat for monitoring purposes. This study investigated Imagine Objective (IO) and Seed Tool (ST) mapping techniques in order to address the problems of manual digitizing. IO maps gully by extracting them from SPOT 5 satellite imagery using functionalities such as threshold and clump, probability and size filters. ST maps gullies individually by visual interpretation of SPOT 5 satellite image and growing the seed pixel

automatically. The kappa accuracy was used to assess the performance of the techniques against manually digitized gullies. IO maps yielded a kappa accuracy of 0.52 whilst ST yielded an accuracy of 0.86. Both techniques were found to be very useful for future studies. IO is particularly useful for identifying priority areas and ST is useful for detailed investigation especially in a smaller area. KEY WORDS: Gully Erosion, Mapping, Imagine Objective, Seed Tool, Capricorn District

Geographical endowment and agriculture in China

Xia Haibin (East China University)

For a populous developing country like China, the importance of agriculture is self-evident. In fact China is still a large agricultural country so far. Geographical endowment played a decisive role in agricultural development. This paper selects three key time points which are the late Qing dynasty representing the Chinese agricultural civilization time, the beginning of the reform and opening up representing the Chinese industrial civilization time, and the tenth year in the 21st century representing Chinese early information era. As times change, Contribution of geographic endowments on agricultural productivity is not the same. The reason is that people improve the ability to use natural resources with the development of industrialization in China. Integrated value of geographical endowments in different times can well explain the Chinese agricultural spatial distribution, which determines the distribution of the population in China. In Qing dynasty, the population center gravity located the zones of the south of the Qingling mountain and Huaihe river. And the zones of the north of the Great Wall were pastoral areas. Since China enter into the industrial society, the population center gravity in China shift to the southeast of Hu Huanyong population line.

Farm families on agricultural holdings on the South Downs, England: Modelling the factors affecting mid-20th continuity of occupation

Nigel Walford (Kingston University)

During the 20th century British agriculture underwent a series of upward and downward economic trends when productivity and output increased or decreased. The Second World War II provided a stimulus for growth and heralded a new era of state intervention that persists in various forms to this day. Following WWII the emphasis was on increasing production, economic efficiency and rationalisation brought about financial and other forms of support. This paper focuses on the decades around WWII when profound changes in the structure and operation of British agriculture occurred, and makes use of a collection of data sets linked through geography that provide unparalleled information on individual, identifiable farms. Anticipation of a war time emergency prompted the national government in the late 1930s to become concerned about the need for information relating to agriculture with the intention of implementing measures to revive this flagging industrial sector. This culminated in the National Farm Survey (NFS) of all farmers with over 5 acres (2.03ha) of land that was carried in 1941-43 in order to marshal information that would enable the government to tackle the problem of food shortages. The NFS is an unrivalled source of information about individual farms that was released to

research and the public through the National Archives in mid-1990s. It comprises three interrelated sets of documents: the 1941 Agricultural Census Returns; Ordnance Survey topographic maps annotated with farm boundaries; and a Primary Record of survey that details the state of each farm and includes an assessment of the farmer's managerial ability. The NFS documents and data on farm occupancy obtained from electoral registers have been captured digitally in a spatio-temporal database of the statistical population of some 500 farms in parishes across the South Downs in South East England. This paper draws on information for these farms together with related geospatial data in order to examine the contribution of a series of spatially uneven variables towards continuity of occupation of farms by the same family during the post-World War II decades. The variables relate to agricultural production, farmer characteristics, physical environment and farm structure and layout, and include farm area, degree of mechanisation, product mix, farm fragmentation, altitude, aspect, farmer's age and managerial ability. A series of spatial analysis techniques are employed to explore possible causes for spatial variability in continuity of occupation by the same family through the post-war decades.

Improving crop yield simulations by taking into account effects of field heterogeneity

Anja Stadler (University of Bonn), Matthias Langensiepen (University of Bonn), Moritz Kupisch (University of Bonn), Frank Ewert (University of Bonn)

Crop growth models are potentially capable of calculating crop growth and yield realistically, provided they are properly parameterized, calibrated and validated using data from field experiments. Plant growth is often characterized in such models based on simplified approaches and assuming homogeneous soil properties within a field. We hypothesized that taking into account effects of soil heterogeneity on plant water and nutrient uptake in these models improves their predictive quality at the field scale. This approach is highly attractive for implementation in the context of precision farming, which is aimed at adapting crop management to spatial heterogeneities in environmental conditions. Combining precise farming techniques with spatially explicit crop modeling for decision making and scenario analyses is likely contributed to reduce the greenhouse gas emissions from agricultural areas and to optimize biomass growth and yield. The crop growth model GECROS was applied using information from winter wheat and sugar beet field trials carried out near Jülich, located in the central western part of Germany. These fields are all characterized by strong spatial variability in soil conditions and managed according to standard agronomic practice. GECROS was calibrated separately for each winter wheat and sugar beet cultivar grown on these fields by adjusting the respective parameters with the help of crop physiological measurements at point level. The soil model was parameterized for different field sample points (6-8 per field) for which measured information about soil physical characteristics was available to account for the spatial heterogeneity in soil conditions within each field. The crop growth model was then

tested whether it could reproduce the observed spatial patterns of crop growth and development in the selected fields through consideration of the spatial variability in soil properties. First results show, that GECROS simulates the measured data of phenological development, biomass, leaf area index and yield under heterogeneous field conditions in a realistic way. Without the adaption of the soil model to the variable soil properties, the crop growth model is not able to reproduce the observed heterogeneity of crop growth within a field. Spatio-temporal variability in soil water distribution and its effects on nitrogen availability are likely the main factors causing spatial variable crop growth within the selected fields of the study region. Considering variable soil water transport and related nutrient dynamics in model scaling to the field level will thus improve the predictive quality of the crop growth model at the field scale.

A General Understanding for the Food Security Situation of North Korea based on Remotely Sensed Data

Hongyan Zhang (Northeast University), Lei Wang (Northeast University), Xiaohui Yang (Northeast University)

North Korea is usually mysterious for the world. Its food security issue is highly concerned by the international communities. In this paper, based on the data from GIMMS, the variables of dynamic yield estimation models for the crops were determined after analyzing the relations between actual crop yields and critical period of growth half-month NDVI of rice and maize in 1995-2005, and the models were established to estimate the grain production between 1982-2005. Based on the meteorological data from 27 observed stations of the country in past 30 years, we calculated the climate productivity in North Korea with Thornthwaite Memorial model and select some indexes, which can objectively reflect the food security situation of North Korea, to build food security evaluation system aiming at reveal the food security of crop estimation and the food security of the potential productivity, it can provide theoretical evidences for international assistance and emergency. The results show that: the linear fitted equation between the NDVI cumulant of second half month of September and the rice production is good, it can be the yield estimation model of rice. The linear fitted equation between the NDVI cumulant of first half month of October and the maize production was the yield estimation model of maize. The comparison of the crop yields estimated by the models and the actual crop yields showed that the relative errors of estimated yields were nearly 12%. The ratio of crop estimation yield and crop potential productivity were mostly between 10% to 20% and individual year was up to 30%. It showed that the North Korea's grain production still had much room for improvement. Finally, This study is to assess the status of food security of North Korea from the year 1982 to 2006. An integrated index of food security, including the food self-sufficiency rate, per capita share of grain, grain production levels, per capita arable land, fluctuation coefficient in grain production etc is constructed for quantitatively assessing the status of its food security by taking the coefficient of food security assessment method. Based on the facts above, the results of

evaluation revealed that the North Korea' grain production was in unsafe or critical safe, but in the ideal situation, it were safe overall, and could sufficiently meet the needs for the citizens in North Korea.

Remote Sensing Image Mining for Mapping Coastal Wetlands Changes in Segara Anakan Lagoon, Central Java, Indonesia

Nur Mohammad Farda (Gadjah Mada University), Projo Danoedoro (Gadjah Mada University), Hartono Hartono (Gadjah Mada University), Agus Harjoko (Gadjah Mada University), Udo Nehren (Cologne University of Applied Sciences)

During the last decade, satellite remote sensing imagery is the source of the most significant recent image database in observing the Earth's surface especially coastal wetlands. Humans will also be trouble, and even almost impossible to find information based on knowledge and patterns in the images when dealing with large data collections. This situation makes the "knowledge gap" in the process of reducing and extracting the information from remotely sensed image. In another side, the symptoms of climate change is also affected from the changes that occur in wetlands, with the release of carbon from slash and burn wetlands forest, drying the wetlands, and land use change that are not controlled in the wetlands. Remote sensing here will play important role to mapping coastal wetlands changes. According to above issues, this research have an objective to develop framework and image mining technique that are suitable for mapping coastal wetlands by considering fuzzy objects. This research study is expected to produce framework and techniques of remote sensing image mining in order to mapping coastal wetlands changes. Keywords: remote sensing, image mining, coastal wetlands changes.

Geospatial methods for collective urban sensing

Thomas Blaschke (University of Salzburg), Bernd Resch (University of Osnabrück), Günther Sagl (Research Studio Austria iSPACE)

Geospatial technologies have been becoming better known to a general audience due to virtual globes such as Google Earth. Despite increasing spatio-temporal resolution and availability of image data, and greater access to data and derived products, the understanding of urban systems will not be satisfied by remote sensing as a stand-alone technology. The combination of in situ data and mobile sensor derived information supports new applications when addressing human-environment interactions, particularly in Public Health and for security and safety applications. Coincidentally, the miniaturization of components has enabled sensor systems to be nearly invisible, and sometimes wearable, so that individuals can move around and interact freely, supported by their personal information domain. We hypothesize that fine-grained urban sensing

coupled with well-established remote sensing mechanisms greatly enhances our knowledge of the environment by adding objective and non-visible data layers in real-time. These systems help us increase our capacity to observe and understand the city, and the impacts on and by society. This seems to be a very desirable state, as more accurate data about local air temperature, atmospheric humidity, air pollution, and traffic flow can positively influence areas such as public health, traffic management and emergency response. Apart from this information enrichment, accurate sensor measurements also have a much broader influence: considering, for example, that 'air quality' is only a surrogate for the effects of pollutants on humans, which make a fine-grained air quality map a very sensitive information layer. We will describe some of the technical realms aiming to support a better understanding of the urban environment and 'ubiquitous-' or 'collective-sensing' and the visions of 'people as sensors' or 'citizen as sensors' may become more realistic. We claim that while useful and important, traditional airborne and spaceborne remote sensing provides limited 'snap-shots' of urban environments that are (currently) unable to fully capture urban dynamics. Urban areas are structurally complex 3D environments that evolve with time. Furthermore, the numerous activities within these environments are typically more dynamic than their physical structure. In an effort to better understand urban environments, we discuss two currently separate technologies: (i) remote sensing and (ii) in situ sensing. At the moment, these two technologies remain predominantly separate but lay a foundation for a common use. A critical part of making sensors webs useful is an adherence to good measurement protocols: understanding the sensor, its source area and its siting, so that the user can understand what the measurement represents and how that fits with a particular application.

Adding the spatial dimension to the assessment of predictive performance of and variable importance in statistical and machine-learning models

Alexander Brenning (University of Waterloo)

Tapping the potential of predictive methods developed in the fields of computational statistics and machine learning in geographical applications has just recently begun. While these relatively novel methods offer new opportunities for modeling nonlinear and interactive relationships and dealing with high-dimensional problems, new challenges as well as opportunities arise due to the presence of spatial autocorrelation in geospatial data. Spatial resampling-based methods (cross-validation, bootstrap) have recently been proposed to assess the performance of such complex models in supervised spatial classification and regression, revealing in some geospatial applications a lack of spatial transferability due to overfitting. Similarly, permutation-based measures of variable importance have been adapted to the context of spatial prediction using spatial resampling, providing a focused assessment of the utility of predictor variables in spatial modeling. This contribution extends this approach to exploring resampling-based predictive performance and variable importance as a function of distance between

training and test samples. This creates a novel tool for the explicitly spatial assessment of prediction models as well as for the characterization of spatial variables. The tool is applied to landslide susceptibility modeling, remotely-sensed land cover classification and spatial interpolation in precision agriculture. In spatial interpolation, the proposed computational measures are compared to traditional geostatistical approaches, specifically the semivariogram for characterizing spatial relationships, and the kriging variance for quantifying predictive uncertainty. It is concluded that the proposed novel spatial accuracy assessment and variable importance tools provide insights that were previously only available in the narrow context of parametric geostatistical methods, and offers these insights in the broader contexts of supervised classification, regression and interpolation. The proposed methods are also relevant to other situations in which autocorrelation occurs in a continuous or discrete space, such as time series, lattice data and data on networks.

Landscape scale digital soil mapping using field scale geophysical sensing data

Karsten Schmidt (University of Tübingen), Thorsten Behrens (University of Tübingen), Ulrike Werban (Centre for Environmental Research), Thomas Scholten (University of Tübingen)

This talk presents and compares multiple approaches to integrate field-scale geophysical sensing data (EM and Gamma) into landscape scale DSM. Hyper-scale digital terrain features were used as the only predictors for building the regression models. The following four concepts were compared: Benchmark: build and apply a landscape-scale soil property model based on the soil samples using terrain features (no geophysics) MoreSoil: i) build and apply a patch-scale soil property model based on the soil samples using the interpolated geophysical data ii) build and apply a landscape-scale soil property model based on the extended soil data pool using terrain features ExGeo: i) build a patch-scale soil property model based on the soil samples using the interpolated geophysical data ii) build and apply a landscape-scale geophysical model based on the interpolated geophysical data using terrain features iii) apply the patch-scale soil property model on the extrapolated (landscape-scale) geophysical data ExGeoAdd: i) build and apply a landscape-scale geophysical model based on the interpolated geophysical data using terrain features ii) build and apply a landscape-scale soil property model based on the soil samples using terrain features and the extrapolated geophysical data as additional predictors Eighty calibration samples covering the feature space of the interpolated geophysical sensor data were used for building the soil property models. Validation was based on 20 samples outside the sampling areas covering the geographical space. Validation shows that neither MoreSoil nor ExGeo show any benefit compared to the Benchmark. Compared to this, the ExGeoAdd concept returns a boost in R² validation accuracy of up to 11 %. This strong increase clearly shows that it is crucial how the field scale geophysical data is included in the landscape scale modeling

framework and that field scale geophysical data can successfully be used for landscape scale DSM.

Chair: Yee Leung

Evaluation of spatial autocorrelation by the concept of intrinsic spatial distance

Yee Leung (University of Hong Kong), Deyu Meng (Xi'an Jiaotong University), Zongben Xu (Xi'an Jiaotong University)

This paper proposes the concept of intrinsic spatial distance (ISD) for the study of spatial autocorrelation between any two points in space. It is a distance measure that takes into account the nearness of two points with respect to their physical and attributes distances. Associated with the concept is the ISD algorithm constructed for the measure of the ISD. Under the concept, two points in space are related through a transitional path linking one to the other. The smaller is the ISD, the stronger two points are auto-correlated. It is theoretically argued and empirically demonstrated that the ISD is not predisposed in favor of the first law of geography but it considers directly the varying situations of nearness in physical distance and attribute distance in order to derive the extent to which two points are spatially auto-correlated. Moreover, the information uncovered by the ISD is more elaborate than that revealed by the Moran's I, the local Moran's I and the semivariogram. It gives a meticulous account of relatedness in both the local and global contexts. It is apparent that in further research, the proposed approach can be extended to the study of spatial autocorrelation in the 3-dimensional space. More importantly, it can be extended to the study of spatial autocorrelation over space and time. The ISD concept is also general enough to study relationship with respect to multiple attributes.

Mapping of Above-Ground Phytomass of Lichen Tundra Using Remote Sensing Methods

Yurate Plyushkyavichyute (ETH Zurich), Elena Golubeva (Moscow University), William Gareth Rees (University of Cambridge), Olga Tutubalina (Moscow University)

Assessment of the supply of Above-Ground phytomass is one of the challenges in addressing to monitoring climate-induced changes. Nowadays using the Remote Sensing methods this goal is achievable. The main aim of the research project was to find the possibility of using very high resolution (QuickBird) satellite images for mapping the supply of Above- Ground phytomass. The research work is focused on three sites of the Kola Peninsula with diverse vegetation types. Therefore were gathered during field works different vegetation samples of phytomass for the further analysis. Optical properties of tundra landscapes in Kola Peninsula are diverse and after analyzing all possibilities were determined, that the main types of vegetation, which values of supply of phytomass can

be easily distinguish- are the lichens. The main correlation parameters were NDVI and Average spectral reflectance value in the visible spectrum. Based on results by using ground spectroradiometry data and ArcGIS programs the maps of above-ground phytomass on the key sites were compiled from QuickBird image. The future goal is to use this method for the other vegetation types. Therefore discover the new parameters, which will allow to mapping the supply of Above- Ground phytomass for the whole vegetation types in Forest-Tundra Ecotone. This research work is a part of PPS Arctic-the IPY project which investigates current status and last changes in the circus-arctic tree line zone. This study is financially supported by the Benefits Russo-Norwegian project of the Norwegian Research Council (OST 185023/S50).

C08.29

Mountain Response to Global Change

C08.29-01 - Environmental history and climate change in the high mountain ecosystems of monsoon Asia during the late Holocene

Chair: Jussi Griebinger

Variations of the Asian Summer Monsoon system derived from millennial juniper tree-ring chronologies.

Achim Bräuning (University of Erlangen-Nuremberg), Bao Yang (CAS), Lily Wang (CAS)

Asian junipers provide millennial or even multi-millennial archives for the reconstruction of moisture conditions in High Asia. Precipitation reconstructions are usually derived from local or regional tree-ring chronologies that may reflect long-term local precipitation variations, but rarely take spatial changes of atmospheric moisture sources into account. We study tree growth variations within a unique tree-ring network of 15 juniper sites covering the northern, eastern and southern fringes of the Tibetan plateau, covering the climatic realms of the eastern and southwestern branches of the Asian summer monsoon season, respectively. By applying Rotated Principal Component Analysis (RPCA) for different time slots, we evaluate temporal changes in the similarity patterns of ring-width variations and investigate tree growth behaviour during prominent climate excursions like the well known drought period of the 1920s, the coldest phase of the Little Ice Age period and the Medieval Climatic Optimum. Furthermore, we test the temporal stability of climate-growth relationships to see if the influence of monsoon variations on local tree growth underwent changes during the late 20th century. In addition, the spatial extend of drought periods is mapped from the chronology characteristics of the tree-ring network. Finally, we study the temporal stability of certain frequency bands in the chronologies by wavelet analyses and evaluate spatial changes in characteristic frequency bands related to variations in summer monsoon patterns.

Tree ring recorded May–August temperature variations since A.D. 1585 in the Gaoligong Mountains, Southeastern Tibetan Plateau

Ze-Xin Fan (Chinese Academy of Sciences), Achim Bräuning (University of Erlangen-Nuremberg)

High-resolution proxy data are still scarce in the southeastern Tibetan Plateau, which limit our understanding of climatic variability before instrumental records. In this study, we developed 595-year tree ring-width chronology from *Larix speciosa* near the timberlines of the Gaoligong Mountains, southeastern Tibetan Plateau. Ring-width site chronologies and a well-replicated regional chronology (RC) showed significant positive correlations with warm season temperatures from May to August. Using RC as predictor, we

reconstructed mean May/August temperature for the study region that extends back to A.D. 1585. Cold conditions prevailed during the periods 1600s, 1620'30, 1640'50s, 1700s, 1730'40s, 1760s, 1810'20s, 1850s, 1900'10s and 1955'70. Warm episodes occurred during 1610s, 1660'1680s, 1710'20s, 1750s, 1780'90s, 1820'40, 1920'50 and 1980'present. Spatial correlations with gridded land surface temperatures revealed that our reconstruction represents regional temperature signal for the southern Tibetan Plateau. Comparison with other tree ring-based temperature reconstructions from surrounding areas implies a high degree of confidence for our reconstruction.

Altitude-dependent Characteristics of tree-ring width of *Sabina przewalskii* Kom in the Western of Qilian Mountains and its linkages to the Atlantic Ocean climate variability

Chun Qin (Chinese Academy of Sciences), Bao Yang (Chinese Academy of Sciences)

The western Qilian Mountains lie close to the boundary between the continental westerly-dominated west and the monsoon-dominated east. Due to lack of historical documents and other proxy data, Qilian juniper is unique proxy record. Many studies were carried out with respect to the tree ring-based climate reconstructions. However, little is known about the altitude effect on ring width/climate relationship. In this study, we attempted to clarify whether there is a difference in tree growth-climate relationships along an altitudinal gradient in a mountain slope in the western part of the Qilian Mountains. For this purpose, we collected 140 trees from the mountain slope. The relationship between tree-ring width and age, temperature, precipitation were investigated based on four elevations ranging from 3000-3500 m. In addition, we established a moisture-sensitive chronology, and found out that there is a good relationship between tree growth and NAO SST variations.

Climate-induced changes in geomorphological processes in the high mountains of Taiwan

Margot Böse (Universität Berlin), Dirk Wenske (Universität Berlin)

Present-day geomorphological processes in the mountainous landscape of Taiwan are driven by three main factors: 1) seismicity and uplift, 2) humid monsoon climate including typhoons, and 3) the resulting steep slopes. Though these factors seem very dominant, the results of recent studies provide evidence that hillslope processes are variable in space and time. On short time scales, erosion is related to high-magnitude rainfall events, often but not exclusively linked with typhoons, and sometimes its impact is only local. The combination of earthquakes and subsequent typhoons increases the propensity of slopes for landslides. Consequently, interdependent slope and river systems show an unsteady, more or less chaotic behaviour, making it difficult to identify phases of specific activity from few archives. Slope-riverbed coupling is a major research issue in the attempt to learn more about present-day processes. Even today, processes

change with altitude, the highest part of the mountains being less affected by climatic forcing. Reduced precipitation above the monsoon circulation provides less soil moisture. In addition, the slope processes depend also on the catchment situation, either belonging to the short eastward directed valleys with strong headward erosion or the westward directed valley systems with much reduced present-day hillslope processes and the preservation of older landforms such as glacial landforms and sediments. Climate changes in the Late Quaternary may have influenced erosional activities. The preserved archives are sparse, but detailed studies of sediment properties as well as dating by means of OSL protocols and the radiocarbon method have brought insights into the timeframe of varying processes. During the Late Holocene a phase from about 4 to 2 ka was characterised by increased slope activity relative to present-day conditions in high altitudes above 3000 m asl, possibly including a phase with wildfires, as charcoal has been found repeatedly. In the non-glaciated mid-altitudes, a reduced slope activity in late MIS 4 / early MIS 3 appears possible; silt was deposited in a depositional sequence of a terrace remnant. This silt layer is referred to as loess-like sediment, as no present-day processes form similar deposits in this environment. This suggests a drier climatic phase with transport and deposition of exclusively fine-grained material. By contrast, the presented evidence points again to a phase of high slope activity around 38.5 ka. The climatic LGM is still not well documented, whereas at least in altitudes above 3200 m glacial slope formation and glacial deposits such as terminal moraines and boulders deposited by glaciers are dated to the Late Glacial / Holocene transition. Besides the strong internal geological factors, Late Quaternary climate change has also played a role in changing erosional activities in Taiwan.

C08.29-02 - From Himalayan Dilemma to Climate Change Dilemma? Challenges for High Mountain Development 1

Chair: Hermann Kreutzmann, Teiji Watanabe

Climate Change and Social History of Mountain Regions in the Modern Period

Jon Mathieu (Universität Luzern)

During the recent decades, the evidence-based reconstruction of past climates has progressed rapidly. For the modern period since the sixteenth century, used as reference period in the present paper, the available data have multiplied and been processed in sophisticated ways. Together these research efforts have resulted in a high-resolution portrait of climate change during the last five hundred years. At the same time, however, the knowledge about impacts of climate change on past societies has not progressed very much. We are still lacking basic empirical and analytical knowledge of many regions and periods. Moreover, there are still fundamental discussions as to the adequate method of impact assessment. How can the effects of climate variability on livelihoods and development be examined in a truly interdisciplinary way? In mountain regions this unbalanced state of the art is perhaps even more conspicuous than in other regions. Most scholars start from the assumption that upland societies are particularly sensitive to climate change. The assumption appears to be safe, yet it is not easy to provide relevant and systematic proofs for it. The paper deals with the issue on different levels: it points at current scholarly contributions to the field, discusses methodological strategies and presents selected regional evidence. In general, it aims at sharpening our sense for present and future relationships of climate and mountain society, by critically looking at aspects of its known historical past.

Climate change and Natural Hazards: Probable Impacts in the Upper Kali Gandaki, Central Himalayas (Nepal)

Monique Fort (Université Paris)

The consequences of climate change have recently become a major concern, especially in mountain regions. In the Himalayas, this issue is particularly debated, with different outcomes depending on the type of primary data and scaling methods utilized, and the areas considered along this 2500 km long mountain range. In the last decades, glaciers decline and their consequences on natural hazards and water resource have been the focus of most studies. Precipitation nature (rainfall, snowfall), amount and seasonality were also considered, with more uncertainty in their evolution hence in their impacts. Other parameters such as ground ice are less considered yet in the upper Himalayan valleys they might be significant and affect local populations. Our focus is on upper

basins of Central Nepal. There, the Himalayan range is at its narrowest with, on very short distance, strong contrasts between low valleys and high peaks, between monsoon and arid environments. Settlements are concentrated either on quaternary terraces or along valleys and river junctions, mostly relying economically on irrigated crops, trade and tourism. We focus on the upper Kali Gandaki, characterized by a semi-arid, continental climate. The impacts of climatic change may appear in different ways. Firstly, despite limited glacial cover, the possibility of glacial outburst flood may again occur from the Man Shail such as the one in the late 1980?. Secondly, increasing ground instability is also expected along north facing, shaly slopes such as in the vicinity of Muktinath, hence triggering earthflows and occasional debris flows activity that might affect the new road and growing settlements. Thirdly, rock avalanches induced by permafrost melting of the steepest cliffs (i.e. Nilgiri North face) may also develop and impact the valleys floors of tributaries and Kali Gandaki (see '1000 yr-old rock avalanche remnants between Jomosom and Tukuhe). Fourthly, water availability in the near future is more difficult to predict, due to possible change in the spatial influence, intensity and timing (onset and duration) of the monsoon precipitation, all parameters poorly constrained by the models. Any change in precipitation amount may affect groundwater reserves, hence springs discharge. The combination of higher snowfall and rapid melting may also favour the occurrence of destructive flash floods with direct impacts on irrigation canals and fields. Eventually, the overall potential increase of natural hazards may jeopardize any efforts of opening these upper valleys and their integration to the rest of the country.

Irrigation Problems in Hussaini Village within the Valley of the Karakoram Mountain Range

Kazuo Mizushima (Nihon University)

This report deals with the problem of irrigation in Hussaini village and also with the development of a commercial economy. Hussaini village, comprised of the ethnic Wakhi minority, is located on moraine sediment of the Gulkin glacier. The Wakhi economy depends on raising transhumance livestock and the irrigational farming of rotated wheat and bean crops. Although the geographical environment of the Hussaini village does not allow for easy access to sufficient irrigation water even with traditional irrigation farming, water shortages are not much of a problem. In the 1990s, a goods/money economy penetrated the geographically remote mountainous area where the uncivilized Wakhi had settled. Hussaini village coped with the situation, as did other Wakhi villages. Under the guidance of AKRSP, Hussaini village started potato cultivation, selling the potatoes to obtain the cash necessary for a transition to a cash-based lifestyle. It is noteworthy that Hussaini village had no tourist facilities and thus could not obtain income from tourism. The village was left to depend on potato cultivation alone. Ample irrigation water is a requisite for sustaining the volume and quality of cash crops in the dry mountainous area directly impacting cash flow. However, the problem of chronic water shortage in Hussaini village presented a serious challenge for the expansion of the potato cropland. As a

solution, Hussaini village decided to draw water from the end of the Gulkin glacier, and to transport the water approximately 1 km to the existing five irrigation ditches at the water intake point. The method involved installing steel pipes to serve as an aqueduct. After Hussaini village got money from the Pakistani government to purchase the pipes, the three pipes were placed at the end of the glacier. In 2005, water drawn through the steel pipes poured into irrigation ditches. The long-sought solution for the irrigation water problem of Hussaini village was finally found. This report clarifies the contributing factors for the shortage of irrigation water in the vast alteration of irrigation farming in the Hussaini village and the method that was adopted for resolving this issue.

The Current Status of Lifestyle and Industry in the Wakhan Area of Tajikistan

Yasuhiro Ochiai (Nihon University)

Wakhan lies in the southern part of the Pamirs beyond the Panj River, which serves as a border between Tajikistan and Afghanistan. The Tajikistan Wakhan area covers the main part of Ishkashim, the southernmost area of Gorno-Badakhshan Autonomous Oblast. The inhabitants of the area are called the Wakhi, and they are spread out in the four countries of Afghanistan, Pakistan, China, and Tajikistan. Although the people of each country originally have had similar culture, the separation of their domiciles has given rise to differences in each one's lifestyles. Especially in Tajikistan, since its inhabitants have lived through the era of the Soviet Union and have witnessed drastic changes in its economy, they show peculiar patterns and face several problems in industry and lifestyle. The traditional irrigated cultivation and transhumance styles are still prevalent in Tajikistan Wakhan area. Recently, however, the innovations in the cultivation of cash crops, and selling of animals and dairy products have been general status in this area, most of the inhabitants are not able to make an adequate living out of agriculture. As the result, with the exception of a few people who are able to find employment in other industries in the local area, plenty of youth have emigrated or migrated to cities in Tajikistan or Russia. Promoting innovation in tourism is most effective way of increasing opportunities for the local people to earn a decent living, as regional resources for tourism (e.g. the magnificent landscape of the Pamirs, the unique culture of the Wakhi, historical ruins, hot spas, and so on) are abundant. Lately, foreign visitors to this area are increasing, and several 'home stay's, which are the small lodgings kept by villagers at their private houses, have been established in each village. Although this area shows great promise for development of new industries connected to tourism, it faces several problems in the promotion of the tourism industry. Improvement of infrastructure (e.g. provision of electricity and drinking water, paving of roads, and improvements in the transportation system) is necessary in order to construct suitable lodging establishments and attract foreign tourists. Moreover, for promoting individual and sustainable development of tourism, upholding traditional agriculture styles and the original culture of the Wakhi and encouraging the formation of independent tourism organizations are important.

C08.29-03 - From Himalayan Dilemma to Climate Change Dilemma? Challenges for High Mountain Development 2

Chair: Hermann Kreutzmann, Teiji Watanabe

Himalayan pastures are overgrown on this side: Land use history of Nepalese transhumant sheep herders.

Kazuyuki Watanabe (Ritsmeikan University)

Pastoralism has been misreading frequently. It was seen as causes of forest degradation or grazing of goat promotes desertification. Also, in recently, as global warming started to be alarmed, discourse of forest degradation influenced environmental policies, grazing of livestock could be banned or restricted for protection of forests. In order to revise such a discourse, contribution of historical ecology is considerably important. As studies of 'slash and burn cultivation creates increasing of forest'. Geographical data of land use or historical changes of distribution of forests are should be exemplified where and how forests are increasing or decreasing. In addition of land use, change of the land users is also important. In case of Himalaya, population pressure has been seen as main cause of forest degradations. However, Neo-Malthusian discourse faces empirical phenomena. Recently, decreasing of population is faster than increasing by migration to cities or oversea employment. This paper aims land use history of grazing pasture. Using maps of 1960 and 1990, land use change of pastures are shown. Fieldworks are also carried out. Users of the pastures are compared 1998 to 2010. Research is carried out among transhumant Sheep herders of East Nepal. They have a village in the midland mountain (1300m), and migrate from summer pasture (4700m) to winter pasture (650m). As a result, it is considered that their use of pastures is far less below the limit of over grazing. Reclamation of forest lands or establishment of villages carried out even before past 40 years especially among the midlands areas where the sheep herders use as their village and seasonal pastures. Users of pastures and numbers of gazing livestock are decreasing considerably (-33%) between 1998 and 2006 due to retirement sheep herders. Rather than forest degradation, abandoned use of forest is more important problem. Abandoned fields and pastures are also emerged. They are almost forest because succession is rapidly going on. This is not sustainable for sheep herders. Poisonous grass grows thick on migration route, where sheep herders stopped their uses, and emergent of worm sucks the blood of their sheep. So, nature of the pastures is maintained when it is used by farmers and herders appropriately. Effect of global warming is also not simple for pastoralists. In case of Nepalese pastoralists, where monsoon rains come considerably, serious problem is not expected. Rather, for the Tibetan pastoralists, where monsoon rains blocked by Himalayan mountains, water supply for seasonal pastures could be decreased, if rise of temperature would cause meltdown of glaciers. So, geographical variety should be considered by extended fieldworks.

Landscape vulnerability and rehabilitation issues to the context of hydropower projects in Garhwal region, Himalaya

Vishwambhar Prasad Sati (Govt. KRG PG Autonomous College)

The Himalaya enjoys with rich bio-diversity and provides wide varieties of natural resources including the life sustaining water to the Indian sub-continent. Significant increase in the number of proposed hydropower projects has been witnessed in various river basins. During the 1980's, there were 22-hydropower projects proposed in the areas of dense human settlements and productive agricultural patches. Further, mushrooming hydropower projects started immediately after Uttarakhand got statehood. Currently, there are 220-power projects proposed with capacity of 30,000 MW electricity generations. Out of which 52 large, 36 medium and 132 are small-scale projects. These projects are certainly going to engulf the already marginalized productive agricultural fields, thus implying more hardship to local population in times to come. Landscape of Garhwal region is vulnerable as it is ecologically fragile, geologically unstable, and tectonically and seismically active. Here, ecological and rehabilitation issues, due to the construction of hydropower projects, are renowned. Most of the villages are located along the river valleys. Due to construction of dams, natural resources base - agricultural land, forest land, and grass land are being depleted. It has negative impacts on the culture - distinct identity, language, customs and location, and on the ecology - fauna, flora, avi-fauna as above 65% geographical land is forested, although, hydropower projects lead to the economic development, if properly commence. The Garhwal Himalaya is witnessed to a large-scale agitation against the construction of power projects by the local people and the environmentalists due to mismanagement and poor policy measures. Lacking in proper site selection and compensation packages further accentuated it in the Garhwal Himalaya. This article looks into the issues of ecological, rehabilitation and landscape vulnerability. It also focuses for the better policy frame and implementation of the hydropower projects. Keywords: Rehabilitation issue, landscape vulnerability, hydropower project, agitation, Garhwal region

Mountain Poverty and Climate Change in the Nepal-Himalayas

Alexandra Titz (Institute of Geography)

Various scientific studies suggest that mountain environments are particularly sensitive to climate change and it is assumed that mountain environments are likely to be amongst the most severely affected regions. Nepal, where fragile mountain environments share the total land area in large parts, is among the poorest and least developed countries in the world. Almost 84 percent of the population lives as subsistence farmers in rural areas. Agriculture is the principal source of food, income, and employment for the majority of the rural population, particularly the poorest. Therefore, mountain people will feel the most adverse effects of climate change on various conditions affecting agriculture in particular. Having only marginal coping and adaptation strategies, they are particularly vulnerable to climate change. Impacts could be even more severe for women and marginalized,

socially excluded groups. Climate change and its various impacts on agricultural resources will likely exacerbate the poverty situation and continue to hamper the economic growth. Nevertheless, there do still exist gaps in understanding the nature of both ecological and societal vulnerability to climate change impacts and opportunities for adaptation measures to increase resilience on a regional and local scale. Since mountain people in the Nepal-Himalayas always had to adapt to climatic variability, their livelihoods are actually quite diversified and perfectly adapted to their habitat. Thus, they already have skills and experience in adaptation. Nevertheless, climate variability may increase in the future, confronting mountain people to swiftly adapt to dramatically changing environmental conditions. A study carried out in three villages in Kaski-District/Nepal showed that mountain communities are already noticing the effects of climate change in the Himalayan region. A decline in agricultural productivity, an increased incidence of pests and diseases as well as less flow in springs and streams were some of the impacts on their livelihood system they experienced. Even if the livelihoods of the communities are quite diversified, surprisingly, only few coping and adaptation mechanisms were currently utilized. One explanation can be seen the fact that the communities are exposed to multiple stressors like food insecurity, frequent natural disasters, domestic conflicts and political instability and insecurity. Most important, a trend towards feminization of agriculture as a result of migration of men for work can be observed. Thus, in their income diversification strategy, farming only plays a secondary role, and adaptation measures to climate change are rarely utilized. In order to respond adequately to climate change impacts in a timely way, mountain communities in the Nepal-Himalayas may need external support to expand their existing opportunities for adaptation measures.

High mountain geosystem response on climate change in Altai-Tuva region

Kirill Chistyakov (Saint Petersburg University), Dmitry Ganushkin (Saint Petersburg University)

To estimate the factors of dynamics of high mountain landscapes in Altai-Tuva region from the LIA we analyzed spatial structure and variability of climatic characteristics and modeled variability of landscape structure determined by climate. Dynamics of nival-glacial landscapes was studied within mountain massifs Mongun-Taiga, Tavan-Boghdola, Turgeni-Nuru, Harhira. Beside the study of present state of the glaciers we generalized information on the structure of moraine complexes to characterize the evolution of glaciation since the finishing of the LIA. Most detailed information was obtained for the glaciers of Mongun-Taiga massif. The period after the maximum of the LIA in general was unfavorable for them. Intervals of positive mass balance took place from the mid-1910-s to the mid-1920-s and 1950-s - 1960-s. Both of them were caused by the increase of precipitation: on the background of high temperatures in the first period and cooling in the second one. After the mid-1960-s, especially in 1995-2008 mass balance was negative, aridization and distinct warming took place. In 2009-2011 a sufficient increase of snow accumulation in the massif is observed, the snow line returned to its position of 1994-1995. Similar features of dynamics of glaciation are observed within other mountain massifs of the region. Ubsu-Nur depression and its mountain outline were used as a main model polygon for the study of the reaction of landscape structure on climate change. Summer precipitation and average summer temperature are the limiting factors of the extension of forest geosystems. 150 mm of summer rainfall is considered as the value that limits the lower tree line. Optimal average summer temperature is 12-13°. The upper tree line can be defined by the average summer temperature 9°. Considering model scenarios of warming/cooling we admitted 2° increase of summer temperature over present values as basic condition, for the scenarios of fluctuation of precipitation we admitted 25% decrease of summer rainfall (relative to present amount). In case of aridization decrease of mountain tundra and forest geosystems in general, expansion of psammophyte and valley solonchak geosystems, decrease of area of caragan and koeleria steppes, increase of area of herb-feather grass steppes can be asserted. In case of changes of temperature we revealed different tendencies of changes of the state of the geosystems. In case of cooling the area of Kobresia mountain tundra geosystems can increase sufficiently; the area of cedar-larch and steppified forest geosystems will increase slightly. In case of warming oat grass steppes will expand, the area of sheep fescue steppes will remain the same. We revealed

that precipitation is the most important factor of transformations of the landscapes of the region.

Comprehensive Analysis of Hydrological Responses and Resulting Constraints under Climate Change in mountainous Switzerland

Ole Rössler (University of Bern), Pascal Hänggi (University of Bern), Nina Köplin (University of Bern), Raphael Meyer (University of Bern), Bruno Schädler (University of Bern), Rolf Weingartner (University of Bern)

Mountains are meaningful indicators of climate change since wide ranges of climate zones occur at a very small horizontal extend. In terms of hydrologic responses, a potential effect of climate change is the acceleration of the hydrological cycle that in turn will likely cause changes in the discharge regime towards higher winter discharge, earlier snow melt, and changed annual discharge distribution. As a result, socio-economic systems (e.g., tourism, hydropower industry) may be drastically affected. In this study, the various effects of climate change on mountain hydrology in Switzerland are analyzed: At first, discharge responses of approx. 200 catchments covering almost entire Switzerland were simulated using PREVAH and driven by latest CH2011 climate scenario data sets. Seasonal discharge changes are presented, the driving factors for these changes are analyzed and the most vulnerable catchments are identified. We found eight distinct response types of catchments, each exhibiting a characteristic annual cycle of hydrologic change. A general pattern observed for all catchments, is the clearly decreasing summer runoff. At second, within the analysis of future discharge a special focus is set on summer low flow situations in a selection of 29 catchments in the Swiss Midlands for which extreme situations might have great implications on water usage and biodiversity. The hydrological model PREVAH was re-calibrated with a multi-variable approach using base-flow and gauged discharge and driven by the same CH2011 climate data set. The magnitude and the duration of climate change induced low flows are presented and discussed. We found extreme low flow situations to be very likely to increase in both, magnitude and duration. At third, the spatial drought stress potential was analyzed by simulating the soil moisture level under climate change conditions in a high mountain catchment. Due to the spatial explicit character of the study, the distributed hydrological model WaSiM-ETH was applied. The results show soil moisture conditions in forests below 2000 m a.s.l. are affected at most, which might have implication to their function as avalanche protection forests. However, we found the results to be highly dependent on the downscaling method applied. At last, we analyzed the effect of hydroclimatological variability on the hydropower production by coupling the hydrological model BERNHYDRO with a hydropower management model, both driven by climate change scenario data. We found that hydro power production will benefit from the changes in discharge regime, at least until 2050. This holds especially true if hydropower management is able to deal with the presumable increasing natural hazards. These different aspects of climate change impacts on the hydrosphere reveal a differentiated

picture involving potentially threatened and widely unaffected catchments, hydrologic parameters and hydrologic constraints to the society.

Forest cover change and its impact on water and sediment fluxes in degraded Andean catchments

Veerle Vanacker (University of Louvain), Armando Molina (Universität Göttingen), Gerard Govers (KU Leuven)

In human-modified landscapes, land use/-cover change may have a profound effect on riverine water and sediment fluxes. The effect of forest cover on water yields has been demonstrated for small catchments where natural vegetation was removed and/or replaced by plantation forests. Little is known about disturbed ecosystems where forest plantations have been established on highly degraded land. In this paper, we analyse the hydrological response to complex forest cover change for a highly degraded Andean catchment. The land cover analysis (1963-2007) indicates different pathways of change : deforestation, reforestation, and spontaneous recovery. Forest cover changes occur in spatially distinct regions, with deforestation taking place in remote uplands and recovery and reforestation were particularly important in the lower parts where agricultural and bare lands are prevalent. There was a net average loss of native forests of ca. 45.5 ha y⁻¹, and 74% of the total deforestation results from conversion from native forests to agricultural land. The total area of 'bare land' decreased with 28 ha y⁻¹. Time series analyses of streamflow and rainfall data (1979-2007) indicate that the removal of native forest (by -22%) has contributed to the increase in total annual water yield, through an increase in annual baseflow by 25mm. The observed changes in extreme events are important as the maximum daily runoff decreased by ca. 5 mm despite somewhat higher daily rainfall amounts. The observed decrease in peakflows cannot be explained by clearcut of native forest, as the effect of deforestation on surface runoff generation is limited. This reduction is, on the contrary, related to reforestation of degraded lands to exotic forest plantations as well as spontaneous recovery of vegetation on remaining grazing lands.

Treeline changes at Khibiny Mountains, Kola Peninsula, Russia as the indicator of climate change

Anna Mikheeva (Moscow University), Ingrid Mathisen (Norwegian Institute for Nature Research), Olga Tutubalina (Moscow University), Annika Hofgaard (Norwegian Institute for Nature Research)

The interface between the boreal forest and the arctic tundra is the Earth's largest vegetation transition. It plays a key role in the global climate system because it is sensitive to climatic changes. Global warming in many Arctic regions has induced northward shifts in boreal vegetation distribution. Changes of the treeline transition zone have been analysed for the Khibiny Mountains, Kola Peninsula using aerial photos, high-resolution satellite imagery, and age structure data of birch (Tuliok River valley) and pine (Yumechorr mountain). Recorded changes were compared with regional temperature and precipitation data (Murmansk meteorological station) since 1936. The temperatures show no trend during the last 70 years, while precipitation shows a clear increasing trend. The uppermost trees were identified in the multitemporal imagery: air photos of 14/08/1958 (2 m spatial resolution) for both sites; QuickBird satellite image of 28/06/2006 (0.6 and 2.4 m) for Tuliok; and WorldView satellite image of 29/07/2008 (0.5 m) for Yumechorr. Locations of these trees were used as reference points and indicators of treeline change over the study period. Age structures of trees and saplings were derived from field data. According to the age structure analysis, treelines at both sites show consistent but slow upward movement of <30 m over the 50-year period. According to the remote sensing data, at Tuliok the treeline advance (birch) has been 29 ± 4 m in 48 years; at Umechorr (birch and pine) it has been 27 ± 21 m in 50 years. The large error margin at Umechorr is due to the absence of a detailed digital elevation model, which precluded precise analysis. Comparison with regional climate data indicated that the recorded treeline advance could be due to the increase of winter precipitation since the 1960s. This study is a product under the IPY core project PPS Arctic and is financially supported by the Research Council of Norway (grants 185023/S50 and 176065/S30 to A. Hofgaard), the Russian Leading Science Schools Programme, and Russian Scientific Educational Centres programme (grant 14.740.11.0200).

Do trees and shrubs respond the same way? Dendroecological studies on birch trees and dwarf shrubs in the Scandes Mountains, Southern Norway

Cathrin Meinardus (University of Erlangen-Nuremberg), Britta Weinert (University of Erlangen-Nuremberg), Jörg Löffler (University of Bonn), Anders Lundberg (University of Bergen), Achim Bräuning (University of Erlangen-Nuremberg)

Because of the absence of trees, polar latitudes and high mountain areas remained unnoticed from dendroecological research for a long time. However, dwarf shrubs as woody plants represent a potential complement to dendroecological studies of trees beyond arctic and altitudinal tree limits. Among them, dwarf birch (*Betula nana*) is a particularly interesting species to study because of its wide circumpolar distribution. However, it is not clear if dwarf shrubs and trees reflect the same climatological signals in their growth variations, since the former endure a different microclimate under winter snow protection. In our study we investigate growth histories of birch trees and dwarf shrubs and compare their growth-climate relationships in the lower alpine belt of the Norwegian Scandes (Filefjell), where both species occur close together. Samples of *Betula nana* were collected at different microsites along a snow depth gradient through a snowbed. Ring-width was measured from digital photographs of microscopic thin sections of the dwarf shrub stems. By using a variant of the 'serial-sectioning-method', most of the ring-width curves could be synchronized. Two ring-width chronologies of *B. nana* were established, including plants from the ridges and the inner part of the snowbed, representing sites with low and high winter snow cover depth, respectively. Surprisingly, the chronologies showed high similarity and were therefore merged into one dwarf shrub chronology. This dwarf shrub chronology was compared to a reference tree chronology of *Betula pubescens* ssp. *czerepanovii* growing at lower altitudes on the same slope. Despite representing different life-forms, the ring-width chronologies of both species showed a high similarity. Positive correlations between the ring-width indices of *B. nana* and *B. pubescens* ssp. *czerepanovii* and monthly mean temperatures indicate that growth-ring variations are mainly influenced by summer temperature, particularly of July. The results suggest that ring-width variations of *B. nana* are not strongly influenced by the snow gradient, and that in contrast the growth-ring variations from all microtopographical sites contain a regional climate signal. Furthermore, because of the strong influence of mean temperature in July, the species can be used as an indicator for summer temperature above the alpine timberline.

Recession of Tipra Glacier in Nanda Devi Biosphere Reserve, Garhwal Himalaya

Suraj Mal (University of Delhi), R.B. Singh (University of Delhi)

Glaciers are promising indicators of climate change. They have been receding rapidly in the Himalayan region over last few decades. Glacial retreat and mass loss have significant implications on fresh water supply, hydropower and other economic activities

in Himalayan high land and low land (Indo-Gangetic Plain). Therefore, continuous monitoring of Himalayan glaciers is immediately required. The snout, surface area, volume and elevation change of Tipra Glacier of Garhwal Himalaya were examined using Survey of India (SOI-1962) topographical sheet and ASTER images (2004) together with intensive field investigation. Snout positions and other glacial feature e.g. moraine and glacial lakes were surveyed using GARMIN Etrex GPS in 2010. Two DEMs generated from SOI and ASTER data were compared for calculating volume and surface elevation change of Tipra glacier. The study reveals that area of glacier decreased from 9.09 sq km (1962) to 8.53 sq km (2010). The total loss of glacier's area is estimated to be about 0.54 sq km. The snout retreated about 288, 404 and 600 meters in right, central and left part of the glacier with average rate of 6 m a⁻¹, 8.41 m a⁻¹ and 12.5 m a⁻¹ respectively during 1962 to 2010. The snout retreated about 60 mts upslope. Presently, the snout is located at 3820 mts about msl. Its mean width reduced by about 10 mts. The range of elevation has significantly decreased from 3760-5739 mts (1962) to 3820-5532 mts (2004). Total ice mass loss is estimated about -470×10^6 m³ we during 1962 to 2004. The snout retreat rate is not high as it is heavily debris covered. However, lower ablation part has become dead ice mound due to inadequate supply of ice from accumulation zone. Besides, the glacier appeared empty during field survey in lower ablation part with many longitudinal cracks and debris cover making its surface collapse any time.

Dynamics of the nival-glacial systems of the mountain massifs of the Eastern Altai and Western Tuva

Dmitry Ganushkin (Saint Petersburg University), Kirill Chistyakov (Saint Petersburg University)

Mongun-Taiga, Harhira, Turgeni, Tavan-Boghd-Ola mountain massifs are situated in the center of Altai-Sayan mountain system, they reach the altitude of 3900-4300 m. Average annual temperature in the region is from 0 to -3°C, annual precipitation 100-400 mm. Perennial snow patches are the most sensitive to climate change among the studied objects. In 1966-2008 their number in Mongun-Taiga massif reduced 4-fold, their area - 15-fold. Snow patches on western slopes disappeared. The altitudinal belt of snow patches moved 300-400 m up. Diversity of morphological types also reduced. In 2009-2011 the area and the number of perennial snow patches increased. The lower limit of their distribution descended 250 m. Total modern glaciation of 4 massifs is about 120 km². Areas of most glaciers do not exceed 1 km², valley glaciers reach 2-5 km². Glaciers form several complexes with united accumulation zones. Since the maximum of the LIA the glaciers retreat. Glaciation of Mongun-Taiga massif lost 59% of area, glaciation of Tavan-Boghd-Ola massif - 41%, Turgeni-Nuru - 34%, Harhira-Nuru - 50%. Short stabilizations of glaciers took place in early 1920-s, mid-1960-s and mid-1980-s. Deglaciation was especially fast after 1995. In 1995-2008 glaciation of Mongun-Taiga massif lost 19% of area (1,5%/year), glaciation of Tavan-Boghd-Ola massif in 2002-2009 lost 12% of its area (1,7%/year). Firn line on the glaciers in 1995-2008 elevated 200-300

m. In 2008-2011 snow accumulation increased, firn line returned to the level of 1994-1995. degradation of small glaciers became slower, valley glaciers continued to retreat with average rate 5-10 m/year. Ground ice in high altitude zone is represented mostly by bodies of glacial genesis divided into 3 groups. The first is connected with moraines of LIA which consist of ice core and debris cover. The second group objects were formed after the middle of 1960-s. They are debris covered parts of the former glacier. Objects of the third group lost their connection with the main glacial masses and turned into dead ice in 1995-2008. Main modern processes for the first 2 groups are exposure of ice by melt water streams, collapse of moraine cover and melting out of the ice core. Objects of the third group are in the process of intense armoring, in the last 3 years perennial snow patches appeared on the surface of armored glaciers, creating their multilevel vertical structure. Rock glaciers of the region have mostly glacial genesis. We mapped 17 rock glaciers with total area of 5.5 km². We estimate the average rate of the advance from the beginning of LIA of 2 active rock glaciers in Mongun-Taiga massif 0.5-0.7 m/year. The main cause of trends in dynamics of the studied object was aridization on the background of warming with cooler and more humid conditions in early 1920-s, mid-1960-s, mid-1980-s and 2008-2011.

C08.29-06 - Mountain Environment and Rural Livelihoods in the Tropical Andes: Local Responses to Global Change

Chair: Perdita Pohle, María Fernanda Lopez Sandoval

Governance of complex socio-ecological systems in the Andes of Bolivia: toward a transdisciplinary and reflexive approaches

Patrick Bottazzi (Center for Development and Environment), Stephan Rist (Centre for Development and Environment)

'Governance' is a core concept of sustainable development. It refers to the ways multiples stakeholders collectively take decisions or influence each other during the process of creating, implementing and actualizing norms, rules and regulations related to natural resource appropriation. In the field of sustainability sciences, governance approaches are facing a double complexity. On the one hand, the inclusion of multiple stakeholders from diverse socio-cultural origin are extending and diversifying the ways in which a given problem is perceived and transformed into institutional decisions. On the other hand systemic approaches of natural sciences are considering a growing number of interrelated biophysical parameters that are making the scientific field even more complex increasing through this the distance between the views of scientists local resource users and practitioners. Knowledge provided by social and natural sciences need to be more systematically related, but not to define immutable dependencies internal to the scientific view; the integration must rather provide core transversal variables that support stakeholders in making decisions in complex situations. Governance in sustainability science is the target of a large number of theories but synthetic approaches are still needed to help understanding core aspects of socio-ecological system. The aims of this paper, is thus to revise some of the most recent approaches of natural resource governance and to see how reflexivity and transdisciplinarity approaches can help finding acceptable compromise in a growing level of complexity. Based on results from inter and transdisciplinary research carried out by the broad network of scientific cooperation that CDE maintains with Andean Universities in Bolivia and Peru this presentation addresses the following three important key criteria to be considered in order to facilitate transdisciplinary integration different forms of knowledge into more reflexive processes of governance of natural resources in view of the principles of sustainability: · 1) a better articulation between biophysical and sociological scales and levels of collective action; · 2) the importance to include sociological and ecological system characteristics into an holistic understanding of the roles and functions played by institutions; · 3) the role of different forms of knowledge production by different 'epistemic communities' and valuation on the power distribution influencing governance processes This paper will successively discuss each of those dimensions to propose a reflexive and transdisciplinary governance framework that can be useful for researchers as well as practitioners in the field of sustainable development.

The role of vertical exchange for socio-ecological resilience in the Andes, the example of climate change

Dorothea Hamilton (Universität Marburg)

Using the altering climate between the different ecological floors has always been one of the main Andean strategies for survival. The Quechua people living in the Andes have traditionally made use of the climate variability in two ways; for creating resilience by planting at different altitudes, and increasing variability through the use of crops with different climatic necessities. In this sense, the climatic diversity has been the main driver for the evolution of the high bio-cultural diversity we find in this region, have created a high agrobiodiversity in the area. This is argued, to be among the main forces behind a highly resilient environment. As the Andean region is a fairly densely populated mountainous region, resilience has to be seen in a socio-ecological context; considering the human and environment interaction and the role of customs and institutions is crucial for sustainability. In Andean terminology this is known as 'Ayllus' meaning the interchange and interaction between different realms, as well as the tangible as the intangible aspects, which have been the basis for survival for millennia. The traditional Andean system of resource management has proven to be highly resilient to ecological and social shocks. Nonetheless, external influences such as the introduction of a market economy, altering beliefs, demographic growth and the influence of government and NGO activities are having strong impacts on the Ayllu system. Furthermore, ecosystem changes mostly seen in extreme weather events are impacting the rural livelihoods in the Andes in a negative way, and are threatening the socio-ecological resilience of the fragile ecosystem. In this presentation I will discuss the findings and reflections of action research undertaken in the Cusco region of Peru. I will focus on the historical role of verticality for resilience and the current climate challenges that Andean communities are faced with. As the socio-ecological adaptation to climate change is a complex system, the implication of changing climate in one of the ecological niches for the neighboring regions, such as the tropical Andes will be explored. Solutions to climate change in a vertical environment can only be found in the context of distinct ecosystems following the traditional way of resilience. Possibilities and challenges for Andes communities shall be subject to discussion.

Integrating farming and paramo conservation on the Colombian paramo

Ophélie Robineau (CIRAD/INRA UMR Innovation), Martin Châtelet

The Andean páramo is a unique mountain grassland ecosystem, with high biodiversity and endemism, located between 3,000 and 4,200 m.a.s.l. The will to strictly protect paramo in Colombia has led to the creation of conservation areas where all kinds of productive activities are excluded. Although the Colombian environmental policy is unfavorable to farming in the páramo ecosystem, it is believed that an integrated management of the páramo is possible, and that farming activities can be part of the solution at this agriculture-environment problem. This issue has become particularly acute

on the Rabanal páramo (western cordillera) where the projected expansion of a core protection zone will soon include major areas used for agriculture and settlements. We show how a multi-scale approach combining agronomy, geography and management sciences, can help to identify areas of flexibility within the páramo farms for the introduction of technical and organizational changes that combine conservation and sustainable livelihoods. A study of local agrarian history and aerial photos indicates that this zone has been a dynamic part of local farming systems since at least the 1950s and that the páramo has evolved from a subsistence farming area to a zone that now includes intensive potato production conducted by external entrepreneurs. The presence of entrepreneurs is mainly due to the need of family farmers for a solution to maintain the productivity of their pastures. Through a process of interviewing participants in the debate, as well as mapping land use in the contested area, perspectives for action were developed that would result in more sustainable farming practices.

Global Change and territorial transformations in mountain areas of Northwest-Argentina

*Pablo Paolasso (ISES-CONICET-UNT), Gerhard Rainer (Universität Innsbruck),
Fernando Ruiz Peyré (Universität Innsbruck), Martin Coy (Universität Innsbruck)*

Northwest-Argentina comprises five provinces with a land surface of approximately 470.000 km². From a physical-geographical point of view the region can be subdivided into two main areas: the western part is dominated by a high mountain range that surpasses 6000m of altitude while the eastern part consists of an extensive lowland plain with an extremely low gradient (Llanura Chaqueña). The altitudinal variations cause profound differences in precipitation levels, soils, types of vegetation etc. which, together with a great variety of societies, have led to the formation of diverse territories. Historically, Northwest-Argentina was characterized by a strong interdependency between mountain range and lowland plain. While the population center was originally located in the mountain range, with the arrival of the Spaniards and especially with the advance of capitalism from the second half of the XIX century on, the lowland plain converted into the economic and demographic core of the region. This growth was based on the use of natural and human resources from the mountain range (water, soil, climate, seasonal labor force). The agro industrial economy that was promoted in the lowland plain (principally the cultivation and industrialization of sugar cane) caused massive seasonal movements of population from the mountain range to the lowland plain contributing to a displacement of population and to a strong economic regression in the mountain range. Today the mountain range of Northwest-Argentina is one of the poorest regions of the country. Nevertheless, in the last decades some areas of the mountain range have experienced a process of revitalization caused by changes in the demand of national and global markets. The strong orientation towards international markets provoked a restructuring of certain traditional activities (vitiviniculture, horticultural production and tourism) and the appearance of new activities (olive farming, large-scale

mining). This process was made possible by the appearance of new actors, from local to global, and by climatic changes (fundamentally an increase of precipitation - something of fundamental importance in an area that is characterized by its aridity). These processes can be subsumed into what is known as Global Change. Due to this fact, the goal of the presentation is to analyze the changes that occurred in the territorial structure of the Northwest-Argentinean mountain range as a result of Global Change, knowing that the articulation between global processes, different actors and local processes that intervene in the area of study caused the (re) construction of diverse territories.

C08.29-07 - Vegetation response to climate change in tropical mountain ecosystems and consequences for biodiversity and land-use options

Chair: Achim Bräuning, Aster Gebrekirstos

Vegetation succession in relation to glacial fluctuation and global warming on Mt. Kenya

Kazuharu Mizuno (Kyoto University)

Dramatic changes are taking place in the glacier-covered high mountains of Africa. The only African mountains still capped by glaciers are Mt. Kilimanjaro, Mt. Kenya, and Mt. Rwenzori. Recently, these glaciers have been retreating at an accelerated rate. Mt. Kenya (5199 m) is an isolated, extinct, denuded volcano that lies on the equator (0°6' S, 37°18' E), approximately 150 km NNE of Nairobi. Although there were 18 glaciers on Mt. Kenya at the end of the 19th century, only a few remain, including the Lewis and Tyndall Glaciers. The glaciers of Mt. Kenya have been diminishing rapidly in recent years, and plant species have advanced in response. This study primarily examines the real-time response of plant communities to glacial retreat and global warming during the last half-century, as well as the recent glacial fluctuations, and discusses the effects of glacial retreat and global warming on ecosystems. The Tyndall Glacier, the second largest glacier on Mt. Kenya, retreated at a rate of approximately 3 m year⁻¹ from 1958 to 1997, but the rate increased to approximately 10 m year⁻¹ from 1997 to 2002, 15 m year⁻¹ from 2002 to 2006, 9 m year⁻¹ from 2006 to 2009, and 7.5 m year⁻¹ from 2009 to 2011. The leading edge of *Senecio keniophytum*, the first pioneer species to establish after glacial retreat, has advanced in close correlation with glacier recession. Other pioneer species including *Arabis alpine*, mosses, lichens, and *Agrostis trachyphylla* are also advancing. The distribution of plants in quadrat (80 m x 20 m) placed in frontier region with the glacier snout in 1996 was very different from that same quadrat in 2011, from the distribution coverage of *Senecio keniophytum* and the number of species (from one to four). Although changes in the leading edges of *Lobelia telekii* and *Senecio keniodendron*, large woody rosette plants, appeared unrelated to glacial retreat until 1997, the species have advanced since then. The succession of these species does not appear to be directly related to glacial retreat, but rather may be linked to soil development. Although *Helichrysum citrispinum* had not grown at altitudes higher than the Tyndall Tarn (4470 m) before 2006, 32 plants of this species were identified on lateral moraines above 4470 m in 2009. The advance of this species in outer areas of old glacial flow paths may also be linked to recent increases in air temperature rather than being directly related to glacial retreat. Monthly mean minimum and maximum temperatures at the 1890 m site of Mt. Kenya have increased by more than 2°C over 47 years from 1963 to 2010 at 1890 m. The recent temperature increases are thought to be accelerating the expansion of some species into higher altitudes.

How do tropical tree species respond to nitrogen fertilisation? Tree growth along elevational and nutritional gradients in Southern Ecuador

Susanne Spann (University of Erlangen-Nuremberg), Thorsten Peters (University of Erlangen-Nuremberg), Achim Bräuning (University of Erlangen-Nuremberg)

The tropical mountain forests of southern Ecuador are strongly threatened by land-use changes and degrading environmental effects. In the near future increasing frequency and intensity of drought-events and higher atmospheric nitrogen depositions are expected (IPCC 2007), thereby affecting tree-physiological processes in a major way. As part of a scientific nutrient manipulation experiment, tree growth of different tropical tree species (*Podocarpus oleifolius*, *Graffenrieda emarginata*, *Persea feruginea*, *Alchornea grandiflora*, *Prunus* sp., *Weinmannia elliptica*, *Weinmannia ovata*, *Graffenrieda harlingii*, and *Prumnopitys montana*) were examined at two elevations (2000m and 3000m a.s.l.). The aim of our study is to investigate to what extent long-term fertilization with nitrogen will affect tree growth and variations of stable carbon isotopes in the wood as indicators of changes in water budget of the trees along this altitudinal gradient. Since July 2010 high resolution dendrometers have been installed measuring stem-diameter variations of fertilised and non fertilised trees in 30 minutes intervals. Cumulative growth, daily radial change and daily amplitudes were calculated and linked to climatic factors like precipitation, vapour pressure deficit and irradiation with particular attention to drought events. In addition, intra-annual variation of carbon and nitrogen isotopes will be analysed by cores which have been taken from the different tree species. We expect that intra-annual variations of stable carbon isotopes provide a further technique to detect seasonal, environmental-induced plant physiological reactions.

Responses of African species to climate variability and change

Aster Gebrekirstos (World Agroforestry Centre)

In vast areas of Africa, knowledge on the range of natural climate variability and the range of tree species tolerance to climatic extremes is scarce. We have used stable carbon and oxygen isotopes in tree rings to explore their potential as climate proxies and as a means to assess adaptations of tree species from East to west Africa along altitudinal gradients. Most of the study sites and species in Ethiopia, Tanzania and Burkina Faso showed vulnerability and substantial growth reduction during drought years. Stable carbon (δ¹³C) and oxygen (δ¹⁸O) mean values showed similar inter annual patterns. In general, both δ¹³C and δ¹⁸O show negative correlations with rainfall, humidity and PDSI. On the contrary, they are positively correlated with sunshine hours, maximum temperature and evaporation. The results showed valuable information with regard to the adaptation and vulnerability of African species to climate variability in different agro-ecological zones. This has great implication in land use management, species selection in restoration and agroforestry practices and in our efforts to adapt and mitigate climate changes.

Growth-climate responses of various sub-tropical tree species in Ailao Mountains, southwestern China

Ze-Xin Fan (Chinese Academy of Sciences), Achim Bräuning (University of Erlangen-Nuremberg), Aster Gebrekirstos (World Agroforestry Centre)

Climatic conditions in the Chinese monsoon regions are changing, affecting local hydrological and land-use systems. The Ailao Mountains of central Yunnan (southwestern China) lie in the region of Asian summer monsoon. Evergreen broadleaved forests flourish in this mountain area, with a humid summer and cloudy winter climatic conditions. Using dendrochronological techniques, we explored the effects of inter- and intra-annual climate variations on radial growth of various tree species growing in the subtropical forests. Regional moisture variability during the past two centuries was reconstructed from tree-ring parameters, like ring width and stable carbon and oxygen isotope variations derived from multiple tree species. Seasonal cambial growth dynamics were monitored by high-resolution electronic dendrometers for ten studied species. Our results showed that most of the studied tree species had visible tree-ring boundaries and it was possible to cross-date the interannual growth patterns. Correlation analyses with regional climate data revealed that trees growing in the mountain cloud forest are sensitive to climate variations. Thus we conclude that many evergreen tree species in this subtropical mountain climate are suitable for dendrochronological studies and that the dendroclimatological potential to study regional climate change in the subtropical evergreen forests is much higher than so far explored. Further exploration should focus on long-term climate reconstruction, as well as modeling growth-climate response of different species, especially under future climate change scenarios.

Political Geography

C08.30-01 - Conflicts over natural resources

Chair: Paul Reuber

Social Movements and the Political Geography of Water Conflicts in India

Michael Brinkschröder (IfG Münster)

After the introduction of India's New Economic Policy in the 1990s, processes of liberalization, urbanization and ambitions of modernization have rapidly changed developmental choices and priorities in the country. This trend has drastic consequences on the availability of natural resources, particularly water, leading to a great variety of water related conflicts. Social movements that developed around water distribution conflicts between industry and agriculture are a prime example for this. The mass rally of 30.000 peasants against the water distribution from the Hirakud reservoir to industries in Orissa in 2008 and the protest mobilization against the Maha Mumbai Special Economic Zone (SEZ), connected to water distribution from the Hetavane dam in 2009, are only two current examples. This PhD project utilizes both examples as case studies because of their regional peculiarities. In both cases, civil society movements managed under very different regional circumstances to initiate mass rallies around water related issues and rise to powerful political actors. But their influence on processes of water governance and rural territorial development in the respective federal states differ significantly. In the case of Mumbai, the highly strategic resistance movement managed in 2011 to withhold the biggest SEZ project in India's history. In the case of Hirakud, the mass movement is still ongoing and confronted with various problems. In this short presentation, I would like to present a few empirical findings and theoretical ideas that may lend to support the discussion about Water Conflicts in India, particularly the genesis of regional specific protest movements and their influence on water governance and rural territorial development processes. The study focuses on the following questions: 1. How did the regional specific protest movements around the Maha Mumbai Special Economic Zone and the Hirakud dam arise and how did they manage to persist over time? 2. If, and to what extent, have these protest movements been able to participate in and influence the establishment of norms, regulations and practices that direct the water governance processes in the respective regional case studies? 3. Which relationships between the analyzed water conflicts can be drawn with special emphasis to the development of new civil society movements and their influence on water governance processes? The empirical findings are based on the results of a 6 months field research, conducted through an internship in the Forum for Policy Dialogue on Water Conflict in India.

Comparing political frameworks: What lessons can China's South-North Water Diversion learn from Spain's Ebro Water Transfer?

Teresa Sprague (TU Dortmund)

In response to the combination of anthropogenic and naturally occurring stress to water resources, state actors use frameworks to guide decisions-making and to find solution to the uneven distribution of resources. One theme that emerges within this discussion is the construction of large infrastructural schemes such as major water diversion projects. This paper provides a case study comparison of the political frameworks determining water diversion projects in the Ebro River Basin in Spain (the 2001 Ebro Water Transfer), and in the North China Plain, (the South-North Water Diversion). The study applies an original application of a framework analysis based on Tony Allen's Five Water Management Paradigms. The focus and purpose of this study is the determination of what decision-makers in China can learn and apply from major water diversion projects, particularly focussing on the diversion project within the Ebro River Basin. The analysis first evaluates the comparability of political frameworks and then specifically what recommendations are offered to the South-North Water Diversion (SNWD). Recommendations, or 'lessons learnt', are evaluated through three categories: the shift to the Third Paradigm, ecological considerations, and alternative strategies. Concluding recommendations are comprised of the realization of limits imposed by a lingering Hydraulic Mission, the importance of increased public participation, and the need for further attention to alternatives and environmental concerns as political frameworks shift toward the Third Paradigm.

Struggling for inclusion: The quest for collective action of Tamil Fisheries Cooperatives Societies in North Sri Lanka

Joeri Scholtens (University of Amsterdam)

Collective action literature in the context of natural resource management has revealed a range of conditions which make it more likely for communities to build successful institutions to use their common property resources in a sustainable fashion (e.g. Ostrom 1990, 2002). In recent years, Agrawal (2001, 2003) and others have criticized this approach for being too a-political and a-historical, as institutions tend to be politically contested and operate in a historical-political context which, for example, determines their position vis-à-vis the state. This article contributes to this discussion by analyzing novel empirical material on collective action among Tamil fisheries cooperative societies (FCS) in post-war Northern Sri Lanka. These FCS, which function as producer organizations and local governance bodies at the same time, are just recovering from a protracted 30-years civil war in Sri Lanka, during which the fisheries sector faced severe restrictions and fishermen multiple hardships. As the war is over and the dust settling since 2009, FCS have shown to play a vital role not only in the reconstruction of the sector, but even more pronounced in taking the lead in a highly politicized struggle to

reclaim their traditional fishing grounds from poaching Indian trawlers. The FCS' capacity for effective collective action, however, appears to be critically affected by political interference in the organization's functioning, which is connected to a more general marginalization of the Tamil community. Apart from local conditions, these political-historical factors appear crucial for understanding the characteristics of collective action among fishermen, both in terms coordinating sustainable resource use, production benefits, and their struggle for fishing rights. This research is based on a complementary combination of quantitative and qualitative research, conducted during 12 months fieldwork among fishermen in Northern Sri Lanka.

Geography of natural resources. Biofuels, Brazil and potential new conflicts in the international arena.

Elisa Freitas (University of São Paulo and University of Lisbon)

In this period there is a global race for food and alternative energy, it is necessary to meet the growing global demand and find an alternative to replace oil that is considered a major contributor to global warming. In this case, Brazil is one of the most important countries in the world that can produce food and biofuels at the same time. First, because it has a large territory containing a large amount of natural resources. Secondly, Brazil has the technical conditions to produce them in large numbers. Therefore, we can observe that there have been some phenomena, such as the acquisition of Brazilian land especially by transnational corporations Cargill, ADM, Morgan Stanley, Bunge and others. These transnational corporations want to produce agricultural commodities and raw materials for biofuels such as sugar cane to produce ethanol, and soybeans for biodiesel and food. In addition, supranational actor like the UN (United Nations), EU (European Union), OECD (Organization for Economic Cooperation and Development) and others have raised question, the production of biofuels in Brazil is sustainable or not. In addition, major NGOs (Non-Governmental Organizations) such as Greenpeace and WWF have argued that biofuel production can result in change of land use (LUC). For these reasons, it is noteworthy that Brazil will have to go a long way until you reach the leadership in the global biofuels market. For both the Brazilian government will have to demonstrate that the Brazilian production of biofuels is sustainable. After this, Brazil must promote the sustainable expansion of sugarcane production in countries that can produce this kind of raw material as the Latin American countries and African countries, especially those who have natural conditions for it. Our purpose in this article, therefore, will discuss policies and actions that the Brazilian government is creating to lead a global biofuels market and how these policies can cause some conflicts between the various countries that make up the world of the international system. Finally, we would like to find an answer to this question: Will biofuels are a solution or a problem to address environmental challenges?

C08.30-02 - Environmental Geopolitics and Climate Change

Chair: Jürgen Oßenbrügge

The imaginative geographies of climate wars

Benedikt Korf (University of Zurich)

There has been much talk about 'climate wars', both in public discourse as well as in academic publications (e.g. themed issue in *Political Geography*, 26 (6)). Most of these writings predict a neo-Malthusian kind of scenario of climate change leading to resource scarcity, which in turn is likely to trigger violent conflict. This discourse of 'climate wars' has even been co-opted by UN general secretary Ban Ki Moon and his advisor Jeffrey Sachs who suggested that the Darfur crisis was the first onset of such climate war. In this paper, I will argue, that these neo-Malthusian predicaments are deeply flawed for two reasons, one methodological, the other empirical. Methodologically, it is difficult to extrapolate from current or past conflict dynamics to what will happen in the future. Empirically, the neo-Malthusian hypothesis has been proven inadequate in explaining current and past environmental conflicts on various accounts. I will trace these inadequacies and illustrate the tacit geographical imaginations that trigger the talk about climate wars and its hidden and open geopolitics.

The Effect of Vulnerability on Climate Change Mitigation Policies

Amit Tubi (University of Jerusalem), Eran Feitelson (University of Jerusalem), Itay Fischhendler (University of Jerusalem)

The problem of climate change negatively affects many countries throughout the world, and will most likely be exacerbated by rising concentrations of green house gases in the atmosphere. The success of measures meant to mitigate climate change is highly uncertain, and previous attempts to explain countries' mitigative policies have been largely deficient. Thus, the purpose of this study is to improve the comprehension of mitigation policies adopted by various countries, through the introduction of the different factors that comprise vulnerability. For this purpose, vulnerability has been defined in the widest possible manner, including factors of its two basic components: impacts (expected damages due to climate change) and adaptive capacity (the ability to moderate those damages). These factors include both socio-economic and natural variables. In addition, the declared and implemented components of mitigation policy have been differentiated and examined separately. The effect of vulnerability on climate change mitigation policies was examined by OLS regressions, incorporating a wide range of control variables. Results obtained by the analyses indicate that vulnerability has only a limited effect on mitigation policies. Adaptive capacity, the factor mitigating vulnerability, has a positive effect on the level of declared policy, though it becomes insignificant once

implemented policy is examined. This finding suggests that the 'free-rider' problem prevents high capacity countries from following through on much of their declared policy. Furthermore, the effect of impacts on both declared and implemented policies is insignificant. Further analyses indicate that this insignificance is caused by the uncertainty in assessments of future impacts, as well as pressing domestic problems in low capacity countries. Finally, findings obtained by this research suggest new hypotheses regarding the effect of vulnerability on mitigation policies.

Regulating the Future? Geoengineering as Techno-Political Assemblage

Thilo Wiertz (Heidelberg University)

How can we explain the political changes that accompany new technological developments? Contemporary approaches within Political and Cultural Geography have demonstrated how the Social is produced and renegotiated through language. More specifically, post-structuralist approaches explain the formation of regimes as discursive formations that organize the social but that are, at the same time, subject to critique and dislocation. These approaches point to the tension between stabilization and (re)negotiation of social relations, emphasizing their radical contingency and the working of power in discourse. However, conceptualizing the social as an exclusively symbolic domain is limited in understanding political change in relation to physical-environmental and technological change. In this contribution, I will draw on recent writing on assemblage and on lines of thought within Gilles Deleuze philosophical project to discuss technological regimes as a concept to critically explain (de)stabilizations of socio-material reality. This allows taking serious the role of natural scientific research and geophysical processes in explanations of political change, and it allows extending conceptions of space beyond a merely discursive category. The implications for political geographical research on emerging technologies are discussed using geo-engineering and its implications for climate politics as an example: the debate about large-scale manipulations of the climate system has emerged as a field in which scientific research is particularly powerful in anticipating - and potentially regulating - future socio-material realities.

Environmental dystopias, popular geopolitics and the (missing) political geography of corporations

Elena dell'Agnese (University of Milano-Bicocca)

Representing the future is always a good strategy to speak of the present. While describing a threatening future, dystopian texts offer a glimpse of the worries of their time: the first dystopian fictions, at the beginning of the Twentieth century, were haunted by over-urbanization; the ones of the Fifties by autocratic governments; in the Seventies, limits of growth and gender relations were the most relevant issues; and now, the most ominous aspects for the future seem to be the consequences of our lack of respect

towards "nature", in terms of genetic manipulation or, simply, bad behaviour. Indeed, environmental dystopias, offering apocalyptic visions of post-human landscapes dotted with the remnants of consumerism and abundance, are fashionable, both as works of arts (such as Cormac McCarthy's *The Road*), and as more commercial products, such as videogames, or feature films. If McCarthy's literary masterpiece leaves unknown the causes of the disaster that has cancelled the biosphere, other products tend to conjugate their open environmental message with a more political undertone, underlining the incumbent presence of corporations. The theme was present since the first dystopian images: already in the German movie *Metropolis* (1926), a forerunner of the genre, the urban landscape is metaphorically dominated by corporate buildings. And it is also central in celebrated 'film vert' of the Seventies; in *Soylent Green* (1976); for instance, a private corporation has the total biopolitical control over individuals' life. In contemporary environmental dystopias, however, private corporations assume a role even more relevant, not only as their greed is often the ultimate reason of disaster (*The dawn of the planet of the apes*, 2011); but also because they play a central political role, orienting public institutions (like in *Idiocracy* (2006), where the Brawnco Corporation purchases the U.S. Food and Drug Administration, in order to promote its beverages, instead of water, for any use, even irrigating crops), or even assuming the functions of governments themselves. In the computer-animated movie *Wall-E* (2008), the situation is pushed to its extremes, since a super-corporation, called Buy n Large, after dominating every conceivable field in human life, has reduced the planet to a pile of garbage, forcing the last human survivors (all fat and unable to walk) to live in a giant spaceship. The idea of a private corporation assuming world leadership still belongs to dystopia. But the political power of corporations is a reality, as the role of United Fruit Co. in the Fifties Central America, should remind us. Popular geopolitics is offering its own specific contribution to the topic. While, unfortunately, political geography, and formal geopolitics more in general, seem to be, in this perspective, still lagging behind.

C08.30-03 - Conceptual approaches and theoretical debates within Political Geography: The relationship of representation and practise

Chair: Annika Mattissek

Political geographies: Being more-than-representational

Matthias Lahr-Kurten (University Mainz)

In political geography, in recent years the aftermath of the representational turn led to discussions about the relevance of 'discourses' and 'practices'. Some tried to find the answer in enhancing the concept of discourse in order to include practices (Müller 2008), others tended towards the importance of the everyday state in some sort of practices (e.g. Painter 2006). In my paper, I want to shed light on the question what political geographies could look like if we were to use a theory that combined both: 'practices' and 'arrangements' (e.g. discourses). The US-American social philosopher Theodore Schatzki offers such a theory that is entirely based on these two analytical categories (Schatzki 2002). In my talk, I will draw on findings taken from my recently finished PhD thesis (i.e. German foreign language politics) where I consequently applied this approach and wanted to show how political geography could be 'more-than-representational' (Lorimer 2005) - without either focusing on 'mere emotions' or losing hold of geometries of power.

About Loopings, Structuration and complexity: Integrating Politics of Representation and Practices.

Frank Meyer (Leibniz Institute for Regional Geography)

Critical geopolitics as well as other political-geographical sub-disciplines have concentrated on representational articulations and effects of politics such as geopolitical imaginations. In a different field, Marston, Smith and Jones have undertaken efforts to transform the influential scale debate away from pre-given hierarchical orders towards a relational conception of power. In addition, Painter managed to articulate territory/territoriality - one of the most popular representational geographical topics of research - within a re-conceptualization as the effect of power-networks. This theoretical move has led - in analogy to similar moves within political sciences such as the government stories (Rhodes/Bevir) or political practices (Nullmeyer/Pritzlaff) - to the ability of political studies to engage both matters - representation and practice - within research designs. This borders key topics of recent theoretical debates such as the one about the distinction of matter and discourse. The presentation will attempt to present a coherent depiction of the foundations for a praxeological account of representational politics. Especially in combination with premises of complexity theory such as nonlinearity and

circularity, one will be able to reconfigure this account into heuristic designs to approach complex relationships (e.g. such as the relation between border regulation, border discourses and subverting practices) and help design theoretically sound empirical studies. Example-research designs from border studies (regarding the EU external border), peripherization studies (regarding shrinkage and its discourse) and the studies of antagonistic political projects will be used to detail these theoretical elaborations along the key question of 'How can be the intergration of representation and practice be achieved are operationalized empirically'?

Contesting the rules of the game!? - New forms of disagreement in urban development conflicts.

Iris Dzudzek (University Frankfurt)

Conflicts over urban development strategies seem to have radicalized. Struggles over large-scale projects such as Stuttgart 21 or the question 'in whose name' the creative city develops in Hamburg, for example, show that more and more citizens do no longer agree with the formalized rules of political participation and do not feel represented by their elected representatives anymore. Participatory planning tools seem to have shifted from an emancipatory instrument into a neoliberal rationality of governance. The governmentality studies have criticized participatory planning processes as a form of 'governing through community' (Rose 1996). They mainly focus on hegemonic rationalities and interpellations of (neoliberal) governance. But forms of contention, practices of resistance and their role for the change of common forms of political participation more than often remain black-boxed. This paper tries to open this black box through a case study on conflicts over the transformation of the university campus in Frankfurt/Main into a so-called 'campus for culture', where different cultural institutions and industries will be located. The planning process is highly contested because people fear the loss of affordable housing and locally rooted non-profit cultural institutions. The local newspaper writes about the planning conflict: 'Petra Roth' Lord Mayor of Frankfurt/Main 'fights her own battle. 'Participatory democracy' she calls it? (Journal Frankfurt 2011-02-22). Participation occurs as conflict, consensus as weapon. New forms of protest, resistance and subversion which are connected to the right-to-the-city-movement can be observed in this context. They question established forms of political participation and representation. Based on several weeks of participatory observation and qualitative interviews the presentation focuses on new forms of disagreement in the sense of Rancière and on processes of articulating new political identities in the context of contemporary urban development in Frankfurt/Main. The presentation shows that these new forms of performative critique are able to question and contest the 'rules of the participatory game', neoliberal forms of exclusion and thus the post-political consent in a way that traditional forms of protest were not able to do.

Spatial Practices in Italian Autonomist Movements: “Taking over the City” by Milanese Social Centers

Shinya Kitagawa (Mie University)

The purpose of this paper is to analyze spatial practices to invent social relations autonomously from the below under the condition where the society or the nationalized social citizenship has been disrupted and has tended to be subsumed really under capital. Some scholars say recently that urban scale is critical for such invention of alternative society or citizenship. There we focus upon autonomous geographies of Italian social centers (*centri sociali*) particularly in Milan as one of the (re-)creation of “the right to the city” under the neoliberal condition. It is worthwhile to note the concept of autonomy in Italian political context. Roughly, it began to be used actively in a radical-left movement in 1950s and 60s that was called “workerism (*operaismo*)”. The theoretical point put in emphasis was that mass workers could organize themselves, create collective relations for struggles on their own, autonomously, without the Communist party and Unions, in factories as a site of production. However, as class composition has changed, as immaterial workers have become one of the main figures in semio-capitalism since 1970s, and as productive labor has diffused from the factory to the whole society, autonomous practices were developed both in the level of intensity and of the sphere. In this phase, material and immaterial workers have found that they could organize themselves, create relations for struggles and social lives autonomously, without the state and corporations in cities as a site of production and reproduction or of biopolitical struggles. Therefore, autonomy means refusal of the exiting social, economic, and political condition and, importantly, also autonomous production of alternative collective subjectivities. To consider its potentiality in the past and the present in which being precarious become hegemonic ontological condition, we analyze the space of the social centers which have created convergent relations or sociability, being based upon its physical space in which subjectivities can be expressed in territories like the neighborhood and the city. These practices of the social centers are processes in which it proposes and searches for some urban society differing from existent one. They can be called as “social opposition” in the city not for helping the state and capital but for de-centering and challenging them. We can say that they imply a form of common practices creating a way to urban citizenship.

C08.30-04 - The (Geo-)Politics of Identity: Case Studies on Different Scales

Chair: Anton Gosar

Nation-Creation in Turkmenistan

Hendrik Meurs (Universität Heidelberg)

In a difficult neighbourhood and after a series of coloured revolutions in other post-soviet countries, the Turkmen autocracy shows great political stability. To a considerable degree this is owing to an efficient system of government induced nation building, paternalist allocation of income from the rentier state's vast gas reserves, extreme repressions, international isolation, the usage of foreign countries for the creation of legitimacy, widespread surveillance and an unmatched cult of personality created around the country's presidents. Most of these measures penetrate public and private spaces alike. Since all aspects of this system are interrelated, the term "nation building" is seen as insufficient and "nation creation" is being suggested instead. Until today largely isolated, Turkmenistan receives little attention in international media. And the majority of reports focus on its vast gas reserves and the country's presidents' extravagant cults of personality. The cult, however, is only the most visible part of a complex system of top-down nation creation. When Turkmenistan became an independent nation in 1991, it was without any national legacy. Therefore a great history of Turkmen nationhood has been constructed as both, proof for the right of independence and to develop the incumbent president as legitimate successor of great ancient forefathers. Additionally by renaming cities, landscapes or streets, Soviet space was turkmenified. Turkmenistan's borders, de facto drawn in the early 1920s are claimed to define a territory, Turkmen people have inhabited for millennia, largely ignoring the people's nomadic past. This is supported by the repetitive usage of national myths, traditions and symbols. Furthermore the president was established as omnipresent, omnipotent and omniscient producer of apodictic truths. An exceptional governmental construction-boom in the country's capital Ashgabat aims at the creation of pride among the population and supports clientelistic structures among elite groups. Finally a vast system of extreme restrictions of even the most basic human rights complements this development. Foreign newspapers, satellite dishes and foreign mobile phone providers, to name only very few, are being banned. Freedom of information and media have been restricted to insignificance. The government controls virtually all aspects of public and many parts of the Turkmen people's private life. Thus nation creation combines traditional aspects of nation building (such as the usage and/or invention of history, myths, symbols, images and territory) with an extreme cult of personality, excessive repressions, the usage of crowd psychology, sultanistic patterns and governmental behaviour of exceedingly rich rentier-states. It is the aim of this presentation to describe both, the interwoven methods as well as the flaws of the Turkmen system of nation creation.

An exception in the Balkans: Albania's multiconfessional identity

Peter Jordan (Austrian Academy of Sciences), Gottfried Hofmann (Austrian Academy of Sciences)

Much in contrast to the other nation states in the Balkans, Albanian national identity is not bound to a denomination. While all the Orthodox nations (Greeks, Bulgarians, Macedonians, Romanians, Serbs, Montenegrins), but also the Roman-Catholic Croats and the Muslim Bosniaks define themselves primarily by religion, the population of Albania is split into three confessions roughly in the proportion 70% Muslims, 20% Orthodox and 10% Roman Catholics, which makes religion not an appropriate identity marker. Communist Albania had declared itself even an atheist state and had suppressed religion even more than other Communist countries - not the least to overcome this internal division and to enforce national homogeneity. Post-Communist Albania was quick to restore freedom of religious confession and to re-establish all religious denominations into their religious and societal functions. All of them have indeed used this opportunity very well and substantially gained ground. They are appreciated by the population as institutions not having been involved into Communist policies and play important roles also in the social field and in education. And although the vast majority of Albanians are Muslims, the state has avoided any privileged relation to this denomination and is also on the international scene not acting as a Muslim country or cultivating more than expectable relations with other Muslim countries in the wider region (e.g. Turkey). It goes even as far as to style the Roman-Catholic nun Mother Theresa, an Albanian from Skopje in Macedonia, an icon of Albanian identity - stressing in this way the nation's multi-confessional identity. The Roman-Catholic church, the smallest of religious groups and regionally concentrated on the Shkodra region in the north of Albania, is also - supported by Rome - more than proportionally visible in the fields of social and educational activities. The paper will investigate into the current development of denominations in Albania, into their extra-religious activities and into their relation to nation and state.

Mapping neoliberal Bavarian identity. A contribution to applied critical geography.

Gregor Glötl (Universität Bamberg), Holger Lehmeier (Universität Bamberg)

In early 2011, a report about the future development of Germany's federal state Bavaria was discussed quite emotionally in the local media. The debated document was the result of the deliberations of an independent 'future council' ('Zukunftsrat') and should only have been a consultative resource for the federal state government. Its publication had not been intended, but due to an information leak and the following political pressure it was nonetheless released and discussed in the media. Despite the neoliberal ideology prevalent in the whole document, critical comments almost exclusively focused on a map which depicted a sharp distinction between well-performing centers and disconnected peripheral zones. In the course of discussion, local newspapers used modified versions of

the original map to illustrate the intentions of the council and/or the federal government. Without doubt, the report itself poses an interesting topic for political geographical research; for the debated map, which serves as essence of the document's message, this is even more the case. Following a critical cartography approach based on Harley (1989) and Glasze (2009), the study analyses the map's inherent statements as well as its interpretation and further use in the medial discourse. Furthermore, it deals with issues of political power and regional identity addressed in the map. Symbols, colors and descriptions show where the productive and non-productive parts of Bavaria are (or should be). To understand the messages hidden in the map, a cartographic interpretation inspired by Foucault's notion of discourse is applied. Not only the original map, but also the modified versions appearing in the media coverage are analyzed in this way. First results show that the discussion about the map quickly became independent from the original report. Due to the map's symbolic power, it became the representation for the whole report, notwithstanding the fact that it only referred to a very small part of its content. At the same time, the map's new versions step by step altered the original cartographic language by changing and omitting some elements or even adding completely new ones. References to the 'Bavarian' identity have received an especially great deal of attention. The distinction between the productive and well interconnected 'core regions' and the peripheral 'others', who should cooperate more closely with other centers outside Bavaria, was the main reason for the emotional discussion in the media. All in all, the study aims to contribute to post-structuralist political geography (Reuber 2011). By referring to regional development policies and the perception of rural areas, it addresses less commonly described - but nonetheless relevant - non-urban research questions of political geography.

Critical geopolitics of global management gurus

Sami Moisio (University of Oulu)

One of the challenges of critical geopolitics is to inquire into the highly economized spatiality of contemporary world politics. This paper explores the content and operation of particular knowledge which treats the world in economic terms and which is an integral part of constituting the rational action within polities. Particular strategic theorizing, thus, denotes an emergence of specific political conditions out of which certain political practices become rational and some others irrational. By reading management texts of some of the "global management gurus" against the concept of global governmentality, I first discuss the role of management authorities not only as public intellectuals who portray the spatiality of the world primarily in relation to the market rationality but also as geopolitical theorists. Secondly, I explicate the ways in which the contemporary condition is conceptualized as a particular spatial order in selected writings of Harvard Professor Michael Porter. In so doing, I shall contribute to the recent debate on the linkages between capital-driven globalization, new forms of state power and the ongoing crafting of subjectivity as it unfolds in neoliberal governmentality.

C08.30-05 - Conflicts and Revolutions in the Near and Middle East

Chair: Vladimir Kolosov

Changes in muslim world - The Egyptian Revolution

Dragos Frasineanu (Spiru Haret University), Mihaela Frasineanu (Spiru Haret University)

Without claiming completeness, this document attempts to explain recent events have included a Muslim majority area, spread over three major regions of the world: North Africa, Middle East and the Middle East. Analysis of the situation in Egypt, emblematic as we shall see, was chosen as a landmark interpretation of the complex geopolitical process currently taking place in this space. Propagating on the classical principle of domino effect, involving elements of classical and modern means of expression but the ongoing revolutions in Muslim states continue to capture the complexity. The state of turbulence in the company included a breathtaking speed accused for years of apathy among policy, manifested in the form of real earthquakes whose strength has led to the overthrow of autocratic regimes stronger. The causes and impact of this geopolitical region and beyond boundaries of this, the ramifications of the most diverse areas ranging and complex, and the implications can not be contained point.

Géostratégie de la conflictualité dans le Golfe arabo-Persique

Philippe Boulanger (Université de Cergy-Pontoise)

Le Golfe Arabo-Persique représente un centre névralgique de la sécurité internationale au Moyen-Orient. Pendant des millénaires, cette région a formé une aire d'échanges entre toutes les grandes civilisations qu'elles soient européenne, arabe, perse et asiatique. Cette vocation de « pont entre les civilisations » s'est modifiée sans disparaître à partir du XXe siècle. L'exploitation des richesses énergétiques et le développement économique après 1945, la diversité des régimes politiques mis en place, la présence de puissances militaires mondiales pour contrôler la plus importante voie maritime du pétrole, la permanence de tensions entre les Etats et la fréquence des guerres depuis 1980 témoignent de cette importance géostratégique qui s'est accrue encore au début du XXIe siècle. La conflictualité régionale, c'est-à-dire les formes d'opposition entre les Etats et les communautés, prend de nouvelles dimensions actuellement en fonction de la posture iranienne sur la question nucléaire, de la menace terroriste, des risques d'instabilité intérieure. La géostratégie du Golfe s'est donc complexifiée et chaque forme de conflictualité constitue un défi nouveau. Quelles sont les formes de conflictualité dans le Golfe - Pour y répondre, trois aspects sont abordés : les principales mutations géostratégiques du Golfe, les formes de rivalités majeures entre les Etats, les autres risques d'instabilité pouvant influencer l'équilibre régional.

'Contiguity' and 'Safe Passage': The Gaza - West Bank Disconnect in Israeli-Palestinian Conflict Resolution

Aharon Klieman (Tel-Aviv University)

Split polities and bifurcated states, territorially segmented and noncontiguous, pose a serious problem for peace making and for peace building. To the extent the Middle East peace process focuses on substance, diplomatic efforts aimed at a 'two-state' solution showcase the most contentious issues of borders, security, the right of return by Palestinian refugees, and the future status of Jerusalem. This paper redirects attention to the seemingly technical secondary agenda item of the relationship between the Gaza Strip and the West Bank since effective control over land and people goes to the very heart of Palestinian self-rule, Israeli-Palestinian coexistence and functional Middle Eastern regional integration. Dictated by human and physical circumstances, the arteries interlacing the area west of the Jordan River constitute the crucial 'integrative factor' in any blueprint for territorial compromise. Nevertheless, Israeli and Palestinian negotiators have been at an impasse since 1995 over the true intent of the 'contiguity' and 'safe passage' principles enshrined in the breakthrough 1993 Oslo accords. How to give these linkage clauses practical expression challenges cartographers, strategists and statesmen alike. Noting the West Bank and Gaza do not represent a natural territorial unit but are spatially partitioned by 32.1-56.2 kilometers of sovereign Israeli territory, the first section of this paper underscores the centrifugal effect of Gaza's remoteness from the West Bank seat of Palestinian authority, including the emergence of rival power centers and competing political elites. Bifurcation geographically, economically and politically into 'West Filastin' (Gaza) and 'East Filastin' (the West Bank) thus poses arguably the greatest challenge to Palestinian national unity and effective self-rule. The second section proceeds to outline legal, logistical and administrative barriers this Gaza Strip-West Bank disjuncture raises in bilateral Israeli-Palestinian negotiations, including the exact number of land and air corridors necessary for linking the two constituent parts of a future Palestinian state, their precise routes across Israel, as well as who is to exercise control. A concluding section cautions that an ungenerous or imposed territorial settlement premised on mutual separation could result in either extreme configuration: Israel interposing itself as a buffer between two divided Palestinian wings, versus a contiguous Palestinian state leaving Israel segmented. Juxtaposing stark scenarios of Israeli bifurcation or Palestinian bifurcation underscores which negotiating strategy -- zero-sum exclusivity or mutual compromise -- Israelis and Palestinians bring to bear on final borders and, daring to look beyond, on the nature of their inter-state relations.

Sitting of the Fence

Nurit Kliot (University of Haifa)

Israelis are sitting or standing on their fences at all levels and scales: home, community region and country and fences of all kinds in Israel are neither neutral nor indecisive. Four conceptual contexts (not mutually exclusive) are presented for the study of fences:

Territoriality which involves the exclusive control of tract of land by an individual and a group and is expressed by aggression, displays of which are necessary to defend the territory (keep in/keep out). Defence and Security. Fence is short for defense and it is a barrier intended to prevent escape or intrusion or to mark a boundary. This is the political function of borders and fences. Defence and Protection of Property: the first fences were erected to protect and symbolize private ownership of property. Cultural - Social function of fences: relates to segregation of populations - voluntary and involuntary. This paper explores the motivations (real, assumed, perceived) for the construction of defences around rural communities in Israel. Forty-eight Regional Councils which incorporate 1018 rural communities were surveyed in relation to their system of fences and other security components such as gates, shelters, watch duties, watch towers, patrol roads and search lights. It was found that 485 rural communities out of the 1018 were classified by the Government as entitled for a full defence envelope mainly because of their proximity to the international borders of Israel which are depicted hostile (Lebanon, Syria, Jordan, Egypt and the Palestinian Authority). Sixty two communities which are located in a close proximity to Israeli-Arab villages also got a full defence package. Finally, rear settlements which are not entitled to Government funded defences, use their own resources to fend for themselves against criminal activities and to pronounce themselves as gated communities.

C08.30-06 - Political Geographies of the European Union

Chair: Georg Glasze

Transnational Expertise: Political Geographies of Knowledge in Brussels

Merje Kuus (University of British Columbia)

At the heart of European integration is the production of knowledge about how European space works or ought to work. To comprehend the process, we must understand what knowledge claims, from where, succeed in Brussels and what claims do not and how and why this is so. The most recent governance crises in the European Union underscore that the political and social space of Brussels knowledge production is far from the positivist image of objective expertise that is projected by the EU's bureaucracy itself. Rather, there are distinct geographical and geopolitical dynamics at play, especially the newly resurgent East-West and North-South stereotypes. Such stereotypes are especially visible in relations with Russia, which continues to be the subject of intense geopolitical maneuvering in Brussels. This paper examines what transnational expertise might mean in the context of EU-Russia relations: who make knowledge claims, how, and with what effects, and how they use geographical and geopolitical tropes in that process. The empirical material is derived from over eighty in-depth interviews with EU policy professionals, mostly in Brussels. Empirically, the paper clarifies how geographical stereotypes are being rejuvenated, contested, and transformed in Brussels today: how concepts such as northern and southern, eastern and western, old and new, member states are actually used by the EU policy professionals who devise and implement EU's policies toward Russia. Conceptually, the analysis is situated within the scholarship of critical geopolitics, critical policy studies, and geographies of knowledge. It contributes to our understanding of geopolitical and policy processes in the bureaucratic settings in which they actually unfold on a daily basis. Keywords: geopolitics, transnationalism, policy, Europe

Europeanising Governance – blurring the nation state? The new tool “European Grouping of Territorial Cooperation”

Tobias Chilla (University of Erlangen), Estelle Evrard (University of Luxembourg)

In 2007, the European Commission invented and established for the first time its “own” juridical tool of governance for (sub-) national authorities, the so called “European Grouping of Territorial Cooperation” (EGTC). This tool officially aims to facilitate and to promote the “territorial cooperation” between public authorities on different political levels and on different sides of national borders. The paper at hand starts with a brief overview on how the already established ECTCs in different regions of Europe have developed. In particular, the sensitive question if and how competences can be delegated, is addressed. The main objective of the paper is to reflect on whose interest the new tool

actually can serve, beyond some technical facilitation: is there a by-pass of the national level? Can we observe a strengthening of the European institutions? Moreover, the potential establishment of a new political level is a crucial question: after some decades of an establishing trans-national political level, the trans-regional level might be a new form of European Integration. From a geographical point of view, it is interesting to note that this political process of establishing a new tool is linked to “territorial” cooperation: the fundamental category of territoriality has to be taken into account when reflecting on this link. The arguments of this paper are partly based on the involvement in several ESPON projects, notably ULYSSES and TERCO.

Frontiere et technologie

Amaël Cattaruzza (Ecoles de Saint-Cyr - Coëtquidan)

L'usage des nouvelles technologies dans le domaine de la surveillance et du contrôle des flux aux frontières se généralise de nos jours. Autrefois limitée aux frontières contestées, les nouvelles technologies (senseurs, drones, robots sentinelles, etc.) sont aujourd'hui utilisées sur des frontières « pacifiées » dans un but de filtrage des flux (migrants, marchandises, etc.). Cette « technologisation » prend trois formes principales : numérisation (systèmes de fichages et d'informatisation du renseignement), développement de dispositifs de surveillance (senseurs, drones, etc.), robotisation (robot-sentinelle, entre autres). Aussi, cette diffusion des nouvelles technologies aux frontières a amorcé une double processus : d'une part une virtualisation de la frontière (virtualisation du renseignement informatisé, virtualisation de la surveillance, etc.), d'autre part, l'apparition d'une architecture frontalière de plus en plus complexe passant de la frontière-ligne à la frontière-zone et « pixelisée ». Ainsi, la technologie aux frontières permet de renforcer la possibilité de surveillance et de contrôle en-deçà et au-delà de la frontière. Pour Stephen Graham, cette transformation de la frontière entraîne l'apparition d'une frontière omniprésente (« ubiquitous border »), l'espace territorial étant intégralement « frontiérisé », permettant une surveillance et un contrôle permanent de l'étranger (comme du citoyen). Philippe Bonditti met pour sa part en exergue le fait qu'« effacer la frontière » dans le cas de l'espace Schengen a pour contrepartie le « traçage des individus ». Le lieu de contrôle physique et territorialisé que représentait la frontière tend à se transformer en un contrôle mobile (ou omniprésent), au fur et à mesure que l'identification des individus se fait plus précise dans l'espace européen. Ce constat présage une mondialisation à plusieurs vitesses, avec des phénomènes de blocages aux frontières non plus territoriaux (politique des visas), mais sociaux (contrôles sélectifs individualisés). Cette communication propose d'aborder et de développer ces différents aspects pour voir en quoi les frontières ainsi « technologiques » peuvent, ou non, changer de nature.

Transborder openness of companies in divided cities at the Polish-German and Polish-Czech border

Sylvia Dozbasz (University of Wrocław)

The existence of national borders does not only mean formal-legal barriers, but also mental and economical barriers. Integration processes in the European Union create opportunities for the disappearance of internal borders and their separating impact. However, it seems that the effects of political barriers vanishing will occur with varying intensity not only at different national borders but also within particular borderlands. The pace and scope of integration processes will depend on local conditions e.g. local actors, physical barriers, infrastructural connections, differences in the level of economic development. Divided cities appear to be a good research subject for the integration processes at local level. It is connected with high intensity of social, economic and spatial phenomena and processes on both sides of the border and the opportunity to research the impact of the border on these processes, the border's existence in everyday life of the inhabitants (e.g. practical and really visible consequences of the border removal) and ample potential opportunities for integration. In order to assess the advancement of integration processes on a local scale, the divided city at the Polish-German border - Gubin/Guben, and at the Polish-Czech border - Cieszyn/ěeský Třín were chosen for analysis. The aim of this study was to research the permeability of Polish and its neighbours institutional space in a divided cities from the point of view of the everyday life of its inhabitants. The study covered the urban centres on both sides of the border. Economic entities providing chosen services for the people, such as: retailers, gastronomy, museums and selected offices were researched. The study aimed to show the level of openness of these institutions to clients from the other side of the border (e.g. offers in the language of the neighbour, possibilities of payment in the neighbour's currency, knowledge of the language). This allows, in turn, to determine the level of permeability of institutional space, its character, strength etc. The integration of institutional space is one of the first stages of integration of the divided city. This may lead to the formation of a common public space and strong functional connections. Comparison of Gubin/Guben and Cieszyn/ěeský Třín as regards transborder openness was also the aim of the study. Analysis has shown a significantly varying level of transborder openness of institutional space in examined divided cities. Moreover, differences in level of openness of companies depending on the type of activity were observed as well as an asymmetry in the scope of the influence of Polish, Czech and German institutional space. When comparing Gubin/Guben and Cieszyn/ěeský Třín, significant differences were observed, but there were also similarities found in character of transborder openness.

Critical and functional approaches in geopolitics: Geopolitical vision of the world and the space of flows

Vladimir Kolosov (Russian Academy of Sciences)

The paper is based on the findings of the EuroBroadMap international project funded by the 7th European Framework Programme and, in particular, on the survey of about 9,400 undergraduate students from 18 countries. The objective of the project was two-fold. On the one hand, to analyse how their vision of the world is shaped by the historical and economic background, gender, number of languages spoken and personal experience. On the other hand, to reveal the relation of representations about a country and its 'visibility' in the mind of the young people with the 'real' importance of that country in the world economy and politics, its place in the space of flows. It was estimated through an analysis of the geographical distribution of foreign trade and direct investments, the pattern of migrations, regular air flights and the voting at the UN General Assembly. The initial hypothesis supposed that the geopolitical vision of the world depended on physical and cultural distance between the countries. This task required a combination of the methods developed in the framework of the critical and the functional approaches in geopolitics. Therefore, the methods typical for critical geopolitics like surveys, discourse and texts' analysis, and mental mapping were used together with a diachronic analysis of world flows and patterns. In general, the results of the survey and of the discourse analysis confirmed the initial hypothesis: a higher spatial mobility and income, the knowledge of foreign languages, as well as a broader personal acquaintance with the outside world contribute to a more positive but at the same time realistic perception of foreign countries, to the shaping of a more complicate feelings of belonging. Though 44% of the respondents have never been abroad, new generations are much more mobile than their parents. Most often the geography of respondents' travels includes three types of regions: 1) neighboring countries; 2) traditional historical centers in Germany, Italy, France, Great Britain, Greece, Spain, Czech Republic and Austria, 3) other popular tourist destinations. The geography of students' travels determines their knowledge of the world. The people who have a broader personal experience of the world have a more complicated identity and are more prone to associate themselves with supra-national communities. In answering to the key questions about the most and the least attractive countries where the respondents liked or do not like to live, in all countries they mentioned particularly often major world powers, neighboring states, the principal tourist destinations and few other countries - 'news-makers' like Israel, Afghanistan or Iraq.

Gerrymandering in the Puszta

Zoltán Kovács (University of Szeged)

In Hungary when the collapse of the communist system became obvious the ruling party started 'roundtable discussions' with several opposition groups and organisations regarding the possibility of amending the Hungarian constitution and establishing a multi-party system. During these negotiations a compromise was reached and a new electoral law was passed by the Parliament with full consensus at the end of 1989. The post-communist Hungarian electoral system was modelled according to the German electoral system and comprised a mixture of a single-member electoral district and proportional representation using two rounds of balloting. The size of electoral districts was in harmony; their boundaries were set with consensus. Six free-elections were successfully held in the subsequent two decades according to the first post-communist electoral law. Even though the system of electoral districts became disproportionate over time due to demographic and migratory processes, no amendments were possible because for that the approval of at least two thirds of the MPs was needed. With the landslide victory of the conservative party in the 2010 Hungarian elections over two-thirds majority in the Parliament was achieved. With this political power a new electoral law was prepared by the ruling party provoking strong criticism on the side of opposition. This paper intends to point out the geographical bias of the new Hungarian electoral system. The main focus of investigation is the system of electoral districts. The new electoral law reduced the number of electoral districts from 176 to 106, consequently the map of electoral districts had to be completely redrawn. Using the results of the 2010 parliamentary elections we critically analyse how political advantages for the ruling party were created by the new division of electoral districts and what are the future prospects for malapportionment.

Historical roots of contemporary voting patterns in the Czech Republic

Tomas Kostecky (Institute of Sociology, Academy of Sciences)

To pursue the aim of the paper we conduct an analysis of voting patterns in selected parliamentary elections that were conducted on the territory of the contemporary Czech Republic between 1920 and 2010. In each election the observed parties will be classified into six different party families (social-democratic, free-market liberal, Christian-democratic/conservative, extreme-left authoritarian and extreme-right authoritarian, ethnic). Voting patterns of individual parties as well as spatial patterns of electoral support for party families will be analyzed. The electoral results from the elections to the lower chamber of parliament in pre-WWII elections (1920, 1925, 1929, 1935), in the semi-democratic elections taking place during the early post-WWII era (1946), and from all but one of the elections that took place in the post-communist era (1992, 1996, 1998, 2002, 2006, 2010) will be used as the data source. Municipalities and districts will serve as units of observation. The main aims are:

Semi-centennial Antarctic Governance: Lessons Learned from the Antarctic Treaty System

Andrii Fedchuk (National Antarctic Scientific Centre)

It is now widely acknowledged that the Antarctic Treaty signed on 1 December 1959 has become one of the most important milestones in solving the problems of international relations in the South Polar Region and the first well-developed institution to govern all kinds of human activities in the area south of latitude 60°S covering nearly 10% of the Earth's surface. This paper summarizes the results of activity of the Antarctic Treaty System and determines perspectives of its further development. In particular, it indicates the four main political precedents of the Antarctic international-legal regime. Firstly, the use of a whole continent exclusively for peaceful purposes. It is the first nuclear-free zone in the world. Secondly, it is a continuing and outstanding mechanism for resolution and prevention of international conflicts. Thirdly, it is an unprecedented international scientific collaboration. Finally, its well-developed environmental management based on ecosystem approach applied at continent-wide large scale. This study indicates the existence of an effective multilevel system of control for the political-economical decisions adopted within the Antarctic Treaty System by means of two major institutional principles: political-legal and organizational. The first one includes the Antarctic Treaty, relevant Conventions and Measures adopted by the Antarctic Treaty Consultative Meetings. For regulating the activities of the Antarctic community, the international governance bodies were established, which also serve as components of the Antarctic Treaty System. The current Antarctic legal regime is a dynamic system flexibly and timely responding to new regional issues such as demarcation of outer continental shelves, bioprospecting and regulation of tourist and non-governmental activity in the region. It is demonstrated that the absence of local authorities in Antarctica makes spatial management based on the principles of sustainable development a useful for a strategic approach, for regulating rapidly growing and diversified human activities in Antarctica, based on the principles of sustainable development. It is suggested that the basic provisions of the Antarctic legal regime might be contributed into international governance of another significant spaces beyond national jurisdictions, which all likely to become more contested in the future as environmental changes take effect and finite natural resources become scarce.

C08.31

Population Geography

C08.31-01 - Demographic divide 1: Coping with local challenges of population decline and ageing

Chair: Allan Findlay, Paul Gans

Coping with the consequences of demographic shrinkage and ageing: Strategies of decision-makers and households in rural inner peripheries in Germany

Annett Steinführer (Johann Heinrich von Thünen Institute), Patrick Küpper (Johann Heinrich von Thünen Institute), Alexandra Tautz (Johann Heinrich von Thünen Institute)

Demographic shrinkage and ageing to the east and west of the former Inner German Border are no new phenomena. Already in the 1970s 'dying' villages were predicted for the western parts of this region. Yet, these settlements exist still today. Once again, however, the whole region is subject to a demographic turnaround. The western parts which have been ageing and declining in their number of inhabitants since the 1970s experienced considerable migration influx immediately after the border was opened. Since the mid-1990s, however, migration balance is in most cases negative. Due to long-term negative natural population development, demographic shrinkage is accompanied by considerable ageing that brings some of the areas west to the former Inner German Border on the top of the ageing regions in whole Germany. In contrast, in the eastern parts out-migration used to be a continuous phenomenon after the fall of the Iron Curtain. Also here negative natural and migration balances lead to long-term population decline accompanied by ageing. Amounting to two or even more decades of demographic shrinkage, one can expect the existence of a number of established coping strategies on the side of both local and regional decision-makers and the population. Coping with and adapting to the consequences of the demographic (as well as the simultaneous economic and social) changes here is not a future question to be dealt with just theoretically but one of the present. Schools and surgeries were already closed down and transport connection thinned out, infrastructures are under-utilised and the number of vacant properties is increasing. Therefore, in a recent research project in the Harz Mountains, an inner periphery in Central Germany, we dealt with the questions of how decision-makers and the population cope with the negative impacts of the socio-demographic and economic decline of their regions and with the capacities they built these strategies on. The findings are based on semi-structured interviews with decision-makers and group discussions with senior residents. They indicate a wide range of such strategies applied but also their precarious dependence upon resources which are to be made available time and again. Coping and adaptation strategies of decision-makers and residents on all levels investigated (households, villages, small towns and regions) are therefore long-term endeavours which are themselves subject to continuous change. We distinguish defensive, reactive and pro-active types of strategies. In our paper we will

show under which conditions and with which rationales these strategies are applied and how they contribute to a further internal differentiation of the region investigated and, possibly, its socio-demographic future.

Demographic decline and changing local governance in the rural areas of Japan

Satoshi Nakagawa (Kobe University)

This paper concerns demographic divide at national/provincial level and focuses on changing local governance affected by population decline and population aging. Low fertility and smaller number of reproductive-age population compared with preceding cohorts lead population decline and rapid population aging after 2000 in Japan. According to the official population projection based on the 2005 census, Tokyo Metropolitan Area continues to raise its proportion of population to the whole country in the next decades, however rural areas will lose 20-25 % of its population till 2035. Several hundreds of settlements are estimated to become uninhabited in the next decades. There is an apparent demographic divide even within Japan. We investigate rural/urban population dynamics of Hyogo province. Hyogo province is neighboring to Osaka, second largest metropolitan area of Japan, and Kobe city, the capital city of the province and located southernmost of the province, has 1.4 million inhabitants. Hyogo province has 5.6 mil. inhabitants in 2005 and the population is estimated to decline to 4.8 mil. in 2035. The population of the Kobe Metropolitan Area is almost stable till 2035, however several rural municipalities located central and northern part of the province will decrease more than one-thirds of their population in the same period. We have visited two rural municipalities of the Hyogo province intensively since 2006 and discussed with the residents how to improve local governance and attract young native residents to stay in a settlement or to return to the settlement after finishing higher education or after marriage in the urban areas. We conducted questionnaire surveys there, as well. Many young people born in the rural areas think even nowadays that they have to take care of their parents and the farmland inherited from the ancestry, even if the farmland yields only debt. And, the number of siblings is around two in the last decades even in the rural areas, and parents expect their limited number of children to live in the settlement and to succeed the farm. Nevertheless, it becomes more and more difficult to live only on the agriculture there and there are not enough non-agriculture job opportunities, in particular for those with higher educational attainment. The conservative atmosphere of rural settlements is unattractive for the younger generation. As a result, they tend to leave the settlements away and rural settlements continue to lose its population. Population projection of the rural area of Hyogo province on the settlement level is presented as well. We also draw the future settlement system of the region, which influences local people's purchasing behaviors and public services such as medical/welfare services. We show the results of the population projection and future changes in settlement system to the residents and discuss what we do now.

The Role of Urban Planning in Germany within the Context of Demographic Aging

Stella Altenburg (TU Dresden)

The proposed paper addresses the question 'Which strategies for coping with demographic decline are most appropriate at the urban level?' The main focus is put on the role of planning in cities and how they deal with the challenge of demographic aging - the most distinctive aspect of demographic change in Germany. The repercussions of aging within the wide spectrum of urban planning are already discernable and will be a considerable undertaking for cities now and in the future. Different fields of actions are affected by the increasing number of people aged 65 plus and 80plus who require specific services, products or help. These fields include: social and technical infrastructure, mobility, housing, civic engagement, economy, labor market etc. To deal with the impacts of aging on these topic (e.g. changing patterns of demand) it is necessary to get a full understanding of the organization and actors within the field of urban planning. Accordingly, the proposed paper is dealing with the role of urban planning, using case studies of two cities in Germany which are both affected by aging in their own way: first, Bielefeld (North Rhine-Westphalia) which has chosen to let a so called 'Demography Commissioner' work for the city to put the topic on the political agenda and second, Baden-Baden (Baden-Württemberg) which has been heavily affected by the process of aging in the last decades while remaining a prosperous city with a wide spectrum of touristic attractions. The presentation discusses the following research questions: (1): How are cities affected by aging? (2): How is the topic 'demographic aging' integrated into the scope of city planning duties? (3): How is the field of actors shaped? (4): Is it possible to distinguish different approaches to the topic of demographic aging in urban development? A general overview of the spatial relevance of demographic aging (including duties and responsibilities) precedes the results of the case study as the main part of the presentation. Using them, multiple ways to approach the topic of aging can be revealed and distinguished. It can be shown that there has not been an exclusive focus on the constituent 'aging' within the context of demographic change so far. Considering the fact that both an aging population and urban planning are processes - not sudden events - discussions on demography should not be one-dimensional. Due to the diversity it is more decisive to develop overarching objectives and implementation measures. Hence, the selected cities show different approaches and strategies to the challenges of demographic aging. According to their individual and specific demographic conditions, city history and development they both implemented ways of actions which suit best for their cities and the respective challenges. The proposed presentation eventually leads to general conclusions and recommendations for practice and further research.

The changing education infrastructure in shrinking regions

Walter Bartl (Universität Halle-Wittenberg)

Demographic change and economisation are among the central challenges of the welfare state. The proposed paper assumes that demographic change might enforce a further economisation of welfare services. It investigates demographically triggered mechanisms of economisation focussing on a comparison of education sectors in demographically shrinking regions. Institutions and infrastructures of the welfare state are geared towards certain volumes of (sub) populations. Due to education expansion participation rates are relatively high in the different education sectors of modern society. Hence declining population numbers might lead to less demand for education services. Therefore it is hypothesised that demographic decline creates a pressure to economise oversized education infrastructures. The analysis concentrates on a comparative study of education sectors in the East German state with the most pronounced fertility decline and outmigration. The analysis of the education system is based on secondary statistical analysis (state and county level) and expert interviews. Selective comparisons with other regions are applied complementarily. First results show that the economic pressure on education sectors created through smaller age groups is highly dependent on participation rates. In elementary education, where participation rates are traditionally high in East Germany, the number of organisations was reduced almost proportionally to the decline of the number of children up to six years. Nevertheless the economic pressure also stimulated the creation of multifunctional organisations providing care not only to one but to several age groups. The expansion of child care service units to after-school care was enhanced through the political decision of transferring this task during the transformation process from primary schools to child care organisations. Obligatory school attendance similarly makes general schools vulnerable to demographic decline. Economising effects of population decline are less obvious in tertiary education. Due to low participation rates and recently through education migration this education sector was able to further expand its size concerning numbers of students. Furthermore disciplinary differentiation was enhanced. The results can mostly be interpreted as supporting the proposed relationship between demographic decline and the economisation of welfare services. This relationship seems to be based on administrative planning and evaluation techniques within the public sector (e.g. in-kind calculations like "headcounts") fostered during the last years of NPM discourse. But they also show that not all fields are affected equally by the economising pressure of demographic decline and that other conditions (e.g. political programmes) have to be considered as well.

C08.31-02 - Demographic divide 2: Migration and population change on regional level

Chair: Prof Allan Findlay, Paul Gans

Spatial patterns of demographic shrinkage in post-soviet state (Lithuanian case)

Dovil Krupickait (Vilnius University)

Shrinkage of total population in 17% in 22 years (or in 12.3% in 10 years), net migration decrease -13.5%, natural decrease -3.5%: no war, no natural disasters, no urbanization or industrialization, but in some municipalities of Lithuania population decrease reached 20% in 10 years. Which spatial patterns did they have? What are the main spatial factors of the changes? According to analyse of long time tendencies of spatial population processes in Lithuania, we points out different patterns of devastating depopulation, depending of local demographical structure, post soviet transformations of urban structures and globalization.

'Go West, Young Man'!? The spatial structure of inter-regional migration in Germany and it's impact on regional population growth and age structure, 1995-2009.

Nikola Sander (Wittgenstein Centre)

Germany is currently undergoing a demographic revolution that is fundamentally transforming the country's population age structure. The pace of population ageing is set to rapidly accelerate when the oldest members of the baby boomer generation pass the traditional retirement age of 65 in 2020. As the number and proportion of elderly Germans increases, the processes underlying continuity and change in the spatial structure of internal migration become a fundamental issue. This is because internal migration is the most volatile component of population change and has thus become more important than fertility and mortality in shaping regional population growth and age structure. Migration among the elderly and out-migration of younger adults has far-reaching implications for economic development and for planning strategies to ensure adequate health, housing and welfare in the right place at the right time. However, little research has been conducted in Germany to identify past and potential shifts in spatial patterns. Existing work on internal migration is largely descriptive, mostly focusing on net-migration, or exclusively on migration streams between eastern and western states. This paper aims to provide a comprehensive profile of internal migration between Germany's regions. Central goals are to identify enduring empirical regularities and changes in the spatial structure of internal migration, to estimate the spatial interaction between regions and to determine the impact of internal migration on regional populations. Moving beyond

state-level analyses, migration flows by age and sex between 96 'Raumordnungsregionen' are analysed along the four dimensions intensity, connectivity, impact and distance (see Bell et al., 2002) to obtain a comprehensive picture of the spatial structure of international migration flows over the period 1995 - 2009. In addition, intensities and distance-decay of age- and sex-specific flows between 295 'Kreisen' are analysed to shed light on migration patterns within 'Raumordnungsregionen', and to take into account commuting patterns and labour mobility. The results are visualized using a novel mapping technique. The analysis reveals systematic spatio-temporal variation in the intensity and connectivity of migration, and in the impact of migration on regional population growth and age structure. It is demonstrated that analyses of migration at the level of the sixteen federal states fall short of providing a sound understanding of the spatial structure of internal migration, including patterns and intensities of east-west migration.

A Study on the Rules of Rural-urban Migration during China's economic transitional period

Guoxia Wang (Shanxi University)

Since China's Reform and Opening-up there have been great changes and some rules are demonstrated in the rural-urban migration in China in the aspects of migration demographic characteristics, migration approach, spatial pattern and so on. Chinese scholars have been paying more attention to case studies of migration due to more availability to migration data since 1980's and making considerable accomplishments, but little progress has been made on migration theories. By doing a tentative work, the author concludes three migration laws by extending and integrating the present research results. 1.The migration motivation and the spatial pattern of migration follow the Economy-incentive Rule. The economic factor acts as the main driving factor of rural-urban labor force migration. The migration destination is adjacent to the migration departure. The spatial pattern of inter-provincial migration demonstrates a polarization trend. 2.The demographical features and the migration behavior demonstrate the Human Capital Differentiation Rule. Most migrants are elites in rural areas. The migration distance varies according to the migration's population: first an inverse increase and then an accelerative increase. Migrants with high human capital value tend to migrate to the urban areas with their family members. The new generations of urban migrant workers more desire to integrate into the city than their peasants. 3.The migration patterns and the employment selection follow the Social Relationship Rule. The chain migration is the most common migration pattern and their access to employment information still relies upon their social networks. In the future, a large-scale rural-urban migration will continue with the economic incentive still being one of the important factors affecting the population migration. Since urban areas centering metropolitans will continue to promote China's economic development and play an significant role in the process of urbanization, the places such as the cities in eastern China and the large and medium cities will

continue to be ideal destinations for migration workers. But with the implementation of China's policies on regional balanced development and other related efforts, the trend of large-scale inter-regional migration will be on decline and rural labor force will move to central and western regions or smaller cities (towns). Although the new generation of farmers have a strong will to live in cities, China's present institutional arrangement can not realize their dream at once so the migrant workers will continue to move between urban and rural areas. But the population who choose to live in the cities is predicted to rise. Key words: rural-urban migration, migration rules, China

Rural-to-Urban Migration in Turkey During the Past Thirty-Five Years: 1965-2000

Ayşe Gedik (Middle East Technical University)

This study analyzes rural-to-urban out-migration during thirty-five years between 1965-2000 in the five five-year periods of 1965-1970, 1975-1980, 1980-1985, 1985-1990, and 1995-2000. Rural-to-urban out-migration is studied in terms of village-to-province center out-migration. The data is from the Population Censuses which are 100% sample, and the migration data are based on the de jure population. Various measures such as the size and the distribution of the village population, out-migration rates, percentage of intra-province migration, and the significance of the three largest metropolises are analyzed. The analyses are mainly descriptive. Some of the significant findings are as follows. Although after 1980, the village population decreased, and the number and rates of out-migrants displayed a V-shape with a dip in 1975-80 period. Percentage of intra-province out-migration decreased consistently. The distribution of the above stated measures of out-migration became more homogeneous, i.e. the respective entropy levels increased. Spatially, however, the differences between regions increased--especially between southeastern region (where fertility rates are 3-4 folds of the average for Turkey) and the rest of Turkey. The effects of the immense interregional differences in the fertility rates and the resultant differences in the pool of potential out-migrants, and the consequent possible significant future changes in the directions of the village out-migration patterns and the serious future problems are discussed.

C08.31-03 - Demographic divide 3: Population decline in post-socialist countries

Chair: Prof Allan Findlay, Paul Gans

Population changes in postindustrial areas in Poland

Slawomir Kurek (University of Cracow), Tomasz Rachwa' (University of Cracow)

Demographic trends in postindustrial areas can show a considerable differences depending on the level of their current economic development. In Poland and other Central-Eastern European countries, after the collapse of central planned economy and implementation of market economy, a rapid changes in migrations and fertility rates were observed. A consequence of these changes was acceleration of population ageing, which is one of the most distinctive demographic issues in modern society. There are, however, significant differences in the intensity of the population processes between countries and even more between regions. Population ageing leading to depopulation is particularly strong in old industrial areas with decreasing employment resulting in declining in-migration and fertility. Acceleration of ageing has been particularly observed in regions of countries which underwent the process of economic transition to market economy with declining heavy industry and restructuring old industrial areas. Most of those industrial districts underwent the process of restructuring with the development of services, closing down ineffective plants and reindustrialization. The changes resulted in profound increase in unemployment and re-orientation of migration processes. In some of them special economic zones were created to attract foreign investors in order to reduce regional economic disparities. However, the process of re-conversion of traditional industrial centers into modern technology clusters was mostly successful in the vicinity of largest cities with appropriate infrastructure. In some industrial centers with mono-functional type of economy and lack of qualified staff, a process of economic marginalization and negative demographic trends has taken place leading to increased economic disparities and social exclusion. This demographic divide between rapidly developing metropolitan centers and declining old industrial areas poses challenge to policy-makers how to level out existing socio-economic differences. The aim of the paper is to show population growth or decline, including the magnitude of migration and changes in fertility in postindustrial areas in Poland, according to a division into industrial areas from 1988 (before the transition). Changes in population age composition as a result of above mentioned population changes were also taken into account. The data comes from Central Statistical Office of Poland from 1988 and 2010. An attempt was taken to answer the questions how degraded and restructured postindustrial areas have an impact on population development in a local scale in the conditions of European integrations on the example of a country under economic transition.

Demographic and social challenges in the rural areas of Romania

Liliana Guran-Nica (Spiru Haret University), Mihaela Persu (Romanian Academy), Daniela Mihaela Nancu (Romanian Academy)

Much of Romania is basically country-side, a significant proportion of population and of socio-economic life being profoundly rural, compared to other countries in which villages are not that numerous. The current demographic situation in Romania is unprecedented, e.g. lower birth-rates, a negative migration balance, intense labour migration abroad, higher life expectancy and hence a more numerous elderly population. This situation is supposed to continue and even worsen in the future, with detrimental consequences for society as a whole, given that the state-run social security system and other types of benefits will be subjected to greater pressure. The decline of the rural began under communism (in the 1980s) when the industrialisation drive used to attract large numbers of villagers to town. The restructuring process and the Land Law 18/1991 made the industrial population return to the native country-side. However, there are still many settlements that have been losing their population through aging and inevitably a higher mortality rate, and moreover the long-term migration abroad of the active and experienced labour force, in particular. In this way, the respective communities are being faced with acute social and economic problems. The aim of this paper has been to analyse the difficulties experienced by rural communities and the measures taken by the Romanian state and by the local authorities in order to revitalise the rural space.

Population ageing – recent Demographic characteristics in Bosnia & Herzegovina

Alma Pobric (Faculty of Science), Nusret Dreskovic (University of Sarajevo), Nusret Dreskovic (University of Sarajevo)

At the turn of the 21st century population ageing has become dominant demographic process of many European countries as well as of Bosnia and Herzegovina. Bosnia and Herzegovina is the transitional country which is facing rapidity of ageing and its demographic situation is mostly similar to western style developed countries. One of the main drivers of population ageing is transition from high fertility to the low fertility which country recently experience. Bosnia and Herzegovina became society which is characterised by a decline in the proportion of younger people and increase of oldery as the result of decline in total fertility rate more than decline in mortality rates; this ageing is known as 'ageing at the bottom of the age pyramid'. The demographic trends is characterized not only by lower fertility but by emigration of working-age population and reproductive-age adults as well. The analysis are based on statistical data from the last two population censuses and estimates for the recent period. Recent demographic trends not only reflect contemporary socio-economic adjustments, but also past demographic characteristics, war and political events. Keywords: Population ageing,

Bosnia-Herzegovina, transitional country, fertility decline, increase number of older population

Below-replacement Fertility in European Post-Socialist Countries – the Example of Croatia

Vera Graovac Matassi (University of Zadar)

At the beginning of 1990s, significant political changes occurred in European socialist countries, which resulted in new social and economic relations and in a remarkable demographic transformation. This transformation has been remarkable in its speed and scope and today most of European post-socialist countries are similar to Western European countries in view of fertility and marriage patterns, age at first marriage and child birth, population aging, etc. Croatia, as a post-socialist country, has experienced significant economic and demographic changes since its independence. However, the roots of negative demographic processes in Croatia date back to late 1960s. In the last twenty years, the most prominent demographic processes in Croatia have been depopulation and population aging. Additionally, since 1991 Croatia has had constant natural decrease whose consequences are visible in both economic and demographic aspects. For the last forty years, Croatia has been characterized by persistent below-replacement fertility levels. Namely, since the beginning of 1970s, TFR in Croatia has been below the level of replacement (in 1961 TFR was 2.15 and in 1971 it was 1.96). In the following decades the situation worsened significantly and since 2001 the TFR has been between 1.33 and 1.50 children per woman. Due to population decline and other negative demographic changes, coupled with specific socio-political changes, Croatia has been faced with many difficulties which are particularly evident at regional and sub-regional levels. In attempt to respond to natural population decline the Government introduced a new population policy in 2006, but its realization and effects are still questionable. The aim of this paper is to investigate the causes and effects of long-term below-replacement fertility in Croatia, the changes in age and marital status of child-bearing women, and compare fertility changes in Croatia with other European post-socialist countries. The secondary aim is to analyze demographic changes at regional level within Croatia and identify the differences between rural and urban areas. It is also necessary to investigate the influence of fertility and population declines, which have been more prominent in rural areas, on education, economy and infrastructure.

C08.31-04 - Demographic divide 4: Differences in fertility and mortality

Chair: Allan Findlay, Paul Gans

Global Population Trends – Convergence and Divergence

Frank Swiaczny (Federal Institute for Population Research)

In 2011 the world population hit the threshold of 7 Billion people and according to the latest population projections of the United Nations Population Division the population will continue to grow in the foreseeable future. Especially in the least developed countries fertility and related growth rates are still high and a population growth of another Billion within the next 14 years is most likely. At the same time more and more countries face ageing populations as a result of past declines in fertility and a growing life expectancy. According to the UN data global population trends are characterised by a general convergence of demographic indicators as more and more countries are moving forward in the process of the demographic transition. The United Nations Population Division has recently issued time a population projection covering the period up to 2100 for the first which is also based on a new method to derive the assumptions underlying the projection. The recent projection applies a probabilistic Bayesian Hierarchical Model to derive individual trajectories of fertility change for each country and probabilistic population projections are released as well. With the new method's use of past trends of fertility decline of individual countries the respective probabilistic projections produce more divergence among country's demographic patterns compared to previous projections. The presentation will provide an overview of global convergence and divergence of demographic processes based on the latest UN World Population Prospects and try to question consequences for the interpretation of the demographic transition of developing countries in the light of the newly available data.

Changes of fertility patterns in Poland and UK

Slawomir Kurek (University of Cracow), Nigel Walford (Kingston University)

The decline of fertility below the replacement level is one of the indicators of the second demographic transition. The onset of the second demographic transition in Europe covered Western Europe in 1960s and diffused subsequently to other parts of the continent. In Eastern Europe a fall in total fertility rates below the value of 2.1 was recorded at the beginning of 1990s and was associated by some scholars to the collapse of the communist system and introducing market economy. At present countries of Eastern Europe show the lowest values of TFR (at 1.3-1.4) while in the west a fertility recovery is observed. Regional disparities in fertility within particular countries also exist resulting from different timing in the spread of value orientations associated with SDT, especially between urban, suburban and rural areas. The aim of this paper is a

comparative study of changes in fertility patterns between Poland and UK in spatial layout at the beginning of 21st century. Despite apparent differences at the national level, this research seeks to find similarities in the spread of second demographic transition from core to peripheral areas taking into account its diffusive character as well as to show what are the possibilities to reduce demographic divide between western and eastern Europe on the example of these two countries. The data were taken from national statistical offices.

Comparison of urbanization's influence for demographic behavior in South and North Korea after 1950

Pavel Em (Russian Academy of Sciences)

Korean War divided ethnically identical nation to two countries in 1953. The main goal is to compare influence of urbanization to demographical behavior in two Koreas. For this research we used statistical materials of North Korea Central Yearbooks, Official Report of population census of 2008, Korea Statistical Yearbooks and South Korea's Statistical Information Service (KOSIS). Urban policy made main influence for development of demographical behavior. Northern part blocked excessive development of urbanization. Cities were closed for those who were born in rural locality. In contrast, cities in Southern part became magnets for a huge number of chip workforces. Urban policy began only on 1990 with partial decentralization of some industries. Comparison of urbanization showed that in the North urbanization increased twice from 1950 to 2010, and almost for four times in the South! Lifestyle in the South is absolutely changed. In the North idea of Juche is still dominated and deviations are abruptly punishable. From 1950 to 2010 main demographic indexes decreased, but in the South much more than in the North. Crude birth and death indexes decreased in the South accordingly at 3.3 and 1.6 times while only 1.6 and 1.2 in the North. At that, natural increase rate is still satisfied for normal reproduction in the North and do not in the South. Active building of careers and women's involving for economy were main reasons for increasing for age of marriage. In the South it is bigger for about 5 years than in the North. So, both Korean societies characterized by modern type of reproduction with stable decreasing of fertility rate (from 2.7 to 2.2 in the North and from 4.5 to 1.2 in the South). Herewith, stably increased number and rate of divorced, especially in the South. Better medical care rapidly decreased rate of infant mortality in the South and weakened it in the North. Boys always dominate in natural sex ratio. In Orient it is compounded with marked preference for boys. Remarkable changing in age-sex pyramid is increased rate of old people with parallel decreasing of children and employable people's rate. So, population in the South is getting older faster than in the North. Population in the North is almost identical regardless from type of settlement. At the same time differentiation of main indexes in rural and urban settlements in the South might be impressive. Regional differentiation of the demographic indexes is in the direct ratio from level of urban rate. These changes showed that Korean societies are on the first steps of demographic transition.

Socio-Spatial Patterns of Population Growth and Associated Demographic Character in India

Bimal K Kar (Gauhati University), Madhushree Das (Gauhati University)

With 1.21 billion people (Census of India, 2011) the world's second most populous country India, which constitutes 2.4 per cent and 17.3 per cent of the world's land area and population respectively, has still been passing through a critical demographic phase. Although the annual growth rate of population in the country has witnessed a slight decline during the last two decades, it has still been as high as 1.65 per cent during 2001-11 as against world's 1.5 per cent, and it varies from 1.19 per cent in the country's southern zone to 1.83 per cent in the northern zone. Moreover, in respect of inter-religion variation in population growth rate, it has been as high as 3.12 per cent among the Muslims and 1.87 per cent among the Hindus during 1991-2001. Such a high population growth in the country is associated with the prevalence of considerably high birth rate and immigration particularly in the northern and eastern parts of the country. This is reflected in the significant increase of population share in the northern zone from 32.86 per cent to 36.46 per cent during 1971-2011 with consequent decline from 24.80 per cent to 20.90 per cent in the southern zone. What is more important here is that such a spatio-socially varied population growth rate with varying base population size in each zone/state witnesses significantly varied demographic character with far reaching future consequences. Moreover, if this trend continues, it is not very far for India to cross even the most populous country China. With this background an attempt is made in this paper to analyse the pattern of population growth and its associated demographic implications including changing pattern of population composition in India mainly during 1971-2011 primarily based on secondary data obtained from different Census of India volumes, UNDP's Human Development Report and Population Reference Bureau.

C08.31-05 - Population geography in a post-census world 1

Chair: Allan Findlay, Etienne Piguet

For better or for worse: The new population census in Switzerland

Alexandra Stam (FORS)

During the 2010 Census round, almost half of the European countries applied alternative census approaches, attesting to an increasing trend of moving away from traditional data collection methods. The alternative approaches are mostly based on register data, either exclusively or in combination with other data sources. In Switzerland, the new Federal population census results from the combination of four surveys. While the register survey provides information on the entire resident population as drawn from various registers, it is completed with a structural survey (an annual written survey of 200,000 people); thematic surveys (telephone sample surveys of 10,000 to 40,000 persons); and the Omnibus, a telephone sample survey of 3,000 persons on current issues. Changes occasioned by the move towards register and survey based censuses is of particular interest to FORS, the Swiss Centre of Expertise in the Social Sciences. FORS is actively involved in methodological research on data quality, including issues of survey non-response and minority representation. In addition, it closely collaborates with the Swiss Federal Statistical Office (SFSO) and serves as an intermediary between the SFSO and the research community in Switzerland. Rather than discussing empirical results - 2010 data have only been recently and partially released - the presentation will provide an overview of what is delivered to researchers and how this contrasts with the traditional approach. Based on discussions with key representatives of the SFSO, but also with some methodologists and users of census data, it will aim to share and trigger reflections on the consequences of such a move in terms of geographical representation, analytical content, data access, and data quality. Such reflections should contribute to framing researchers' needs and outlining strategies as to how improve data quality.

Exploiting administrative data in the UK as an alternative to the census

Gillian Harper (MHA and Cass Business School), Leslie Mayhew (Cass Business School)

This paper takes the view that in the UK, not only is a 'post-Census' world possible, but also desirable and inevitable. This is based on our experience of developing and providing a methodology that counts populations entirely from local administrative datasets, bypassing any dependence on official statistics from the Census entirely. It discusses the datasets that feed into the process, the techniques that are required to link data in the absence of consistent personal identifiers in the UK, and how the different sources are combined into one population database. The methodology was devised over a period of

years in response to numerous local government and health authority concerns about potential population undercounting, the infrequency and high cost of the Census, two-year delays in the dissemination of results, and the inflexibility of Census outputs once they become available. In July 2010, the British government announced their intention to scrap the Census in its existing format, deeming it as 'an expensive and inaccurate way of measuring the number of people in Britain'. In December 2011, one of the authors appeared before the Government Science and Technology Committee to provide evidence on alternatives to the Census for use in research. In this paper we will give an overview of our methodology, focusing on the advantages it offers, highlighting the wealth of socio-economic variables available based on administrative sources at a person and household level, including ethnicity. In terms of consequences, although we firmly take a positive view of administrative alternatives, we acknowledge that it depends on users and their perspectives and that this methodology benefits local analysts and planners in particular; however, it also depends on the quality of data sources and continued access to them. We further show that administrative based population counts, although able to provide more detailed and comprehensive data, are not complete substitutes for a Census. A final section will consider the gains and losses of information that might result and how and whether these could be reconciled by exploring what other forms a post-Census world in the UK may take, including a hybrid of administrative data and surveys.

The move to register-based census: Pro's and con's for migration statistics

Anne Herm (Université de Louvain / Tallinn University), Luule Sakkeus (Tallinn University), Allan Puur (Tallinn University), Michel Poulain (Université de Louvain / Tallinn University)

Obtaining reliable migration data may be challenging when moving from traditional population censuses to register-based censuses. Traditional censuses face increasing difficulties to collect complete and high quality data due to increasing cost, limitation in questions, higher mobility of person making contact difficult, and increasing proportion of no answer. The move from traditional to register-based census is unavoidable in Europe and 2021 round censuses will probably be register-based. Nearly half of European countries already used in 2011 census register data in various ways from a fully register-based census combining data from numerous administrative registers to register-assisted enumeration replacing door-to-door enumeration in traditional censuses. The register-based census has advantages and limitations. The main advantages are lower cost and easier operational conditions while it can be reproduced more often than traditional census. Our research in EU countries confirm that register-based data have less coverage problems than traditional censuses and surveys and provide equally reliable data except in countries where the centralised population system is still not fully operational. Register data may give even more detailed geographical disaggregation compared to traditional census. The limitations of administrative registers come from the applied administrative rules as variables and their definition are fixed by legislation and do

not necessarily fit with international census recommendations. Concerning migration statistics the traditional census has never been a rich data source for producing data on migration flows except for internal migrants by using information on the place of previous residence while international emigrants are by definition not enumerated. On another side, censuses are appropriate to characterize the population with foreign or migration background by considering variables such as country of birth, country of citizenship, country of previous residence and year of immigration and socio-economic characteristics. Concretely the register-based census could be more favourable for migration statistics as migration flows are continuously registered in population register except for emigrating nationals that often do not report their departure. In addition, the population register as well as other registers (like aliens register, social security register, education register, etc?) include on a continuous and exhaustive base most needed socio-demographic characteristics of the population with foreign background, as well as a unique personal identification code allowing linked data from several registers. We will present concrete experiences of countries in improving the availability of data on population groups with migration background by exploring the possibilities and potentiality of population registers data in the framework of the implementation of a register based census.

Understanding and Validating Acxiom's Research Opinion Poll Data for Social Science Research in Post-census Britain

Chris Thompson (University of Leeds), John Stillwell (University of Leeds), Paul Norman (University of Leeds), Martin Clarke (University of Leeds), Martin Clarke (University of Leeds)

Historically, the decadal population censuses have produced the base for many of the population and socio-demographic statistics across the United Kingdom (UK), providing comparable information from the national to the local level on a range of topics, and acting as a benchmark for many other statistics. However, the 2011 Census may well be the last to be administered across the UK if Cabinet Office Minister Francis Maude and the Conservative/Liberal Coalition Government decide to scrap any future censuses in favour of alternative means of counting the population. Therefore, in April 2011, the Office for National Statistics (ONS) established the 'Beyond 2011' Programme to consider how to provide more cost-effective and frequent population statistics than a 2021 Census. As well as exploring a wide range of administrative and survey sources of demographic data, the ONS as part of 'Beyond 2011' is also investigating the potential of commercial data sets; simultaneously, social science researchers are beginning to investigate whether transactional data provide credible insights into societal behaviour. Consequently, this paper provides an independent review of a large commercial data set available annually from a company called Acxiom. Acxiom's Research Opinion Poll (ROP) is a private sector sample survey designed to capture detailed information about households across Great Britain (GB). To ensure an inclusive discussion, we combine a number of the questions

set in the literature for analysing secondary data sources with the criteria for assessing the statistical options of data from the 'Beyond 2011' Programme. This allows us to create a framework to validate the data recorded via the ROP on a number of factors such as the purpose of collection, the methodology, the frequency of collection, the geography, its content, accuracy, and its credibility. Furthermore, the paper also offers a comparative analysis against well-known datasets including the 2001 Census, the Living Costs and Food Survey (LCF), the Labour Force Survey (LFS), Understanding Society (US), the General Lifestyle Survey (GLF) and the English Housing survey (EHS). The paper reveals that the ROP survey generates over one million household responses a year, available for analysis at household address level. Additionally, when compared to other surveys, the ROP offers a good selection of core variables typically used in social science research, whilst also providing data that comparable surveys do not (income). The paper demonstrates through a combination of univariate comparisons, bivariate analysis and logistic regression modelling that the ROP data are reliable, robust and repeatable over time. To close, a summary of the main findings from the paper are given as criticisms and recommendations are provided on the suitability of Acxiom's ROP data for use within social science research.

C08.31-06 - Population geography in a post-census world 2

Chair: Allan Findlay, Etienne Piguet

Calling Time on the Census? Using surnames and telecoms for population geography

James Cheshire (UCL Centre for Advanced Spatial Analysis), Jonathan Reades (UCL Centre for Advanced Spatial Analysis), Paul Longley (University College London)

Rising rates of international migration have made the monitoring of increasingly complex population flows through traditional sources of fine-scale demographic data increasingly problematic. Combined with the spiralling costs of data collection by house-to-house visits and mass mailings - to say nothing of the processing costs - there is serious discussion as to whether the 2011 Census should be the last 'traditional' one undertaken in Britain. So as we move 'Beyond 2011', the search is on for proxy or replacement datasets capable of replicating some of the richness of data offered by a traditional long Census form, but at a fraction of the cost. The impetus for radical change comes at a time when a widespread shift to digitally-enabled transactions and interactions across a range of platforms has made it possible to conceive of data that might deliver similar coverage while offering far lower latencies in collection and reporting. It is in this context that we need to understand the interest in repurposing public or private sector datasets and analysing them using powerful public computing infrastructures. Such developments present an important opportunity to work towards a census solution that is both more cost effective and offers a higher temporal resolution without compromising detail. However, for data from the public (such as electoral rolls, medical registers, employment databases) and private (such as telecommunications records, storecard and credit card databases) sectors to be used in this way, urgent efforts are needed to combine and validate them. Accordingly, in this paper we will examine two 'big data' sources previously considered separately: surnames taken from the electoral roll, and international calling activity collected from a telecommunications network. We then propose to compare the results derived from these datasets with Britain's Census outputs to look for structural correspondences between, or biases in, one or more of the sources. Although these two datasets both have a higher temporal resolution, their spatial resolution is variable with respect to the current Census Output Areas for Britain and they are representative of fewer people. We present findings from an initial investigation into whether combining these two relatively novel data sources enables us to infer information conventionally offered by the national identity and ethnic grouping questions on the British Census. By using small-area statistics from alternate sources to examine international migration, we hope to help policy-makers and population researchers better understand the degree of cross-validation or mutual incompatibility

between widely varied, large-volume data sets. We will also consider the potential privacy issues involved in this type of 'big data' research and the challenge of identifying 'hard to reach' populations in the absence of more costly outreach efforts.

Geodemographics: Creating a Classification at the Level of the Individual

Luke Burns (University of Leeds), Mark Birkin (University of Leeds), Alison Heppenstall (University of Leeds), Linda See (International Institute for Applied Systems Analysis)

Area-based geodemographic classification schemes are a popular means of population categorisation across a variety of fields spanning both public and private sector applications. This form of segmentation enables relatively efficient population targeting to be conducted in fields such as commercial marketing and at-risk population identification. This research aims to challenge the current geodemographics ethos by investigating the benefit to be gained by a move away from conventional areal unit categorisation to a system capable of classifying at the level of the person. A classification for Leeds, UK will be presented with a further overview of an ongoing national (UK) classification of individuals, something which remains untried in academia. Undoubtedly, any system with this level of discrimination will by far surpass existing schemes confined to spatial units. Furthermore, issues such as ecological fallacy, the Modifiable Area Unit problem, and generalisation are three aspects to be considered when interpreting any spatially aggregated data and hence a move away from such problems is one of the objectives of this research. Data variables from the 2001 Small Area Microdata file underpin this research. These variables undergo transformation from categorical/ordinal states into scale variables based on average gross monthly income data present in the British Household Panel Survey (BHPS) thus enabling effective hierarchical clustering. Micro-simulation is then employed to create a complete individual population. The initial system to be presented will comprise fifteen fundamental census variables including age, sex, ethnicity, and social-economic classification. Linkage to other datasets, including the BHPS, is also facilitated to validate the classification and draw upon more behavioral variables. The final classification will enable not only a highly discriminate system extending beyond current academic and private sector schemes but also a system through which household and neighborhood effects can be analysed. Such an assessment of drivers behind individual-level characteristics represents new ground within the domain of geodemographics. Furthermore, the final output will allow for informed policy decisions to be made across multiple social science areas, such as migration. The application of the complete classification to specific case studies will illustrate this.

Synthesising data sources to produce migration estimates for the UK

Nik Lomax (University of Leeds), John Stillwell (University of Leeds), Paul Norman (University of Leeds), Phil Rees (University of Leeds)

Migration is the most significant contributor to population change in the UK. The most comprehensive source of migration data has been the decennial census, capturing information about the level, pattern and composition of migration from overseas, across the borders of the constituent countries of the UK and between areas within these countries. Whilst census migration statistics are produced by three national statistical agencies (NSAs) - the Office for National Statistics in England and Wales (ONS), the National Records of Scotland (NRS) and the Northern Ireland Statistics and Research Agency (NISRA) - the availability and level of detail of migration data for non-census years utilised by the NSAs varies considerably from country to country. This paper presents the results of an exercise in consolidating the data produced by the NSAs and constructing a time series of consistent migration flow estimates for the whole of the UK throughout the 2000s which can be carried forward beyond the 2011 Census. The database contains three migration components: (i) international flows to and from outside the UK; (ii) cross-border flows between the countries; and (iii) flows within each country. The flows are estimated for a number of geographic systems including local authority districts and European NUTS geographies. We first identify what data are available to estimate internal and international migration in the UK and assess the gaps that need to be filled. Second we synthesise the available data for mid-year 2000 to 2011 to take in to account inconsistencies and boundary changes during the decade. Finally we employ a modelling strategy to estimate flows for which the data are either insufficient or non-existent. A major gap in the database is the flows between regions that cross the national borders of the three countries of the UK and one of the key aims of this paper is to estimate this missing information at local authority districts level. Currently the only comprehensive source of data for cross-border flows is the National Health Service Central Register (NHSCR), which captures movements of doctor's patients between health areas: Former Health Authorities (FHA) in England and Wales, Health Boards in Scotland and Health and Social Service Boards Northern Ireland. These geographies are increasingly obsolete for the purpose of recording migration (especially in England and Wales where FHAs no longer play a role in resource provision). The estimation presented uses the NHSCR and additional data sources augmented with area information such as the presence of armed forces bases, prisons or higher education establishments to adjust initial estimates. By producing a consistent time series for mid-2000 to mid-2011, we are able to benchmark against the results of the 2001 and 2011 Censuses, giving the opportunity to test the methodology with a view to continuing the comprehensive UK migration database in the post-census world.

Integrating Population Data for Development: The Case of Population Census, Vital Registration and Targeted Surveys in Nigeria

Godwin Ikwuyatun (University of Ibadan)

Population data is a major factor in national development planning; hence, the quest for accurate, current and acceptable population census data in Nigeria has remained a major challenge from its first attempt in national census taking in 1911 to the last exercise in 2006. If population data is conceptualized as a system of data, it implies that a comprehensive population data in Nigeria should involve the integration of population census, vital registration and targeted surveys. This is however not the case, as these population data sourcing structures tend to stand alone, leading to inadequacies, litigation and politicization of population data in Nigeria. It is in this light that the paper examines the challenges and prospects of the various population data sources; and that of integrating them for national development planning in Nigeria. The paper argued that for accurate, current and acceptable population data in Nigeria, the various sources of population data in Nigeria needs to be integrated on sustained basis for national development.

Producing Whiteness: The British in South Africa

Pauline Leonard (University of Southampton), Daniel Conway (Loughborough University)

This paper draws on new ethnographic research to interrogate the positions and experiences of white British residents in South Africa as the post-apartheid government approaches its twentieth year in office. South Africa's British-born community is the eighth largest British-born community in the world and South Africa itself is the seventh most popular destination for retired British migrants- and yet it has been long overlooked by the literature analysing British expatriates. This paper aims to remedy this gap in knowledge by looking at the everyday lives and attitudes of longstanding and short term British residents in Cape Town and Johannesburg to explore and conceptualise broader questions of expatriate migration, transnationalism, diasporic identities and whiteness. The paper focuses on the ways in which, at various moments throughout the twentieth century, the white British have been encouraged to migrate to South Africa with promises of upward economic and social mobility. Even before the apartheid regime, the white British, both male and female, conformed to notions of 'the 'good worker'. During apartheid, although relations with the Afrikaans regime were fragile and unstable, the British were encouraged to migrate through a range of assisted passage and recruitment schemes. For much of South Africa's recent history therefore, white British people were seen by those in power to possess the correct sort of social capital. However, the research also reveals a complexity and diversity of identities, positions and experiences within this broad community, with notions of belonging between its members towards South Africa and Britain often experienced as increasingly problematic. Historically seen as having divided loyalties between Britain and South Africa and residing in South Africa for benefits of lifestyle rather than committing to the nation as full citizens, an important question to emerge is the extent to which the transnational identities and relations of British people are changing in accordance with the new political climate.

An Island as a gated space: The case of Latvian migrant workers in Guernsey

Aija Lulle (University of Latvia)

Islands are both bounded geographical places and constantly changing social spaces and are particularly dense fieldwork sites for current migration research. Despite the fact that in popular perception islands are linked to localness, settled populations and the

preservation of culture, migrant populations do often constitute a part of the whole story of an island. In this paper I put temporary migrant agency at the centre of the analysis. The study is based on ethnographic research that I carried out in the Channel Island of Guernsey in 2010-11. Guernsey was among the first places where Latvians searched for employment abroad, starting in the mid-1990s, and currently Latvians form one of the biggest communities of migrant workers there. Inspired by ideas of time geography and relational space theory, I revise the concept of time-space punctuation in border studies, and develop an alternative relational concept of a gated space to interpret spaces of flows and migrant agency on the island. I suggest that a multi-scalar spatial analysis of flows enables the development of a deeper understanding of the frictions between bounded and fluid spaces that shape transnational migration practices. Firstly, I conduct a relational analysis of legal constructions, as laws in a limited natural space demand the constant rotation of migrants, but place-specific attachments encourage people to continuously move back and forth, creating a particular manifestation of the phenomenon of permanent temporariness. Secondly, I analyse the community level, where the saturation of Guernsey with Latvians creates gatedness of the internal dynamics of migration over time. The existing ethnic Latvian community can be an obstacle for new migrants, rather than facilitating access to jobs and housing permits. Finally, I examine micro relational gated spaces through the lens of individual mobility projects. In migrant stories, gated spaces of flows on the island signify the particular ways in which people sense the place and enact their agency in it, as a migrant him/herself goes through different migration- and life-stages. Subjective experiences of mobility and immobility form an island story, where 'a dream island', 'a refuge', and 'a place to escape' co-exist with the place that 'imprisons', where a person has been 'stuck' and kept in a strictly defined place, and where opportunities for social and physical mobility are quickly exhausted. Based on this analysis I suggest that the interpretation of complex relational modalities of openness and gatedness to migration flows helps to develop a more detailed understanding of space-mobility relations on the island. Furthermore, instead of being portrayed as insular and bounded spaces, the whole concept of islands could be reconceptualised as both open and gated spaces in which to both welcome and to hide from the winds of change.

Images of the ideal migrant: Patterns of expectations towards British lifestyle migrants as new members of French rural communes

Martina Kobras (WWU Münster)

In the course of its political integration, the European Union has been producing migration which is granted by the Maastricht Treaty and the four freedoms of movement. Initially aiming at the adjustment of labour market mismatches (cf. Vandenbrande 2006: 3), more or less all union citizens have the right to long-term settlement in the other EU member states. This is a central structural condition for people who move not seeking for higher income but better quality of life. The so-called lifestyle migrants - among them many

British citizens - are incited to migrate by individual, structural, and spatial factors: individualisation of Western society; structural differences of national markets; a spirit of adventure and lifestyle; and romantic nostalgia attached to living in the countryside etc. (cf. Kobras 2007). In France, the phenomenon of British lifestyle migration has established since about 30 years in remarkable number; often, they are married couples aged 50+ in their (early) retirement but also younger families with children; prevalently, the chosen living environments are small, rural communes where they wish to enjoy a slower pace of life. The particularity of this migration phenomenon is the fact that, due to the legal situation, there is no way to control or even to prevent the British settlement and inclusion into the societal systems: notably the local population is directly confronted with their arrival; it finds itself in the unexpected role of a receiving society. The lack of influence does not hinder the locals - following the unwritten law of the privileges for the old-established - to closely observe the newcomers, who are classified as being different in spite of the rather minor difference in comparison to the largest migrant groups in France. These observations are matched with the social and cultural constructions of the 'typical good migrant' and translated into expectations and demands. A recent, quantitative study is focussing how the French local, autochthon population is judging the settlement of British lifestyle migrants and which expectations have emerged. Through an ample questionnaire, 300 French inhabitants of typical destination communes give evidence of their expectations in many respects: on the adaptation of the British migrants in the fields of language, culture and social contacts; on the inclusion into societal systems such as the job market and the social security system; on the will of participating in society resp. the wish for separation. Statistically significant, the study shows that the patterns of expectation are influenced not only by demographic data but individually experienced foreignness and personal contacts to British migrants. Patterns of expectations are visible which frame and shape the coexistence with the new British inhabitants after their move; these patterns are influencing the stay or further movements of the migrants, possible chain migration and other cumulative effects.

Moroccan migrants in Germany – structural influences on migration patterns and individual subjectivities

Maïke Didero (RWTH Aachen)

This paper draws on the example of the German-Moroccan migration system to discuss to what extent different types of migration (work migration, student migration, family migration) are shaped by economic and political structuring influences. The case of the Moroccan-German migration system is of particular interest since - on the one hand - it confirms that political and economic actors and intra-national imbalances contributed to the establishment to a very selective migration pattern between the Moroccan North-East and two industrial regions in Germany (NRW and Rhein-Main). Established through the recruitment of Moroccan workers in the 1960s, this regional selectivity is traceable until today. Contrary to this first wave of work migration and family reunification however,

student migration from Morocco to Germany - which set off in the 1990s - has contributed to a regional diversification with regard of both provenance and settlement areas. Although triggered and facilitated a political decision, namely the bilateral agreement on cultural cooperation signed in 1987, the regional dimension of the following migration flow is much less channeled by external political and economic agencies and structures and depends more on individual decisions based on hearsay information and networks. What the German case equally well displays is how close discourses on the 'ideal migrant' and immigration policies are entangled. The common stance of Germany not being an immigration country, upheld until the turn of the millennium, meant that until this time a 'good migrant' was either an ethnic German 'coming back' to his/her home country, or else someone willing to return when no longer needed. Immigrants and their descendents were consequently represented and addressed as foreigners who don't belong. Integration policies didn't exist. Since the end of the 1990s a noticeable shift occurred: immigration was finally admitted as a fact, and novel immigration, integration and citizenship laws were initiated. At the same time, however, particularly in the wake of 9/11, the 'ideal migrant' has been increasingly defined in the negative as not being Muslim, and not coming from Turkey or the MENA region. Although this new discourse nexus on Islam and Migration has influenced and shaped a number of immigration policy measures, large scale impacts on migration flows to Germany have not yet materialized. What can be noted however, is that the negative image attributed to Muslims in Germany does play a role in the production of individual identities and subjectivities. Based on 40 interviews with Moroccan migrants in NRW, the author is able to show that the way in which respondents articulate themselves within these discourses differ according to their socially acquired dispositions and habitus.

Russian Population and Migrations in the 20th century: Role, Image and Discourse of the migration matters in the development of a country

Pavel Polian (University of Freiburg), Zhanna Zajonchkovskaja (High School of Economics), Vitalij Belozerov (Stavropol University)

The population in Russia increased twice in the century due to a huge natural mostly rural country's population growth (more than 85% at the beginning of the century), not common with the abortions, contraceptives and passing through "the social experiments" of the soviet authority. All those causes excluded, the population could have increased three times: demographic back-log at the beginning of the XX century turned to be not enough for the millennium and despite the immigration flows from the neighboring countries the population in Russia had been simply decreasing. In the XXth century Russia faced at least three demographic catastrophes- all of them at the first half of the century, each lasted 7-9 years and followed by one or two hunger bursts: 1) 1915-1922: the First World War and the Civil Wars; 2) 1930-1936: the Collectivization; 3) 1941-1948: The Great Patriotic war and postwar ruin. We may estimate demographic losses only nominally and only through the experiment or calculation with possible assumptions. The population losses on the current territory of the Russian Federation during catastrophes make: for the first period – 12 million people or 13% of the pre-crisis population rate; for the second period – 5 million people (or 5 %); for the third period – 21 million people (or 19%). If we take into account circumstantial losses, that means that the growth rate is preserved on the pre-catastrophe level, the estimated value for the first crises would have made – 18,6 million people, for the second – 6,5 million people and for the third – 24,5 million people. All three demographic catastrophes took place in the first half of the century. They had seriously knocked out the demographic potential of the country in terms of the common Russia's population evolution that deprived it of the demographic advantage, which proposed both to Russia and other countries demographic pass and temporal but rapid population growth caused by it. When Russia had overcome prolonged period of catastrophes and the balance between the death and birth rate had been redressed, it was late to catch up with the lost possibility of natural population growth in Russia. The first half of the century, especially 40 years between 1914 and 1953, had also faced mass and compulsory migrations. In soviet times during the internal migration more than 6 million people were deported, and during the international migration, including ostarbeiters deportation by Germans and forced repatriation- 9 million people. At least every second citizen of Russia was a migrant. The last decade of the century had at one moment locked the expansion centuries-long circle, having defined the shift to the compression of the developed space, its more effective usage,

opening the way to the next phase of modernization, which would unfold in the coming century. Migration had played the role of the bright marker in the current changes.

Embodying the 'good' worker: The imagination and production of the ideal labour migrant

Allan Findlay (University of St Andrews), David McCollum (University of St Andrews), Sergei Shubin (Swansea University), Zaiga Krisjane (University of Latvia), Elina Apsite (University of Latvia)

The focus of this paper is representations of labour migrants and how they shape migrant recruitment and employment regimes. The recruitment and employment of labour migrants inevitably involves a range of knowledge practices which shape who is recruited, from where and for what purposes. However research often explores recruitment and employment practices and outcomes without paying attention to the normative judgements and understandings that underpin them. There is thus scope for research that examines the influence of idealised images of workers on migrant labour recruitment and employment regimes. This analysis seeks to advance the concept of embodied representations of migrant workers and their effects by investigating how perceptions influence practices in the case of labour migration flows from Latvia. The Latvian economy boomed in the years prior to the global economic recession but the country now has one of the highest unemployment and emigration rates in Europe. The research elicits labour provider, policymaker and employer conceptions of the ideal migrant worker and shows the demonstrable impact that these perceptions have on their practices, and thus the recruitment and employment regimes that shape the nature of labour migration flows. The analysis finds that various 'filtering' processes are enacted which serve to 'produce' the ideal migrant worker.

Diasporic and post-colonial linkages in the current international migration trends. The cases of Spain and Japan.

Rosalía Avila-Tapiés (Association of Spanish Geographers), Josefina Domínguez-Mujica (University of Las Palmas)

Immigration policies are considered the single most important determinant of worldwide immigration flows. Throughout history, such policies have not only determined how many immigrants can arrive and in what circumstances, but also who can do so. Good examples of this are the countries of European Union and the post-industrial nations of eastern Asia, which impose barriers to international migration, excluding or favoring certain flows and producing 'new migration geographies'. Despite declaring themselves non-immigration countries, many of these states have adopted expansive immigration policies due to the needs of their industry, health-care system, service sector and other effects of ageing population societies. Within this context, some of these countries have revised their legislation to grant preferential treatment to the citizens of the former

colonies and their own overseas diaspora communities. There have been some actions that have precedents in certain treaties and agreements from the past and that rest on the conviction that these citizens can culturally or racially belong to the ancestral homeland ('ethnic belongers'), as in the case, particularly, of the Latin Americans and the Caribbeans for Spain; and Brazilian and Peruvian citizens of Japanese ancestry for Japan. It could be stated that the Spanish and Japanese governments have realized the growing economic importance of their networked diaspora and of their contribution to the countries' economic growth. Traditionally, the loyalties and commitments to Spanish and Japanese diasporas in the exterior have been driven by a range of motivations, which have been translated into grass-roots and state-sponsored transnational activities. From a comparative perspective, we present an overview of the migratory and nationalization legislation in Spain and Japan. The available statistical data allow us to analyze the effect of this regulation on the volume and profile of the migratory flows. In the recent years of economic crisis, first Spain (2008) and then Japan (2009) have reversed their open-door policies in a government-sponsored voluntary return program that has also selectively favored the return of these new immigrants to their native birthplaces. All this reveals that the links with the past and the legislation that protects them have reinforced certain current cross-national migratory processes or, in other words, that the colonial inheritance has led to greater flexibility, frequency, and facility of migratory contacts between certain spaces, which has contributed to strengthening 'old migration geographies'. In conclusion, the object of this paper is to demonstrate that the transnational networks of bi-national citizens, supported by the history and the legislation, link Spain and Japan with fast-growing Latin America, turning old migration geographies into new migration geographies in the 21st century.

Agency-Led Migration, Individual Choice, Tensions and Outcomes: Refugees to the US

Lawrence Brown (Ohio State University), Tamar Mott Forrest (Ohio University)

Friedmann and Wulff (1976), said 'migration ... [is] merely a demographic adjustment to changes in the spatial structure of economic and social opportunities ... a derived phenomenon ... not the thing itself.' This premise is explored in x steps. After briefly setting out the traditional model of migration and citing several examples in US economic history wherein its assumptions have been contravened by the actions of intermediaries, attention first turns to Refugee Resettlement Agencies, in particular the Hebrew Immigrant Aid Society (HIAS), founded in 1881, as a case study of changing practices through the years in response to local situations, changing government regulations, etc. Second, we focus on the current-day refugee resettlement system in the US, including the US Office of Refugee Resettlement, voluntary agents with which it works (VOLAGS), and community-based organizations. Focusing primarily on African refugees, we show their place of original settlement, and their place of current residence, i.e., destination of secondary migration following resettlement (proprietary data). To obtain a deeper

understanding of the process, mail-surveys were done of State Refugee Coordinators and in-depth case studies of Columbus Ohio, Minneapolis Minnesota, and Lewiston Maine - all major recipients of secondary migration and two MSAs with the first and second largest Somali populations in the US. Case study procedures included in-depth key informant interviews, focus groups, and surveys, as well as secondary data. Finally, secondary data characterizing the 41 MSAs that were origin points for secondary migration to Columbus, Minneapolis, and Lewiston were subject to principal components analysis that enables identifying six urban profiles of 'sender' cities, several of which provide a contradiction between Somali actions and social science expectations. While Somali's are the focus of this study, similar patterns and processes have characterized, at least, Cuban, Hmong, Vietnam, Laotian, Chinese and many other US migrants brought as either refugees or labor. We conclude, then, that (i) Migration Theory has virtually neglected the derived nature of movements and the role of government and/or business entities in creating opportunities; (ii) That at certain historical moments, directed migrations and/or similar interventions have played a highly significant, if not dominant, role in population redistribution; but that (iii) Voluntary migration nevertheless has a role, albeit much less so than that suggested by abstract conceptual frameworks.

Transnational migrant communities in the context of changing recruitment and Omanisation policies in Muscat (Oman)

Veronika Deffner (RWTH Aachen), Carmella Pfaffenbach (RWTH Aachen)

As in all other GCC countries, the modernisation drive the Sultanate of Oman has experienced over the last 40 years was only made possible through systematically recruiting foreign labourers. Two types of migrants stand out: The low-skilled labour workers from Asia and the high skilled experts from the Global North. The 'ideal' labourers from an Omani perspective are young, dynamic, able to adapt to the hegemonial claims of Omani society and willing to work hard for very little salary. These labourers also return to their native countries after finishing their work contract. In the majority of the cases recruitment agencies at home arrange the jobs in Oman. They are supported both politically and institutionally by Overseas Employment Ministries; political bodies specifically established as outgoing labourers make for a very important 'economic sector' with high remittances. The transnational expatriates are mainly dispatched by international companies of which the majority works in the oil industry. Usually, they are more senior, receive the highest incomes and enjoy the most privileges amongst the foreigners. They share their expertise and contribute to modernising the country further. Such expatriates establish transnational trade relations and economic ties for Oman, too. They leave the country to pursue the next career opportunity elsewhere. However, a limited employment contract, which is terminable any time, also applies for these skilled transnationals. The labour market policies as well as the recruitment practices in Oman follow the main agenda of an open-market policy; i.e. the recruiting countries determine which migrant groups should be hired for which jobs and who can obtain a work permit. Two legal and administrative regulations are important in this regard: Firstly, the entry and residence permits for partners and children can only be obtained by the highly qualified and secondly, non-Omanis are not allowed to buy property with the exception of a few new real estate projects. The Omani citizenship is not granted to foreign employees either independent of their duration of stay. Over the last few years the political and social claims to hegemony have become especially explicit in the implementation of the so-called Omanisation policy. It entails that foreign employees in the public and increasingly also in the private sector should gradually be replaced by domestic work force. These political and economic transformations have led to social changes within the heterogeneous urban society of Muscat. Based on empirical results, this talk presents how these changes are perceived by the individual foreign migrants and how it influences everyday life and work of different migrant communities.

Analysis of Interregional Migration Changes in China 1985-2000

Jianfa Shen (University of Hong Kong)

This paper uses a macro modeling approach to examine the causes of changing migration patterns in China. A migration model describes the relationship between explanatory variables with the migration flow with model parameters. Theoretically, the migration pattern and the migration flows will change due to changes in explanatory variables such as regional economic development or changes in model parameters, which is called system shift in migrants' response to migration determinants in this paper. No attempt has been made to systematically estimate the exact impact of a change in the value of independent variable or model parameter on the migration flow. This paper analyzes the effects of changing parameters in a migration model and the changing attributes in origin and destinations on migration flows. A decomposition approach is developed based on migration models and multilevel Poisson migration models are estimated for migration in China for the period 1985-1990 and 1995-2000 respectively using the same set of variables to make above decomposition. The models for 1985-1990 and 1995-2000 explained 41.6% and 54.1% of the variation of the number of migrants in all flows respectively. There were significant differences in model parameters between multilevel Poisson models for 1985-1990 and 1995-2000. For instances, absolute parameters of most variables become bigger to reflect the increasing scale of migration. The distance parameter becomes smaller in absolute value. How these changes affect the migration is revealed using the decomposition approach in this paper. Overall, the total inter-provincial migration was increased by 21 million in China from 1985-1990 to 1995-2000. The decomposition result shows that 68.46% of this increase was due to changes in the value of explanatory variables while 31.54% was due to changes in the value of model parameters. Thus the demographic, social and economic changes among various provinces play a greater role than the changes in the parameters of migration models in the dramatic rise of the inter-provincial migration in China.

Likelihoods and realities of return migration to Latvia

Elina Apsite (University of Latvia)

International emigration from Latvia to other European countries started since 1 May 2004 along with opening of the EU labour market. English speaking destination countries the UK and Ireland have been one of the main destinations for Latvian labour migrants. Second out-flow from Latvia increased with the start of economic crisis around 2008 which can be characterised by slight change of destination countries and extent of returns. In this paper data from comprehensive web-based survey with Latvians residing in the UK is used in order to analyse likelihoods of return migration for different migrant groups. As well as semi-structured interviews with returnees who have returned to Latvia. Are they all gone for good? Are there still number of emigres who will return, are planning to return or have returned already? Overall, the findings indicate that large proportion of Latvians currently living in the UK is more likely to stay in the UK. Analysis distinguishes

only certain groups of people who would be in favor of return. However in context of economic conditions, uncertainty and unemployment in country of origin restrain from return. According to returnees economic conditions do not play important role in return decision making. Most of the returnees' stress the importance of emotional and family reasons.

Explaining urban migration from Mexico City to the U.S.: Social networks and territorial attachments

Cristóbal Mendoza (Universidad Iztapalapa)

This paper focuses on international migration from Valle de Chalco-Solidaridad, a municipality which is part of the Mexico City Metropolitan Area. In this way, it fills a gap in the literature, since studies on international migration from urban settings, and particularly Mexico City, are still scarce. The paper has two related but separate goals, namely to examine what Mexican migration from Valle de Chalco-Solidaridad reveals about the functions and dynamics of social networks as compared to rural-based networks, and to test whether and to what extent territorial and place attachments affect the likelihood of migration to the U.S. Theoretically the article takes into account the social networks theoretical framework and sheds light from a different angle on a classical theory that has mainly been tested in rural settings in Mexico. Also the article takes an original geographical stance and explores the role of place attachment in understanding out-migration patterns. This perspective has barely been explored in migration studies, and when it has been, the approach has been qualitative. Methodology, the paper is based on the May 2007 Migration, Place and Employment in Valle de Chalco-Solidaridad (Estado de México). This is an original randomized representative survey of 759 households from the municipality of Valle de Chalco-Solidaridad representing information on 3,488 individuals (confidence interval 95%, $2 \cdot \sqrt{P \cdot Q} = 50$, error 3.6%). Using probabilistic techniques, census blocks were randomly chosen from the cartography of the municipality by census tracts (AGEBS in Mexico; INEGI, 2007). The article explores the relevance of both social networks and place attachments for US migration. It demonstrates that the impact of socio-demographic variables on emigration is mediated by the household's past migration. By comparing households with and without migrants, several logistic regression models show that social networks make emigration more selective with respect 'education', but less selective regarding 'sex' and 'marital status'. As for territorial variables, the general impression is one of placelessness, apart from attachment to the municipality, but here again social networks act as an intervening variable.

Urban Land Use Planning and the Production of Retirement Migration Patterns in Cities: Evidence from Australia

Amanda Davies (Curtin University)

The world's population is ageing at a rate unprecedented in human history. This spatially pervasive trend has serious social, economic and environmental consequences. Importantly, population ageing is occurring in a spatially uneven manner with some countries and regions ageing at a much faster rate than others. This unevenness in population ageing also exists within cities and towns where older populations tend to cluster into specific localities. The unevenness in the distribution of older populations within towns and cities has implications for the design and delivery of social, healthcare and housing support for elderly people. To address the social and economic demands of older populations, many governments of advanced industrial societies have developed policies to support ageing in place. Ageing in place is where older people remain in their home and or community of choice as they grow old rather than move into institutional care. Ageing in place is often facilitated by a move on (or near) retirement into a locality or home that can meet the needs of the residents as they progress into older age. Elderly people who choose to age in place are not evenly distributed across space. Rather, distinct spatial patterns form whereby older people cluster in particular localities. These spatial patterns are shaped by the institutions and social networks that enable retirement migration (and non-migration) to occur. This paper examines the clustering trends of older people within cities and the relationship to urban land use planning. The paper argues that urban land use planning policy produces specific patterns of retirement migration (and non-migration) within cities. Evidence from the Australian city of Perth is used to support the argument. Perth is one of the most geographically remote advanced industrial cities in the world. It has a population ageing trend similar to many major cities in Europe and North America. It is also a relatively young city with an urban form that has been considerably shaped by successive urban land use strategies and plans. As such, Perth makes a useful case to examine how retirement migration (or non-migration) within the city has been influenced by successive urban land use plans.

Economie des mobilités internationales de travail des Marocains en Plaine Orientale corse

Josepha Milazzo (Aix-Marseille Université / Université de Barcelone)

Nombreuses sont les populations qui ont foulé de leurs pieds la Corse, "terre d'immigration". La présence de populations ressortissantes du Maghreb n'apparaît pourtant que très tardivement, au début des années 1960, le rapatriement des Pieds noirs des grands domaines agricoles d'Afrique du Nord et leur installation en Plaine Orientale donnant lieu à la venue conjointe de leurs ouvriers marocains, suivie d'un phénomène d'immigration bientôt relayé par l'institutionnalisation au niveau national de ces circulations étrangères de travail. Selon une approche systémique, nous proposons une analyse des modalités actuelles de sélection des migrations internationales marocaines de travail liées au secteur agricole de la Plaine Orientale corse. Nous démontrerons que ces processus sont d'autant plus complexes à étudier qu'ils interviennent à des échelles géographiques variables et interconnectées et qu'ils s'inscrivent dans la genèse continue des territoires mis en contact par les histoires migratoires croisées de leurs populations: ces mobilités s'appuient sur un passé migratoire pour mieux faire face aux nouveaux enjeux de la mondialisation. Nous ferons ainsi la lumière sur les ferments à l'origine du champ migratoire corso-marocain et sur ceux responsables de ses inerties comme de ses mutations, nous appuyant pour cela sur une soixantaine d'entretiens réalisés en 2008 et en 2009 auprès des exploitants, des travailleurs migrants marocains de la Plaine Orientale et des responsables des antennes locales des services publics de l'emploi et sur l'exploitation des données statistiques de l'Office Français de l'Immigration et de l'Intégration. Les modalités spatiales et professionnelles actuelles des migrations marocaines, notamment en termes de recrutement, soulignent que ces circulations de travail désormais réglementées s'appuient sur des filières migratoires historiques, les migrants étant généralement originaires des mêmes régions marocaines, voire issus des mêmes familles. Cependant, si ces processus structurants sont d'une importance indéniable, ceux intervenant aux échelles méso et micro exercent une influence prépondérante dans la sélection de ces migrants. Celle-ci est l'objet d'incessantes négociations et de rivalités entre les services déconcentrés de l'Etat, les exploitants agricoles et les migrants et ne manque pas de susciter un recours aux réseaux familiaux, amicaux et professionnels, constitutifs d'un espace migratoire corso-marocain ainsi mis en place au début des années 1960.

Post-accession migration of Poles to European Union countries

Dariusz Nowotnik (University of Cracow)

Dariusz Nowotnik Pedagogical University National Education Commission in Cracow Post-accession migration of Poles to European Union countries In 2004, the European Union has made the biggest enlargement in its history. Along with this event, most of the "old Union" countries have introduced a transitional period for opening their labor markets for the people of the new ones. This was to protect them from sudden increases in

unemployment and as a consequence of social discontent. EU countries afraid of low-cost and well-educated workforce that would be competitive for the local community. At this step not only decided to Great Britain, Ireland and Sweden have not adopted any restrictions on access to their labour markets. The two-year transitional period to opening labour markets occurred in Finland, Italy, Greece, Spain and Portugal. Next, the Netherlands and Luxembourg opened their labour markets in 2007, France in 2008, Belgium and Denmark in 2009, and finally Germany and Austria in 2011. Not the simultaneous opening of labour markets in European Union countries contributed to the impact of these decisions on the direction and volume of foreign migration from new Member States to other countries of the European Union. The aim of the article is to present the evolution and spatial patterns of emigration of Polish people since 2004 with particular reference to the composition of Polish emigrants by sex and age as well as to show the magnitude and direction of emigration to the countries of the European Union. Article also shows the impact of the gradual abolition of restrictions on access to labour markets on Polish foreign migration trends and changes in the level of unemployment in European Union countries in the studied years. The data for this research were taken from Eurostat database, Central Statistical Office in Warsaw, and the national statistical offices of the Member States of the European Union.

Spatial Selectivity and Demographic Impact of German Immigrants in the Swiss regions

Ilka Steiner (University of Geneva)

Since 1997, Germans are the largest immigrant group in Switzerland. 8'200 new arrivals were registered in 1998, a number that reached 46'300 in 2008. The major reason for this increase is the ratification of the Agreement on the free movement of persons between Switzerland and the European Union in June 2002 and the economic growth encountered by Switzerland at the turn of the XXIth century. Little is known about the socio-demographic and professional profile of German immigrants to Switzerland and even less about their distribution within the region. However, the repartition and not least the resulting demographic impact of German immigrants within the Swiss territory underlie a spatial selectivity. In this context, our paper raises the question of "How does the spatial selectivity of German Immigrants in Switzerland influence demographic evolution in the regions"? In a first step, we describe the regional socio-demographic and professional characteristics of German immigrants arrived after 2002 in Switzerland, in order to illustrate spatial selectivity of immigration in the regions. Furthermore, we assess the factors underlying the observed regional disparities. In a second step, the demographic impact in the regions is measured, by means of an analysis of the migrant turnover and net migration, the main factors of demographic dynamics of the German immigrant group in Switzerland. All our analyses rely on the Swiss Central Aliens Register (SCAR) and the Population and Households Statistics (STATPOP) for 2010 as well as on the Swiss Labor Force Survey (SLFS). The analyses cover the period from June 2002 to

December 2010. Immigrant's characteristics are compared between the sixteen job market regions of the country. Analyses show that job market regions that are situated in the Swiss-German speaking part or in the borderland to Germany account for the highest numbers of immigrants. The migrant's profile and the turnover however depend on different factors such as the type of municipalities - the turnover is much smaller in commuter and suburban communes than in touristic regions - on the qualification level and the occupation held - qualified persons, and above all, scientists present a high disposition to re-migrate - and finally age and life course, since retirees or married couples and families present a lower probability to leave the country than other "more independent" migrants. Our paper demonstrates the importance of considering different regions while trying to understand immigration and its impacts in a country like Switzerland. By various reasons, such as the federalist political organization, the linguistic particularities, a variety of economic structures and fields of activity as well as the positions on the center-periphery scale of the Swiss regions, analyses on the aggregated level remain insufficient.

Terraced paddy expansion by ethnic minorities in Sapa, Vietnam: Identifying locations and measuring productivity

Yuzuru Isoda (Tohoku University), Ngu Nguyen Huu (Hue University), Tatsuya Kanda (Okayama University), Yukio Yotsumoto (Ritsumeikan Asia Pacific University), Thinh Nguyen An (Vietnam University), Huong Hoang Thi Thu (Vietnam University), Doo-Chul KIM (Okayama University)

H'Mong and Dao ethnic minorities have expanded their terraced paddy fields to steep slopes in Sapa, Lao Cai in northern Vietnam, but local farmers and officials alike say that the development of terraced paddies are relatively recent, since the 1980s after Agricultural Cooperatives are dismantled, and are still expanding. Such parole evidence seem to suggest a shift in agricultural intensity from the traditional swidden cultivation to wet rice production, driven by rapid population growth supported by ban on swidden cultivation and opium production. Albeit being montagnards, they are not secluded from the forces of Globalization; using Chinese hybrid rice seeds; heavily dependent on chemical fertilizers; selling black cardamom to Chinese market; supplementing their income from international tourism, from activities such as craft production and guiding. The region appears to be an ideal case to study the social conditions of the sustainability of largely subsistent farming under exposure to cash economy and the global market, however, quantitative data were lacking. The paper reports findings from remote sensing and field survey. First, terraced paddy expansion in the last 40 years is identified with the use of archived of satellite images. Because of the lack of ground data for the past, we employed robust logistic regression to use the recent land use map as training data to classify the past satellite images. The paddy fields identified independently for each period are compared post hoc to estimate the period of terrace paddy development. Second, we have done interviews to individual farmers to ask about the location and development year of each plots of terraced field. This data is used to assess the accuracy of the estimated terraced paddy development from the remote sensing mentioned above. The survey is still underway but we have collected data for 89 farms and 205 plots to date. Finally, alongside the interviews above, we have collected items associated with productivity of each plot, such as yield and fertilizer use. These enable analysis of productivity difference by geographical location and development year, to discuss how productivity changed through expansion of terraced paddies and forecasting how much more terraced paddies can be developed.

South American Integration and Impacts on the Population Living in Forested Areas of the State of Acre in the Brazilian Amazon

Ana Maria Bicalho (Universidade do Rio de Janeiro)

New policy of integrating South America through the construction of highways connecting neighbouring countries will cause profound impacts in remote areas of difficult access situated along the national borders of Brazil, Bolivia and Peru in the Amazon. The state of Acre is located in the extreme northwest of Brazil and has extensive forested areas and follows policy focussed on environmental preservation as a means of controlling the frontier expansion of cattle raising and hard wood extraction as well as the historic population resident in forest areas in Extractive Reserves (Resex). This state thus constitutes a focal point of concern about the impact of the new highways. Are the mechanisms which arose over the last decades for regulating land use in Acre enough to guarantee socio-environmental sustainability? Will new mechanisms of state and municipal governance be capable of preserving the forest against the expanding frontier and conciliate conflicting interests between different business groups and the resident population of forested areas? At the centre of new policy is a system of socio-environmental zoning, which involves different forms of intensity and kinds of land use. A major aim is to recuperate forested areas on larger cattle raising and timber extraction units as well as on small farms. A programme of productive certification is being used to reduce deforestation, the use of fire and to increase forested areas to legally mandated levels so legalizing holdings with relation to the Brazilian environmental legislation. In addition a joint state-municipal programme of community development embraces extensive areas of Acre and the greater part of the rural population. The programme provides social assistance and productive assistance to poor small farmers in order to increase commercial production. The unit of action is the community and the first point of connectivity is the local school, which articulates networks of families and government services to municipal and state policy. These are the preventative policy measures meant to minimize the negative impacts of the new highways and the new national and multinational economic interests emerging in the region. Productive inclusion of the poor population is meant to guarantee food security, to help with the shift to a more commercial economy and to maintain it as a local vigilante of forested areas. However, it remains to be seen whether this policy will prove to be effective in face of the rapid expansion of the frontier and the arrival of new economic interest groups in the region and at the same time empower local people to the point of becoming major players in the process and not just cheap labour helping business interests to reap the benefits of logistical integration.

Biofuels or Grazing Lands: Heterogeneous Interests in Tana Delta, Kenya – A Youth Perspective

Ulrich Pickmeier (University Nijmegen), Marcel Rutten (African Studies Centre)

Kenya's Tana Delta imposes extensive wetlands accounting for a total of 1300 km² with high potential for agricultural activities. Located on the edge of Kenya's arid Northeastern Province, it has provided an important fallback area for nomadic pastoralists for generations, next to being home to communities engaging in small scale subsistence farming. The local coexistence between farming and pastoralist communities has been uneasy for a long time involving outbreaks of violence on irregular basis but in recent years the situation calmed down and the communities came to terms with each other. While an increased frequency of droughts and the establishment of hydroelectric power dams upstream have put significant pressure on the area's traditional livelihoods, growing interests of investors mainly originating from the biofuel-sector in the delta's wetlands are about to impose an additional burden for these livelihood strategies. Several domestic and international investors have proposed projects involving the alienation of tens of thousands of hectares from customary use for establishing large scale biofuel-plantations. Opinions differ strongly concerning the impacts large scale land acquisitions in general, and investments for biofuel-productions in particular, could have on local development processes in developing countries. However, regardless if an optimistic or a negative point of view is taken, discussants seem to assume a homogenous stand within the local community. Employing a youth perspective and taking a conflict focus, this paper, however, highlights the heterogeneity of local interests and various attitudes towards large scale land acquisitions in the Tana Delta. Reasons to oppose or welcome these initiatives show a wide range of complex and sometimes even surprising motives. Still, these different opinions concerning the proposed investments embody an inherent potential to induce renewed conflicts between farming and pastoralist communities as well as between varying herding groups in the area. Keywords: biofuels; conflict; youths; Kenya; pastoralism; subsistence farming

Concepts Matter: Emergence of Urban Farmers' Markets and Making of Places in Japanese Cities

Taro Futamura (Doshisha University)

This paper examines emergence of farmers' markets in Japanese cities and the meaning of these places in the context of constructed local food movement. Unlike countries in the United States and others where opportunities of accessing to locally-produced food (such as farmers' markets, farm stands, and Community-Supported Agriculture (CSA)) grew tremendously over the last few decades, there have been very little markets in major Japanese cities. Specifically, the local food movement that encourage production of "locally grown food" and its direct sales by farmers to consumers has been gaining rapidly in rural areas but has struggled to become well-known in Japanese cities. In

Tokyo, for example, there are very few producers-oriented produce markets. Although some periodic farmers' markets were run by non-profit organizations (NPOs), because of lack of capital and resources, they could not operate on a large enough scale and frequencies to have much of an impact on consumer behavior. Thus, so-called "local food movement" that have gradually appeared in many Anglophone countries as an alternative to neoliberal global food system was yet to be seen in Japan. In May 2009, however, the Ministry of Agriculture, Forestry, and Fishery (MAFF) started a program called "Marche Japon Project" to expand direct sales of food products at Japanese cities by funding launching and development of urban markets. Although "Marche" (originally French) gradually became a familiar word in Japan, what was critically problematic about the program was that, for whatever invisible processes, MAFF decided to rely on big corporations rather than organizations that had already been in the field. Because the program was developed by national government, not only did it established top-down power relations, but it also created a completely different model and concepts of markets from those that are led by communities, producer-groups or third parties. Therefore, based on author's ongoing field research at several Marche as well as a comparative case study of NPO-led market in Tokyo, this paper critically looks into changes that these Marches have brought in Japanese urban landscapes in terms of food supply, and argues how the concepts of each markets ultimately develop meanings of places. Data for this study is based on several research methods: 1) multi-site participatory observation at various Marches and other farmers' markets, with the emphasis at monthly NPO-led market in Tokyo, 2) observation and informal communication with vendors, organizers, and consumers at markets; 3) analysis of media reports and documents, and 4) semi-structural interviews with managers. In addition to findings and issues that will be presented, this paper concludes with potential solutions that make the emergence of Japanese urban farmers' markets more fair and successful.

C08.32-02 - Consumer markets, quality products, aggregated value and rural sustainability

Organic Farming in Germany and Portugal: A comparative study

Ana Maria Firmino (University of Lisbon)

Organic Farming in Germany is a very dynamic sector which benefits from the fact that the German consumer has progressively got aware of the importance that this mode of production may represent either to the Nature (balanced ecosystems, biodiversity, landscape, quality of water, soils and air) or to the quality of production and to the health itself, as a result of marketing programs and material for the schools specially in the last decade. This concern with the quality of the food and local self-reliance (short circuits) conjugated with a relative high income contributes to the predominant place occupied by the German retail sector as one of the most important markets for organic products in the world. Even conventional retailers, as REWE, started exploring the organic retail sector, making these products available at a cheaper price for a larger number of consumers. In Portugal, although the organic sector had been expanding until three years ago, lack of information of the population in general in what concerns the characteristics of this mode of production, associated to a low income aggravated by the recent economic crisis, condemns the sector to a marginal relevance, in spite of the opportunity that it constitutes to the Portuguese farmers, since the offer does not match the demand of the internal market and for the added value that it represents, namely in terms of export. Indeed most of the transformed organic products sold in Portugal are imported from Germany, France and Spain, except wines, olive oil, preserves and salt, for instance, although the country has the tradition and the capacity to produce with high quality (circa of 15% of all the products with denomination of origin in the European Union are Portuguese, although not all of them are certified as organic). A survey launched by us in the Land of Hessen, in December 2010, shows some characteristics of the local organic farmers and their farms that will be compared with a similar approach carried out in Portugal. According to this study the German organic farmers in Hessen present an entrepreneurial profile, positive in the way they face the market and the challenges that this represents. Contrarily the Portuguese organic farmers are much more dependent on the subsidies and are not willing to risk, as a result of the small dimension of the internal market and the difficulties to secure a constant supply for export due to the low production and lack of association. Finally this comparative study will point out what the Portuguese organic sector can learn with the German experience, namely in terms of organization and marketing and will present some examples of well succeeded Portuguese initiatives in this sector.

Alternative Food Networks. Patterns of organisation from a territorial perspective.

Matteo Puttilli (University of Torino), Egidio Dansero (University of Torino)

Originally defined and conceived as practices of resistance in front of a globalizing food market, Alternative Food Networks (AFN) have recently gained a growing international scientific attention and policy support in the field of rural development. This growing interest is built upon the assumption that AFN would perform better than conventional markets in many fields, such as quality, transparency, local specificity, consumers' trust and, last but not least, sustainability and revitalization of rural areas. Though, the international debate shows that AFN are a heterogeneous reality, may assume very differentiated forms and follow very different paths, both from the point of view of their objective (as they can be either alternative or competitive with conventional food markets) and from the point of view of spatial organization (as they can be differently embedded in local/global supply chains and markets). In the same place, multiple AFN may coexist and concur to re-define the food regime and the relationships between food production, distribution and consumption. Thus, the performance of AFN has to be valued from very different perspectives and avoiding generalizations. The objective of this contribution is to propose a critical reflection upon the relation between territorial organization and AFN, aiming at systematizing the complex reality of AFN identifying and describing the main pattern of organisation moving from a territorial perspective. The first part briefly presents the general debate upon AFN, then focusing on their relationship with territorial organization. Thus, AFN are described making reference to four different 'territorial' aspects: embeddedness in locality; scales of organisation; typologies of actors involved in the network; hierarchical organizational pattern. Moving from the multiple description derived from the first part, the second part applies the territorial typologies of AFN in the case of Piedmont region, Italy. Maybe more than in other European countries, Italian food culture is deeply founded on highly regionalized productions, with a long-lasting tradition in quality and direct selling. In this context, Piedmont is nationally recognized as a territory with a plurality of cultural-food sub-regions strongly embedded in typical production systems. In the last years, Piedmont has been widely interested by the diffusion of different typologies of AFN, from the worldwide known initiative of Slow Food (born in the cultural region of Langhe at the end of the Eighties and focused on the valorization of the cultural value of food) to many micro-experiences of farmers markets, direct selling, and other short supply chains in mixed urban and rural contexts.

City and agriculture: urban-rural links, farmers' representations and rationales in Pisa plain (Tuscany)

Salma Loudiyi (UMR Metafort), Elisa Marraccini (INRA-AgroParisTech ENGREF / UMR Metafort), Mariassunta Galli (Scuola Superiore di studi universitari e di perfezionamento S.Anna), Sylvie Lardon (INRA-AgroParisTech ENGREF / UMR Metafort)

For many decades, strong urban expansion has produced equally loss of agricultural lands in periurban areas, disconnecting major cities from their resource-bases and production systems that were historically associated with. Thus, urban-rural links have been weakened and for some cities, have completely disappeared. Nevertheless, developed countries are now facing new challenges in term of climate change, environmental stakes and food security that keep raising debates about agriculture and its contribution to the sustainability of rural - urban systems. Many cities are nowadays developing actions to re-design food procurement as well as some farmers (located near the city) are taking initiatives in relation with agri-food systems. Agriculture food function is thus rising with urban demand asking for local and secure foods. Yet, when city planners tackle open spaces, farmers' rationales and representations are not often integrated to the processes. In this research we aimed at understanding how farmers are integrating these issues. We wondered how individual and collective actions of farmers contribute to reinforce urban-rural links? What were the different city representations that lead such initiatives? Were there special adaptations to the urban opportunity and how these initiatives contribute to the sustainability of territorial systems? To answer to these questions, we studied the periurban area of Pisa (Tuscany, Italy), where numerous experiences in terms of alternative food networks have been reported and which presents still a large part of agricultural land use. By conducting interviews with farmers and other actors of the local food-supply chain, we investigated agricultural production systems diversity and how farmers represent and assess their related evolutions with the city. In particular, because our goal was to characterize and explain agriculture-city links through the food function following a sustainable perspective, from the farmers' points of view, we assumed that urban planners have to integrate farmers' individual and collective rationales to insure urban-rural sustainability.

The contested and congested spaces of local food supply

Lex Chalmers (University of Waikato)

The contested and congested spaces of local food supply Lex Chalmers, University of Waikato, Hamilton, New Zealand Markets for agricultural produce have long been a feature of human settlements, but the branding and commercial promotion associated with contemporary farmers' markets is a relatively new phenomenon in many countries. In the early literature commenting on the emergence of the farmers' market 'brand' they were presented in positive and largely unproblematic terms. The linkages to local farming,

circuits in the local economy and assertions of alterity or 'otherness' in relation to the commercial food retail sector characterise this literature. More recently, farmers' markets have become sites of contestation in both the public domain and academic discourse. One of the most frequent questions addressed in the discourse has been around the regulation of the farmers' market brand, with assertions that the success of the brand is dependent upon clarity and conformity in these areas. The first section of this paper explores the space of contestation in New Zealand, noting the roles of a variety of different actors interested in the governance of farmers markets. In the second section, the important role of Farmer' Markets New Zealand in local food supply is documented and used as a backdrop in a review of the congested space of local food retailing. Regulation issues in the Farmers' Markets of New Zealand has encouraged a variety of alternatives, from country markets, through local collectives organising food production and sale on a seasonal basis to the wholesaling of international produce. Congestion in the local food supply is examined through a study in which several forms of food production and marketing competed for custom in an area of less than 50,000 consumers. The concluding section of the paper argues that without effective governance and effective promotion of the brand nationally, the future of local farmers' markets is not secure.

Linking urban and rural territories: The meaning of agrarian landscapes. Some contributions from Catalonia (Spain, EU)

Alexis Sancho-Reinoso (Universitat de Barcelona), Joan Tort (University de Barcelona)

The concept of landscape (not just understood as the landforms of a certain area but also as the manner that such landforms are perceived by the population -Ojeda 2005) has arisen as a powerful tool to foster interdisciplinarity. At the same time, it also represents a challenge within Geography, in order to overcome the gap between the material and the non-material aspects that shape such concept. This paper is based on the solid tradition of landscape studies in Geography (Ortega Cantero 1987) and particularly focuses on the concept of 'agrarian landscape'. These 'agrarian landscapes' where strongly linked to rural landscape and thus to rural Geography (especially in French Geography -Meynier 1959); however, the fact that nowadays they correspond to two independent dimensions is self-evident (Paül et al 2011). The paper takes part of a wider six-year R+D project (divided into two periods, namely 2007-2009 and 2010-2012) aiming to identify, classify and assess Spanish agrarian landscapes. Such project is being financed by the Spanish Ministry of Science and its first partial results were recently published (Molinero et al 2011). The two authors of the paper are active members of it. The paper aims to present some results derived from the research undertaken in the self-governed nationality of Catalonia. Four case studies were selected in order to focus on the diversity of landscapes of Catalonia, especially in terms of their historical, geographical, economic and social significance. Three examples are devoted to marginal mid-mountain areas (i.e. the Pyrenees and the Catalan Coastal Ranges), while the fourth example is located in the metropolitan region of Barcelona (RMB), where the urban development is the main driving force affecting such landscapes. The results show, first, the dynamics that affect the landscape diversity and their spatial consequences (including changes in land-use pattern, a progressive dismantling of cultural landscapes and a loss of individual and collective identity related to certain places). Secondly, the research suggests the idea that the assessment of agricultural landscapes becomes an important indicator to evaluate (at least qualitatively) the connection between the local population and a certain place. These links lead to a certain degree of recognition of the existing agricultural landscape, not only from the point of view of the material reality, but also the intangible aspects (Roger 1997, Berque 2009). In some cases (i.e. the case study located in the RMB), such recognition could be exploited to overcome the blurred borderline between urban and rural societies.

Integrated Heritage Landscapes in Rural Areas as opposed to Open Space in National and Regional Planning: The Case of Communal Settlements in Israel

Irit Amit-Cohen (Bar Ilan University)

In recent years we have witnessed a tendency in many countries to include rural areas in the definition of open space: settlements and agricultural utilization of land, fields and orchards. Two reasons underscore this tendency: First is the massive pressure for development manifested in these countries with mounting apprehension of losing open spaces and damaging rural areas. The second stems from the similar characteristics of the two spaces (open spaces characterized by low building density, planted areas integrated in the natural landscape and low utilization variety), which underscore their contrast with the intensively developed urban texture. The debate on including rural areas in open spaces in Israel differs from that in other countries in several aspects: - The intensity of demographic changes, due to the intensive immigration within a short time span (950,000 immigrants in the years 1990-2000, ultimately constituting 15% of Israel's total population in 2000), as well as a very high natural growth rate. - Limited and restricted space - leading to mounting competition for every patch of land. - The powerful impact of the 'American Dream' of a ground level private home, due both to the competition for the land, as well as a social and political ideology that assigns social and cultural importance to land. - The uniqueness, from the social-cultural as well as planning aspects, of rural settlement in Israel, of which is the cooperative settlement form is most prominent. The purpose of this research is to examine the methods of preservation of rural textures (the rural grid, the agricultural land and agricultural infrastructures) and their unique cultural assets: their physical planning, built cultural heritage and agricultural landscape, and the manner of integrating it in the regional and national outline plans for open spaces. Such integration will make it easier to proclaim this entire area for preservation. The proclamation will be adjusted to the needs of the rural population as well as to Israeli population in general, and its economic, recreational, ecological and social needs. The adjustment will be made by creating a complex of rural heritage textures integrated with open spaces, so designated due to their high ecological value. The methods used in this research are based on field research, documentation and G.I.S. mapping of the historical findings. Integrating the historical findings with the national and regional outline plans for open spaces might help identify a continuum of landscapes defined and united by their common historical, economic, ecological and social values.

Searching for the village of tomorrow – Scenarios on the functionality of Bavarian villages in 2020

Anne Ritzinger (Akademie für Raumforschung und Landesplanung)

Rural settlements in Bavaria are undergoing fundamental transformations due to demographical change and structural changes in economy and agriculture. Predicting

future consequences arising at local level is complex and depends on various influences. The scenario technique is one way to support policy development under these uncertain circumstances. This paper presents four scenarios depicting the future of Bavarian villages in 2020 under different preconditions regarding spatial context and the range of functions and services villages provide for their residents. The scenarios illustrate possible future paths both in economically weak peripheral regions and in prospering agglomerations and outline how the functionality of settlements varies. Contrasting the multifunctional best-case scenarios with the monofunctional scenarios helps to set out strategies for successful village development: The provision of attractive living conditions in rural areas will depend on the consistent adaptation of planning instruments to new challenges and different spatial contexts, regional cooperation in municipal networks, anticipatory and community-based development of local strategies and a fundamental debate on lifestyle and values in relation to public services in rural contexts. Capacity-building measures for all actors and the encouragement of innovation prove to be essential success factors. The scenarios were developed in the course of a research project that examined the changes Bavarian villages will potentially undergo in future. The project resulted in suggestions for the adaptation of the Bavarian Village Development Program how to best support rural livelihoods under changing conditions. As the results of the study outline essential requirements for sustainable development of rural areas, they can be transferred to other regions with comparable situations. As the process of village renewal in Bavaria is based on a bottom-up approach, it assists rural regions to develop a culture of shared responsibility contributing to a de-centralized provision of public services and the achievement of quality of life in rural areas. The comprehensive planning process is an important basis for understanding correlations and for building up cooperation schemes with neighbouring municipalities as well as between different policy sectors.

Remarkable Villages: Local combinations of backwardness and development in small border villages in Western-Flanders

Frans Thissen (Universiteit van Amsterdam)

Villages near borders (language borders and national borders) face dual influences from their geographical position. They are coping with a peripheral position with respect to employment and service centers within their own territory. But at the same time they show sometimes specific local developments that are related to their boundary position. The Westhoek, the most rural part of Flanders (Belgium), is faced with persistent stagnation in small villages along the language border with Wallony and the national border with France. However, some of these villages show at the same time new local developments that are related to their border position. The national border between Western Flanders (Belgium) and the Côte d'Opale (Nord - Pas-de-Calais, France) exists 300 years in 2013. The language border with Wallony is of more recent date (1963). In this paper evidence is presented about the meaning of these two borders for the rural

border population in the Westhoek villages. The meaning of these boundaries for everyday life is described by the perceptions of the borders, the cross-border networks, and cross-border activities.

Das Gehoeft. Place/House: Living In (and with) History

Esther Hagenlocher (University of Oregon)

This paper concerns the Gehoeft, an archetypal Southwest German house. Gehoeft are built in clusters of one or more principal houses and other buildings, usually on a farm. I observed these Gehoeft, and if one part is more important than the others it is the courtyard, which provides access to all the structures in the complex. The entrance from the street to the yard is through the gate. The barn and stable are set back at right angles to the farmhouse, with other smaller buildings grouped loosely along the perimeter wall. The courtyard is effectively enclosed, providing the requisite workplace and storage room. The front section of the yard is semi-public and the rear/inside section is semi-private. This spatial organization reflected the lives and customs of generations of farmers and craftsmen. Unfortunately, these houses are now being neglected and are in danger of being lost. These observations have lead me to further questions about how the use of these spaces has changed over time, over the course of a day and how the fragmentary organization of the buildings relates to the growth of a family over time. How did the visual aspects, as described, correspond to the evolution of the families? How did the users change, the number of residents and the families? The purpose of this research was to look at the building type to understand both its current and future usefulness. The maximization and use of transitional space in the Gehoeft stands in contrast to the wasted space of much contemporary semi-private areas, and this is one reason for further study. This research has extended the basic knowledge of the Gehoeft. The methodology for this investigation entailed

Vicissitudes of Gentrification and Sustainability of Rural Areas in Japan: The Case of Hotaka District, Azumino City, Nagano Prefecture

Ryo Iizuka (Tokyo University)

Today, rural areas are changing due to globalization. The majority of rural areas are suffering from various problems and difficulties. On the other hand, positive tendencies have occurred in some rural areas. In those areas, farmers continue to reside and manage their farms, in-migration flow exists and rural environment, such as infrastructure, services and landscape, is improved. These positive movements are captured as rural gentrification and to reveal the nature of that phenomenon is essential for rural planning and sustainable rural development. Rural gentrification is the phenomenon by which rural landscape is changed due to the inflow of middle-class people from urban areas. In this context 'landscape' not only means the superstructure of landscape which is visible,

superficial scenery, but also includes the structure under-laying it, comprising invisible factors, such as population, society, economy and culture. The purpose of this research is to reveal the phenomenon of rural gentrification from the perspective of the interaction between the superstructure and under-laying structure of landscape in Hotaka District, Azumino city, Nagano prefecture, a Japanese rural area. To capture the superstructure of landscape, architectural style and roof style of buildings in the area were investigated. Furthermore, the under-lying structure of landscape was identified, using statistics analysis and interview data analysed by applying Q-methodology approach. We found that the inflow of population from urban areas affected factors which composed the rural area and as a result the improvement of the rural landscape occurred. Such landscape change and beautification became local resources which kept attracting people from urban areas. These interactions between the superstructure and under-lying structure of the landscape explain the process of rural gentrification. However, from late 1990's due to the decrease in land prices, new residential development disregarding of landscape value has occurred, and rural gentrification in the area has declined. Therefore, this research defines the development and decline of this area within the framework of rural gentrification cycle.

The Manor Douro house and its agricultural estate: A heritage to enhance while conserving and innovating

Maria Helena Mesquita Pina (University of Porto)

Keywords: Tourism, Rural Development, Sustainability, Landscape Heritage The emblematic Demarcated Douro Region is not only a privileged area where high-quality wines are produced, among which Port naturally stands out, but it is also an extended landscape that is home to a superb heritage reflecting centuries of history. Indeed, throughout its 250000 hectares, we find countless terraces laden with vines rising up the slopes of the Douro River and its main tributaries, as well as a valuable architectural heritage, which includes manor houses in agricultural estates or within the towns and villages. They are part of a breathtaking and distinctive landscape which was classified as "Evolving Living Landscape, World Heritage" by UNESCO in December 2001. Despite the region's heritage value and clear appeal, there is an acute diversity within the landscape in terms of the problems certain areas have to face, among which the stagnation/decline of the social and economic fabric is paramount, particularly within the wine sector. A sector which is, nevertheless, the region's economic backbone. In this setting, which urgently needs to be reverted, and at a time when the role of tourism is increasingly highlighted in regional dynamics, quite besides issues such as the restructuring of the vineyards and training of landowners and workers, how can spatial planning be developed without underestimating or defacing the region's many potentialities, particularly its architectural heritage? How can regional competitiveness be boosted and, at the same time, the sustainability of these landscapes and their heritage be enhanced? A strategy we can mention is centred on the manor houses and their respective

vineyards. In this paper, we present four examples of wine estates with a manor house and a wealth of history, that have overcome the stagnation with which they were afflicted, by following a strategy of combining winegrowing with tourism. The effects of these dynamics can be felt not only locally, but throughout the region as a whole. These four distinctive yet complementary examples include family-based approaches, under the coordination of landowners, who are over sixty years old in some cases, but quite young in others, as well as a holding which is currently integrated in a business group. In all the cases presented here, conservation has been combined with the sustainability of the investment and innovation, since what is at stake is an area that has been classified as a World Heritage site. To achieve this goal, we have followed a methodology which combines documental and bibliographical research which extensive fieldwork, including interviews in the selected units and the consequent processing of the information.

Development of Rurality-based on Tourism through the Commodification of Rurality in the Jike Area, Yokohama City, the Tokyo Metropolitan Fringe

Toshio Kikuchi (Tokyo University)

In this paper the author focuses on rurality as an option of urbanity in the Jike area, Yokohama city, the Tokyo metropolitan fringe, and discusses the sustainable commodification of rural space in the area. The traditional rurality consisted of farms, their community, their ecological bases such as farmlands and rural forests (satoyama), and economic activities such as farming and produce selling. This rurality was based on the interrelationship among these elements. Following his discussion, the author identifies some conditions that supported the commodification of rurality and their interaction in the outer fringe of the metropolitan area. In the Jike area, the decrease in area of rural forests has led to the decline of rural landscape; the development of affordable housing lots in the outer fringe and the continuous inflow of urban residents into the newly developed areas have led to serious conflicts between rural and urban land uses. Recently however, activities that aim at recreating rurality, such as conservation of rural forests, have been promoted as a means to mitigate such conflicts, and to develop these areas as nodes of rurality and urbanity. Thus, the perpetuation of rurality has been assured by the sustainable relationships between rurality and urbanity. With the recreation of rurality, rural landscape plays an important role in the commodification of rural space. Rural landscape in the Tokyo metropolitan suburbs is generally suitable for leisure and health-enhancing activities, because it is easily accessible for urban residents. Visitors are enjoying the rurality through walks, rural landscape observation, shopping for agricultural products and friendly exchanges with farmers. In spite of their advanced age, rural residents continue to cultivate crops such as 'hama-yasai (Yokohama grown vegetables)' and 'hama-nashi (Yokohama grown Japanese pear)' for visitors, and to preserve rural land use and landscape for themselves as well as visitors. In the process of recreating rurality, rural residents preserve their traditions and identity, their religion of rural life and the spirituality of the rural space. Urban residents, on the other hand, enjoy rural recreation, the

understanding of natural environment, and satisfy their inner yearning for a sense of belonging. Although some plots of rural forests in the Jike area were on sale (either by farmers under tax pressure or for the construction of a large scale housing complex), most forests were managed for the conservation of natural and rural environment by the association of conservation activities. Because these activities have become the node of rurality and urbanity, the conservation of rurality has been assured with the sustainable relationships between rurality and urbanity. The conservation of rurality leads to its commodification in rural spaces, which has played an important role in developing rurality-based tourism.

Cultivation abandonment and its regional characteristics and factors in Japan in the 2000s

Takehiro Morimoto (University of Tsukuba)

This study aims to examine the expansion of abandonment of cultivation in Japan, regional difference of abandonment, and regional characteristics of processes of abandonment. The author mapped the ratio and area of cultivation abandonment and investigated the relationship between abandonment and regional indices from the geographical point of view. He used agricultural census statistics of various scales and other sources on land use and regional characteristics. The results are described as follows: 1) abandonment of cultivation has advanced not only in less favoured areas but also plain areas, 2) the ratio of abandonment was higher in hilly or mountainous areas where population aging had progressed, 3) area of abandonment was larger in plain areas where extensive farming are minor, and 4) the policy measures against abandonment had been introduced but their effects were limited. Cultivation abandonment is strongly connected to contemporary economy, policy, and society in Japanese rural area. Societal factors such as aging, emigration and depopulation in remote rural area are major factors. Off-farm employment of farm family members has been a strong factor in wider area. Price decline of agricultural products has caused shrinkage of farming. Reductions of consumption and increasing in import of agricultural products through tariff policy change have resulted in a decrease of product price.

Change and management in peri-urban landscapes

Elin Slätmo (Department of Human and Economic Geography)

Topic 3: Rural-urban interaction and competition for land and resources Change and management in peri-urban landscapes Elin Slätmo In order to manage the rural landscape we must acknowledge what is changing it. Rural landscapes of Europe today are not only influenced by strictly agricultural activities. In addition to producing food and fiber, management of natural and cultural values along with opportunities for recreation and outdoor activities constitute an increasingly important role in goals and strategies of rural development. Acknowledging the range of activities taking place in rural landscapes of today, and that influential processes are working on different temporal and spatial scales, this paper aims to create a wider understanding about what is changing peri-urban land use and which possibilities spatial planning has to manage these landscapes. Land use change is primarily caused by human actions. To understand why land use is changing it is therefore necessary to investigate the drivers for human actions in the physical

landscape. In order to grasp the complex web of factors causing land use change it appears to be favorable to connect the concept of driving forces to a relational arena perspective, as it accentuates actions and events in the physical landscape. By the arena perspective's inherent emphasis on spatial proximity, the range of activities taken place in the rural landscape can be more carefully considered in the analysis of why land use change. The complexity of land use changes are here investigated by a case study methodology focusing on peri-urban agricultural lands, using interviews among stakeholders on several spatial levels and a document study of municipal and regional plans. Two case areas, the municipalities of Sarpsborg and Sandnes, characterised by a fast urbanization and high valued agricultural land in Norway are chosen. The results of the study show that maintenance of agricultural land in the peri-urban areas is strongly connected to political decisions in spatial planning. Even though regulations about maintaining an active agricultural land use is working as a strong friction in the Norwegian context, high prices for the land in the peri-urban areas creates a strong pressure to sell land for development. The selling is in turn strongly regulated by development decisions in the spatial planning. The strong influence of spatial planning on land use in the peri-urban landscapes implies that planning processes should be further scrutinized. Issues of specific interests are: which knowledge and data are used as decision basis in the planning processes? What synergies exist between different land use interests? How do power relations between sectors and institutional levels affect change and management of land? Key words: Land use change, driving forces, management, peri-urban, spatial planning

Regional Identity and Rural Livelihoods on the Eastern and Western Brazilian Frontier

Scott Hoefle (Universidade do Rio de Janeiro)

This presentation treats the relationship between regional origin and identity and different kinds of rural livelihood undertaken by settlers along the two major logistic axes of the BR-230/BR-163 and BR-230/BR-319 highways of northern Brazil. These axes now constitute the main eastern and western frontiers of the Amazon region and have attracted a diversity of settlers who practice very different kinds of agriculture with specific environmental and social impacts. Along the advancing eastern frontier in western Pará State small farmers who have settled along road heads of the BR-163 (Cuiabá-Santarém) and BR-230 (Transamazonian) highways are almost all from impoverished rural areas of the Northeast region and passed through years of gold prospecting before becoming semi-subsistence frontier farmers. Ranchers are usually of local urban origin or from North-eastern cities and after becoming successful merchants in the cities of Santarém and Itaituba later took up medium to large-scale commercial cattle raising in areas located up to 100km from these cities. Soybean farmers are almost all southerners with high levels of formal education and with a tradition of moving along the commodity frontiers of the Central-West region before establishing themselves near the Cargill export

port in Santarém. Along the advancing western frontier in southern Amazonas state Small frontier farmers who hail from all over Brazil have settled forested zones to the north, east and west of the city of Humaitá, located at the crossroads of the BR-230 (Transamazonian) and BR-319 (Porto Velho-Manaus) highways. Ranchers have settled in the same area and are usually southerners who arrive with capital and take up medium-scale cattle raising. Soybean and rice farmers are also from the South and South-east of Brazil and have moved along the commodity frontiers of the Central-West region before establishing themselves in a zone of savannah south of Humaitá.

Colonist evasion among agricultural settlements in Roraima State, Brazil: The latest Amazonian frontier

Alexandre Diniz (PUC-Minas), Felipe Borges (PUC-Minas), Elisangela Lacerda (PUC-Minas)

Brazil is notorious for its deep social inequalities, especially when it comes to its huge asymmetries in land distribution. Successive governments have consistently neglected this historical debt, dealing with the land concentration problem with policies limited in scope postponing the much needed agrarian reform. The traditional response has been the expansion of agriculture frontiers and directed or spontaneous colonization, which have led to tremendous environmental and social impacts, let alone the recurrent armed conflicts over land ownership. These processes acquire bitter implications in the Amazon region, which since the military governments (1964-1985) has been the subject of a series of development plans which called for the economic and demographic exploration of the region. Nonetheless, the colonization and settlement projects undertaken by federal and state governments in the region display low migrant retention rates. In the process, directed or spontaneous colonists are faced with all sorts of impediments to their subsistence in the agricultural settlements, besides being neglected technical and financial support by the state. As a result, colonists are forced to seek livelihood in the emerging urban regional centers, or new colonization areas, reproducing the vicious circle, recasting all social and environmental problems associated with it. This process has been organized by some authors on a series of linear stages models, in which time plays a significant role. As time progresses, agricultural settlements gradually move from pre-capitalist to capitalist modes of production, undergoing a series of landscape and social transformations, including the evasion of colonists. This paper examines the relationship between the age of agricultural settlements and the categories of settlers typified by the National Institute of Colonization and Agrarian Reform (INCRA), the Brazilian federal land granting agency. We explore various categories of colonists (seated, evaded, deceased, titled and transferred), seeking to analyze the process of colonist evasion in the Amazon region. To this end, we work with the records of the 66 official settlement projects led by INCRA in Roraima State, the northernmost Brazilian territory. We apply a series of ANOVA and correlation tests to explore the interplay between the proportions associated with each colonist category and the age of agricultural

settlements. Results confirm strong and positive relationships between age of settlements and the proportions of evaded, deceased, titled and transferred colonists; while holding a negative association with the proportion of settled ones. These findings suggest that processes observed in the Amazon during the 1970s and 1980s are still in course in the latest agricultural frontier areas of Roraima state, fact that demands urgent attention given its environmental and social repercussions.

Conflicts over land and natural resources at Madlangala Village, Eastern Cape

Musa Khanyile (University of KwaZulu-Natal)

Conflicts over land and natural resources at Madlangala Village, Eastern Cape Musa Khanyile University of KwaZulu-Natal South Africa The question of who accesses and controls land and natural resources is politically loaded and contested. The above situation increasingly becomes critical as the resource base diminishes. The majority of the communities in Eastern Cape depend on subsistence agricultural production, remittances and access to natural resources. There is awareness among these communities that a growing number of rural families have to share decreasing resources. Furthermore, deteriorating living conditions which reflect the lack of income generating opportunities and the inability to implement viable agricultural projects mean that community households also become reliant on natural resources. Failure to benefit from land and natural resource management practices or gain access to natural resources leads to inter-/intra-community tensions and conflicts. This paper examines the capacities and constraints related to the management of natural resources in marginalized communities. It also assesses issues related to governance, rural poverty, power structures and social differentiation.

Entreprise et développement durable en amazonie brésilienne: Le projet Vale Forestier de l'entreprise Vale

Jodival da Costa (Université de São Paulo/Paris Sorbonne)

En Amazonie brésilienne, la dernière décennie a été marquée par l'idée d'une « Amazonie durable ». Le discours de durabilité et de préservation de l'Amazonie est fortement inscrit dans l'orientation politique de l'état brésilien et des grandes entreprises. Dans ce contexte, ce travail analyse le « Vale Forestier » : projet de monoculture d'eucalyptus initié par la compagnie minière Vale en 2007. Créé par le gouvernement brésilien en 1942. La Vale, rapidement, devient l'une des principales entreprises brésiliennes. Durant les années 1960, début ses actions en Amazonie, à laquelle des gouvernements militaires mettent en œuvre plusieurs politiques territoriales dans la région. En 1997, la compagnie est privatisée. Dès lors, elle intensifie son action dans le domaine de l'exploration minérale. Dans les années 2000, investit d'une part, dans la monoculture d'eucalyptus, destinée à la production de papier et, d'autre part, dans la plantation d'autres espèces dans le but de créer des forêts de réserve pour les projets de Mécanisme de

Développement Propre (MDP). Aujourd'hui, la Vale possède plus de 30 millions d'arbres d'eucalyptus plantées, en 62 fermes, l'équivalent de 100.000 ha, la plupart est d'eucalyptus. Dans cette étude, nous proposons de discuter les impacts de ce projet à partir d'analyse des actions de la compagnie et, de ses alliances avec l'État brésilien, les grands propriétaires de terre et les mouvements sociaux. Pour cela, nous adoptons la méthodologie de l'échelle, pour étudier des plusieurs échelles d'action des acteurs. Tout d'abord, nous discutons le concept de développement durable et son appropriation en tant que discours par les grandes entreprises, mais aussi en tant qu'idéologie instrumentalisée par ces dernières pour qualifier leurs actions comme « environnemental corrects ». Ensuite, nous aborderons le projet Vale Forestier à travers ses impacts territoriaux, environnementaux et sociaux. Le Vale Forestier ne modifie pas la forme de l'utilisation de terre. Même avec actions environnementales importants, parce qu'elle dégrade moins le sol, le projet conserve l'ancienne structure de concentration de propriété foncière à la monoculture, l'utilisation de terre contenu dans les grosses détenues et contrôlée par des mécanismes du marché.

Impacts of the human activities on the fisheries resources of the Venezuelan Western plains

Luis Alfonso Sandia Rondón (Universidad de Chile)

The fishery resource of the rivers located on the Venezuelan western plains has constituted for many decades one of the most important base of economic development for this region. Its exploitation represents both the direct source of alimentation of the many towns and communities, and the source of incomes for the families, by means of the commercialization of the fishery production in the local and regional markets. Despite the importance of the fishery resource and its related economical activities, today there are many factors which affect its sustainability. In this paper, based on literature reviews and consultations with experts and local fishermen, some of the most important threats to the survival of the fish fauna with commercial interest in the area, are discussed. The deforestation of the high watershed, that impact negatively on the quality and the quantity of the water resource; the contamination of the natural water by the pesticides and domestic and industrial uses; the loss of the natural habitats along of the rivers; the overexploitation of the fishery resource; the inadequate fish methods; the poor observance of the legal normative; and the construction of the high and low dams on the rivers of the region; are some of the most threats for the fish communities and, consequently, for the daily work and the life of the fisheries communities of the Venezuelan western plains.

Geographies of local arrangements between farmers and other stakeholders for a sustainable urban agriculture. A case study in Western Africa

Ophélie Robineau (CIRAD/INRA UMR Innovation), Christophe Soulard, Patrick Dugué

In Sub-Saharan African cities, agriculture remains a key activity for many families and plays a crucial role in the supply of food to urban centers. However, urban agriculture is often marginalized. Thus, in countries where public policies are weak, informal modes of governance can often be observed to maintain it. Through the investigation of modes of governance (that we also call formal or informal arrangements), our contribution questions the socio-spatial integration of agriculture into an urban environment in a medium sized african city : Bobo-Dioulasso (Burkina Faso). Based on surveys, we have have built a typology of urban farmers according to their anchorage into the urban territory and connection to the urban market. Two main types were identified: 1) small-scale urban farmers highly anchored into the urban space (selling to the local market and depending on urban resources), and 2) specialized and speculative urban farmers little anchored into the urban space (they aspire to move their production to the hinterland and are oriented to the export market). When considering exogenous sustainability of both (that is to say, the contribution of agriculture to the sustainability of urban territories and the vision urban planners and citizens have about agriculture) we found that investigating informal modes of governance developed by small-scale urban farmers is relevant regarding the sustainability of their farms and their integration at local levels (in the neighbourhood). We are thus investigating informal arrangements to understand how small-scale agriculture participates to the urban life and which modes of governance allow it to maintain itself and be anchored into the local urban territory. From three cases study, we underline the interest to detect local and informal arrangements - which emanate from a poor category of dwellers and of urban farmers who maintain local forms of agriculture - to question the sustainability of urban agriculture and its scale of urban integration. This investigation, through a "geography of arrangements", questions the interest of 1) these local informal modes of governance to develop an integrated agri-urban strategy and 2) linking local solutions to institutional programs.

Demographic Dynamics and Livelihoods in the Forest: A Longitudinal Study for Machadinho, Brazilian Amazon, 1985 to 2010

Gilvan Guedes (Vale do Rio Doce University), Alisson Barbieri (University of Minas Gerais)

The main purpose of this paper is to discuss how the changing nature of household livelihoods in the Brazilian Amazonia over time may be explained by the changing demographic composition, their access and diversification of sources of income and welfare, and stages and evolution of frontier settlements the changing composition of their sources of income and welfare and stages and evolution of frontier settlements. In particular, we focus on the impacts, on livelihoods in the Amazon, of population mobility, intergenerational and government transfers, management of land, forests and natural resources, changes in household composition and contextual changes related to urbanization, and infrastructure development in the frontier. We use as case study a colonization project in the municipality of Machadinho. Colonist settlers have occupied this region since 1984, leading to important socioeconomic, demographic and environmental changes in the following decades. We build on two theories that place key individual and collective decisions at the household level: "household life cycle", and "livelihood approaches". These theories are particularly useful in understanding the many components of colonist's decision-making, individual aspirations of income and welfare, collective needs of familiar group(s) in rural settings, and the context (community, region, nation) in which these decisions are made. We use an unique longitudinal panel of plots and their related households based on field surveys carried out in Machadinho in 1985/1986 and 1995 (1,742 farm households); and 2010 (a sample of 259 farm households), allowing for a dynamic analysis of how a colonization area evolves through time. To our knowledge, it is the longest panel of farm plots in the Amazon, and the only one which follows colonists since the very beginning of the colonists' occupation.

Understanding the vulnerability of African farmers living with uncertainty

Shuhei Shimada (Tokyo University)

African farmers face increased vulnerability but at the same time they possess remarkable ability to respond to and cope with risks and uncertainty. Social relationships, among other factors, play an important role in the management of their vulnerability. This paper highlights changes in social institutions, from 1991 onward, within a village located in Central Zambia and discusses their effect on farmers' vulnerability. The following events

and changes were observed: 1) destruction of the Forest Reserve, 2) land dispute, 3) an eviction issue, 4) a weakening of group farming, 5) failure of the first savings and credit (S&C) program, 6) a growth in small-scale S&C groups, and 7) increases in the practice of lending cow and plow sets ('set') for cultivation and weeding. These events and changes can be explained happened in a process of modernization that evolved since 1990 in Zambia. However, from a vulnerability point of view, they should be interpreted prudently: the first five events and changes resulted in an increase in the vulnerability of farmers and the latter two had mitigation effects. The destruction of the Forest Reserve had direct effect on the access to common natural resources. The failure of the first S&C program had a negative impact on those who had intended to benefit from it. Land dispute and an eviction issue created a heightened feeling of mistrust among the farmers and shook the power of village head. The decline of group farming increased the vulnerability of ill-equipped farmers. In contrast, the growing of small S&C groups strengthened social relations by opening new channels with which to access resources and a proliferation of 'set' lending also helped to reduce the vulnerability of ill-equipped farming families. The increase in new S&C groups began in 2007 after the failure of the first S&C program which was initiated by a NGO in 2000. The practice of 'set' lending increased alongside the weakening practice of group farming. These findings suggest that institutional changes have both increasing and reducing effects on farmers' vulnerability. The vulnerability of farmers cannot be defined using a single index to reflect changes within an institution; instead, multiple indices should be employed. To cope with the difficulties related to uncertainty, farmers dispense with, invent, or restructure institutions in daily life, which may or may not increase the vulnerability of farmers. Therefore, to understand farmers' vulnerability we need to identify the nature of vulnerabilities influenced by institutional changes and then determine how to judge integrated vulnerability by synthesizing them.

Necessity and opportunity entrepreneurship in rural Vietnam – characteristics and performance

Jürgen Brünjes (Universität Hannover), Javier Revilla Diez (Universität Hannover)

In this paper we apply the concept of necessity and opportunity entrepreneurship to rural Vietnam. Our results show that, also in a rural developing context, necessity is not the most important motivation for starting a business. When comparing opportunity and necessity entrepreneurs, it becomes clear that rural opportunity entrepreneurs less often have an agricultural background and are better educated and skilled. In addition, they are more successful in terms of profits, even after controlling for general business and locational characteristics. Nonetheless, businesses started out of necessity are only less successful if they did not perceive an opportunity at the same time. Finally, only opportunity entrepreneurship significantly reduces the perceived vulnerability to natural shocks while necessity entrepreneurship appears to coincide with higher vulnerability to natural shocks. The results show that, although the concept has so far been primarily

applied to developed countries, distinguishing opportunity and necessity entrepreneurship is very suitable in a rural developing context if some contextual specifics of the rural environment are taken into account.

India's White Revolution & Cooperative Dairying in the Global South

Bruce Scholten (Durham University)

The United Nations declares 2012 the International Year of Cooperatives. Coops led India's White Revolution (Scholten 2010), by monetising European milk lakes into infrastructure that helped double per capita milk consumption and pass USA as top world producer. The UN Food & Agricultural Organisation (Dugdill, Phelan, Bennett & Scholten 2012) notes there is rising demand for dairy products in the Global South, and therefore: (a) Smallholders and women can earn more from 1-or-2 cows than crops, or contract labour, keeping children in school (FAO/IDF 2007); (b) Smallholder dairying stimulates more off-farm jobs than crops (Stahl, et al. 2008); (c) Lactose-intolerance may be a myth. Milk provides rare micronutrients. North Korean and Thai children quickly adjust to pasteurized liquid milk, and adults enjoy yogurt and cheese pizza (Bender, 1992; Ahmed et al., 2000; Dugdill, 2004; Dugdill & Morgan 2008a:p.11); (d) In livestock-fish-crops systems, cattle eat crop residues and provide energy, traction and fertilizer. Yet, while the East Africa Dairy Development project, launched 2008 by the Bill & Melinda Gates Foundation and Heifer International, is linked to cooperatives, India's National Dairy Development Board downplays coops. This paper analyses such policies vis-à-vis Ban Ki-moon's observation that: 'Cooperatives are a reminder that it is possible to pursue both economic viability and social responsibility.' (United Nations, <http://social.un.org/coopsyear/index.html>)

Transformation of Urban Spatial Structure under Service Economy: The Case of Beijing

Chaolin GU (Tsinghua University)

Urban spatial structure is the space projection of urban economic structure and urban social structure. Urban economic restructure must promote the transformation of urban spatial structure. Since 1949, almost all the Chinese cities have experienced their transformation from the service center to the production center. Since China launched the reform and opening up policy, especially after of the urban reform in the 1990s, city's role as the center of the region has been consolidated, and some cities have changed their urban functions from the production center to the service center. These cities have had rapid growth of service economy and also experienced urban spatial restructure and function shifting. This paper applies the data of added value in all sections of tertiary industry in Beijing between 1949 and 2010, and the data of land-use and layout in key periods. Special attention goes to the urban spatial structure transformation led by the development of service economy sections such as financial industry, wholesale and retail trade, information industry, real estate, renting and business services, science and technology, etc., since 1995, a year of which the output value of tertiary industry accounted for more than 50% of GDP. The paper analyzes four service economic models which are the industrial chain, industrial support, industrial integration as well as service outsourcing. It also interprets the internal mechanism and trends of service economy as transformation of urban spatial structure in Beijing. Key Words: Service economy, Transformation of Urban Spatial Structure, Beijing

Space of Creative Industries: a Case Study of Spatial Characteristics of Creative Clusters in Shanghai

Jinliao He (Geographisches Institut)

The rapidly emerging creative or cultural industries not only contribute to the growth of economy, but also to a revised spatial model of urban structure, helping in redeveloping old town spaces. However, the spatial characteristics of creative clusters, especially at the micro-city level, have not been fully examined. This study attempts to characterize the spatiality of creative clusters on the basis of literature review and empirical study of Shanghai. It finds that creative clusters are primarily distributed in inner-city, preferably located in districts of old factories/buildings and universities, embedded deeply in urban context and often boundary-blurred. These conclusions were thereafter proved by the evidence of Shanghai. The results showed that Shanghai is a particularly interesting case study for researching creative industries because of its special history and urban culture

which is distinct within Chinese cities. For instance, the old colonial zones play an important role in the clustering of creative industries. Moreover this case indicates that before the old inner-city in megacities of China really deteriorated, newly emerging creative industries re-occupied these abandoned urban spaces; meanwhile, to a certain extent, it enriches the classic models of urban structures. Additionally, a categorical differentiation of creative clusters in Shanghai was also noticed by this study.

Strategic choices in the regional planning of the Pearl River Delta mega urban region

Werner Breitung (Sun Yatsen University)

The Chinese Pearl River Delta Region is one of the major megaurban areas in China and indeed the world. It has developed into the current polycentric agglomeration of over 50 Million inhabitants largely without any regional plan under a regime of intraregional competition and disintegrated planning. Only recently, the Chinese Central Government has stepped in to outline directives for future coordinated and integrated planning. This step is relevant not only for the Pearl River Delta Region, but it is also meant to serve as a model for other Chinese megaurban regions. An additional significance lies in the inclusion of Hong Kong and Macau into regional planning considerations, which requires coordination across more than just municipal borders. This paper analyses the specific conditions for integrated planning in this particular region and presents then an overview over the recently developed planning outline. It highlights a new emphasis on major urban centres such as especially Guangzhou and Hong Kong and the related tension between coordination and competition of these centers. This points to the need for strategic choices first between polarisation and equal distribution of resources and second of the degree of competition desired. Further strategic choices concern the levels and institutional set-up of cross-boundary decision-making. The discussion will focus on these key questions, which are fundamental for regional planning in metropolitan regions in general.

Study on the Urbanization in Rural Area of the Mega City Tianjin

Guangwen Meng (Tianjin University)

The suburban areas in metropolis of China now often face the challenge of the shortage of construction funds and land in the process of urbanization. Hua-MingTown, based on the new model of land consolidation 'House Exchange with Homestead', not only provides a large number of urban construction land for the central city, but also provides the funds for rural urbanization. In this case analysis, this paper analyzes the background of the 'Model of House Exchange with Homestead' of Hua-Ming Town, describes the key contents and operational process of 'Hua-Ming's Model', and discusses the practical and theoretical significance of 'Hua-Ming's Model', such as the transfer of agricultural land, the standard of land compensation, intensive use of land, optimization of the industrial

structure, the urban planning and the integration between the urban and rural area, and reveal some still existence practical and theoretical issues .Finally, the paper summarizes a conclusion that 'Hua-Ming Model' is one of available solution for land and funds shortage in the urbanization progress in the suburbs of the big cities of China. Key words: land consolidation; House Exchange with Homestead; urbanization'Hua-Ming Town'Tianjin

Recent urbanization trends in Hungary. Suburbanization, desurbanization and/or re-urbanization?

Péter Bajmócy (University of Szeged)

The decades before 1990 were the years of the mass-urbanization (mass migration from rural areas to the large towns) in Hungary. After the change of political and economic system in 1990, new urbanization trends had been started. The population of the large towns started to decline, while population of the nearby villages and small towns started to grow because of the suburbanization process. The population of the rural areas stagnated on the same level in these years due to the out-migration of mainly poor urban people back to the countryside. In the last five years these trends changed again. The population of the large towns, especially Budapest started to grow again, because of the larger amount of the in-migrants from the rural areas. Large migration and population can be observed again in the rural areas, and also the increasing population and migration trends of the suburban areas started to decline. Nowadays the suburbanization, desurbanization and re-urbanization are concurrent phenomena in Hungary. In roughly 200 suburban and desurban municipalities almost 400 households surveys were queried. Using empirical and statistical data this paper aims to explore the motivations and behaviours of the migrating people. Suburbanization became the field of interest of migration issues in the last two decades in Hungary. In contrast desurbanization, which is a well known phenomenon in the developed part of the world, has been a rather neglected topic. The present paper examines the nature of desurbanization in Hungary comparing with suburbanization. It also gives a general view of regional differences of different urbanization trends in Hungary in an Eastern-European context.

Innovation nodes in collapse: Between competitive cities and exclusive areas

Helga Scarwell (Lab. TVES, School of Geography and Planning), Divya Leducq (University of Lille)

Everyone can read, here and there, that metropolitan areas have to aim for excellence, considering global competition and expected trickle-down effects for the bigger ones. This new context blatantly modifies planning and management of cities. Within this framework, implementation of spatial policies, as for instance, the ones based on knowledge economy, are introduced as innovative planning. Then, reshaping policies which affect urban space disclose social divisions, because the land-revaluing sometimes encourage gentrification of working-class areas. We can argue that it justifies the subordination of « innovative » city to economic imperatives and its conversion into a

tradable object of consumption. Benchmarking studies largely contribute to this phenomenon of « city branding ». Their communication systems use misapplications of notions and concepts, as for example « diversity » and « sociability », or extend new organic metaphor as « revitalization » and « renewal », which sound legitimate facing « urban shrinkage » rhetoric. Indeed, looking for more spatial justice will lead to take into account spatial inequalities, and more generally environmental inequalities. However, excellence investments bring technology and growth in a tricky issue, which creates recurring inequalities between human beings. Those innovative cluster policies also express unequal nature of urban and facilities planning at the environmental level and regressive nature of environmental policies at the social level. This paper aims to discuss about spatial justice concept from the role of knowledge economy within socio-spatial organization of city. We will focus on how planning tools, land control instruments and finance mechanisms produce urban spaces. To sum up, we will illustrate the debate networks/ territories thought a deep presentation of digital mega-projects in two different cities. The first field located within an ancient industrialized country, in the metropolitan area of Lille (Nord-Pas de Calais Region, France). The second field located in an emerging country's tier-two city named Pune (State of Maharashtra). The purpose is absolutely not to compare both, rather than highlight the common and different key issues within planning process of knowledge economy. In fact, and maybe more than anywhere else, observed gaps and geographical disparities on environmental level within these territories, prompt us to know better and bring in question some aspects of collective reality, even if it's strongly linked to resources issue. To what extent urban planning based on knowledge sufficiently consider gentrification phenomenon noticed on our cases studied?

Urban capacities to foster inter-organizational relations: Firms' board of directories linkages into Swiss cities

Olivier Di Lello (University of Lausanne)

Switzerland, and more precisely Swiss cities, can be considered as a relative attractive place for multinational firms in the world. The location of some big multinational firms and subsidiaries in this place can only witness of the attractiveness of Swiss cities. At a time when processes like globalization and financialization are always more leading the economy, the Swiss case analysis shows that finance and taxes are a decisive factor that could explain location of firms. Somehow, we suggest that processes acting at urban scale can also have an important effect on the global processes and should as well be taken into account as a major factor explaining multinational firm's location. From a worldwide database, containing information on multinational firms networks of subsidiaries (ORBIS, 2010 IGUL, 2011), we built additional information on board of directory of firms located in Switzerland (Orell Füssli, 2011). This kind of data brings a new network of firms that is not based on "classical" financial firms' ownership networks. Firms sharing together a common member in the firm's board could mean exchanging

different kind of knowledge. Thus, we built links between firms sharing common members. In fact, we suppose here that firms are not only exchanging between several unities belonging to the same multinational group, but that multinational groups are exchanging between themselves and exchanging with local firms, without having formal financial relationships. At this point, the role of location in a city or a region should be seen as an opportunity and a willingness to cooperate and exchange information with other firms. It results some intra and interurban linkages that one can analyse and interpret as the capacities of cities to generate agglomeration economies (intra urban links) or networks economies (inter-urban links). In this presentation, focused on such networks in Swiss cities, we figure out that some strategic and specific economic sectors are in the middle of these processes. Finally, to add a pure spatial dimension, we illustrate that some Swiss cities seem to be more central than others thanks to nodes of specific firms' networks and that they are playing a relevant role in the embedding process of firms at the local scale.

The Creation of the Metropolis in Post-Socialist Space: The 'Metropolis Silesia' in Poland

Jacek Petryszyn (University of Silesia), Alicja Szajnowska-Wysocka (University of Silesia), El'bieta Żuzaska-yko (University of Silesia)

When conducting geographical studies in the areas with increased concentration of population, which are mainly large city agglomerations or conurbations, it is essential to remember about proper evaluation of the urbanisation processes in this area. One of the symptoms of intensive urbanisation is metropolisation. It is a process of concentration of metropolitan functions in the growing centre of the metropolis. As for Middle Europe a post-socialist city (conurbation) should meet the following criteria to be recognised as a metropolis: the size of at least 500,000 inhabitants, significant economic potential, well developed high-level services sector, large innovative potential, presence of scientific as well as research and development units. The studies emphasise that not only a large mono-centric place can be a metropolis, but also several nearby cities may form one, creating potential development opportunities in the area of a vast technical conurbation of a metropolis with few centres. Selected functions occurring in 14 cities, that together with the surrounding municipalities form an area of the Upper Silesian conurbation in Poland, are the subject of the analysis in this paper. The main purpose of the study is the need to determine precisely the centres of the currently forming Upper Silesia metropolis, quite frequently called Metropolis Silesia. According to the given terms a metropolis should be characterised by metropolitan functions occurring in its territory. Among the institutions representing the high-order functions, colleges and various institutions engaged in education, research and development activity are frequently mentioned. All kind of high standard services for very demanding clientele, in other words, those defined as luxurious and costly are important as far as development of the metropolis is concerned. Finally high prices of flats, offered on the real estate market, are frequently treated as the evidence of a high degree of development of the urban centre. The Metropolis Silesia is an indispensable subject integrating a group of cities and urbanised housing estates in the centre of the Upper Silesia due to their post-socialist industrial genesis and poly-centric character. Due to a complex analysis of five selected factors determining development of the metropolis, a few potential centres which altogether form metropolitan centres have been chosen out of several dozens of cities. First of all the centre of Metropolis Silesia is very distinctly formed in Katowice. As the second metropolis centre, although with lesser significance and in some part complementary to Katowice, Gliwice at the western end of the Metropolis Silesia could be appointed. Sosnowiec, Zabrze, and Tychy also appear as auxiliary and developing centres of the vast metropolis.

Metropolitanization processes in Spain: from the traditional city to the "city of cities"

Rubén Camilo Lois-González (Universidade de Santiago de Compostela), Maria-Jose Piñeira (Universidade de Santiago de Compostela)

Since mid-1980 in Spain have been observed metropolitanization processes that have been favored by factors such as improvements in transport and communications, a favorable economic situation, the urge investment of the population and a neoliberal philosophy of urban growth that promoted the massive construction of new residential areas. In this context, the idea of traditional city that concentrates population, activities and services lost its meaning, and takes hold the concept "city of cities." Madrid, Barcelona, Seville, saw its population moved progressively to municipalities within its area of influence either because in them housing are cheaper either because they have a higher quality of life to live. The end result is that today we can see the Spanish urban system within a set of large urban agglomerations in which meanwhile the central city still has some weight, other smaller cities have gained a leading role and have a specific role within the set. Throughout this paper, we will establish a classification of the Spanish urban system, we will discuss the main urban areas, analyze what factors determined its development, study how are they articulated and what are the advantages and disadvantages we observe in them.

Metropolitan areas in Europe

Peter Schön (BBSR)

The new BBSR study focuses on redefining metropolitan functions beyond classical explanatory models. For that purpose, theories and patterns from the fields of social science and regional economics have been analyzed. Secondly, metropolitan functions and their spatial distribution in Europe have been analyzed. The result is an analytically and theoretically substantiated, comprehensive view of European metropolitan areas. In order to find appropriate indicators to give a quantitative description of metropolitan functions, a theory-based classification of clearly defined subfunctions is required. Based on the principle of the functional differentiation of social systems and on the findings of regional-economic theories, five areas of metropolitan functions were defined: "politics" including international relations of national governments and supranational organisations, "economy" including global production, trade and financial relations, "science" including globally significant universities, research networks and innovations, "transport" and its role in the worldwide networking of persons, goods and information and "culture" including arts and sports events being of worldwide importance. To operationalise the theoretical concept of metropolitan functions, 38 indicators were analyzed, meeting the following requirements: cover the whole investigated territory of Europe; defined for all countries according to standard criteria; high qualitative standard and reliable unofficial statistical data; exact geocoding of data on the level of local administrative units or based on exact

local coordinates; highly specified indicator value to depict the European and global context.

European cities' system: Between hierarchies and specialization

Céline Rozenblat (University of Lausanne)

The globalization processes developing during the second half of the XXth century were mainly supported by city regions that in turn encountered visible economic and social transformations since the 1980's summed up in a process called metropolization. Concomitantly, Europe built an economic and social space, strengthening interdependencies between countries, and integrating all together national urban systems. The European cities' developments are becoming more and more interdependent. Their specialization in a variety of urban functions is the result of their integration and their active role into multi-scalar networks of capital, enterprises, people, innovations and culture. In order to evaluate the role and position of each city in this European urban system, a multi-criteria analysis was conducted in 2011 on the European system of cities, following previous studies in 1989 (Brunet) and 2003 (Rozenblat, Cicille: presented in IGU Urban commission of Glasgow, 2004). To detect the metropolization dynamics, we collected for the 357 European Functional Urban Areas with more than 200,000 inhab., on a comparative way, more than 70 mixed urban indicators of stocks and flows, including criteria concerning 5 thematic: - Transport and communication, - Research and Innovation, - Economic functions, - Culture and tourism, - Political power. A multivariate analysis on 25 main criteria highlights the strong hierarchical differentiation as well as the diversity of specializations among European cities. If the diversity of urban activities is often linked with their size, there are specialities that follow other spatial organizations, selecting cities that appear as exceptions. The interpretation of these phenomena is made in terms of innovation waves and their diffusion, as well as network integration processes. This combines the two intrinsic dimensions of cities being both places of space and places of flows.

Villes et ports dans la globalisation: Le cas de l'Italie

Sebastien Antoine (Université de Bourgogne)

La position de la ville portuaire dans les différentes chaînes et réseaux de production, ainsi que la manière dont ces derniers s'inscrivent dans la "ville globale", comprise, suivant Peter Taylor, comme un ensemble de villes inter-reliées par des firmes de services avancés aux entreprises, n'est pas bien connue. Si l'Italie dispose de deux villes globales importantes, Milan et Rome, les deux grandes villes portuaires, Gênes et Naples, sont dans les profondeurs du classement des villes globales du GaWC. Si les villes portuaires cherchent en général à développer des services avancés reliés au transport maritime, du point de vue de la ville globale, les services avancés de très haut niveau sont associés à une économie d'urbanisation et non pas de spécialisation. Autrement dit, une grande ville a vocation à être reliée à une autre grande ville plutôt qu'à un port ou une industrie particulière. En se concentrant sur Gênes et Naples, ainsi que sur Milan et Rome, ce travail propose d'évaluer la diversité, ou, au contraire, la spécialisation dans le transport et la logistique, du secteur des services avancés aux entreprises dans ces quatre villes. Une méthode, développée par le laboratoire GaWC, basée sur la localisation des transactions entre les producteurs de services avancés et les industries clientes de ces services, permet d'attacher les échanges internationaux (commerce, industrie, transport) à la ville globale, et de cartographier des réseaux de villes à différentes échelles (régionale, nationale, européenne et mondiale). Les résultats préliminaires, qui se préoccupent seulement de l'échelle italienne, font apparaître la faible connectivité générale de Gênes, mais montrent la forte spécialisation de cette ville dans l'économie du transport maritime et de la logistique, de manière complémentaire avec Milan. Naples, quant à elle, dispose d'une connectivité nationale qui s'accroît. La ville se trouve en concurrence avec Rome à propos des services logistiques en relation avec Milan, tandis que les services maritimes proposés par le grand port du sud sont étroitement associés à Gênes. Enfin Milan et Rome apparaissent comme complémentaires, mais aussi concurrents sur certaines offres de services.

Strategic Development of Moscow as a Global City

Vladimir Klimanov (Institute for Public Finance Reform)

Moscow as the largest city in Russia and in the Eastern Europe needs to adopt a totally new kind model of its development. The city's economy has radically changed during the post-Soviet period. Moscow, which was the biggest industrial city in the former Soviet Union, has lost a substantial share of its manufacturing during last twenty years. Different service industries, including real estate and finances, have increased rapidly at the same

period. So, Moscow stands among other leading global post-industrial megalopolises now. Manufacturing accounts about 20 per cent of the composition of the Moscow's gross regional product including about 4 per cent for production and distribution of electric power, gas and water. The most of city's economy is therefore due to the service industries. In fact, the official statistics does not give real figures of them because of some specific methods of accounting. For example, banking and other finance sector production are in the so called non-regional portion of the Russian gross domestic product. So, the role of such sector in Moscow is higher in fact than according to formal figures. But concentration of finance capital has not decided many of current problems in the city's development of Moscow. These strategic problems include a low quality of life of citizens, lack or low quality of many public goods and social services, transport collapse and other negative elements of city's spatial structure. The latter is really a key limiting factor in the Moscow's development. According to different estimations, the pendulum migration to Moscow and back has increased to one and a half or even two million persons. But any united governance in the Moscow's agglomeration included the city itself and its region is absent totally. The expansion of the city's boundaries made formally in the beginning of 2012 is clearly unable to solve this problem. Moscow is also marked by high air and water pollution, reduction of green areas and quality of landscaped areas. There is a very low effectiveness of public goods in Moscow which were mostly inherited from the Soviet era. These problems are major hindrances to the development of Moscow as an international finance centre, a global city specialized in high-tech industry, knowledge production and one of the educational and cultural capital in Eurasia. Besides, to develop Moscow as a global city, it is necessary to aim the economic policy provided by the city's government to promote specialization in sectors those are typical for post-industrial megalopolises. To solve different problems in the Moscow's development is possible with realization of the draft city's strategy till 2020 prepared at the Russian Presidential Academy of National Economy and Public Administration and about twenty new city's target programs covered all industries and sectors.

Cities in multi-scale and multi-dimensional processes of globalization

Céline Rozenblat (University of Lausanne)

This study of multinational firms networks aim to explore the "duality" between world urban integration and firms' networks extensions, focusing on the imbrication of multi-scale advantages and on differences between economic sectors. An empirical study is developed on the network of the 1 million ownership links between direct and indirect 800'000 subsidiaries of the 3'000 first multinational firms of the world. All units have been located at the scale of cities (delineated in a comparative way). The multi-scale approach and the multi-dimensional one (by activity sector) show the remaining coherence of national and continental territories that interplay with cities in order to support and create these global links. A very new approach showing the intra-urban links has revealed the

importance of local linkages in the production of global networks. The main activities in the core of the whole networks are finance and information and communication, while the more growing sector seems to be the ones whose hierarchize more the cities: research and information-communication. In this respect, German cities and capital cities, which are specialized in these sectors, seem to have future advantage.

Busting Neighbourhoods in a Booming City: The Spatial Side Effects of Entrepreneurial Urban Politics in Tokyo

Ralph Lützel (University of Bonn)

Until a decade or so, Japanese cities were usually portrayed as displaying no social disparities or residential segregation of any relevant proportions. This was attributed to the effectiveness of a "state-centered political-bureaucratic" or "developmental capitalist" (Hill and Kim 2000) tradition of governance. From the enactment of the "Urban Revitalisation Law" in 2002, however, a new era of Japanese urban politics was ushered in that has been labelled "entrepreneurial" or "led by capital" (Jacobs 2005; Waley 2007). Spatially, and in Tokyo in particular, totally opposite trends unfolded: Whereas the city centre and part of the waterfront area were stylishly redeveloped to cater to the needs of foreign expatriates and the domestic upper middle class triggering a massive reurbanisation process in the core city area as a whole, many inner city areas and sections of the industrial north east of the Japanese capital were left in visible decline. While these transformations have been covered frequently already by either relating to isolated cases or macro-scale disparities between wards, so far no western-language papers and only a few Japanese studies have examined the topic of growing socio-spatial disparities at the small-area district level (each containing about 2,000 to 6,000 inhabitants on average). Furthermore, in regard to Tokyo deprived neighbourhoods have as yet attracted much less attention in the literature than reurbanised and gentrified areas. This paper will examine (1) to what degree urban politics in Tokyo have turned "entrepreneurial" in the sense of the eponymous concept evolved by David Harvey (1989), (2) what features deprived small-area districts are showing in the Tokyo core city area, and (3) which causes have led to their current state, i.e., can decline in fact be related to the entrepreneurial turn in urban politics? Since demographic change and growing socioeconomic inequality are currently the most heavily debated social problems in the Japanese media and academic discourse alike, the level of decline will be determined by using census data on population decrease and ageing, unemployment levels, and occupational status. By employing hierarchical cluster analysis, all districts of four selected wards are first classified into internally homogeneous groups according to these four variables. As a result, it becomes evident that there are three different types of deprived neighbourhoods in Tokyo. These types are then further characterised by including other variables what will add a diachronic dimension to my arguments as well as pointing at the causes responsible for deprivation. The findings of this study lend support to the hypothesis that entrepreneurial urban politics, in whatever cultural context they are

established, tend to worsen social conditions in certain neighbourhoods even amidst urban prosperity.

La gentrification, une stratégie municipale conflictuelle à Harlem

Charlotte Recoquillon (French Institute of Geopolitics)

La gentrification de Harlem est le produit d'une intervention publique massive et très volontariste qui a transformé le quartier par étapes depuis les années 1980 avec une accélération très forte depuis le début des années 2000. Cependant, la reconquête de ce territoire historique et symbolique, capitale des Africains-Américains par excellence, provoque de nombreuses tensions tant les intérêts sont contradictoires. Ainsi, des projets urbains comme la requalification de la 125ème Rue (le zonage étant devenu l'instrument préféré de Michael Bloomberg pour favoriser le développement économique) ou l'expansion de l'université Columbia ont donné lieu à plusieurs années de mobilisation, de conflits et de négociations. Les processus de consultation publique qui ont encadré ces projets se sont montrés inefficaces à désamorcer les conflits et n'ont pas permis d'aboutir à un consensus tant les rapports de force étaient inégaux. À la lumière de ces exemples concrets, cette intervention, basée sur un travail de thèse, explore aussi la question du droit à la ville et de la production de l'espace urbain dans un contexte de compétitivité entre les territoires accrue et où l'objectif de développement économique impose une quasi-dictature aux habitants. Pourtant, comment nous habitons la ville et comment nous y organisons nos sociétés est une préoccupation partagée par de plus en plus de citoyens et est, à ce titre, un enjeu démocratique et politique majeur. Ainsi, les débats sur le droit à la ville et la justice spatiale ont connu un vif regain d'intérêt. Cette intervention évoque donc à la fois les conflits engendrés par la politique municipale de revitalisation qui, de fait, gentrifie Harlem ainsi qu'aux tentatives de résistances citoyennes et les raisons de leur relatif échec.

Economic restructuring, 'counter-conduct' and local political representation – The struggle around big-box shopping in Vancouver, Canada

Marit Rosol (Universität Bremen /Universität Frankfurt)

In November 2007 Vancouver City Council decided to approve a rezoning application for a new 'big-box' store, submitted by a major Canadian retail and service chain. This decision had been preceded by an intensive public debate and a failed first application in 2005. The controversial rezoning application, expression of the expansive strategy of the chain, and the support by Vancouver City Council also led to a conflict around political representation of the adjacent neighbourhoods. Specifically, it started a conflict around the political mandate of a group watching over the implementation of a neighbourhood planning process, which had previously decided against such developments. Hence the group did not fight against the rezoning application only but had to fight for their political mandate as well. In my presentation I will focus on this struggle for a political mandate as

a form of local resistance. Particularly, I will present, how the concept of governmentality by Michel Foucault and his notion of governing as the 'conduct of conduct', of resistance and 'counter-conduct', is instrumental for analyzing the different strategies of resistance by opposing neighbourhood groups. The case is instructive because it shows how economically driven land use decisions are intertwined with questions of political representation.

Producing space for cosmopolis, urban development in Olympic cities in Europe: Lessons from Barcelona, Athens and London

Petros Petsimeris (Université Paris)

This paper analyses the production of extensive development sites within European cities occasioned by the attribution of Olympic city status, in order to examine the role that Olympic game mega events play inlevering contradictory urban developments on the host city-region. Planning policy responses to global and local investment-development trends are found to be reflected in the symbolic value of a number of urban projects. The focus is on three European metropolises that have been chosen to organize the Olympics: Barcelona, Athens and London. These are examined in terms of the location of new infrastructure and the social topography of the city, and the relationship between the rhetorics of urban development and the outcomes. Attention is paid to the social and functional transformation of the city in terms of shifting centralities, the production of new centralities, and deconcentration and urban sprawl in a context of Pax Urbanistica. The analysis suggests a number of cautionary tales for the dozen or so cities trying to compete for Olympic or other mega events.

Closing the City: Extinguishment of Rights of Way in Urban Ireland

Denis Linehan (University College Cork)

No national record exists of the extinguishment of rights of way in urban Ireland, in spite of the very significant consequences this phenomena has had on the social sustainability of neighbourhoods, and the implications it may have in reducing the mobility of people in local communities. This paper, based on collection and analysis of almost 600 closures in the last decade, provides unique insight into the contested politics of urban community building in Ireland, due to the intersection of the extinguishment of rights of way with issues around the geographies of youth, anti-social behaviour and urban design and planning

Changing urban living environments in the context of megaurbanization – perspectives from Pune, India

Mareike Kroll (University of Cologne)

The rapid urbanization process in India has a strong impact on living environments in cities. Especially since the liberalization of the Indian economy in the early 1990s, rapid economic and population growth in cities have induced fundamental changes in the physical and social environment, leading for example to land use changes and pollution problems on the hand and changing occupational structures and consumption patterns on the other hand. In the emerging megacity of Pune, the population has doubled in the last 20 years from 2.6 to 5 million inhabitants overstressing massively the existing infrastructure. Economic growth is giving rise to an emerging middle class and at the same time to a growing number of slum dwellers through immigration. The heterogeneity of the urban society and the steep socioeconomic gradient among different socioeconomic population groups are leading to an increasing fragmentation in Pune. Target of the paper is to present different living environments of distinct socioeconomic groups in Pune. Research is based on a household survey in six different areas in Pune: two urban middle class neighbourhoods with semi-gated housing societies and one traditional middle class neighbourhood in the old city centre, as well as three slum areas which are located close to the middle class neighbourhoods. Material factors such as housing conditions and income, social factors (occupational structures, education, social networks) and behavioural factors in the six research areas will be addressed. Further, changes in the living environments over the last decade will be brought up as well in order to understand the impact of urbanization and neo-liberalization in different socioeconomic

groups. The study exemplifies the process of fragmentation in a rapidly changing society as well as risks which occur with increasing socioeconomic disparities.

Internally Displaced Persons (IDPs) in the cities of post-Soviet Georgia: Coping with marginality and exclusion

Joseph Salukvadze (Tbilisi University), David Sichinava (Tbilisi University), David Gogishvili (Tbilisi University)

After the collapse of the Soviet Union, citizen's alienation and marginalization became a serious problem in all post-Soviet cities, as a significant part of the population has struggled to adjust to the new economic conditions. In Georgia this overall problem has been aggravated by an inflow of internally displaced people (IDP), fleeing from ethno-political conflicts and wars. In fact, IDPs have formed a distinctive group in today's Georgian urban society, which differs from the 'mainstream' social groups in terms of its identity, networking, mobility, residential and place-making patterns and which may be considered as one of the most socially and spatially excluded and vulnerable strata of the Georgian population. Can refugees/IDP communities successfully integrate into mainstream urban societies in Georgia? This is the main scientific question of the paper. The paper intends to explore social and spatial barriers for the inclusion of the IDPs groups into the 'mainstream' urban societies, based on the experience of a variety of urban contexts across Georgia. In particular, it reveals the role of social networks, informal and formal institutions, and spatial practices for either assisting or impeding the coping strategies that IDPs undertake in order to adapt to the challenging circumstances of their everyday life and to integrate into the mainstream societies. We analyze these issues in the context of adopted legislation and policies, strategies and practices of responsible public institutions, local governments, and planning authorities that are in charge of improving physical environment and housing conditions. As a result of the research we try to assess the correspondence of governmental policies with the real necessities and demands of IDP population, including provision of decent living and employment conditions and mitigation of barriers for their integration in respective urban societies. The scientific approach of the research is determined by the application of, and contribution to, a number of theoretical insights and underpinnings: theories of social capital, social networks and social mobility; conceptual developments on social resilience, including those on 'persistent resilience'; 'Multiple economies'; 'Right to the city' and post-socialist city. The empirical part of the research is based on data collection, and analysis from case study areas - mostly including the city of Tbilisi with the largest IDP population and one newly-formed IDP settlement. The research methods include: semi-structured interviews and focus groups with IDP communities and government officials; social network analysis; analysis of media and official documents (including statistical data); field observations; GIS (spatial) analysis of residence locations, including time series.

Socio-Spatial Integration in Late Modern Societies: The Case of Arabs in Israel

Izhak Schnell (Tel Aviv University)

Research on ethnic relations frequently adopts quantitative description of groups\' residential distribution and segregation and structural approaches focusing on the analysis of exclusionary forces. I study the more concrete everyday life practices claiming that parallel to the exclusionary forces, many Arabs in Israel seek socio-spatial integration. I aim at exposing Arabs\' routes of integration in Israel. I introduce a novel concept \'socio-spatial lifestyle\' as a tangible methodological tool that focuses on analyzing Arabs routes of integration and separation in Israeli everyday life. It is based on the assumptions that socio-spatial lifestyle capture both choices and structural aspects according to the Weberian model, it views individuals as active agents who participate in forming their social spaces and spaces are analyzed as networked spaces that may transcend local boundaries. Growing number of young Arabs seek to leave their traditional binding lifestyles seeking more complex individualistic repertoires of identities open to the broader society as part of the globalizing late modern world. In this context we ask two interrelated questions: To what extent and what forms of socio-spatial lifestyles are emerging among Arabs and how do they represent different levels and forms of exclusion vs. inclusion in the broader society? The research is based on a questionnaire that relates to five aspects of socio-spatial lifestyles: residential location; corporeal daily activity patterns; social networks; the structures of sense of attachment to places and communities; Attitudes toward self affiliation like gender, family, career, ethnicity leisure etc.

C08.34

Water Sustainability

C08.34-01 - GIS in water research (Hydro GIS)

Chair: Frank Winde

Synoptic visualization of dynamic changes in water flow and quality using GIS capabilities and slide animation

Emile Hoffmann (North-West University), Frank Winde (North-West University)

This paper relates to a DWAF-funded project aimed at the characterisation of impacts associated with the extraction of peat on water flow and quality of an affected wetland system downstream of the Gerhard Minnebron Eye (North West Province, South Africa). The focus of this paper is on the development of a methodology that assists with the synoptic interpretation of a range of inter-dependent hydrologically relevant parameters through a combination of GIS-generated data (ESRI's ArcGIS?) and animation capabilities of presentation software (Microsoft's PowerPoint?). The motivation for developing such a tool of visualisation, arise from the difficulties frequently associated with the interpretation of large data sets. In this case it comprises point data for parameters very different in nature (such as water level, rainfall, pH, electrical conductivity, water temperature, vegetation cover etc.) in their horizontal and vertical distribution (e.g. boreholes measured at different sites and at different depths) as well as their changes over time. While GIS components are used to transform the point data derived from weekly field measurements in different boreholes first into areal (2D) and later 3D information, animation techniques are subsequently employed to incorporate non-hydrological information such as observed changes in vegetation cover and meteorological data (rainfall, sunshine) and finally illustrate associated temporal changes at discrete (in this case weekly) intervals. Adding the time dimension to a 3D-reflection of the spatial distribution of measured parameters effectively creates a 3.5D model which allows for the simultaneous display of (quasi-continuous) changes of each measured parameter for all measuring points over a period of a full hydrological year. Combining the visualisation of the spatial distribution of water quality parameters and accompanying changes in rainfall and vegetation as main governing factors in wetland hydrology with a quasi-continuous display of their temporal changes assist with the synoptic interpretation of a very complex system of interdependent time series of several. Despite remaining on a semi-quantitative level (at best) the method was found to add to our understanding of interactions between factors in multi-parameter systems which otherwise appear dauntingly complex.

GIS applications as a tool for wetland research – generating high-resolution 3D-elevation models using free satellite imagery

Emile Hoffmann (North-West University), Frank Winde (North-West University)

This paper is on results of a DWAF-funded research project on characterizing the impacts of peat mining operations at the Gerhard Minnebron peatland (North-West Province,

South Africa) on the associated aquatic environment currently conducted at the North-West University, Potchefstroom Campus. The main focus is on using GIS capabilities and more specifically digital elevation models (DEM) as tools in hydrological research. 3D DEMs can be useful for a number of hydrological aspects of the project such as the delineation of surface water catchment boundaries associated with the wetland, the determination of potential inflow areas into the wetland during floods of adjacent streams and helping to find potentially exfiltrating or infiltrating conditions in certain reaches of streams and wetland areas. In order to generate a reliable DEM an accurate reflection of topographic features is essential. Using the standard SA 1:50000 topographic map series as a data source had a number of shortcomings. Apart from a lack of up to date data and the misinterpretation of some of the crucial hydrographical features, the contour intervals of 20m are too coarse to allow for an adequate reflection of the especially for comparably flat areas such as wetlands. Using contours, at 5m intervals, derived from 1:10000 orthophotos (from the then Chief Directorate Survey and Mapping) considerably improved the accuracy of the DEM. The DEM was still did not reflect relief changes of the study area at the needed level of detail. In order to overcome these problems freely available satellite imagery and collated elevation data provided by Google Earth was used. For the study area this imagery was updated three times since the project commenced. The imagery allowed for the detailed mapping of the recent hydrography and the retrieval of elevation data at 1m intervals. This paper describes a method through which point elevation data were converted into contours from a generated high-resolution DEM. Misfits between the different datasets were compared to each other and found that the highest deviations occurred in flattest areas. Recently contour data generated through an airborne radar survey were acquired that contained elevation data at 50cm intervals. From these contours a benchmark DEM was generated and used to assess the accuracy of the DEMs produced from different sources. It is concluded that in the absence of alternatives to often outdated and coarse 1:50000 maps, Google Earth imagery for sites covered at sufficient resolution constitutes a viable and inexpensive option to update maps and to generate high resolution DEMs. Generated DEMs based on the latter are useful tools to assist with certain aspects of hydrological research in flat areas such as wetlands and peatlands. However one must take into account that errors and uncertainties increase with decreasing relief energy and are therefore particular pronounced in flat terrain, where they are most needed.

Selection of Suitable sites for Water Harvesting Structures using Remote Sensing and GIS-A Case study of Solani Watershed, Uttarkhand, India

B.C. Jat (Govt. College, Neemkathana)

Site suitability studies for rainwater harvesting structures are an integral part of watershed management. The most important component of watershed management is the soil and water conservation. To deal with these aggravating problems different types of structures have been evolved which facilitate the rainwater harvesting. The structures are designed

based on a set of geographical factors. The major challenges are to find a suitable location for construction of these structures. Remote sensing and GIS application is needed, which is to be based on a set of geographical parameters for locating the suitable sites for the structures. The main aim of the study is to GIS application for the location of suitable sites for construction of different water harvesting structures. Selection of suitable sites for construction of farm pond and check dam was based on IMSD guidelines for water resources development and analysed using remote sensing and GIS technology. For construction of farm pond the suitable site were selected in agriculture, agriculture-plantation and barren land. In Solani watershed those areas were selected for construction of farm pond where flat topography with less than 5 percentage of slope and location having low soil permeability. In this watershed 1587.59 hectare area was selected for construction of farm pond. Results are displayed on the map, as the sites where the farm ponds are to be constructed for water harvesting. Selection of suitable site for construction of check dams was also based on IMSD guidelines. The parameters to be considered are slope(in percentage),HSG,lulc and stream order. Those areas were selected for construction of check dams where slope was 5 percent to 15 percent(moderately sloping to steep)and location having low soil permeability(HSG-D) on first to third order streams. In Solani watershed there were five sites selected for constructing check dams, from which two sites situated on second order stream and three sites situated on first order stream. Results are displayed on the map, as the sites where the check dams are to be constructed for water harvesting.In this study area, out of total area of the watershed 1687.59 hectare area is found suitable for construction of farm ponds and five locations are identified for construction of check dams.

C08.34-02 - Hydrological Process and Watershed Management in Arid Regions

Chair: Chansheng He

The anthropogenic influences on water resources ecosystem (case study of lake sevan catchment basin)

Vahram Vardanyan (Yerevan University)

In nature, surface and ground waters and their basins are subjected to anthropogenic influences; therefore, their water ecosystem is frequently disturbed. Lake Sevan catchment basin can serve as a typical example of this phenomenon. The rates of economic development, especially agriculture and mineral resource industry, promoted the growth of anthropogenic load that had a significant impact on water ecosystem. In Sevan catchment basin there are a few small towns and two-three dozens of villages, where several plant facilities have been constructed and exploited. Agricultural, industrial and domestic waste, mixed with regional surface and ground waters, flow into Lake Sevan and have an effect on its ecosystem. The rivers and streamlets, that flow into Sevan passing through the settlements and subjected to anthropogenic influences, greatly affect the lake's water ecosystem. The most significant influence on the basin ecosystem has been caused by the artificial decrease of the water level of the lake that has been realized in 1930s. The decrease of the lake's water level by about 18 meters (for elimination of irrigation and energy crisis) posed great hazard to the flora and fauna of the lake. This anthropogenic influence had negative effect on the lake's normal (regular) balance. The damages caused to Lake Sevan ecosystem forced to take a decision to stop decreasing and create conditions for raising the water level. In 1961, the construction of Arpa-Sevan large underground canal (48,3km) had begun, which was completed in 1981. On the one side, the water of the Arpa river flowing into Sevan yielded positive results, the level of the lake increased by several meters. On the other side, it had negative influence on the lake's ecosystem. Flowing through different types of rocks and passing about 48,3km, the water of the Arpa river, dissolves large amount of toxic chemical elements and heavy metals and carries it to lake Sevan; with relation to ecology, it has a negative influence on the lake's flora and fauna. Hence, humans must be consecutive in their activities in different spheres, so as not to violate the balance of nature or negatively influence the ecosystem of geographical mantle.

RCM-HM, Coupling Regional Climate Model and Hydrological Model for Watershed Modeling

Zhang lanhui (Lanzhou University), He Chansheng (Lanzhou University, Western Michigan University)

Simulation models are powerful tools in support of watershed analysis under climate change. This paper presents RCM-HM, an interface that links regional climate model (RCM) and hydrological models (HM) on a GIS platform to facilitate watershed modeling. The interface consists of seven modules: (1) a RCM input processor which processes input files and sets up parameters of regional climate model; (2) a RCM executor which automatically runs regional climate model; (3) a RCM output processor which converts output of regional climate model to appropriate input format of hydrological model; (4) a HM input processor which processes input variables of hydrological model; (5) a HM executor that runs hydrological model automatically; (6) an output visualizer which displays outputs of regional climate model and hydrological model in tables, graphs, and animations; and (7) a statistical analyzer which analyses simulation results of both climate model and hydrological model. Currently, the interface links the ICTP (International Centre for Theoretical Physics) regional climate model (RegCM3) and a distributed- large basin runoff model (DLBRM) for watershed modeling in Northwestern China. Databases required for the interface include climate, soil, digital elevation, land use/cover, hydrology, and management practices. Application of the RCM-HM to the study watershed indicates that it is user friendly, flexible, and robust, and significantly improves the efficiency of modeling process in hydrological response to climate change. keywords: Climate change; hydrological modeling; RCM-HM; GIS-interface; watershed analysis

Assessment of sediment transport processes on hillslope scale in semi-arid environments of Northern Tanzania

Geraldine Quénéhervé (Heidelberg Academy of Sciences and Humanities), Michael Märker (Heidelberg Academy of Sciences and Humanities)

Semi-arid environments such as in Northern Tanzania are characterized by a variety of degradation processes due to long dry periods and short but intensive rainfall events. Especially at the end of dry periods the landscape is characterized by a poor vegetation cover and low infiltration rates. Thus, first precipitation events generate high surface runoff rates.. To assess the terrain hydrological characteristics and overland flow generation dynamics we conducted hydrological measurements with Permeameters as well as Hood Infiltrimeters. Moreover, we tested a new minimal-invasive automatic Surface Runoff Detector (aSRD) for the measurement of surface runoff height on different slopes positions. The precipitation input to the slope system was measured with high temporal resolution from a close by digital weather station. Soil surface information was derived along a catena including grain size, organic content and shear strength. According to the pedo-hydrological conditions on the hillslope, a connectivity index driven sediment routing

was applied to transport the sediments down the river network and to quantify the sediment transport capacity. The study shows that with minimal invasive techniques also in difficult environments such as in Northern Tanzania detailed results on runoff generation dynamics and related sediment transport can be derived.

Effects of Precipitation Uncertainty on Modeling of the Heihe River Watershed Hydrology, Northwest China

Chansheng He (Western Michigan University)

The Heihe (or Black) River in Northwest China is the second largest inland river in China, with a drainage area of over 128,000 km². From the headwaters in the south to the lower reach in the north, it physically consists of the Qilian Mountain (upstream), the Hexi Corridor (middle reach), and the Alashan Highland (lower reach). The Qilian Mountain is situated at the south of the watershed, with a peak elevation of 5,584 m. Precipitation and snow and glacial melt in the Qilian Mountain is the main source of water supply for the middle reach oasis and lower reach desert. However, absence of weather stations in the high altitude (above 3300 m) often leads to uncertainties in precipitation estimates, which in turn causes errors in modeling of the watershed hydrology. This paper adapts the Distributed Large Basin Runoff Model to the Heihe River Watershed for assessing the effects of uncertainty in precipitation on the distribution of glacial/snow melt, groundwater, surface runoff, and evapotranspiration in the upper reach of the watershed. The simulated daily river flows of the 1990-2008 results show that Qilian mountain in the upper reach area produces most runoff in the Heihe River watershed. Errors in precipitation estimates have a large impact on modeling the watershed hydrology. Different efforts (e.g. multiple interpolation methods and installation of ground radar stations) are needed to improve accuracy in precipitation estimates and in turn the hydrological processes of the watershed.

Flooding of abandoned deep-level gold mines in South Africa: Risks vs. risk perceptions and proposed vs. alternative solutions

Frank Winde (North-West University)

Some 125 years after gold mining triggered the development of Johannesburg as one of the largest metropolitan areas in Africa, an increasing number of deep level gold mines across the Witwatersrand basin is no longer operational and associated underground void systems ('basins') are being gradually filled with infiltrating (ingress) water. Owing to the oxidation of sulphides contained in the mined gold ore and the resulting tailings much of the water is acidic and contaminated with a range of heavy metals including uranium. Experiences from the Western Basin that overflowed in September 2002 suggest that the uncontrolled decant of acidic water poses a serious threat to the receiving environment. Currently two more goldfields in and around Johannesburg are in the process of being flooded, namely the Central and Eastern Basin with predicted decant dates of mid 2012 and end 2014 respectively. Apart from polluting rivers and shallow aquifers in highly urbanised areas the decanting acid mine drainage (AMD) is assumed to cause geotechnical instability of high-rise buildings in downtown Johannesburg through the rapid dissolution of basement structures. Moreover, AMD is predicted to lead to the formation of sinkholes and increased seismicity. A report on AMD compiled by a Team of Experts for the Inter-Ministerial Commission recommends to prevent the rising mine water from reaching the surface through continuous pumping and the subsequent neutralisation and discharge into local streams. Cost estimates for implementing the pump-and-treat approach rose significantly over the past few months currently exceeding R1.3bn (> 130m). Based on a desk-top study which the Mine Water Research Group (MWRG) compiled for two major banking groups located in the Central Business District (CBD) of Johannesburg this paper presents findings that differ significantly in a range of important aspects from the official report including the rate of rise, sources and pathways of ingress and ways to manage it and, perhaps most significant, a different spectrum and appraisal of resulting risks. Regarding the latter it was found that the risk of water pollution, flooding and destabilisation of basement structures as well as the formation of sinkholes in the city centre were frequently overstated and sensationalized in the media which may have possibly unduly impacted on political decision making. Opposing the pump-and-treat-approach currently favoured by Government a number of low-cost, low-energy alternatives are presented aiming at arriving at significantly less energy- and cost intensive and thus more sustainable solutions.

Suspended sediment load below open-cast mines for ungauged river basin

Ludmila Kuksina (Moscow University)

Placer mines are located in river valleys along river benches or river ancient channels. Frequently the existing mining sites are characterized by low contribution of the environmental technologies. Therefore open-pit mining alters stream hydrology and sediment processes and enhances sediment transport. The most serious environmental consequences of the sediment yield increase occur in the rivers populated by salmon fish community because salmon species prefer clean water with low turbidity. For instance, placer mining located in Kamchatka peninsula (Far East of Russia) which is regarded to be the last global gene pool of wild salmon *Oncorhynchus* threatens rivers ecosystems significantly. Impact assessment is limited by the hydrological observations scarcity. Gauging network is rare and in many cases whole basins up to 200 km length miss any hydrological data. The main purpose of the work is elaboration of methods for sediment yield estimation in rivers under mining impact and implementation of corresponding calculations. Subjects of the study are rivers of the Vivenka river basin where open-cast platinum mine is situated. It's one of the largest platinum mines in Russian Federation and in the world. This mine is the most well-studied in Kamchatka (research covers a period from 2003 to 2011). Empirical - analytical model of suspended sediment yield estimation was elaborated for rivers draining mine's territories. Sediment delivery at the open-cast mine happens due to the following sediment processes: erosion in the channel diversions; soil erosion on the exposed hillsides; effluent from settling ponds; mine waste water inflow; accident mine waste water escape into rivers. Sediment washout caused by erosion was estimated by repeated measurements of the channel profiles in 2003, 2006 and 2008. Estimation of bank erosion rates was carried out on the basis of erosion dependence on water discharge rates, slopes and composition of sediments. Soil erosion on the exposed hillsides was estimated taking into account precipitation of various intensity and solid material washout during this period. Effluent from settling ponds was calculated on the basis of minimum anthropogenic turbidity. Its value is difference in background turbidity and minimal turbidity caused by effluent and waste water overflow. Mine waste water inflow was estimated due to actual data on water balance of purification system. Accident mine waste water escape into rivers was estimated by duration and material washout during accidents data measured during observation period. Total sediment supply from mining site is 24.7 % from the Vivenka sediment yield. Polluted placer-mined rivers contribute about 35.4 % of the whole sediment yield of the Vivenka river. At the same time the catchment area of these rivers is less than 0.2 % from the whole Vivenka catchment area.

Water management concepts in the coal mining areas "Ruhrgebiet" (Germany) and Xuzhou (PR of China)

Detlef Rieger (Emscher/Lippe Gesellsch. f. Wassertechnik), Johannes Meßer (Emscher/Lippe Gesellsch. f. Wassertechnik), Britta Kettelför (Emscher/Lippe Gesellsch. f. Wassertechnik)

For about 150 years, coal mining activities have effected the environment, economy and social development in the German coal mining area 'Ruhrgebiet', Northrhine-Westphalia. The mine working management has to consider the consequences of impacts and the necessity of measuring concepts. Operating concepts to restore ground water level, water courses, lakes and biotopes are necessary. The area of coal mining influence covers about 2.500 km² in six areas of mining activity. Mining subsidences cause depressions on the surface and ground water filtration spring. During the mining process, deeper ground water bodies are drained, the direction of flow can be diverted, the depths of ground water level is changed and regulated by wells and drainage systems. The quality of ground- and surface water bodies may be influenced by mining manufacturing plants and reactions in the subsurface. Inclines of water courses are disturbed; the properties of flow and ecology are modified. Intending to prevent degradation of protective goods, the environmental impact assessment became obligatory. For approval, expert reports including an environment impact assessment and measuring concepts have to be delivered to the mining authorities. They subject the results of monitoring and status/prognosis of maximum/average runoff rates, quality of ground- and surface water bodies, water level and flood plains, ground water level and changing geometry of lakes. The results are estimated applying criteria of water management and ecology. Measuring concepts intend reduction and compensation of negative effects, as for instance vertical filtering well systems descending ground water level, descending the bottom of water courses to recreate the properties of flow and ecological development. The target is to keep up the properties of ground-/surface water bodies and biotope areas. Interdisciplinary teams are engaged with the expert reports. Creating a master plan about sustainable water management for the coal mining area 'Jiuli' near the city of Xuzhou (PR of China), similarities and differences to the 'Ruhrgebiet' are noticed. Similarities are the conflict about mining activities and their influence to ground- and surface water bodies on one hand and the intended land use and ecological objectives on the other hand. In both areas, a sustainable development of the landscape is intended. Differences are ascertained in the legal obligations about mining, water management, ecology and the data base. The measures to be applied regulating ground water level, water courses, lake water levels and water pollution are similar in both regions. Key words: coal mining, measuring concepts, ground water level, surface waters, monitoring, recultivation, environmental impact assessment, sustainable development

Predicting hydraulic effects of mine closure on spring flow in dewatered karst aquifers of the Far West Rand goldfield (South Africa)

Aljoscha Schrader (North-West University), Ewald Erasmus (Geotechnical Environmental Specialists), Frank Winde (North-West University)

Mined ore deposits in the Far West Rand southwest of Johannesburg, South Africa, are overlain by an up to 1.200 m thick karstified dolomite aquifer storing great volumes of groundwater. Intrusive southeast to northwest striking syenite dykes subdivide the karst aquifer into single groundwater compartments showing water table differences across dykes of up to approx. 50 m. To reduce leakage of dolomitic groundwater from the aquifer to the underlying mine void in order to secure safe and economic mining three of the compartments were to some extent dewatered from the 1940ies onwards. Lowering of the water table of up to 1.000 m in places had profound environmental consequences such as extensive sinkhole formation and the drying-up of three high yield karst springs feeding irrigation farming as well as municipal water supply. After cessation of mining the compartments are expected to fill up again with naturally infiltrating water. Uncertainty exists, however, as to what the final elevation of the water table will be which, in turn, will determine whether or not the dried-up springs may ever flow again. The reason for this uncertainty are non-reversible changes in the hydrological system such as mining through dykes and hydraulically linking the previously disconnected compartments as well as increased groundwater recharge rates through the formation of over 1000 sinkholes since dewatering commenced. With ground stability, water availability and water quality being highly depended on the elevation of the final groundwater table, its reliable prediction for the post-mining period is of crucial importance for future economic and ecologic considerations. In this context the inter-compartmental groundwater flow through the pierced dykes is of particular importance as it will determine whether pre-mining water level differences between the compartments will be re-established or a single large so called 'mega-compartment' be formed instead. To predict the inter-compartmental groundwater flow long-term water level drawdown time series, in a sense resembling the results of an ultra-large pump test, are used employing different methodical approaches. Several aquifer parameters such as transmissivity and storativity are derived and used to predict the likely leakage to the mine void under fully re-watered aquifer conditions. Furthermore, comparing results of the different methodical approaches allows to assess the validity of applying Darcy's law to a karst aquifer.

Seasonal Change in the Water Quality around the Angkor Park, Cambodia

Hideo Oyagi (Nihon University)

A development of the Siem Reap basin has been recently planned in Cambodia. In addition, tropical lowland is a fragile area where global climatic change has a great effect on its physical environment. From such point of view, fundamental data on physical as well as human conditions should be collected and scientifically analyzed. The water environment research group investigated water quality such as chemical constitutions, turbidity and so on in the water at certain station around the Siem Reap city and some water areas of the Angkor monument area such as the moat of Angkor Vat and Angkor Thom to clarify their seasonal fluctuations as the basic information of the water environment. The purpose of the present study is to evaluate the flowing and physicochemical properties of Siem Reap River as affected by human activity. It is important to make clear the hydrological characteristics and their factor in Siem Reap River as a basic study in order to advance the environmental preservation in the Angkor monument area. According to the investigation on water quality along the river, the characteristic of river water quality is the type of Na/Ca-HCO₃. The type of Na-HCO₃ was mainly recognized through the city area. On the contrary, the dominant composition of water quality in the rainy season was the type of Na/Ca-HCO₃. Especially, Na⁺ and Cl⁻, it becomes the index of the human activity, are increased greatly around the city area. Of particular interest according to the flowing city is the increase of ratio of Cl⁻ to the total dissolved substances. The water quality of river during the rainy season does not appear to be affected by man activity. By comparing water quality from dry season to rainy season, difference is mainly recognized in the ownstream of the river. In dry season, the concentration of chloride ion ranged from 1.2 to 7.0 mg L⁻¹ in the Siem Reap River basin, whereas the concentration of chloride ion ranged from 1.4 to 2.0 mg L⁻¹ in rainy season. Especially, the phenomenon of high concentration of chloride ion was admitted after the flowing of the city area. Furthermore, the situation is worsened in the dry season when reduced water volumes increase the concentrations of dissolved substances in the water. It is considered that the phenomenon of the increase in chloride ion is caused by anthropogenic contamination.

Sustainable Lake Basin Management in Turkey

Muhammet Kaçmaz (Sakarya University)

Lakes are key components of our planet's hydrological cycle. They provide important social and ecological functions because much of the earth's available fresh water is contained in lakes. Despite their crucial importance, most lakes are undervalued and

therefore face stresses resulting from inappropriate management. These problems occur in developed as well as developing countries. Also Lakes are intimately connected to their drainage basins. For most lakes, the majority of water inflow comes from the surface catchment; a smaller amount enters the lake directly from precipitation, and some lakes have groundwater inflows. In this paper we examined the importance and the problems of lake drainage basins in case of the lakes of Turkey. Key Words: Lake Basins, Sustainable Lake Basin Management, Turkey

Urban water and sanitation under arid conditions in developing countries. Case study Bahawalpur, Pakistan

Daniel Wurster (University of Salzburg), Juergen Breuste (University of Salzburg)

Urban water and sanitation are a great concern especially in developing countries. In this case study in Bahawalpur, Pakistan, problems, people and local authorities are facing in a city located in a desert area, are investigated. Due to the meager regenerative properties of the groundwater caused by a precipitation less than 250 mm per year, along with a constantly growing population with rates up to 5% per year, it has become clear that without changing the water consumption behavior, this city will run out of water within the next decades. A survey with 2000 private households (randomly sampled within chosen representatives of urban structural units) and interviews with local authorities and experts have shown a severe lack of awareness about this issue. The water demand of 600,000 (est. for 2008) people is covered by an uncontrolled withdrawal by electrical pumps by the inhabitants from the fossil groundwater while the official water and sanitation is insufficient and constantly going worse. Due to this double tracked production system, the uncontrolled extraction, and the missing awareness of both people and administration, the groundwater table shrank by 4 meters within the last 5 years. Missing administrative awareness and control is expressed by a very low and arbitrary pricing and coverage. The responsible institutions are missing internal cooperation and are characterized by factionalism. The study shows up the governmental plans to solve the problems and discusses the chances of demand management and implementing appropriate technologies like decentralized sanitation, regeneration of groundwater by infiltration of processed sewage water or rainwater harvesting. Additionally a set of multiple scenarios has been developed to show up the expected advantages and disadvantages of several methods to incorporate a sustainable use. Keywords: Water and sanitation, Bahawalpur, Pakistan, arid climate, integrated water resources management, demand management

Domestic water management in the Ga West Municipality of Ghana

Yvonne Ami Adjakloe (University of Cape Coast)

The rising needs of water such as water for industrial and agricultural use have led to inadequate supply of freshwater for domestic use. Many homes now have to find ways of

managing water made available to them to ensure continuous supply. Domestic water in the Ga West Municipality in the Greater Accra Region of Ghana is accessed from groundwater, harvested rainwater, imported tap water, rivers and streams sources. Water from these sources is either expensive or unwholesome. This paper examines the coping strategies adapted for managing this domestic water supply in the Ga West Municipality in the Greater Accra Region of Ghana. Questionnaires were administered to 246 households and 29 stakeholders from the water sector were interviewed. The results of the study show that some homes re-use waste water to reduce the per capita intake of water by households. Others use traditional methods of purifying unwholesome water, while some households accessed water from more than one source to cut down the cost of accessing domestic water from a single source. It is therefore recommended that households adapt cost effective technologies that would allow purification of unwholesome water in large quantities and harvest rainwater in larger quantities.

Water demand in Windhoek, Namibia: Quo vadis?

Thomas Uhlendahl (Universität Freiburg)

Water supply is one of the major challenges in urban water management of Windhoek. It has reached its limits due to the arid climate and high variability in annual rainfall. The increasing water stress is mainly reinforced by the city's fast growing population, caused by migration from the north of Namibia to the informal settlements in northern Windhoek with rates up to 18% per year. Furthermore Windhoek is a city of local disparities reflected by the highest Gini coefficient in the world (HDR 2010, UNDP). These disparities are mirrored in the patterns of water consumption on household level. On the one hand, the rich people in the southern parts of the town waste water for irrigation of the lawn and filling up their pools. On the other hand, the poor in the north living in the informal settlements usually do not have access to water on their ground at all. At the moment, an approximate number of more than 100.000 people live in informal settlements with a low density or no communal water supply services in the area. A higher household income influences the water demand by the ability to have own domestic appliances needing water. In the informal settlements the water consumption depends mainly on water access. Households with access on the ground have a 3.5 times higher consumption per person and day rising with the household income. Rich people consume in average about 10 times of the poorest per person and day. The presentation results from a research conducted in 2010 on household level in Windhoek showing the disparities within the city. About 1000 households all over the city were interviewed on their water related situations and habits (Uhlendahl et al. 2010). The transdisciplinary survey was carried out in close cooperation with official and non-governmental organisations in Windhoek. Besides the actual status of urban water management and water pricing system in Windhoek and the challenge to supply the fast growing and developing population the paper presents latest detailed information on the daily water consumption at household level. This information is gained from different parts of Windhoek related to household income. In addition, it focuses on the purpose of water use in households as well as on the unequal access to water. Findings on the challenges in the field of sanitation, especially in the informal settlements, are also presented. Furthermore, the impacts of Windhoek's urban water management system on the Swakop River Basin are illustrated including the conflicts between the capital and rural areas. Finally, the presentation closes with Windhoek's strategies and activities to cope with mentioned challenges of fast population growth and aridity for a sustainable urban water management. Keywords: Urban water management, water supply, Water Demand, Household Level, Windhoek, Namibia, Disparities

Hydrochemical characteristics of inland waters in the Southern Carpathians with special reference to the influence of human activity

Kazuki Mori (Nihon University), Kazuko Urushibara-Yoshino (Hosei University), Dan Balteanu (Romanian Academy)

Quality and discharge of river water, spring water and lake water were investigated in September 2003 and August 2011 on the northern slope of the Southern Carpathians, central Romania. The main purpose of the present paper is to clarify the actual circumstance of spatial changes in water quality due to human activity. The study area has a mean annual precipitation of approximately 600 mm, and its land use is predominated by grazing land. A distinctive feature of spatial change in water quality was found in the headwater basin of tributary of the Danube drainage system. The concentration of dissolved substances in river water is at maximum value at the uppermost observation point, and decreases downstream by the effect of dilution. It should be emphasized that such a peculiarity in river water quality is closely related with the location of settlement. The settlement is located on mountain ridge in order to put sheep to pasture. For this reason, pollutant loads as derived from untreated household effluent and livestock excrement have significant effects upon water quality at the uppermost site on the river. It is pointed out that the effect of dilution by the confluence of tributaries is relatively high. Pollution by animal waste is also recognized in spring water in grasslands with comparatively high nitrate concentration. On the contrary, the concentration of dissolved substances for spring water, river water and lake water under no human activity shows lower value as compared with that in settlement, whose recharge source comes from only precipitation. It is concluded that the distinguishing features on water quality in the study area are consistent with both human activity and the nature of land use.

Impact of urban cemeteries on groundwater chemistry

Józef 'Zychowski (University of Cracow)

No comprehensive research has been carried out near cemeteries worldwide. The published results pertain to studies undertaken in different geographical and climatic settings, in various types of cemeteries, and the like. The contamination of groundwater in the surroundings of cemeteries results from the presence of increased levels of various ions, including: - chloride, nitrate, bicarbonate, sodium, calcium, iron, aluminium, lead, and zinc near graves e.g. at the Cemetery of Vila Nova Cachoeirinha, Sao Paulo, - nitrate and phosphate as well as ammonium, nitrate, orthophosphate, chloride, bicarbonate, iron, sodium, magnesium, zinc, and potassium, near new internments in a cemetery in Sydney, - nitrate, nitrite, chloride in Melbourne as well as phosphate ions in Sydney and in Perth, with small amounts of precipitation, - the total nitrogen, organic carbon, and increased 5-day biological oxygen demand of water as well as ammonia below a cemetery in Adelaide - orthophosphate and carbon dioxide found in other studies carried

out in Adelaide - chloride, sulphate, sodium and calcium in the lower part of a cemetery in Wolverhampton, while in the middle part of the cemetery, nitrate, sulphate, hydrogencarbonate, carbonate, potassium and magnesium ions were abundant. - phosphate (associated with the impact of cemeteries) and iron (typical of alluvial formations) at the Rakowice Cemetery in Cracow. The highest indices of contamination are found in those cemeteries situated in warm and humid climates, e.g. in RSA and Brazil. The majority of researchers believe that the highest risk from cemeteries comes from ions containing nitrogen and phosphorus, and also from bacteria and viruses. Markedly increased concentrations of contamination indicators, for example, ions containing phosphorus, nitrogen, as well as sulphate, chloride, and sodium ions, were found in shallow water, particularly in loose sands near burial sites. This issue has been highlighted in RSA, England, and Poland. In these water conditions, for example, in Wolverhampton, temporary high concentrations of copper, manganese and zinc ions, and the like, have also occurred. Additionally, the contamination indicators obtained under these conditions show considerable variability over time. Excessively high contamination of underground water is facilitated by a sandy and gravel substrate underlain by impermeable Miocene clays. The reason for a lower contamination of underground waters is a thick aeration layer below the burials (e.g. in cemeteries in Cracow). The issue of the adverse impact of cemeteries must be solved first in large cities where cemeteries are large, there is often a shortage of space for burials and additional land is in short supply. Implementing the idea of sustainable development also requires interment arrangements which take account of environmental concerns.

GIS-based modeling of the small rivers watersheds for the landscape planning of urbanized area (on the example of Tomsk agglomeration)

Alexander Erofeev (Tomsk University)

There are 509 small rivers with sum length 21317 km in the subject of Russian Federation - Tomsk oblast (Information bulletin', 2002). A lot of small rivers watersheds correspond the places of town foundation are located today in the huge urbanized areas. Typical example is Tomsk agglomeration where are situated the basins of Usaika and Samuska rivers, which are the subjects matter of the current research. The methodology of landscape planning in Russian takes into account of watersheds importance and surface run-off in insufficient volume. Many actual tasks of the flows generation did not research at the small rivers watersheds, especially for the specific physical geography condition and economical activity on Russian area. Current article investigates the problem-solving of synthesis of functional and structural landscape approach on the basis of theoretical model of small rivers watershed geosystems and physico-mathematical modeling of surface flow. Such synthesis opens opportunity of landscape ecology prediction and monitoring of geosystem state on antecedent data with minimum measurements. This research conduct with using of the analytical tools - modern GIS-software (SAGA, ArcGIS and others) which allows to compute a lot of geosystems parameters and modeling

functioning and dynamic processes. The processes of water flow are one of the main factors which are determined the structure and functioning of small range geosystem in humidic condition. The modeling of such processes is possible with the help of representation of hierarchy small range watershed on the topographic attributes which are described redistribution water by relief in gravitational field. The theoretical model of watershed geosystem structure was introduced for more correctly mapping of Ushaika and Samuska watershed elementary geosystems. Geosystems, which were created with such method used as polygon of landscape ecology monitoring for waterprotection zoning. Numerical simulation permits to determine the ultimate topographic attribute which is defined the small range geosystem differentiation more authentic. Such parameter is 'catchment area' (Syssuev, Sadkov, Erofeev, 2011). It defines area draining to catchment outlet and it is the basis for calculation of waterprotection zoning keyword rates 'time out' (meter per hour) and 'speed' (meter per second) of the surface flows. Summarize, waterprotection zoning of Ushaika and Samuska watersheds was perform on the basis of the multiparametric modeling. Offered approach can be used for the estimation of the potential pollution is associated with lateral migration of the water-soluble pollutant, such as maximum permissible level of pollution, potential damages estimation and modeling risk of emergency situation.

Water Resources and Climate Change in Israel

Nurit Kliot (University of Haifa)

Israel, together with almost all the Middle-Eastern Countries is classified as a country which suffer from absolute water scarcity due to the combined effects of high demand as a result of population growth and climate changes. The current water deficit in the water storages of Israel is below the Red Lines which point to a long process of unsustainable utilization of water resources in Israel. Israel is already experiencing a constant annual rise in temperature, increase in evapotranspiration, and a reduction in precipitation of about 5-15%. Climatic uncertainty and variability is expanding and it is anticipated that it will increase in the future. Examination of Israel's policies in the water sector reveals a contradicting sustainable and non-sustainable policies for coping with water scarcity. On the one hand, though Israel is a heavy user of irrigation water, water savings are very high due to technological innovations, utilization of marginal water-resources such as treated wastewater, storm water and saline water resources - all of which are considered as sustainable methods. On the other hand, Israel's major adaptation method to water scarcity is desalination of sea water (though saline water resources have been treated too). Israel is in the process of major development of desalination plants, currently producing 370 million/m³ per year which will expand to 750 million/m³ of water in 2020, a production which is not sustainable because of its environmental impacts mainly exacerbating emission of GHG. Israel is also criticized for very weak policy concerning water saving in the domestic sector - the most sustainable method to produce "new" water.

Assessing daily rates of evapotranspiration in the Jordan river basin: Simulations with the TRAIN model versus estimates from satellite data (Landsat TM)

Oliver Schmidt (University of Leipzig), Tobias Törnros (Heidelberg University), Michael Vohland (University of Leipzig), Lucas Menzel (Heidelberg University)

Water scarcity has been one of the most severe limitations in the Jordan River basin during the last decades, but the situation may even change for the worse dramatically by the impact of climate change and regional land use changes. Within the GLOWA Jordan River project, the spatially distributed TRAIN model has been used for a detailed analysis of water balance terms; special focus was on the evapotranspiration process at the soil-vegetation-atmosphere interface (actual evapotranspiration, ETa). TRAIN simulation runs

were carried out for the period from 1961 to 2005 with a grid size of 1x1 km. Thermal satellite imagery - in our study provided by Landsat TM - allows for the assessment of spatial variations of surface temperature and therefore provides a key for evaluating heat flux partitioning. Thus, when combined with ancillary data (e.g. a digital elevation model to simulate global radiation or measured air temperatures), remote sensing data can be used to assess daily rates of the latent heat flux (ETa) on pixel scale, and retrieved spatial patterns of ETa allows the ETa outputs of TRAIN to be evaluated. In our study, we used two different remote sensing approaches that both may be categorized as residual method, which is to calculate sensible heat flux (H) first and then obtain the daily latent heat flux as the residual of the energy balance equation. The first approach we applied was based on the gradient between the maximum surface temperature and the maximum air temperature to obtain H. As an alternative, a modified SEBAL (Surface Energy Balance Algorithm for Land) approach was implemented, which calculates H not from a gradient of temperatures but by contrasting two points, a wet and a hot pixel. For our presentation, a comparison between all ETa methods (TRAIN versus satellite data) is done by a set of selected areas that represent different land use types and a rather wide range of climatic situations; differences between the ETa retrievals are analysed and finally discussed.

The Impacts of Climate Change on River Regimes in Croatia

Ivan Canjevac (University of Zagreb)

Global climate change/variability in the last 30 years has been manifested mainly through average annual temperature rise, resulting in evapotranspiration and precipitation pattern change. Those changes have spatially different impact on river (discharge) regimes. An analyze of changes in river (discharge) regimes in Croatia was made for 53 hydrological stations for the period 1961-2009. To assess the trend, Kendall-Theil (Sen) non-parametric trend test was carried for the yearly and seasonal values of discharge. In addition, comparison of module (Pardé) coefficients between the standard thirty years time period (1961-1990) and the last twenty years period (1990-2009) was done. The results show changes on all analyzed rivers and stations. There is an evidence of redistribution of discharge throughout the year, increase of Autumn and Winter discharge (especially on rivers dominantly fed by snowmelt) and decrease of Summer values of discharge. In addition, we detected the change in the month of the appearance of discharge maxima and minima. Changes can be described through changes in regime of climate elements (temperature, precipitation, evapotranspiration). We also found evidence of intensification of the processes in the last 20 years.

Ice and water regime of the rivers of European Russia under climate change

*Natalia Frolova (Moscow University), Nikolay Alexeevsky (Moscow University),
Victor Zhuk (Moscow University)*

Specific features of water and ice regime of the rivers of European Russia as well as their spatial and temporal variability were studied using the up-to-date hydrometeorological data. Variations in the characteristics of water and ice river regime over the last 125 years are analyzed. For the some rivers potential changes in the dates of the appearance of floating ice and the breakup due to expected changes in the air temperature and the rate of streamflow in rivers are assessed. Special attention is paid to the factors that affect the formation of ice jams and their spatial and temporal variability for the northern rivers. It was found that under low flow conditions, autumn ice and slashed ice drifts became longer, ice jams more frequent, and freeze-up periods shorter. More frequent thawing spells resulted in decreasing ice thickness and snow storage in river basins. Winter break-ups were accompanied by ice jams and floods. High water levels during further freezing-up, as well as large amounts of slashed ice in river channels increased the risk of catastrophic ice jams. It is shown that changes of ice regime are mainly defined by features of water regime. The basic feature of modern changes of rivers' water regime on a prevailing part of the country is significant increase of low flow, especially in winter. Within the European territory of Russia for the majority of considered rivers significant positive trends of winter and summer-autumn low flow are marked. There is an increase of natural regulation of rivers' drainage. New maps of different characteristics of ice and water regime are presented.

Low flow on rivers of European part of Russia under the impact of climate change

Maria Kireeva (Moscow University), Ekaterina Rets (Moscow University)

Two periods of low flow can be emitted for the Russian rivers. The first is connected with cold season, and the second - with dry summer season. In terms of water management, several typical time ranges can be allocated within hydrological year, which started from seasonal flood. First of all the whole year is divided into unlimitative and limitative period. The latter endures approximately 3-6 month. Limitative period in its turn is divided into unlimitative and limitative season. Inside limitative season there is a one month with the lowest flow - limitative month. In terms of hydrological prognoses and standard studies such characteristics of a low flow as 3-6 monthly, 30-days, 10-days, 1 day average discharge and absolutely minimum discharge are used. The growth in water demand for industry and agriculture, as well as the population rise demonstrate increasingly urgent susceptibility of human society to low-flow period and droughts. That's why the questions, connected with low flow, annual distribution of flow and its variability become more and more acute. Such studies build up the basis for sustainable development. Low flow in case of social - economic damage can be classified as dangerous hydrological process. The spatiotemporal variability of low flow characteristics at different scales is discussed in this study. Specific review of small intermittent rivers low flow as the most sensible to climate changes was done. In general, an increase of low flow is identified for the most part of Russian rivers, that is connected with redistribution of flow within the year. Significant positive trends in winter and summer-autumn low-flow period runoff is observed for the most of rivers of European territory of Russia. The biggest change of low flow - more then 75% - is characteristic for the upstream of Oka and Ural rivers. The significant change in low flow occurred on the rivers of southern part of forest belt, eastern part of forest steppe zone and in the most part of Ural River basin. The winter period low flow has increased by 45-70% in Volga and Don River basins, excepting Kama River. The mean low flow value has shown a statistically insignificant decrease or rise in the North of European part of Russia and also to the South of Tsimlyanskoe reservoir. The increase in low flow is connected with the rise in air temperature during the cold year period, which leads to growth in snowbreak amount and length, decrease in duration winter season. Low flow is the most sensitive to anthropogenic pressure phase of the water regime. Economic activity has a great influence on the distribution and variability of all low flow characteristics. Rivers' response to the climate change varies depending on anthropogenic stress rate.

Expectations of water resources in the future climate in Alpine area

Claudio Cassardo (University of Torino), Naima Vela (Department of Physics), Marco Galli (Department of Physics)

The projections for the future Alpine climate show an increase of temperatures by 2.6'3.9 °C above the 1990 level by 2100, and a decrease in summer precipitation, accompanied, in most regions, by an increase in spring and winter. In addition, winter precipitations will increasingly fall as rain rather than snow, leading to fewer days with snow cover. The warming and associated reductions in snow and glacier cover could have grave impacts on water resources, influencing the hydrological cycle in the Alps, leading to more droughts in summer, floods and landslides in winter and higher inter-annual variability. Our study has analyzed in detail the hydrological budget by running a land surface model (UTOPIA) driven by the output of a regional climate model (RegCM3), in turn driven by a global climate model. The simulations have been carried out over a time span of 30 years for the control run (1961-1990) and for the A2 future climate scenario (2071-2100). The simulations show that, in the future climate, evapotranspiration will increase during summer, causing a decrease of the soil moisture that, in most plain areas, will go beyond the wilting point. In mountainous areas, the snow cover will almost completely disappear during summertime, and the period of the year in which the soil is not covered by snow will generally extend by about one month. During winter, the precipitation will be slightly larger than in the control run, causing a small increment of the soil moisture, that will approach the field capacity. Occasionally, convective systems during autumn, winter and spring can produce large precipitations falling as rain also at high elevations, increasing the risk of floods. Thus, the most important characteristic of the future climate is not only the increment of the mean temperature but the depletion of soil moisture, observed both in the Po valley and in mountainous areas. Taking into account the large interannual variability of hydrological variables registered in the PC in those areas, it is expected to have longer dry spells and hence drought conditions and heat waves. As most plants that produce food (e.g., wheat, rice, maize and grapevine, just to mention some of the main products in the Po valley) intensively grow in summer, the elongated drought conditions will exert significant effects on the agricultural production. Other activities related to water supply (e.g., industry, hydroelectric power production, etc.) could suffer serious problems, which could reflect harmful impact on economy and human health in local regions. On the contrary, during winter in the future climate, precipitation will generally increase and, in spring, snow melting will occur earlier by about one month, thus resulting in increase of surface runoff in spring. Again, taking into account the large interannual variability of the precipitation, this will bring about increase in the probability of floods in the future climate, especially in spring.

Hydrological Dynamic of the Bocono River Basin – North Venezuelan Andes using the J2000g model

Joel Mejia (Universität Tübingen), Volker Hochschild (Universität Tübingen)

The tropical river basins are going under growing pressure due the population increase, and the effects derived from the Land Use / Land Cover (LULC) dynamic and the climate change at regional scale. The aim of this still ongoing project is to assess the hydrological dynamic of the Bocono river basin, located at the north part of the Venezuelan Andes, and the possible impacts derived from LULC change and climate change on the hydrological response. For this purpose the hydrological balance under different conditions were simulated using the model J2000g, which is a modular, process-oriented and distributed hydrological modeling system, that implements encapsulated process modules for the simulation of hydrological processes. A methodological approach combining remote sensing and GIS was implemented in order to process the spatial-temporal raw data required for the modeling system, and the model with the various scenarios was built using the JAMS modeling framework. The first simulation results shows that the hydrological response could be reasonable modeled, despite of the relatively scarce raw data basis referred to the hydrometeorological variables. However, a calibration process will be necessary in order to get more realistic results. Hopefully, the results can be a useful basis to promote more effective area-oriented policies within the watershed management. Key words: hydrological dynamic, tropical river basin, J2000g model, watershed management.

Hydrological budget verification in present climate in the Alpine area and Po valley (Italy)

Claudio Cassardo (University of Torino), Marco Galli (Department of Physics), Naima Vela (Department of Physics)

The typical way of examining the future climate characteristics is to compare the simulation results relative to the last years of this century (for instance the period 2071-2100) with a similar period belonging to the past century (for instance, the period 1961-1990, or 1971-2000, or 1981-2010). The use of such kind of methodology will allow the comparison of simulations results obtained using the same methodology and model for present and future climate simulations, in order to exclude any possible source of anomaly in the result analysis, which may be caused by the use of different input data, or grid irregularity, or missing observation interpolation. However, one of the basic questions at the basis of this methodology is the ability in reproducing the most relevant characteristics of the present climate. To give a quantitative answer at this question, an intercomparison project has been planned. The best way should be to compare the simulation results in the surface layer with the observations. Similar works have already been carried out by using as target variables the screen level temperature and the precipitation, which are the most widely observed variables in the surface layer. However, we are interested in analyzing also other variables, as the components of the energy and hydrological budgets in the surface layer, or the soil temperature and moisture, that do not are currently measured extensively on a mesoscale area and for a sufficiently long time to carry climatological analyses. For this reason, we have considered the use of the CLIPS (Climatology of Parameters at the Surface) methodology, ideated with the aim to create an archive of parameters in the surface layer (as well as in the soil and vegetation) in areas where real observations of land surface variables are lacking. The idea of estimating the above mentioned values by using a trusted numerical model could alleviate this kind of problems. Fundamentally, the CLIPS is based on the output of a Soil-Vegetation-Atmosphere Transfer (SVAT) scheme, driven by meteorological observations gathered at some meteorological stations. The application of such approach for a long period (e.g., several years) may create a climatological archive of land surface data over some selected areas. Thus, in our study we have used the same land surface scheme (UTOPIA) for two kind of simulations. In the first one, UTOPIA was driven by the output of a regional climate model over a time span of 10 years (2001-2010). In the second one, by the meteorological observations carried out in a mesoscale area in the same period. Then, the two databases have been analyzed from a statistical point of view in order to infer the main climatic characteristics. At the moment of the abstract preparation, the

work is still in progress. During the talk, the main results of the intercomparison will be presented.

How to avoid global water crises – conservation, innovation or what?

J.A.A. Jones (Aberystwyth University)

The world's per capita water resources have diminished dramatically over the past half-century and the projected explosion in the global population is likely to halve them again over the next 25 years. The UN Millennium Goals aimed at halving the number of people without access to safe drinking water and improved sewage between 2000 and 2015 are badly off-course. Population growth is a major factor, but lack of funds and political issues are also playing a part. The global recession is set to aggravate the problems, as will global warming. Growing regional disparities in wealth and resources could foster conflicts and hinder progress. Past approaches to water resource management have relied too heavily on 'one solution fits all'. Future solutions will need to pay more regard to geographical differences and to develop a variety of sources, perhaps relying less on large dams and centralised sewage. The paper discusses the potentials of a range of new technologies, including desalination, weather modification, rainwater harvesting, snow reservoirs and icebergs, the direct use of seawater and submarine freshwater sources, and human-scale waste disposal and purification systems. Above all, future solutions will need to pay more regard to more integrated management of water resources and the wider environment and the national and local needs of people.

Turbidity for monitoring of sediment transport in rivers

Sergey Chalov (Moscow University), Ekaterina Belozeroва (Moscow University)

The total suspended sediment concentration SSC is a major parameter in fluvial processes. The procedure of measuring SSC is regarded to be time-consuming leading to development new techniques of fast and simple measurement. Turbidity T measuring is alternative way to determine sediment load. The main issue is to estimate turbidity units (NTU) through SSC units (mg/l) via special calibration curves for each stream and water stage. We synthesized results of simultaneous SSC and T measurements in order to understand geographical effects in $SSC=f(T)$ relationships. In our field experiments samples were filtered through preweighed membrane with a filtration system "Millipore". The samples then were oven-dried and reweighed. Turbidity was measured by "HACH" 2100P device. The SSC and turbidity empirical relationships were conducted from rivers draining various environments in different seasons (from high-water to low-water periods). Water samples were collected in rivers of the European part of Russia (Sukhona, Mezen, Pechora, Moscow, Oka, Protva, Sylva, Bol. Kokshaga, Sok), in the mountain rivers of Koryak plateau (Vyvenka and tributaries) and western slope Caucasus (Mzymta and others), in rivers of the south Eastern Siberia and south Mongolia (Selenga river basin). According our results the best-fit SSC and turbidity relationships were linear: SSC
