$= a + bT$, where a and b were regional empirical coefficients. It was found that " a " grows with increasing amount of organic matter. Coefficient b is in ordinal relation with average particle size d . The steepest increase of the SSC with T was found for rivers of the East-European plain under ice-cover conditions with the biggest average particle size ($d = 0.23$ mm) and no organic matter. Equation for the Sylva and Bol. Kokshaga rivers was $SSC = -1.57 + 2.53T$. Middle rivers of the Central Russian (Protva, Sok) are characterized by the smaller average particle size ($d = 0.17$ mm) and medium amount of organic matter. The yielded correlation is $SSC = 4.14 + 0.93T$. Similar conditions were found for the large plain rivers of the East-European plain (Sukhona, Mezen, Pechora, Moscow, Oka) where amount of organic matter is more and average particle size is less ($d = 0.09$ mm). The equation for large plain rivers was $SSC = 7.59 + 0.84T$. Finally, in significantly altered environments (placer-mined in Koryak plateau in Vyvenka drainage and disturbed landscape of Mzymta basin in Sochi region of Caucasus) the polluted mountain rivers give a great access for the fine particles ($d = 0.02$ mm). The relationship alters gently $SSC = 1.92 + 0.75T$. For the SSC and turbidity relationships correlation rates were significant ($r > 0.9$).

River flow in the alpine zone of North Caucasus under the influence of recent climate change

Ekaterina Rets (Moscow University), Maria Kireeva (Moscow University)

The North Caucasus mountain system is situated on the southern border of European territory of Russia. Its length is more than 1100 km, the highest point is Elbrus (5642 m). The alpine zone extends above the orographic snowline (the lower bound of perennial snow), which heights is approximately 2000 m in North Caucasus. An increase of precipitation with altitude and the additional contribution of perennial snow and glaciers determine the definitive role of alpine zone in mountain rivers flow in midlatitudes. The modulus of flow is 2-3 times bigger in alpine zone then in the lower territory in North Caucasus. Consequently, the amount of flow and water regime of alpine zone defines the availability of water recourses and the risk of hazardous hydrological processes in the mountain river basins. The methods of mathematical statistics were used to characterize the spatiotemporal distribution of climate and river flow characteristics in alpine zone of North Caucasus. As for the recent climate change, although the overall picture is quite heterogeneous, it is possible to point out some common tendencies: 1) an increase in total annual precipitation in the central and western part of the territory and a decrease in its driest, eastern part; 2) an increase in the snow-to-rain ratio (P_{snow}/P_{rain}) in most sites; 3) a decrease in the number of days with negative temperatures in the year; 4) a decrease in mean winter temperature in the mountain territory. During 1970-2000, the area of glaciation dropped by 12.6%, the volume of ice by 14.9%, the number of glaciers increased by 2.4%, and the length of glaciers dropped by 100 m on average. The main characteristics of river flow haven't shown as yet any significant change on temporal scale in the alpine zone of North Caucasus. A physically-based mathematical model of

snow and ice melting in the alpine zone, corresponding to the up-to-date measurement facilities, has been developed in the course of our investigation. It has been used to model the possible changes in the liquid runoff of the representative Dzhankuat glacier responding to anticipated climate change and progressive deglaciation. If the counter radiation of the atmosphere increases by 1.5 W/m^2 (which corresponds to the changes that have occurred over the last 100 years), the mean air temperature increases by 4°C (according to the MGEIK forecast), the debris cover increases by 180% (equal to the changes, occurred from 1968 to 1999), the atmosphere transparency index decreases by 5% and the Dzhankuat glacier melting rate will increase by 12-40%, depending on the elevation-slope zone of the glacier. Thus, as the area of glacier is expected to decline, the increase in glacier melting volume will not be dramatic. If the area decreases by 30%, which corresponds to the changes that occurred from 1910 to 1999, the increase in the volume of Dzhankuat glacier melting will be 8%.

New Developments in Flood Risk Management at the Flood Forecasting Centre

Charlie Pilling (Flood Forecasting Centre/ Met Office)

The Flood Forecasting Centre (FFC) is a partnership between the UK Met Office and the Environment Agency, established in 2009, to give an overview of flood risk across England and Wales. It was set up following the summer 2007 floods in England and Wales, and the subsequent recommendations of the Pitt review, to provide longer lead times for flooding. Based at the Met Office in Exeter, the FFC provides flood warning services covering England and Wales, primarily for the emergency response community. In addition, during times of heightened flood risk, close communication between the FFC and the Environment Agency Regions allows mobilization and deployment of staff and flood defenses at longer lead times. The FFC provides forecasts for all sources of flooding, namely fluvial, coastal, surface water and groundwater. This involves an assessment of possible hydrometeorological events in the next five days as well as their likely impacts. This paper will focus on new developments that provide longer lead times for fluvial flood risk, namely: (1) the implementation of the distributed hydrological model, Grid-to-Grid (G2G), which has been calibrated across England and Wales; (2) utilisation of the Met Office advances in deterministic and ensemble high-resolution numerical weather prediction; (3) application, interpretation and further developments of this new science to the benefit flood risk management. Results from some recent flood events will be presented.

Relations between the River Morphology and the Macrozoobenthos in revitalized stretches of the River Lahn (Germany)

Michael Groll (University of Marburg), Christian Opp (University of Marburg)

The European rivers and streams were constantly impacted by anthropogenic intrusions throughout the course of human history, which led to manifold morphological and ecological problems. During the last decades, the public became more aware of these deficits and the European Water Frame Directive (WFD) accelerated this process significantly. Today, the revitalization of river stretches is the most important tool for the improvement of the ecological status of watercourses. In order to reach the ambitious aims of the WFD in time and cost-effective, detailed knowledge about the effectiveness of precise revitalization measures which can be gathered through the detailed evaluation of already implemented projects. In praxis however, a scientific evaluation of the

revitalization success is only seldom done and too superficial so that the knowledge gaps remain. The macrozoobenthos is one of four quality components used for the evaluation of rivers within the WFD and despite more than 100 years of limnological research focused on the benthic invertebrates, the central question of which morphological processes and structures have to be improved in order to reach the "good ecological status" is still largely unanswered. Extensive research is done for the dependencies of the macrozoobenthos from various environmental parameters on the macro- and mesoscale. The key scale of the choriotores as the main habitat for benthic organisms however is hardly analyzed at all. This is in part due to the lack of methods capable of registering the riverbed structures with the required spatial resolution. Extensive research was done in this area of conflict between applied science and fundamental research on the middle reaches of the river Lahn (German river type 9.2) between 2006 and 2008. The riverbed was mapped in three river stretches using the newly developed high-resolution method TRISHa ("Typology of Riverbed Structures and Habitats") and a detailed survey of the macrozoobenthos (165 samples) was done in accordance to the state of the art methods (PERLODES) available. Extensive analysis were done for the spatial distribution and the temporal dynamics (including the effects of a HQ50 flood event) of the structural parameters in revitalized and non-revitalized parts of the research areas. The relations between these microscale structures and the benthic fauna were statistically analyzed in depth and an overall assessment of the revitalization success was done as the final step. This evaluation revealed gaps in the official German river typology and the PERLODES method that might prevent the EU-WFD from fulfilling its purpose. The registered deficits are in dire need of a broader scientific discussion and the results presented in this presentation, most of al the newly developed TRISHa, are a first and important contribution to this dialogue.

Feasibility of Rainwater Harvesting for Sustainable Domestic Water Supply in Rural Areas of Pune District, Maharashtra State, India

Sudhakar Pardeshi (University of Pune)

The water scarcity areas in Pune District of Maharashtra State in India encounter serious problems of domestic water supply. The study is carried out in different sample villages of Pune District in Maharashtra State. In this study, water availability through rooftop rainwater harvesting and through surface runoff harvesting is estimated. In last 35 years none of the stations within Pune district recorded rainfall less than (average - 2%). So the estimations done on the basis of (average - 2%) can safely consider being sufficiently dependable so far as meeting the domestic water requirement is concerned. It is also revealed that dependence on a single technique of rainwater harvesting is not enough in many of the villages. After analysis it is clear that even at (average - 2%) rainfall in the smallest watershed of 0.1211 km² rainwater available after losses is 40225.19 m³ when the village receives annual rainfall 1629.67 mm. If we check water availability for a village Kendur with (average - 2%) rainfall i.e. 213.46 mm, it comes about 847057.9 m³ after

losses. This volume of water is enough to fulfil all the domestic water requirements of the village. In the same fashion assessment of water availability through rainwater harvesting is done for all sample villages and it is found that even at (average - 2%) sufficient water is available to cater the domestic water demand. It highlights that the amount of rainfall received as low as (average - 2%) is also sufficient for rainwater harvesting. The economic feasibility of the rainwater harvesting structures are also checked and it is found that, in rural areas the cost of the structure for individual family is high but for a group of families the cost is low. It reveals that it is one time investment and the recurring cost of the structure is very low. If the initial capital investment is done through government and public participation, the rainwater harvesting is economically feasible. Through field survey the willingness of the local people to harvest rainwater is also checked. It is found that awareness of the rural people is must to accept the rainwater harvesting as an alternate and sustainable source of domestic water supply.

Watershed Management: A Case Study of Umtrew River Basin, North East India

Dhanjit Deka (B.Borooah College), Pradip Sharma (Cotton College)

Watershed is defined as a topographically delineated geographical area in which the entire run-off tends to converge, through the existing drainage system, to the common outlet of the area for subsequent disposal. In other words, a watershed is an independent drainage unit. This drainage unit is the most suitable geomorphologic unit for organization of all kinds of human activities and natural processes continuing within it. But due to tremendous population pressure and their unsustainable activity in the recent years deteriorate the environmental quality of the watersheds of the world in general and North East India in particular. Therefore it is necessary to study the drainage basin characteristics including evaluation of morphometric parameters like preparation of drainage map, contour map, ordering of streams, measurement of catchment area, perimeter, relative relief, relief ratio, length of streams, drainage density, drainage frequency, bifurcation ratio, texture ratio and also the monitoring of changing land use/land cover which further helps in management of the basin environment. The present study involves the evaluation of morphometric analysis of the sub watersheds of Umtrew River as well as the changing pattern of Land Use/Land Cover for the last three decades of the said watershed using Remote Sensing, GIS and GPS techniques so that the data generated from the study will help in environmental management of the said watershed. Keywords: Watershed, Umtrew, Management, Remote Sensing, GIS

The ecological condition of surface waters in Armenia

Trahel Vardanian (Yerevan University)

The ecological condition of river waters is caused by quantitative and qualitative changes of water. The paramount place among the problems directed on protection of water resources, is occupied with an estimation of water quality. In natural state, surface water is characterized by certain physical, chemical and biological indicators which allow defining the degree of its usability. At present, the Environmental Impact Monitoring Center of the RA Ministry of Nature Protection ("Armecomonitoring") carries out monitoring on environmental contamination, including that of surface waters, at the state level in Armenia. The state monitoring program covers 54 water bodies (including 48 rivers, 6 lakes and water basins), and 146 observation posts. The control over water quality is carried out by several parameters: identification of the chemical and physical properties of water, gas structure, basic ions in water, contents of contaminants of organic and inorganic origin, as well as that of about 38 metals. The samples of surface waters, taken in 2010, have shown that water bodies in the country can be united into two groups. One of them encompasses water bodies with extremely high degree of contamination. The other group includes watercourses with high level of water contamination. To note, the "extremely high" level of surface water contamination is identified when the maximum (permissible) exposure limit (MEL) exceeds by 100 times and more, and the biological oxygen demand (BOD₅) composes 60 mg²/dm³ or more. High level of contamination corresponds to MEL exceeding by 10-100 times, and BOD₅ being equal to 15-60 mg²/dm³. Of rivers in Armenia, water of the Debed, Sevjur, Hrazdan and Voghji can be identified as having 'extremely high' and 'high' levels of contamination; there the MELs of separate ions (copper, aluminium, vanadium and ammonium) may exceed by 100 times. However, the observations mainly show 'high' level of contamination, i.e. exceeding by 10-100 times, in the water of the rivers. Thus, in the Voghji river, below town of Kapan, the MEL of copper during a year has exceeded by 93 times (10 occurrences), while in the Hrazdan river, near village Darbnik, the MEL of ammonium ion has exceeded by 34 times (10 occurrences). Summarizing the above stated, it is necessary to point out that the rivers in Armenia are subject to heavy technogenic load. It has led to the change of a river runoff, water regime and quality. Water resources of the Hrazdan, Debed, Metsamor and Voghji rivers underwent a maximum economic change of water runoff by the qualitative indicator and contamination index.

Investigations of ground water in regions of recent volcanism by geophysical methods

Robert Minasyan (YSU), Vahram Vardanyan (Yerevan University), Marat Grigoryan (Yerevan University), Arsen Grigorian (YSU)

The Central volcanic plateau in Armenia is a typical region of recent volcanism. The differentiation of lava rocks by electrical conductivity depending on the degree of their humidity, the groundwater mineralization and the difference of the electrical resistance of lava and sublava water resisting formations allows to use geophysical methods widely there. They are successfully used for: - mapping of the relief of sublava water resisting rocks and determination of the mail ways of flow of underground water streams into artesian basin (electrical sounding, profiling) - determination of the places and the magnitudes of concentrated water losses from water reservoirs and channels (spontaneous potential electric field, charged body, profiling) - determination of water streams cross-section (electrical sounding and profiling) - mapping and estimating the thickness of riverlike deposits which fill local depressions among effusive formations, being of interest as reservoirs for the ground water accumulation (electrical and seismic sounding) - investigation of the well sections, especially to discover and to characterize the water bearing collectors (geophysical investigations of wells) interception of waters of river valleys with powerful groundwater flows on high levels allows usage of this water for supply and also influences hydrodynamic regime of plain territories below. This problem is solved using methods of mathematical modelling with large usage of information obtained by geophysical methods.

Karst Spring Water Quality, Case Study: Beton Spring at Gunungkidul Regency, Yogyakarta, Indonesia

Margaretha Widyastuti (Gadjah Mada Univ.)

Beton spring is located in the Ponjong sub District Gunungkidul Regency, at the western part of Bribin undergorund river catchment area. Therefore, the research becomes an important as part of the validation step on the groundwater vulnerability assessment. The response of spring water quality to the rain indicates the velocity of pollutants to reach the subsurface system. The purpose of this study are: 1) to know the variations of rainfall in the area of "research, 2) to know the variation Beton springs discharge, 3) to know the characteristics of the water quality of Beton spring and 4) to determine the relationship between the variations of the rainfall toward the discharge and the quality of Beton springs. This study uses survey methods and the techniques of data collection using sample by purposive sampling. Measurements are conducted during one year, the frequency of measurement and sampling season as a consideration. The variables are rainfall (the depth and intensity), springs discharge and spring water quality (EC, T, TDS, turbidity, pH, major element, coli bacteria). The data analysis is conducted graphically and descriptively to explain the relationship between the variations of rainfall to the discharge

and water quality of spring. The results showed the rainfall variations include the pattern, events and the amount of rainfall. The peak of rainfall occurs in March-April, 156 days of rainfall within 1426 rainfall events every 30 minutes, and the amount of rainfall is 3332 mm/year. Beton spring has high discharge variations. The physical and chemical water quality of the spring meet to the water quality standards, while the biological quality of the spring water have exceeded the threshold according to the Government Regulation number 82 year 2001. The relationship between rainfall variations to the discharge and the water quality of Beton spring can be seen clearly. Increased discharge Beton spring happens every rainfall event at intervals around hours - day. The discharge and physical water quality has a strong correlation which reflected from the high value of R2, whereas for chemical and biological quality has not strong correlation. Besides, the correlation between rainfall and spring water quality is identical to the correlation between water quality and discharge of Beton spring water. Key words: springs, rainfall, discharge, water quality, response

Droughts in Buenos Aires province (Argentina), their impacts on agricultural emergencies

*Olga Eugenia Scarpatti (CONICET - UNLP), Alberto Daniel Capriolo (CONICET),
María Ines Botana (UNLP), Veronica Pohl Schnake (UNLP)*

The present study analyzes the distribution patterns of drought in the province of Buenos Aires (Argentina) taking into account the agricultural emergencies 'determined by the National Government-', in order to identify areas more vulnerable. The definition of the agricultural emergency in an affected area is concerned to an area with territorial delimitation, when induced factors, climate, telluric, biological or physical, which were not predictable or evitable, either in intensity or opportunity, would affect the production or production capacity of the region and influencing severely the development of farming and the fulfillment of obligations and tax credit. The soil water balance was performed using the evapotranspiration formula of Penman - Monteith and considering the soil water constants: Field Capacity, Soil Water Moisture and Soil Wilting Point for the different types of soils of the Buenos Aires province (307,571 km²). For the statistical study, the series of soil water deficit data obtained were adjusted by means of the theoretical Normal Cubic-root probability distribution. The years 1968, 1972, 1974, 1975, 1979, 1983, 1988, 1989, 1995, 1999, 2005 and 2008 presented high values of soil water deficit. Their data of agricultural emergency level were obtained and then the thematic map reflected the behavior of drought. The results show the distribution by drought-affected areas, their relationship with soil hydrological constants and the degree of vulnerability. The counties with more days of agricultural emergency are those with less than 220 mm of field capacity and where the soil wilting point exceeds 50%. The most affected area is the southwest of the province and it was followed by the central region.

The Channel Tunnel: An Assessment of the Regional Impacts

Daniel O'donoghue (Canterbury Christ Church University), Peter Thomas (Canterbury Christ Church University)

Since its opening in 1994 the Channel Tunnel has become a key element in the transport infrastructure linking Britain and continental Europe. But, as well as forming part of the Trans-European Rail Network, the Channel Tunnel was also seen as a potential stimulus to trans-frontier collaboration and as a possible catalyst for regional economic development. The aim of the paper is to evaluate the regional impacts of the Tunnel within the Anglo-French frontier zone on both sides of the English Channel. Overall, the evidence suggests that the benefits are fewer than had been anticipated. Despite the success of the Channel Tunnel in terms of passenger numbers, the English Channel still represents a psychological barrier (partly due to language differences) and the frontier zone has failed to develop as an integrated labour market. Moreover, the findings suggest that the Tunnel has failed to transform the spatial economy of the trans-frontier zone. Instead, its impacts have been spatially uneven. This has been to the detriment of local economies in Kent and Nord-Pas-de-Calais, while the main beneficiaries are locations at some distance from the Tunnel itself.

The Fehmarnbelt Tunnel: Urban and regional development perspectives

Christian Matthiessen (University of Copenhagen)

The European Round Table of Industrialists identified in the 1980ies 14 missing links in the transportation network of the continent. Three of them were found around the Danish island of Zealand. One link is within the nation, the other two are between nations. One link connects heavy economic centres, one joins more thinly populated regions, and the last one links peripheral areas. Two of them (The Great Belt Link and the Oresund Link) have been constructed and are in full operation. The third (the Fehmarnbelt Link) has been decided 2008 on bilateral government level. The three links are impressive mega structures spanning international waterways. Their lengths are around 20 km (12 mi) each. They concentrate traffic flows and create strong transport corridors. They are the basis of new urban and regional development regimes. 'Ferries connect systems, fixed links unite systems'. The fixed Fehmarnbelt link closes a gap between the Scandinavian and European motorway and rail networks, which eliminate a 160 km. detour for freight trains via the Great Belt and will cut one hour of transport time between Hamburg and

Copenhagen for road and passenger railroad traffic. This will create a strong transport corridor between the Øresund region in Denmark/Sweden and Hamburg in Germany, allowing a new greater and more competitive region - the Fehmarnbelt region - to emerge. New trading opportunities, new forms of tourism, new jobs and new housing opportunities will arise. In turn, this will open up new urban and regional development perspectives for the entire Fehmarnbelt region.

Evaluating the regional integration value of transborder projects based on spatial spillovers and commercial flows

Ana Condeço Melhorado (Universidad Complutense), Javier Gutiérrez (University of Madrid)

Historically, most countries have given priority to the development of their national transport networks; this favoured the integration of their territories and the consolidation of truly national markets. In contrast, less attention was paid to links with other countries. The result at the supranational level, therefore, was the existence of a set of independently developed national transport networks, weakly interconnected. Moreover, some of those links are located in outlying areas and enclaves near the borders of countries, where demand is not enough to justify the need for new infrastructure. However, these cross-border stretches have a crucial importance from an international perspective, because their construction provides a high value from the point of view of regional integration. There is a lack of an integrated approach during the planning, evaluation and funding process of cross-border infrastructure. This creates the potential for difficulties, as conflicts appear between national and local impacts. In this context, our study proposes a methodology based in the concept of spatial spillovers to measure the regional integration value of cross-border projects. Spatial spillovers are defined in this paper as those travel time savings in one country due to new transport infrastructure built in a different country. Travel times are calculated in a Geographical Information System (GIS) environment and weighted by commercial flow data between countries. By doing this we account not only for travel time gains of each section but also for the real use made by each country, when exporting their products. This way, sections with great spillovers will have a higher regional integration value. The validity of the methodology is tested with its application to a selection of TEN-T projects. Each project is split in different stretches and subsequently their regional integration value is evaluated individually for each project section. Generally, sections located in the border have higher regional integration value than those located in the interior of countries. Sometimes border sections are even more important for third countries than for the one responsible for its construction. In those cases it seems logical that the regional integration value should be taken into account in the financing process.

**The role of great infrastructures in the organization of supranational regions:
The Catalan case**

Juli Valdunciel (Universitat de Girona), Jaume Feliu (Universitat de Girona)

Globalization is boosting global city-regions, new spatial platforms for the contemporary economic system. Indeed, great infrastructures have become basic means to articulate these new functional spaces, in many cases supranational, and they are key factors to ensure their performance. However, its construction and implementation involves not only technical and/or planning issues but also cooperation among stakeholders, consensus around new scenarios and strategies for development and conflict resolution. In recent years, two major transport infrastructures crossing Franco-Spanish border through the Catalan region, across the Pyrenees, have been planned, discussed and, in some parts, already built: the high-speed rail and the Mediterranean rail corridor for passengers and goods. These two great infrastructures can cause significant urban and regional transformations in the region of Barcelona. In fact, these changes have already begun to occur in the form of new territorial strategies of cooperation between socio-economic stakeholders and institutions. Moreover, its implementation unleashes as well a strong political and social debate in relation with the efficiency of the Spanish infrastructure model, traditionally built in a radial shape around the capital Madrid, and the option to build it as a network structure. The contribution is divided into three parts. The first part describes the two listed infrastructures and highlights their technical and geographical features. A second section analyses the mobilization of stakeholders due to its planning and construction, the planning and development tools deployed and the conflicts that have arisen. Finally, the paper reflects on the possible impact of such infrastructures on territorial development, taking as horizon the scheduled date of completion: 2025. Key words: Global city-regions; Trans-European transport networks; High-speed rail; Stakeholders; Barcelona.

C08.35-02 - Large scale transport infrastructure and regional and urban impacts 2

Transport and Spatial Networks – an economic geographer's view of the European transport corridor Rotterdam-Genoa with special regards to logistics clusters

Julian Brenienek (Universität Duisburg-Essen)

The department of economic geography of University of Duisburg-Essen (chair of Prof. Dr. Rudolf Juchelka) is a partner in the EU-INTERREG IVb Project 'CODE24'. The project intends the interconnection of economic development, spatial, transport and ecological planning along the trans-European railway axis (TEN-T) no. 24 from Rotterdam to Genoa, which covers a number of most important regions in Europe. Partners of the project are located along this north-south axis across the Netherlands, Germany, Switzerland and Italy and cover different topics from infrastructure development to noise reduction (see official CODE24 homepage: www.code-24.eu). The University of Duisburg-Essen is covering the topic of 'Creation, Development and Evaluation of Impacts of Logistics Clusters' along the corridor. International trade corridors merge traffic and direct them towards a global gateway. This causes spatial networks in great distances of these global gateways to align along these flows. With special emphasis on intermodal traffic, several case studies in the Netherlands, Germany, Switzerland and Italy are conducted in order to research in how far Rotterdam and Genoa influence the formation of logistics networks or clusters within the corridor. The term 'Cluster' as itself is relatively young in scientific terms. Thus, with regards to logistics, not much research on 'logistics clusters' in particular was conducted so far. The scientific demand for the CODE24 team at University of Duisburg-Essen is to develop a generic model for logistics clusters. The focus is on their elements and characteristics: Where are logistics clusters in the CODE24 corridor? How to identify approaches to form a logistics cluster? Furthermore, a 'tool-box' will be developed in order to give advice in how far a logistics cluster can be initiated and promoted. While this is still an ongoing project (runtime till the end of 2013), results can be shown of the case-study Karlsruhe, where two important European transport corridors cross paths. During the case study, logistics service providers within the administrative region of Karlsruhe and bordering districts were quantified. Together with a close look on intermodal loading equipment, statistical data provided by the chamber of industry and commerce and data that was mapped on field trips to Karlsruhe, a first simple model of logistics hierarchies within a region was developed. The paper will be presented by Julian Brenienek, PhD student at the department of economic geography of University of Duisburg-Essen.

Impacts of a fixed link on creation of a bi-national urban region: A case of Öresund Bridge

Jun Yamashita (Kyushu University)

Since the inauguration of Öresund fixed link in July 2000, the number of bi-national trips has increased between Denmark and Sweden. However, it was not quantitatively proved that the Copenhagen and Malmö-Lund urban regions have been merged into a bi-national urban region. The present study attempted to reveal integration of the two urban regions after the construction of Öresund fixed link. As results derived from analyses on commuters' flows, it was concluded that bi-national trips have gradually increased since the bridge inauguration, but a bi-national urban region is not created so far.

How Urban Planning Anticipates Major Changes in European Transport Corridors

Eloise Libourel (LVMT)

Since the early 2000s the concept of 'corridor' has been an architectonic element of European transport policies, as shown by the TEN-T (Trans-European Networks of Transport) priority projects of the European Commission. They aim to improve transnational integration and networks interoperability, in order to overpass the bounded national structure of the main transportation systems. By creating long continental transport infrastructures, European Commission wants to connect countries, to promote relationships between major cities and competitiveness of European regions in a context of globalisation. The trans-European corridors, as continental scale infrastructures, are not yet operational. They already became, however, a category for network analysis at different scales, especially at urban level. The signs of the new infrastructures first appear in the cities, which build new railway stations, make territorial marketing policies and try to attract new industrial and commercial establishment. It is interesting to observe that the argument of the corridor projects is most of the time highlighted by urban institutions. In today's increasing context of metropolisation, cities acquire a nodal position on the proposed trans-European corridors. The notion of 'major axis' as it is now assumed, just as the quest for an increased role in the future, leads the cities towards a particular urban development, building out an idea of 'corridor' based on economic and symbolic considerations rather than on the achievement of the railway infrastructure. The fact is that the 'corridor' actually becomes an argument for increased attractiveness of the city and almost a sort of label. Therefore, the notion of corridor shifts from the infrastructure to the cities on its route. The affected territory has another scale, as if a European scale network were symbolised by a few places. How can urban planning, of either public or private initiative, create a properly speaking 'corridor territory', regardless of the completion of the railway infrastructure on which the corridor is supposed to rely? The first objective of this paper is to show that the concept of corridor, as it is used by the European institutions to refer to large-scale transnational infrastructures, which is subject

to long delays and many adjustments, mostly acts as an impulse for metropolitan projects. It will then be observed how far urban planning and development is leading the infrastructure's construction through the elaboration of hubs, business districts or urban renewal operations. First, we will focus on the case of the Spanish 'Mediterranean corridor', and of the main cities on it. We will then try to link this particular case with other European examples, at various degrees of completion of the corridor projects.

The impact of large investments in transport infrastructure on development of the Poznań Metropolitan area and the Wielkopolska region.

Radosław Bul (Adam Mickiewicz University)

Since the change of the socio - economic system in Poland in 1989, the level of economic development of the city of Poznań, its metropolitan area and the region of Wielkopolska has increased dynamically. The main factors of this impact are connected with a very attractive geographical location and high level of entrepreneurship among residents of the city and the region. One of the main strengths of the city and the region is their accessibility in terms of transport. The configuration of transport networks in Poland makes the city one of three major road and rail hubs. The City of Poznań is the first large urban area in Poland on the route from Berlin to the East. The main factor determining the choice of location by foreign investors in Poland is the accessibility of potential investment field. Development of the city and the region is highly determined by efficient and modern transport infrastructure. Unfortunately, due to the negligence in the development of transport infrastructure in Poland, urban economy has grown slower than it could have. The aim of the paper is to present the most important infrastructural investments and their impact on development of the city and region. Poznań and Wielkopolska are in privileged positions in the country because some of the biggest infrastructural projects in region have already been completed. For that reason, the accessibility of the city compared to the other agglomerations in Poland is high. The most important investments in the region, obviously raising the attractiveness and accessibility are: motorway A2 (Poznań - Berlin), western and eastern Poznań ring road, reconstruction and modernization of rail lines Warsaw - Poznań - Berlin, construction of new main railway station as an integrated communications centers (connecting national and metropolitan railways, buses, trams, fast tram), and development of Poznań-Ławica airport. In addition, a very significant investment in public transport is the construction of the Poznań Fast Tram. Thanks to the construction of large infrastructure projects the city has become more accessible and attractive for investors. This success was possible due to the use of EU funds (f.e. reconstruction and modernization of rail lines Warsaw - Poznań - Berlin), and the program of public-private partnership (motorway A2, new main railway station). Many projects have been financed by the local government too (fast tram, Ławica airport). Thanks to this investments Poznań and its metropolitan area is the only metropolitan region among the regions of Central and Eastern Europe, where GDP per capita is higher than the average for the EU-15, and whose main city is not the national capital.

New high speed rail stations in the metropolitan periphery as gateways of the knowledge economy

Angelika Münter (Research Institute for Regional and Urban Development)

Investments in high speed rail (HSR) infrastructures gained in importance during the last decades. Not least this is encouraged by EU subsidized extension of Trans-European Networks. Within the metropolitan regions on the one hand the central stations profit from the increase in accessibility that come along with these investments. On the other hand constraints in the line routing and the maxim to minimize travel time between metropolises, caused that new HSR stations were build or existing stations were upgraded by the connection to the high speed rail network located outside the traditional CBDs (eg. Cologne-Messe/Deutz) or in the metropolitan periphery (e.g. Siegburg in the hinterland of Bonn). In this paper we focus on new and upgraded HSR stations in the metropolitan periphery, because for these locations improvements in the accessibility of the location can be analyzed detached from other location factors. Good accessibility is also a precondition for as a consequence of increasing economic linkages on all spatial scales, because a high-quality transportation infrastructure reduces the relational distance between different locations. In the case of HSR-infrastructure especially business companies that are heavily dependent on personal contacts on an inter-regional to international scale benefit from this locational advantage. Particularly this applies to companies of the knowledge economy: To generate new knowledge, on the one hand this business sector is due to the urbanisation economics generated in metropolitan regions, and on the other hand is due to interact with national and international partners via ICT but also face-to-face contacts. The general objective of this paper is to examine if HSR-stations in the metropolitan periphery play a role as gateway for the knowledge economy. Especially we want to investigate in what way and to what extend new economic poles of the knowledge economy emerge in the surroundings of these stations. To this end we compare the economic developments around selected new HSR-stations within the metropolitan periphery in Germany and other European countries. We focus on the analysis of the concentration of companies of the knowledge economy as well as on the causes of locational decisions of these companies

Measuring Territorial Effects of High-Speed Trains on Metropolitan Areas. A methodological proposal using path capillarity indices.

Alexis Conesa (LIVE)

Questions about the links between investments in transport infrastructure and regional development is a longstanding topic for spatial planners, specifically economists. According to several transport and urbanism specialists[1], economic effects induced by transport infrastructures are not defined by a deterministic relationship. Moreover, the complexity of transport impacts on development leads Plassard[2], amongst others, to consider the significance of territorial (not only economic) effects. In this context, instead of producing economic predictions, this work proposes a measure of territorial effects of a new transport infrastructure in a forecasting approach. So, the aim of this research is to build a tool for decision support in planning and transport policy that can show the potential of transport networks to provide the structure of a regional and/or metropolitan area. This doesn't mean to replace an economic analysis, but rather to provide further and complementary information to the decision-makers. For instance, french LGV (high-speed train lines) are obviously major tools for development at regional scale. In PACA (Provence-Alpes-Côte d'Azur) region, the project can be seen as a future backbone to economic and social relations between Aix-Marseille metropolitan area and Côte d'Azur conurbation (around Nice). Nonetheless, within these two City-regions[3], LGV can be used as another transport service, thereby support local (urban) relations. To assess this double role of LGV, transport service, understood as the set of speed, schedule and fineness (number of train stops) has to be modelled. Modelling approach is based on a transport-oriented GIS using scheduled graph to represent transport service as previously defined. The model uses scheduled accessibility and path capillarity to define territorial effects of a given transport service. Scheduled accessibility gives disaggregated spatiotemporal distance between two places whereas path capillarity represents the fineness of transport service, i.e. potential for small scale use of the transport service. The confrontation of these two indicators can give an idea of the tension between speed and territorial potential. Indeed, a fine metropolitan service will necessarily damage trip speed at regional scale. At the opposite, a looser transport service (removal of a train stop), involves a speed gain. [1] For instance Offner, J.-M. (1993), « Les effets structurants du transport: mythe politique, mystification scientifique », *L'Espace Géographique*, N°3, pp. 233-242 [2] Plassard, F. (2003), *Transport et Territoire*, La Documentation Française, 97 [3] « considered to be the territorial scale at which international competition now frequently takes place », according to Sykes, O. (2005), « Metropolitan co-operation the gallic way », *Town and Country Planning*, pp. 320-323

Contentious Space and Politics of Scale: Planning for Inter-City Railways in China's Mega-City Regions

Jiang Xu (University of Hong Kong), James Jixian Wang (University of Hong Kong)

Geographers have noted, over the past decade, that China's mega-city regions are coming to represent a new spatial scale for capital accumulation, state regulation, and political compromise. Unlike before, regions are now shaped by the existence of overlapping competencies among contending actors at multiple scales of governance. The 'politics of scale' thesis has thus been helpful in drawing attention to this complex political ballet. However, the growing importance of regional space is punctuated by several inadequacies and missing links in academic inquiry and political discourse. Among these are: (1) a tendency to apply a hegemonic interpretation of city-regionalism, at the expense of knowledge of place-specific practice; (2) a lack of detailed case studies revealing the key political processes and relationships that reflect historical contingencies and path-dependencies under transition; and (3) a reluctance to conduct empirical investigation to reveal the outcomes of the politics of scale in geographical terms. In this paper, we will go some way towards addressing this shortage of geographical research. We will use the Pearl River Delta Intercity Railway System as a case study to explore the ways in which planning decisions for this mega-regional project are initiated, planned, negotiated and implemented in the context of a diffuse regional power structure and an inadequate institutional environment. It is argued that China's multi-level hierarchical intercity railway networks are evolved from a single-level (national) system, and this coincides with the contradiction between the state's monopolistic control of operation and the propensity for a diversified investment regime. Consequently, governments at various levels and their respective functional agencies are engaged in numerous struggles over the design and delivery of railroads, creating much scope for established hierarchies and bureaucracies to 'flex their muscles' and avoid takeover by others.

Effects of growing transport land use on daily mobility and implications for regional development: Case of Slovenia

David Bole (ZRC SAZU)

This paper is part of an ongoing post-doctoral research. The paper will discuss impacts of transport infrastructure growth over the last two decades from an inter- and intra-regional perspective. Slovenia is without doubt one of the countries where land use is radically changing due to the rising rise of needs on the level of motorized mobility. The structure of travelling has changed, most obviously seen in the shift from public to private means of transport. The rising demand of private transportation infrastructure (mainly motorways) has had multiple impacts: changes in land use patterns on a local and even regional scale and changes in the daily interaction of the population, which is supposedly 'more mobile' and makes new and completely changed patterns of daily mobility. In the

paper I will show how the transportation infrastructure has changed in the last 10 to 15 years. I will show that a bulk of these changes can be attributed to the large scale motorway construction, partly to the railway construction and in smaller part to the general suburbanisation of the territory. Later on I will try to show the effects of large scale transportation investments on spatial daily practices of the population. I will focus on daily commuters and their changing statistics, where – there is a clear correlation among the new motorway infrastructure and commuting flows, which follow the new infrastructure corridors. I will present the statistical data and the maps of changing commuter flows. From the abovementioned analysis I will try to form a new hypothesis regarding the effects of large scale transportation infrastructure on inter-regional and intra-regional development in Slovenia. Changes in employee commuting indicate changes in regional structure and infrastructure, and completely personal, psychological motives. However, at the same time changed daily employee commuting has important reciprocal effects on the environment, especially from the viewpoint of the pollution of landscape elements and economic costs. The latter are not only a result of using and building transport infrastructure, but also of polluting and destroying quality farmland, residential areas, and ecosystems. Therefore, studying and planning of large scale transport infrastructure should take into account direct and indirect environmental, social and economic costs.

The viability of Mass Rapid Transit System : A Case of Kolkata City

Eshita Boral (University of Calcutta)

The city of Kolkata supports 11.04 million vehicular population within an area of about 187.33 sq km. While in most modern cities, the road surface area relative to the total area is around 30 percent, here it is barely 6.4 percent. This meager network of roads fall short of requirements, therefore the best possible option is to shift to mass public transport services to reduce ever increasing traffic generated pollution and congestion. In Kolkata most mass transport services are road based. But in a city, where an uncontrolled mix of incompatible forms of traffic and increasing number of personalized vehicles ply on roads, surface transport remains slow and crowded. Moreover the existing infrastructure of roads and the un-segregated road public transport leads to an increase in average travel time and cost of travel. Thus in cities like Kolkata, rail based mass transport services, which have a greater capacity of moving people efficiently and cheaply within the city and even outside it, can be considered as a good alternative. In developing countries like India Mass Rapid Transit modes are only a few decades old, and are being developed in all mega cities to ease off traffic on roads. Kolkata has the privilege of being the first city in India to develop such a mode in form of Metro Railway. Metro railways stand out in comparison to other modes of mass transportation that ply on city roads because they are fast, cheap, pollution-free and safest mode of transport. Bus services, the predominant mass transport mode in the city, have several operational disadvantages. They stop indiscriminately between stoppages, which are just 500m apart adding to the inconveniences of travelling by bus. The Metro railways on the other hand are fast due to fewer stoppages, which are atleast 1-2 km apart and have no other issues than technical glitches to make it slow. The fact that metro rails have a defined route, be it underground or overhead where it does not have to compete with other modes of transport makes it possible to cover the distance between each station within much lesser time. The other rail based mass transportation modes that are in operation in the city are either slow or inefficient. Therefore metro services in Kolkata are gaining importance both for short and long distance travel within the city. This paper attempts to evaluate the viability of Mass Rapid Transit system in a city like Kolkata and analyses its performance and thus its position within the total transportation scenario of the city. It would also attempt to establish the advantages of Mass Rapid Transit over other mass transport services that are in operation in the city. However it could be stated that, effective running of Mass Rapid Transit System in the city depends not only on selection of appropriate technology

and phasing the development but whether it is compatible with city characteristics, requirements and economic capabilities that are existent.

Madrid-Barajas airport as a transport national hub: Contribution of the Spanish policy of infrastructures in the last 20 years

Miguel Pazos-Otón (Universidade de Santiago de Compostela), Rubén Camilo Lois-González (Universidade de Santiago de Compostela)

In the last 20 years, Madrid-Barajas airport has become one of the most important in Europe, developing currently two main functions: main gateway to Europe from Latinamerica and national hub for the Spanish air routes system. In both cases, IBERIA is the main carrier and uses Madrid-Barajas as center of operations. Along these years, a main milestone was the construction and completion of the new Terminal-4 (T4), which symbolizes a political option for the reinforcement of the importance of Madrid in the Spanish infrastructure system and urban network. In fact, the rise of Madrid as a european metropoli and the progressive loss of weight of Barcelona after the Olympic Games (1992) are closely related to the strategy of a new Spanish centralism, easily viewable in transport infrastructure policies. From a geopolitical point of view it means a redrawing of the air routes map in Spain. These concentration of air routes in Madrid and its role as air transport hub have a symbolic representation in the new T4. It is important to analyze the role of AENA (Spanish Airports and Aerian Navigation, public company in charge of the management of Spanish airports), in the promotion of Barajas, which is also related with the big public investments done along these years. We will analyze this process in the last two decades by working with different statistics (investments, passengers, operations, etc) from AENA. We will also develop an evolutive analysis of the main milestones along these years. A last and very important issue to deal with is related to the future development of intermodality between air and high-speed train in Spain. Currently there are no conditions for intermodality in any Spanish airport, but there are plans to make possible the arrival of the AVE (Spanish high-speed train) to Madrid-Barajas. This fact would reinforce even more the power of Madrid-Barajas as a transport national hub, increasing its nodal role at national level.

Transport accessibility of Polish cities and regions

Jan Hauke (Adam Mickiewicz University), Anna Borowczak (Adam Mickiewicz University)

High transport accessibility of cities and regions, which is the result of developed and used transport infrastructure can contribute to the spread of development processes. Development of transport infrastructure can support the positive mechanisms of the diffusion's development, while the lack of effective communication, not only between main centers but also between the main centers and centers of lower rank, not accelerate the economic growth and reduce the development of social bonds. Hence,

the transport accessibility is the basis for the processes of diffusion's development. Socio-economic transformations in Poland after 1990, associated with the transition from centrally planned economy to a market economy, significantly affected the state of the passenger transport sector. In the first years of transition the most important challenge was the introduction of market principles of functioning, which resulted in the necessity to restructure state-owned carriers. Enterprises PKS (State Car Communication) and PKP (Polish State Railways) was divided into dozens of companies responsible for different segments of passenger transport. Unfortunately, these changes were accompanied by reduction of passenger services, which caused a decrease the transport accessibility of cities and regions. These processes have changed significantly the level of transport accessibility of cities and regions in Poland. This situation concerns mainly small towns and those which are located furthest from the country's main transport routes which are Trans-European Transport Networks (TEN-T). It is assumed that modernization of the main transport connections with the development of them will improve the transport accessibility of cities and regions. Unfortunately, the position of large cities and metropolitan regions improves, while centers of lower rank becomes less important in the transport systems of the country. The aim of this study is to analyse the changes in transport accessibility of regions and cities in Poland in the years 1991-2011. Both the state of transport infrastructure and the level of transport accessibility of voivodeship cities in Poland were analysed. In this analysis were taken into account features such as: the extent and intensity of bus and rail services and the mutual time accessibility of selected cities in 1991 and 2011. The analyse attempts to answer the following cognitive questions: (1) How did the state of transport infrastructure change in the years 1991-2011? , (2) How did the level of transport accessibility of Polish cities change in the years 1991-2011?, (3) Which cities and regions did the most "feel" the restructuring processes of transport companies? (4) How did time accessibility change in selected cities in the terms of passenger connections?

The relation between freight transport accessibility and the location of logistics activities; an analysis of US counties

Frank van den Heuvel (Eindhoven University), Liliana Rivera (Massachusetts Institute of Technology), Karel van Donselaar (Eindhoven University), Yossi Sheffi (Massachusetts Institute of Technology), Peter de Langen (Eindhoven University), Jan Fransoo (Eindhoven University)

Although the accessibility of a location is an important factor for the location decision of logistics companies (warehouses, freight truck companies, etc.), there is not much literature that explicitly analyzes the relationship between the location of logistics activities and the accessibility of these locations. One of the reasons may be that existing accessibility measures are focused on measuring accessibility from a passenger transport perspective. For logistics companies, accessibility of a location has to be measured from a freight transport perspective. In this paper, we use three different accessibility measures and apply them on a county level in the U.S. The first measure simply uses the road density, defined as the kilometers of highways per county divided by the county's area, as an accessibility measure. The second measure extends the first one by also taking into account the road density of adjacent counties and not only normalizing by the county's area but also by the county's population. Finally, the third measure is a gravity based accessibility measure, in which a county's accessibility is assumed to be directly proportional to the size of an activity in other counties and inversely proportional to the road travel time between the counties. The advantages and disadvantages of these three measures are discussed. The different accessibility measures are related to the amount of logistics activities per county. This provides additional insights in the usefulness of the three different measures, and allows us to draw conclusions about the relation between freight transport accessibility and the location of logistics activities. Finally, as in addition to road accessibility, the three measures are also used to analyze rail, airport, and port accessibility, we analyzed the relative importance of accessibility to different transport modes.

Impact of new transport infrastructure: Spatial and social transformations beyond economical facts

Maik Hoemke (ETH Zürich)

Increasing expansion of transport infrastructure is taking place in more and more countries. This trend, strongly encouraged by the globalization process, is reflected in ever-shorter journey times in both national and international travel. During such developments, extensive urban-planning alterations in areas that are being provided with new transport infrastructure tend to be viewed purely in terms of economic and efficiency benefits - and particularly in terms of the time saved when travelling the distance from starting-point to destination. However, there has been little research on the socio-spatial effects of new transport infrastructure systems. There is no awareness or sensibility for such changes, and as a result hardly any methods are available to investigate phenomena of this type. The present study is therefore intended to add a new level to research on the efficacy of new transport facilities - namely, the socio-spatial effects of transport infrastructure. The new Lötschberg Base Tunnel in Switzerland is to be taken as an example case for the purpose. When the 34.6-km Lötschberg Base Tunnel opened for scheduled operations in December 2007, the rural communes in the Upper Valais region acquired a strong new link with the catchment area of Berne. For example, the train journey between Visp (in Upper Valais) and Berne was shortened from 2 hours to less than 1 hour. In addition to the link with Berne, internal public transport connections in Upper Valais were also tremendously extended. Interchange links were improved, connections were better organized, high-frequency timetables were introduced and services were substantially increased - transport facilities that are every bit as good as an urban railway network. The present study will establish the following points of emphasis. In an initial step, the newly created infrastructure, the expanded public transport system and the urban development will be examined in greater detail. Following these investigations, the socio-spatial effects of the transport infrastructure are to be examined. Using a wide variety of empirical methods, the intention is to show the ways in which increasing urbanization can be demonstrated, on the basis of social criteria. This will close existing gaps in the way in which the effects of new infrastructure facilities are seen. In addition, alterations in the social perception of the area due to shorter journey times when crossing the Alps will also be investigated. The aim of the study is to demonstrate that research focusing merely on economic and physical effects in a given area, and ignoring the social aspects of new infrastructure, inevitably suffers a loss of quality. The special characteristic of the present study lies in the way in which it assesses infrastructure developments, in regions that were previously peripheral, on the basis of urban development phenomena and social phenomena.

Foreign direct investment (FDI) in large scale transport infrastructure: The case of Poland

Zbigniew Taylor (Stanislaw Leszczycki Institute of Geography and Spatial Organization)

The paper presents results of two-year research project on FDI in the Polish transport sector, in carriage activities as well as in construction of transport infrastructure (without production of transport means, however). In the analysis, the following measures have been applied: (1) number of companies; (2) number of employees in companies; and (3) aggregated value of FDI in companies existing as of end of 2008. Settlements with branches of transport companies have been the basic units of spatial analysis, in other cases the phenomena have been investigated within counties. Majority of FDI is at urban and regional scale, particularly located in the largest cities, and include greenfield investment (such as maritime container terminal, road freight transport, forwarding and cargo throughput) and brownfield investment (such as freight rail transport, air transport, cargo throughput, passenger road transport). Relatively smaller share of FDI in transport is one of the reasons of 'fall' of this sector in the Polish economy. FDI in transport focus mainly on company takeovers by foreign investors (54.5% of total, according to capital invested) while greenfield investments are much smaller (30.7%) but there are great differences among various transport modes. Absolute majority of brownfield investments are observed in passenger road transport (98.7% of capital), in air transport and services (98.4%), and in rail transport (93.7%). Greenfield investments dominate in cargo throughput, logistics, forwarding and storage; maritime and inland shipping; and in freight road transport - but the domination is much smaller rather than in brownfield investments. By and large, much bigger is the share of companies involved in carriage activities rather than in infrastructure activity. Foreign investors influence the development of cities and regions but also modernisation of transport itself. FDI influence transport development in local and regional scale rather than nationwide. Spatial distribution of FDI is extremely uneven, and new investments strengthen existing interregional differences. Particularly many investments were located in metropolitan regions, especially in Warsaw area. Most uneven distribution of FDI is observed in the case of capital invested, smaller in number of employees and the smallest (but also visible) - in number of companies.

Spatial Analysis of Urban Mobility in Belo Horizonte Metropolitan Region: A typology of the inter-city interaction intensity

Renata Oliveira (CEFET-MG), Alexandre Diniz (PUC-Minas), Leônidas Conceição Barroso (PUC Minas)

Urban mobility patterns of a region depend on two essential factors: (i) spatial location and intensity of activities; and (ii) movement patterns, provided by the transportation offer and its quality. A suburbanization process has taken place in many cities, modifying their structure from the concentration of activities in the central area to more complex and

broad distribution of activities, expanding the urban area, changing the inner and outer relation among districts and demanding an aggregate land use planning, especially when providing transportation in metropolitan areas. Belo Horizonte Metropolitan Region (BHMR) is composed by 34 municipalities, with serious differentiations of land use and mobility patterns. In addition, Brazil has signed up to host some major events, such as the Fifa World Cup in 2014 and the Olympic Games in 2016. These events can cause relevant changes on the ordinary demand for mobility, especially considering the inter-city interaction and the impact on the small municipalities, which present low intensity of activities and low transport infrastructure offer. Therefore, this paper intends to provide a typology for the BHMR, considering attributes such as the spatial intensity of activities and the movement patterns, distributed by the cities that compose this region. The highlight of this work is the discussion of the inter-city interaction. The method used for this analysis was the Principal Component Analysis and the implementation was made using the software Ninna. The results were analyzed using Microsoft Excel and the mapping was performed through ArcGis 9.3. The variables considered in this analysis refer to the size and structure of the municipalities, its occupation intensity, the location of jobs, the vehicle fleet (individual, motorcycles and buses), the proportion of trips with destiny in each municipality due to work or study, and movement patterns, such as time and transport mode. These variables were obtained from some IBGE researches, from Denatran and from the origin/destiny research developed by Fundação João Pinheiro in 2002. The typology proposed presents a consistent relation between the spatial location of activities and the transport broadness. The municipalities located in the further areas of the BHMR, especially in the north and south parts of this region, presented high movement broadness and low intensity of activities. On the other hand, the municipality Belo Horizonte, capital of Minas Gerais state, and other municipalities such as Nova Lima and Pedro Leopoldo, were the ones with higher intensity of activities and broader movement pattern. Some decisions regarding land use planning and transportation infrastructure offer can be guided by this typology proposal, especially considering the inter-city interaction among the municipalities that compose Belo Horizonte Metropolitan Region located in Minas Gerais, Brazil.

C08.35-06 - Port hinterlands and urban logistics

Chair: Yves Boquet, Theo Notteboom

The creation of inland port networks in Europe : An analysis of cooperation strategies and institutional structures based on a comparison between the major river basins of France and Germany (the Seine, Rhône, Rhine and Elbe)

Antoine Beyer (Université Paris Est), Jean Debie (Université Paris), Romuald Lacoste (ERA FRET / Cete de l'OUEST / MEEDM)

The links between ports are numerous and extremely varied in range and intensity. Although the links between inland ports have in some cases existed for several years, they are currently enjoying a marked renewal of interest. This seems to highlight the emergence of a new, larger, level of governance which is closely linked to maritime outlets. To illustrate the scale of this activity, it is sufficient to mention a few examples : the Comité de Coordination Interportuaire de la Seine (the Seine Interport Coordination Committee), which brings together Le Havre, Rouen and the Independent Port Authority of Paris, the Comité des ports Saône-Rhône-Méditerranée (the Saône-Rhône-Mediterranean Port Committee), the Verbund der Binnenhäfen Oberelbe (the Association of Inland Ports on the Upper Elbe) or the increased cooperation between the inland ports on the Rhine around Duisburg. Following operators, and in order to meet their needs, port managers are tending to institutionalize new interdependencies. This dynamic seems to be a logical response to the consolidation of maritime traffic into the hinterland. Consolidation is prompting private actors and the public authorities to organize their activities around inland ports which act as relay points. Networking may be initiated by various actors: the maritime ports which seek to strengthen their continental support structures by setting up special partnerships; the public supervisory authorities, operating at different geographical levels, which seek to rationalize the investment that is required to achieve modal transfer, and the managers of the river ports themselves in order to satisfy the expectations of users and achieve a higher profile. In order to reveal the strategies at work, we shall focus on three points: - 1. Conducting a survey of the cooperative structures that covers the diversity of their goals. This requires a thorough understanding of the content and real impact of the agreements in question and how they will affect the future of the selected river basins. - 2. Revealing the reasoning behind the cooperative choices with reference to the theories of political science and regional economics. To what extent is this cooperation driven by the responsible political authorities? How does this influence cooperation? Do the structures in question eradicate competition? The media attention aside, what are the real consequences of these cooperative links? - 3. Establishing a typology of the situations encountered on the basis of two principal variables: the distance between the partners and the intensity of the transactions (these two concepts must obviously be interpreted in a geographical and political sense).

The World Ports Climate Initiative (WPCI) in the ports of the Hamburg – Le Havre range and in their hinterlands

Mathilde De Keukeleire (UCL), Jacques Charlier (UCL)

In 2008, 55 ports launched a major environmental program in order to face the challenges of climate change, the WPCI. Its missions are to raise awareness in the port and maritime community of the need of action and to initiate actions to reduce GHG emissions and improve air quality all along the maritime transport chain (from the sea to the port hinterlands). It has formed subgroups focussing upon themes that will provide guidance to ports looking to reduce GHG emissions; 3 of these will be dealt with here: -at section 1, the introduction of the Environmental Ship Index (ESI) and Onshore Power Supply (OPS) for seagoing vessels; -at section 2, the "greening" of hinterland transport, with a higher share of inland navigation and rail transport in order to reduce the share of road transport. A series of 13 major ports of the Hamburg-Le Havre range with a traffic of at least 25 million tons in 2010 will be taken into account, namely Hamburg, Bremen, Wilhelmshaven, Amsterdam, Rotterdam, Flushing-Terneuzen, Antwerp, Ghent, Zeebrugge, Dunkirk, Calais, Rouen and Le Havre. At section 1, we will show that, in the diffusion process of ESI and OPS, there are pioneers, followers, and outliers. The epicentre lies currently in the largest Dutch and Belgian ports, especially Rotterdam and Antwerp, but also Amsterdam and Zeebrugge. However, the large German ports of Hamburg and Bremen are joining them, as well as the French port of Le Havre. For the time being, the ESI has been introduced in 7 of these ports, whereas 3 are already equipped for OPS. It seems that large general cargo ports are more sensitive to these initiatives than smaller, bulk-oriented ports. As inland navigation is a major hinterland transport mode in many of these ports, some are also providing OPS for river barges. OPS has also been or will be introduced at several Scandinavian ports and a system similar to ESI is already in use in several of these. Even if British ports are currently in a wait and see attitude, one may consider that Northern Europe as a whole will adopt the ESI formula (or a similar one) and that OPS systems will flourish. At section 2, we will show that the epicentre of actions for a greener hinterland transport is located in the same Dutch and Belgian ports. Historically, they have promoted a higher use of inland navigation thanks to their unique location at the mouth of the Rhine, Meuse and Scheldt systems. Despite the fact that the Elbe, Weser and Seine systems remain very isolated, the German and French ports followed the same path, and their interconnection with the Rhine and with the Scheldt will help. The same is true for rail transport, where the Benelux seaports were again the leaders for massive investments favouring modal shift (Betuwe and Port lines for Rotterdam, tunnel under the Scheldt in Antwerp, additional freight tracks from Zeebrugge), and with more recent initiatives in the German and French ports.

The development of a sea and land logistics system in the Philippines: The Strong Nautical Highway System

Yves Boquet (Université de Bourgogne)

As an archipelagic nation, the Philippines suffer from the splintering of its territory between islands which are not linked to each other by fixed structures such as bridges or tunnels, except between Samar and Leyte. In the early 21st century, the Philippine government has started to implement a new nationwide logistics system, dubbed 'Strong National Highway System', aiming at an improvement of the travel experience between the capital region of Manila and distant islands, and also to improve the transfer of goods across the archipelago. It consists in a series of improvement of roads alongside the 3 corridors that make up the system, also improvements in the ports where trucks transfer ro-ro style to other islands. There are also several agreements between trucking and bus companies on one side, shipping companies on the other side. This paper will present the current organization of the system, assess its efficiency in comparison to the stated goals, and will try to determine what kind of new spatial organization - if any - is resulting from its development. Given the position of the Manila metro area within the Philippines, should the system be managed from and for Manila mostly, or can it improve also the interactions between other parts of the Philippine territory - Are there hub effects occurring in major transfer points - Does it help Batangas to become a competitor port to Manila - What is the real hinterland of Manila -

of Hong Kong and its surrounding region, Pearl River Delta, which kind of value-added logistics activities will stay in the city of transport hub in concern is associated with the relative level of the 'dual readiness' that differentiates this city and the rest cities along the GSCs. This leads to a conclusion that the government of advanced hub city is critical for such urban centre to capture value-added logistics and GSC management role by upgrading properly the infrastructural and institutional settings, the latter in particular, as it cannot be done by the market alone.

Adding values to a city of transport hub: A global supply chain perspective

James WANG (University of Hong Kong)

Hub operation in transport is an outcome of efficiency search for a better network structure of supply. The hub-&-spoke (H&S) structure allows the transport providers to gain from the economies of scale. The efficiency gains will then partly pass to the users when the delivery cost via an H&S system is lower than using the point-to-point system. The stop-over for transshipments made at the hub provides a time-window as well as a collective point where shipments of cargo from different origins may be reconsolidated before reaching multiple destinations. Such reconsolidation may be seen as value-added logistics activity that will benefit the end-users as well as the H&S system, as it may bring more business to the hub. However, from a global supply chain (GSC) perspective, which type of logistics and where should it be carried out are not simply depended on the availability and use of a transport hub. To the GSC management, a transport hub is no more than part of infrastructural GSC. The GSCs have three parallel systems, handling physical flow, information flow, and monetary flow respectively. The choice for GSCs to process some components of these flows at some locations rather than others depends largely on the infrastructural and institutional readiness for the shipments to go on schedule at the expected cost. From a GSC perspective we argue that the level of this 'dual readiness' relies on a concerted effort of key players across different hierarchy of the GSCs, which characterizes each transport hub city. We further argue, with the case

Landscape and Landscape Analysis

C08.36-01 - Global Change Session

Chair: Nodar Elizbarashvili

A landscape-ecological assessment of mountain geosystems applying geographical information system (GIS)

Ashot Khoetsyan (Yerevan University), Vahagn Mouradyan

Regional landscape-ecological studies have acquired a special topicality as efficient environmental conservation and rational use of natural and resource potential is a major prerequisite to sustainable development. Such studies are underpinned by collection, systematization and consequent arrangement of information on environmental components. Such an opportunity is provided by geographic information systems (GIS). In mountain regions similar to Syunik marz (province) landscape-ecological problems are sharply manifested. The diversity of the region's natural conditions and high sensibility of natural-territorial complexes to man-made intervention is seen in their poor and unstable ecological state. As a software while preparing a landscape-ecological GIS, we employed GIS package ArcGIS 9.2, with expansion moduli 3D Analyst 1.0, Spatial Analyst 2.0 and ERDAS Imagine 9.1. A landscape-ecological analysis of Syunik marz was performed based on 5 underlying parameters: 1. Assessing ecological potential of mountain landscapes 2. Assessing ecological stability of mountain landscapes 3. Assessing ecological load of mountain landscapes 4. Assessing ecological tension of mountain landscapes 5. Assessing ecological dynamics of mountain landscapes. The values of basic parameters of the landscape-ecological analysis were calculated as sums of respective indices expressed in scores and multiplied by their significance reflecting coefficients. Conversion of natural unit measurement indices to a single score system is implemented through division of natural value (minimal to maximal) segment into a quantity of equal-size segments ('????? 2000), corresponding to the quantity of single-scale scores. To obtain compatible collation units by different indices, a single score scale was assumed (1-5). Then produced were chains of significance of diagnostic indices in a complex index. In agreement with that rule, a formula was derived of calculation of basic indices of landscape-ecological analysis (ecological potential, stability, load and tension): $Mint = K1*(F1) + K2*(F2) + K3*(F3) + \dots + Kn*(Fn)$, where Mint-is an integral assessment of basic indices of landscape-ecological analysis; $F1..Fn$ values of under-consideration indices in scores; n - the number of factors; $K1..Kn$ corresponding weight factors. Subsequently, those factors were integrated by 'Model Builder' in ArcGIS 9.2 applying 'Weighted Sum' functions. The produced maps enabled us to assess general landscape-ecological conditions of Syunik marz. The present-day ecological situation in the region results from the dynamics of landscapes predetermined by natural and man-induced processes. Remote sensing data reflect in detail the current and recent state of basic properties of landscape cover.

Saving of the landscape diversity: Legal support for balanced, harmonious environment

Viacheslav Oleshchenko (National Academy of Science of Ukraine)

Landscape becomes very important object and conceptual approach in regulation of natural environment from the very beginning of the modern period of the Environment Law development in Ukraine. Ukrainian legislation accepted such concept in the Laws About Protection of Natural Environment (1991), Natural Reserved Fund (1992), EcoNet Programme (2000) EcoNet System (2004) and a lot of other acts of national legislation and relevant chapters of laws, devoted to the related spheres of regulation. European Landscape Convention (2000) become more and more important document, which plays significant role in the process of formation and realization of national and international legislation and policy. Due to this Convention Landscape become not only a geographical term but really as a very important instrument for establishment, development and better understanding of human rights, social cohesion, democracy, safety environment, relevant self identification of nationalities, different cultures, for better integration of sectoral policy. One of the ways for making of this activity more effective should be a rising of the role of the diversity of landscapes in supporting of the balanced and harmonious territorial development. More diversified systems as we know are much more sustainable. We should remember too that we dealing with diversity not only of landscapes but of their natural components and interests of society to the concrete territories and resources too. That's why the task is - to reach better integration of possibilities of diversity of landscapes, natural diversity in wider context and interests of society. As we know modern diversity of landscapes was formed on the base of integration of different natural, economical and social processes. Such processes give us different positive and very often negative results. For better organisation of the activity related to territory and it's recourses on the base of the mentioned above European and all other international documents we developed in Ukraine relevant system of legislation and institution for it's implementation, for better saving of landscape diversity and planning of the territories with this aim. A special Law about Landscapes is in the process of development now in the Ukrainian Parliament.

Management and spatial planning of metropolitan areas in the area of economic globalization (Focus on the metropolitan area of Tehran)

Rahim Sarvar (Share Rey Azad University), Hooshang Sarvar (University of Maragheh)

In recent decades, economy globalization process has affected the structure and economic-social and space organization of countries tangibly. This process with integration of countries economy, has led to a new organization of urban areas, particularly metropolitans in global scale, which have close economic and social relations. In this article the relations of globalization process with development of metropolitan

areas, particularly its reflections in spatial-space planning and management of metropolitan areas, has been examined. The analytical - descriptive method with relying on document study has been used. Results of theoretic and case studies of metropolitan areas shows that , the recent structural changes in the global economy has been had extensive reflects in the balance of structures and approaches of spatial-space management and planning in these areas, especially in some developing countries for organization of geographical space for playing the desired in the national and global scale. The results of examining of spatial policies and programs of Tehran metropolitan area already shows that, in the favour distinction in the views of development of Tehran metropolitan, at least in past two decades' spatial policies and programs, the changes of globalization of economy in metropolitan areas and the use of potential capabilities of these areas has been noted . However , because of govern of traditional structures of state management and planning , particularly this region has not been had suitable reactions to requirements of economy globalization process and no ability to regional, national and promotion of national position . Keywords: Spatial planning and management, metropolitan areas, economy globalization, Tehran

Analysis of the fragmentation of vegetation cover in the central region of Benin Republic: Trends and future scenario of change

Joseph Oloukoi (RECTAS)

The present paper analyzes the fragmentation of the ecological landscape with a focus on vegetation formations in the central part of Benin Republic. The land use land cover change has been assessed using remote sensing multispectral and multirate data, Landsat TM 1986, ETM 2000 and NigeriaSat1 of 2006. The landscape pattern and its evolution were investigated by the combined use of Remote Sensing and GIS techniques, based on the theory and method of landscape ecology. Simulations based on a cellular automata application, Spacell model, were used for the projections of the landscape dynamic towards 2016, 2025 and 2034 horizons. Landscape pattern and its evolution was analyzed through the quantity distribution of various landscape patch types, their structure and changes, including the number of patches and the size of every landscape type, diversity and dominance indices, the isolation index and fragmentation index. Land use land cover change has been assessed at an annual rate of change of -4.66 %, expressing a regression of dense vegetation formations and the expansion of farmlands, settlements and savannahs between 1986 and 2006. This analysis made on four landscape units reveals that this trend will be maintained towards 2016, 2025 and 2034. Environmental implications are the fragmentation of the vegetal formations followed by the isolation of some land use land cover units. On the socio-economic aspects, it has been noted the emerging of new economic activities such as wood exploitation and commercialization, charcoal production, activities that are seriously contributing to the degradation of natural resources in the area. Keywords : Fragmentation, Landsat, Dominance, Diversity, Benin

Geoparks

C08.37-01 - Session on Geoparks

Chair: Wei Dongying, Wolfgang Eder

The geodiversity in the Cilento and Vallo di Diano Geopark (Italy) as support in the enhancement of sustainable development

Alessio Valente (University of Sannio), Aniello Aloia (Parco Nazionale del Cilento e Vallo di Diano), Angelo De Vita (Parco Nazionale del Cilento e Vallo di Diano), Domenico Guida (Università di Salerno)

The National Park of Cilento and Vallo di Diano was listed in the European Geoparks Network in 2010. This territory extends over 1800 square kilometres in southern Italy. It includes several mountain ranges, whose peaks reach altitudes above 1900 m, hillside and ridges, interrupted by valleys, often deeply incised. These valleys, where flows the Alento, Mingardo, Lambro and Bussento rivers, sometimes become wider to the coast, creating small alluvial plains. In correspondence of these flat areas, sandy or pebbly beaches are formed, otherwise the coast is dominated by high and rocky cliffs. This articulated morphology is due to the geological nature of the rocks that make up the area, as well as to the geological history, rather complicated, which has suffered this area. Some relieves consist of Mesozoic limestones and dolomites, extremely widespread in the southern Apennines. They have been shaped by karst morphogenesis, with the formation of surface form (dolines and polje) and underground ones (caves). The tectonic is evident along the slopes of the relieves or in the deep gorges and canyons which dissect them. Other relieves are made up of sandstones and conglomerates of the Middle-Upper Miocene, in the upper portion, and of clay and calcarenites with marls of the Paleocene, in the lower ones. These outcrops are exclusive in the southern Apennines. The slopes of these relieves have been shaped by water runoff and gravitational movements. Along the coast, changes in sea level, that succeeded in the Quaternary, are recorded by many significant traces, such as marine terraces, notches and caves, sometimes with associated sediments and fossils. These geological characters can be represented by a large number of emergencies, with different degrees of importance and interest (stratigraphy, geomorphology, hydrogeology, etc.). Their scientific value can be assigned according to research carried out on them that they have also allowed relevant scientific publications. As regard the educational value is related to their representation in the territory, and therefore their inclusion in some learning and /or tourist paths. In addition, these emergencies can be integrated with a wide variety of ecosystems, already include in the UNESCO program "Man and Biosphere" as well as archaeological sites, unique and exceptional, Paestum, Vella and Padula, recognized as World Heritage by UNESCO. However, in this territory, where the physical landscape is an attractive scenario, we can not overlook the areas in their natural state with endemic vegetation and fauna of great ecological value, or the castles, churches and places of worship, indicative of a long history and a unique tradition, expressed in various ways and

attractions. The geodiversity in the Geopark, supported by a cutting-edge scientific research, can contribute to the search of new paths in education and development of sustainable tourism activities.

Geotourism industry & geoparks in Iran (case study: Qeshm geopark in environmental landscape)

Tahereh Sabouri (University), Roya Mousazadeh (Environment), Kaveh Homayoun

Developing geotourism in the world and study of abiotic nature towards growth of nature-based tourism plays an important role in sustainable development of various parts of Iran. The study of the elements of abiotic nature and its zonation in environmental landscape can provide optimal use of nature and God-given facilities in the context of geotourism. Also, registration and protection of national natural properties reveals the necessity of academic zonation of geotourism potentials with the aim of general monitoring and identification of properties of various regions. In the present study, an extensive survey was carried out in order to identify and evaluate areas prone to geotourism and geoparks, and environmental landscape of Qeshm Island as the largest island in Persian Gulf and a potentially touristic region was chosen as a case study to develop tourism industry branches particularly ecotourism and geotourism, beach and marine tourism. This island in terms of cultural, historical and natural attractions is among the richest regions of Iran. Of wonders of Qeshm nature is an attractive and rare complex of geological heritage and unique environmental landscape. This complex was registered in Global Geological Network (GGN) in 2006. Obviously, Qeshm geopark is of special importance due to being located at strategic region of Persian Gulf. In addition, Qeshm geopark that is located between Asian and European geoparks has found a particular position both in the region and in international geoparks. Warm and sunny beaches lying along the geopark has doubled its beauty. The only geopark in the Middle East is placed in a higher rank due to diversity of geological phenomena and the sites. Qeshm has a diversity of all other rare attractions the example of which is mangrove forests and their diversified ecosystems. Key words: Iran, tourism, geopark, geotourism, Qeshm, environmental landscape.

The role of geomorphology studies in site selection for geoparks and sustainable geotourism-proposed geopark: Dorfak and Deylaman (Gilan Province)

Tahereh Sabouri (University)

This paper deals with the role of geomorphologic studies in environmental planning in order to select suited sites and develop geoparks based on sustainable geotourism criteria. Identification and site selection for attractions of establishing a geopark and develop geotourism in Dorfak and Deylaman are main objectives of this research. To establish a geopark, the most important factors are geologic studies, geomorphologic

studies and unique landscapes. Other natural and cultural heritages are also important, which are regarded as a second priority. Dorfak mountainous mass (Gilan Province) was selected due to following particular conditions and environmental potentials: variety of faults, valleys and landslides, picturesque landforms resulting from karst erosion such as dolines and lapies in Dorfak zone. There are also numerous caves in which monuments of early men and Paleolithic tools have been discovered and each of them is a potential geopark to be introduced to UNESCO. Key Words: geomorphology, geopark, geotourism

The Power of the Geographical Names

Paulo Marcio Leal de Menezes (University of Rio de Janeiro), Cláudio João Barreto dos Santos (FIBGE), Ana Cristina Resende (FIBGE)

This paper is part of the research in Geographical Names accomplished by the Laboratory of Cartography of the Department of Geography of the Federal University of Rio de Janeiro. Its main objective is to analyze the aspects of power contained in geographical names and their empowerment characteristics, applied to the research, as well as to emphasize the characteristics and concepts in general on the aspects of power that surrounds geographical names. In a general way the geographical names are supported by a binomial composed by the culture and popular will, for which are settled down the base of its perpetuation. The break of one element of the binomial, give conditions to have actions for changes and in consequence changes about the original characteristics and motivations over the geographical name. The geographical names are, from an unquestionable way, linked also to the conceptual structure of territory, mainly when is focused the quadruple fundamental concept structure: identity, belongment, appropriation and administration. In these four supports, the territory denomination will always be made present and materialized by geographical names. As territory and power are intimately linked, for consequence, the relationship between the geographical names and the structures of power becomes a natural unfolding. In a cartographic way the geographical name has a juridical registration, when it is printed in a official cartographic document. Once put in an official map, he has a juridical recognition and they can be part of referencing cadastral documents, as for instance, for physical limits definition, in any administrative levels, municipal, state or federate. Changes of a geographical name in those cases will have serious impacts on the defined area. Cadastral litigations are still solved for the location confrontation of defined places by geographical names, even when modern cadastral systems established by GNSS are available. Actions for changing names by any reasons must be preceded by an extensive and deep impact study that can be generated. On the other hand, change names took by political aspects or political power, but that also lean on in the basic binomial can perpetuate a geographical name or not, depending more on the popular support than through the binomial's cultural aspects. The geographical names of the population nuclei in Rio de Janeiro State, Brazil will be analyzed under the optics of the power and associated empowerment. Taken into account its original motivation, it will be defined a new kind of relationships of geographical names under the mentioned aspects.

Place name, space and society – The role of place names in relating people and place

Peter Jordan (Austrian Academy of Sciences)

Place name, space and society - The role of place names in relating people and place In its Addendum to the Glossary of Terms for the Standardization of Geographical Names (2007, p. 2) the United Nations define the endonym as a 'name of a geographical feature in an official or well-established language occurring in that area where the feature is situated.' In this definition just the factors 'geographical feature' (as a subunit of the geographical space), 'language' and 'name' are mentioned, as if place names (and languages) could exist without a human community or social group. But place names are not just attached to certain features of the geographical space, they are not just - colloquially speaking - 'hanging around' in space somewhere, but they are also attached to a certain social group in the sociological sense, i.e. in the sense of a number of people characterised by mutual relations and a common culture (ranging in size from a family or a couple of friends to a nation). They have in fact been created and are applied by this group. Without social groups place names simply would not exist. And this is also the very reason and justification for dividing place names into endonyms and exonyms. An endonym is under this aspect a name applied by a social group permanently residing in a certain section of the geographical space for geographical features within this section as opposed to an exonym, which is a name used by another social group residing outside this same section of the geographical space and not corresponding to the endonym. Apart from hinting at this basic relation, this paper will also highlight the meaning of place names for social groups and the concrete roles place names play in relating people and space - in which way and why they convert space into place in the sense of Yi-Fu Tuan. Three roles will be mentioned here: (1) In the naming process social groups highlight what they find to be characteristic for geographical features; (2) social groups construct space-related identities by attaching place names to a feature or section of geographical space - attributing place names functions similar to flags or coats of arms and elevating them to the rank of symbols of space-related identities; (3) place names strengthen emotional ties between man and place and have also in this way an important function in space-related identity building. The paper may be classified as a cultural-geographical approach to place names.

Stone Age place names as markers and ingredients of space-related identity

Peter Raper (University of Free State)

In discussing the semantic contents of place-names, a distinction is noted between lexical, associative, pragmatic, referential and such different meanings. The Stone Age peoples of southern Africa were as aware of the identity-bearing contents of place-names as later immigrants. The ingredients of their place-names were determined by their life-

style as hunter-gatherers. The physical character of their environment determined their toponymic landscape, reflecting the descriptive elements of size, shape, colour, etc.; the flora and fauna on which they depended for their survival, and the like. The role of place-names as markers of their identity is reflected in many ethnonyms derived from the place of habitation of the various groups: Einiquas 'Big River People' on the Orange River (Grootrivier); Chariguriquas 'Great Mountain People' on the Great Berg River; Taaneiquas 'Grass Plains People', etc. Adaptation, desemanticization, reinterpretation of Stone Age place-names by later immigrants, settlers and others resulted in new semantic contents and new markers of identity, and in competing claims to ownership, identity and authenticity.

Identifying seas and their names: Koreans' emotional ties to the seas as reflected in their place names

Sungjae Choo (Kyung Hee University)

A place name is normally given to a geographical feature with some visible limits. But when a feature is big enough to go over to a far unseen limit, e.g. a sea beyond the horizon, it would not be easy to delimit its boundary within which it is called by the given name. One way of its delimitation could be finding a point up to which people's emotional ties reach. When naming a feature, they must have intended one being within their emotional grasp. If there are another group of people at the other side of the feature who have another emotional ties, then it may well have a different name given with different identity. This paper firstly attempts to figure out up to what point Koreans identify the sea with their names and how their emotional ties with the sea are working. A structured questionnaire is suggested. Secondly, the paper tries to reveal how strong Koreans emotional ties are to the sea by examining place names in coastal areas which reflect the traces of the sea name.

Semantic uncertainty of concepts in generic name of undersea features

Hyo Hyun Sung (Ewha University), Hyowon Ban (California University)

There are many existing works that focus on aspects of techniques and methodologies for detection, measurement, modeling, and estimation of concepts in seafloor topography. (Bell, 1975; Goff and Jordan, 1988; Smith and Sandwell, 1997; Wynn, Masson, Stow, Weaver, 2000; Baba and Seama, 2002). However, some of the concepts -for example, seamount, sea valley, basin, or plateau-have multiple different definitions (Pitcher, Morato, Hart, Clark, Haggan, and Santos, 2008; Staudigel, Koppers, Lavelle, Pitcher, and Shank, 2010). When one of the concepts is spatially represented using its multiple definitions, the definitions may not show an identical boundary on a map. Due to the reason there may exist semantic uncertainty (Ahlqvist, 2004) in such concepts. Some studies deal with classification of the concepts in seafloor geology (Mitchella and Clarke, 1994; Jakobsson, Grantz, Kristoffersen, and Macnab, 2003). However few of them have focused on the uncertainty of concepts in seafloor topography. Instead, there exist studies that tried to demonstrate, measure, and represent the uncertainty of geographical concepts such as land-use/land-cover classification system and spatial boundary of urban sprawl (Ahlqvist, 2004; Ban and Ahlqvist, 2009). In those studies locations of the uncertain geographical concepts were represented in fuzzy boundaries rather than crisp boundaries that were created by using approaches of fuzzy-set theory (Zadeh, 1965),

Geographic Information Science (GIScience), and geovisualization techniques. Following Ban and Ahlqvist (2009) this paper aims to 1) identify some existing uncertain concepts in generic term of undersea feature that have multiple different definitions of spatial range, 2) measure and analyze the degree of uncertainty in each concept by using fuzzy-set membership functions, spatial analytical methods, and empirical spatial data, and 3) represent the degree of uncertainty spatially explicit using geovisualization techniques. Results of this study may provide contribution to better understand the uncertainty of concepts in seafloor topography for naming undersea feature by applying existing approaches of measuring and geovisualizing uncertain spatial concepts. The study can be further extended to deal with spatio-temporal characteristics of the uncertain concepts in seafloor topography for generic term of undersea feature. In addition, the methodologies in this study may be applied to some uncertain concepts in geomorphology- such as mountain range- to measure and represent the semantic uncertainty.

Wanganui and Whanganui: Two identities and two names?

Philip Matthews (retired)

Maps of New Zealand, irrespective of scale and purpose, have shown over time the name of a town and the name of the river on which it stands as both Wanganui and Whanganui. The question as to how the names should be spelled has been intermittently controversial over the last 170 years. The issue became more pressing when, in February 2009, a M'ori organization made a submission to the New Zealand Geographic Board seeking a change in the name of a city and its district to Whanganui and in August 2009 a submission was made by the local government authority to retain the Wanganui spelling. This paper discusses the histories of the two names and, more particularly, the two identities underlying the names. Finally the proposed resolution of the matter is commented on.

The Meaning of A Place by VGI-The Case of Gongguan, Taipei

Bor-Wen Tsai (Taiwan University)

Fox (1997) proposed that space is based on directional co-ordinates and symbolic co-ordinates and place is socially constructed and personally experienced. Thomas (2001) also thought that a place is not merely a spatial location but something with meaning. Traditional GIS has implemented space of physical environment successfully based on computational geometry. However, how GIS can implement place which is formed through human experience from the interaction between their culture/social activities and natural environment is still in developing stage. This research employed VGI (volunteer geographic information) concept and used geo-tagged photos from flickr and Picasa web albums to explore human spatial cognition of Gongguan which is a native

place locates in southern part of Taipei city. This article aims to provide a methodology for the study of a native place name in Toponymy and a region in New Regional Geography.

Toponymy and landscape in historical cartography: The case of Josep Aparici's map referred to Catalonia (1720)

Joan Tort (University of Barcelona)

The catalan cartographer and geographer Josep Aparici published in 1720 the map entitled 'Nueva descripción geographica del Principado de Cataluña', devoted to the Spanish King Felipe V. It was drawn in six sheets, and its scale is equivalent to approximately 1:250,000. It is considered a significant document in the context of the history of cartography in Catalonia and Spain. Scholars have stressed the accuracy and the precision concerning its place names as one of the most remarkable qualities of the map. Probably the author's training as a geographer and his detailed empirical knowledge of the Catalan territory, contributed to this attribute. We focus our analysis on a particular aspect of the Aparici's map: the approximately fifty place names that have a regional dimension in terms of spatial meaning. That is, names that refer to places or geographical areas of what in Catalonia is considered 'medium size' (usually between 100 and 500 km²). Areas with a specific name (that usually have persisted with little change throughout time) and which have usually a common feature: they tend to coincide with physically well defined landscapes. On this basis, we ask questions such as the following: 1. In all studied names, which kind of semantic connection does it exist between 'name' and 'landscape'? 2. To what extent this semantic connection has been maintained over time? Is it still valid today? 3. Once the connection between 'name' and 'landscape' has been established, can we verify any specific relationship of this name with the etymological meaning attributed to it? 4. From the names discussed, can we speak of a 'toponymic landscape' of Catalonia around 1720? 5. How different would be this 'toponymic landscape' if we would take as starting point the cartographic toponymy of the sixteenth and seventeenth centuries? In the concluding section, we will consider what might be the most important scientific contributions and the analysis we propose, both in terms of Geography and in terms of Onomastics. For our study, in addition to the main reference, we will consider other maps from earlier and later dates, and relating to both the Catalan and Spanish historical cartography, and also to other countries. Also, we will work with concepts that we have already used in previous analysis, as the toponym as "landscape indicator."

Eléments d'analyse et de compréhension de la toponymie tunisienne: Cas du golfe de Guèbis

Mohsen Dhieb (King Abdulaziz University)

La compréhension de la toponymie des noms géographiques est essentielle pour la construction de l'identité d'un territoire. Elle réfère à une série de facteurs géographiques, historiques, culturels et linguistiques. C'est particulièrement le cas de pays ouverts, à fortes charges historiques ou des interférences linguistiques multiples. Différentes civilisations et cultures se sont succédé en Tunisie. Les événements récents ayant eu pour lieu certaines régions et villes intérieures, ont reposé la question régionale mais aussi la question toponymique. Des noms peu connus jusque là -Sidi Bouzid en est un exemple- sont devenus des symboles ou des icônes pour le peuple tunisien et pour d'autres peuples de la région. En comprendre l'origine ou la signification est devenu une nécessité identitaire. Comprendre l'origine et l'évolution des quelques 15000 toponymes tunisiens que nous avons pu estimer n'est point une entreprise facile. Cela exige un travail collectif systématique qui dépasse l'ambition de ce papier. Les multiples civilisations et cultures qu'a connues la Tunisie, les langues parlées et les dialectes régionaux et les parlers locaux ont contribué à des degrés divers à façonner les toponymes tunisiens. Mais, du fait du jeu de l'évolution de la langue et des parlers, elles ont contribué quelquefois à en camoufler l'origine et la fonction. Très peu de personnes savent que l'actuelle Gafsa renvoie à la civilisation capsienne dont elle tire l'appellation. L'autopsie des toponymes tunisiens devrait s'appuyer sur une démarche objective, tangible et transposable. Le cas étudié ici est celui de 4 cartes topographiques du golfe de Guèbis (Gabès). En l'absence de littérature spécialisée sur la question, notre recherche s'appuiera sur les matériaux existants: significations sémantiques, textes historiques, récits d'auteurs, légendes populaires, croyances locales et connaissance terrain. Cependant, il restera toujours soit des lacunes soit des ambiguïtés par rapport à une reconstitution systématique. Nous posons les jalons d'une démarche de recherche d'éléments fondateurs d'une identité nationale dans une toponymie devenue symbole d'une révolution, nous discutons les résultats, mais nous sommes conscients des limites de la recherche.

Egyptian place names as a reflection of identity, languages changes and emotional ties

Eman Oriby (Central Agency For Public Mobilization And Statistics)

The diversity of Egyptian place names on Egypt represent the rich history of the 7000 years civilization with different languages and written systems and successive conquest from different rulers who had variant cultures .They represent emotional tie between people and places where the majority of place names of Egypt are eponyms ,dates of important events and Sure names .Egypt has a long history of recording Egyptian place names , the oldest known record is Tel Al Amarna tablets ,holly books and later historical

books and maps, gazetteers and census data and finally GIS systems .Through recording there are major challenges that affect recording the correct place names which I will represent them in this paper. Other cultural aspect is using Egyptian place names on other parts of the worlds like pyramids and Cairo and in recognizing Egyptian cotton and lately Tahrir Square for liberty .On the other hand using foreign place names to reflect some properties like Beverly hills city in Cairo governorate for high level standard property.

The Name Brazil – Considerations under a Historical Toponymyc Approach

Paulo Marcio Leal de Menezes (University of Rio de Janeiro)

The name Brazil is known practically since the 12th Century, and was mentioned in the most several legal documents, customs annotations and trade lists, mainly in Italy and old France. As a place name, the name Brazil as a cartographic reference is known at least since 1325, in a map due to the Genoese cartographer Angellinus Dalorto. It was repeated as a representation widely until the 15th Century, without related with the new discoveries happened on the new Continent. These references occurred mainly in maps elaborated by Italians and Catalans cosmographers. The researches show and an extensive bibliography mentions the existence of cartographic references of the place name, mainly as an island with names, under a variety of orthographies, among them: Brazil, Berzil, Bracie, Brazil, Bracir, Brasill, Brezill, Brazail. They also act references to the Mystic islands of the Sea of Darkness. The connection between some of these islands and the place name Brazil is narrow and they possess representations even diversified, just as the Hereford Map, of the 12th century, until to the Vinland Map, of the 15th century. It is included the representations that influenced the subsequent Portuguese cartography. The italic influence began with Andréa Bianco, member of Sagres School turned and elaborated important maps to the study developed for the discoveries. On the maps built between 1436 and 1448, important references and statements are acted, showing the assumed knowledge of the Brazilian lands in a time previous to its discovery. This paper aims to show the cartography pre Portuguese with their references to Brazil.

Romanian Exonyms on the territory of Serbia

Remus Cretan (University of Timisoara)

There are several areas on the territory of Republic of Serbia where Romanian exonyms could be found, mainly at the Serbian-Romanian border where a Romanian minority population lives. Most of the Romanian exonyms are extended in the north part of the Serbian Banat area as well as on the Timoc Valley where the Walahian population (vlasi) preserve their cultural values and still use Romanian names. These exonyms could be categorized in two main groups: habitation names (towns, villages, homestead) and feature names (oronyms, hydronyms, places of natural vegetation growth), expressing both characteristics of the specific places the Romanians migrated in the past and geographical elements related to the Serbian place they settled.

Decoding urban landscapes through the analysis of place names and imaginaries at a local scale

Ayar Rodríguez de Castro (University of Madrid)

Toponomastics is increasingly interested in the subjective role of place names in daily life. In the frame of Urban Geography, the interest in this matter is currently growing, as the recent change in modes of habitation has urged our discipline to find new ways of exploring the cities. In this context, the study of how name's significance is connected to an urban society constitutes a very interesting approach. We believe in the importance of place names as tools for decoding urban areas and societies at a local-scale. This consideration has been frequently taken into account in the analysis of exonyms and macrotoponymy, although in their case they are not exempt of political and practical implications that often prevail over the tool function. The study of toponomastic processes helps us understand how the city works by analyzing the liaison between urban landscape, imaginaries and toponyms. This is reflected in the scarcity of some names, in the biased creation of new toponyms and in the influence of tourists, residents and local government over place names and their changes, maintenance and disappearance. Our study-case, Toledo, is one of the eldest cities in Spain, full of myths, stories and histories that can only be understood in combination with processes of internal evolution of the city linked to the arrival of new residents and the more and more notorious change of its historical landscape. At a local scale, we are willing to decode the information which is contained in its toponyms about its landscape and its society.

An analysis of the use of Catalan on place name signs in València (Spain)

Joan Carles Membrado (Universitat de València)

The land of València (officially Comunitat Valenciana) is a bilingual territory in eastern Spain inhabited by five million people where both Catalan (officially known as Valencian in this territory) and Spanish are official languages. The official use of Catalan/Valencian was banned there in 1707, but restored in 1983, after democracy arrived in Spain. From 1983 to the present, Catalan/Valencian has made significant advances in València as regards its legal and official status, advances that have not been accompanied by a rise in the number of Catalan speakers, since the migrants who have come to Valencia -2 in 6 of the current inhabitants of this territory were born outside it in areas where Catalan is not spoken- have not usually learned Catalan, but have used Spanish instead for integration into Valencian society. Among the legal advances, we have to mention the reinstatement in most Valencian municipalities of their original Catalan names as the official ones. Nowadays, 350 out of 396 Catalan-speaking municipalities in Valencia have a Catalan official name. As a result, most signs in Valencian roads referring to place names are written in Catalan nowadays. Also street name signs have regained their Catalan form, or have been translated into this language. It must be remembered that road signs (for drivers), along with street names (for pedestrians) are perhaps the main instrument of symbolic perception for understanding the sociolinguistic situation of a territory. There is no doubt that the presence of Catalan in signs has increased over the last decades -not just in road or street signs, but also in those belonging to many private businesses, for instance restaurants or baker's shops, which are often given Catalan names in order to emphasize their Valencian identity. The regional Valencian government, and most Valencian municipalities as well, have made a considerable effort over the last decades in order to promote signage in Catalan in streets, roads, businesses, etc. We do not find that a comparable effort has been made in order to promote the public use of this language and give it prestige. Many Valencian authorities do not speak Catalan in public ever. It is therefore unsurprising that, for most people -including most Valencian speakers of Catalan- Spanish remains the important language, whereas Catalan is still relegated to secondary, subordinate, symbolic status.

Transonimization of the ancient toponyms of Split

Marina Marasovic-Alujevic (Faculty of Philosophy), Katarina Lozic Knezovic (Faculty of Philosophy)

The paper deals with the toponyms of Split, centre of the Croatian region of Dalmatia. The revitalization of its ancient toponyms is achieved by their transonimization into the category of chrematonyms, by the nomination of institutions, shops, restaurants, sport facilities etc. The toponyms are etymologically analyzed and classified into respective semantic categories. These names continue emotional connection with the inhabitants and the denominated place. This is the most appropriate way to avoid the oblivion of the extinct appellatives from which the toponyms have been formed and to re-enrich the

active vocabulary. Along with numerous monuments of spiritual and material culture, in which the city of Split abounds, toponyms are evident examples of the preservation of immaterial heritage of the two-millennial city. Key words: toponyms, chrematonyms, etimology, lexis, Split

Managing mega-cities growth – from the perspective of university relocation in Hochiminh city

Hieu Nguyen Ngoc (National Academy of Public Administration of Vietnam), Ha Le Thuy (VIAP)

Relocation of universities from city centre to the outer region is a solution for resolving overpopulated and congested problems in mega-cities of Vietnam. Hochiminh city, the largest city in Vietnam, accommodates over 30% of Vietnam's student. The current ratio of student to local citizen is 1/13 seems small; however, the number of students has grown over 20 times over 5 decades, compared with city area grew 2 times. Students are blamed for its new demand for housing, infrastructure, and services, which is overload for city's capacity now and future. Therefore, the relocation plan has been approved with many new restricting measures on renovating campuses of the universities in the city centers. However, the search for effective solution is a long process, as there were no sign of decrease of student number in the old districts so far. It seems that universities find no trade-off at current plan. Outside city centre, they may have weak attraction to students and lecturers. The cost of operation may underestimate in new campuses comparing to the old ones, given the current development status. For municipalities, there are no clues for lowering the floor area ratio and attraction power of new types of building in the old campuses. Until recently, the management of relocation may have to rely on external factors such as the emerging demand from the region as well as new linkage of new express way. Perhaps the more matured urbanisation of satellite towns in the region would balance the trade offs for relocating universities in the city centers. If it is the case, the new plan for the relocation may have to boost its incentive measures to the right objectives besides the strict control of development as they are doing over past few years. Key words: urbanisation, mega-cities, university relocation, regional planning, demographic changes, planning.

In the absence of statutory planning – planning on the ground

Wolfgang Scholz (TU Dortmund)

Joint research project together with Prof. Dr. Sabine Baumgart, Faculty of Spatial Planning, TU Dortmund and Prof. Dr. Wilbard Kombe, Ardhi University, Dar es Salaam, Tanzania In the absence of statutory planning - planning on the ground In Sub-Saharan Africa urbanization is progressing at a rate unprecedented in human history. In most countries, the state is not in a position to apply a responsive legal framework and to mobilize adequate resources to guide urbanization. A major obstacle are the outdated legal framework and the inappropriate planning concepts inherited from colonial

governments which often contradict post colonial policies and are unsuitable to respond to rapid urban growth. The chronic underperformance of the public sector vis-à-vis rapid urban growth caused a large cumulative backlog in the provision of building land and basic services. In addition, uncontrolled informal urbanization has often caused dysfunctional settlement lay-outs and urban structures. In Dar es Salaam, Tanzania, informal settlements cover now more than 70% of the city areas because the statutory system cannot provide sufficient building land and settlers have to find plots on the informal land market. It shows the need for a new approach to statutory planning in order to guide urban development effectively, to create more functional settlements, to assist the urban poor to access affordable plots with basic services, and to release financial assets for the urban economy. The paper will present results of a joint research analyzing empirically factors that determine space standards and land use in prevalent types of formally planned and informal settlements in Dar es Salaam. Goal is to identify parameters to ascertain the long-term suitability of settlements, understood as being functional and flexible to respond to future demands reflecting from socio-economic development. The research reveals that today there is not much difference between planned and unplanned settlements in regards to land use changes, land use conflicts and violation of planning regulations and procedures. More important are therefore negotiation procedures on the local level to replace the statutory system and to find solutions on the ground. The paper will present potentials but also limitation of this approach. At the centre of the research are the livelihood strategies of the residents. The overall aim is to evolve a responsive framework for statutory planning including spatial standards for settlements that reflect the current reality of urbanization under poverty while addressing future needs. Main actors will be local leaders and the community to ensure sustainable planning.

Urban security governance in São Paulo – a multilevel analysis of in_formal structures and agencies

Dominik Haubrich (University of Kiel), Rainer Wehrhahn (University of Kiel)

In Latin American metropolises we recently observe substantial qualitative changes of public security policies at all administration levels as well as a proliferation of technical and personal security measures in residential areas of the broad middle class. The scientific discussion of these processes usually concentrates on their relationship with complex urban insecurity situation, the privatization of public space or fragmentation processes of parts of the urban society. Urban geography and geographical security research rarely focus on the reciprocal processes of (permanently and rapidly changing) public security care on the one side and in_formal activities of the local people with respect to security measures in urban neighbourhoods on the other side. Against this background the paper discusses the questions, if local debates on security and order - based on increasingly consolidating security councils at the city quarter level (CONSEGs - Conselhos de Segurança comunitária) - help institutionalize public cooperative structures or if the civil society organizes itself bottom-up like without the influence of public actors. In this

context, questions of neighbourhood empowerment and governance have been researched using qualitative interviews with stakeholders of public and civil society entities as well as with inhabitants of non-gated residential middle class areas in São Paulo. The results help understanding if different kinds of organization and cooperation in the field of security policies can be interpreted as a constitutive part of urban security governance.

Contentions for Water: Case of Chennai Metro Region

Sridharan Nomperumal (School of Planning and Architecture)

Historically, water has been a contentious issue among nations and states. From source sharing to final pricing, institutional conflicts dominate and get manifested in various forms. These conflicts deprive access to water by various segments of the population, especially the marginalized groups. To achieve the Millennium Development Goal of bringing down by half (MDGs), 90 million urban Indians have to be provided with safe and sustainable drinking water by 2015. Taking Chennai metropolitan area as an example, which has perennial water crisis and institutional conflicts, this paper analyses contestations over source, contestation over distribution and resultant marginalization of various population sub-groups. It probes into aspects such as urban form, territorial and institutional conflicts, regulation over water and its impact. It shows how the water provision has become a private good from that of public good due to political interests. It analyses the water policy in the context of local politics. It reviews how far the local commitment exists towards achieving MDG in drinking water. Using the information gathered from various stakeholders in the city and from secondary sources, this paper evaluates the sufficiency and sustainability of existing water supply system to meet the equity and efficiency criteria of the city. The paper argues that even in certain sectors, such as water, decentralization will not address efficiency and equity concerns, especially in favour of vulnerable groups, though the State and Local Governments have come out with pro-water harvesting and high tech water production policies.

Contribution of an Optimized Waste Management to Energy Supply in Santiago de Chile under Climate Change Conditions

Rainer Bräutigam (Karlsruhe Institute of Technology), Volker Stelzer (Karlsruhe Institute of Technology)

Total production of Municipal Solid Waste (MSW) in the Metropolitan Region of Santiago de Chile (MRS) in 2007 was roughly 2.9 million tonnes, representing 1.2 kg/(cap*day). The organic fraction, which is responsible for the production of greenhouse gases (CO₂ and CH₄) in the case of disposal in sanitary landfills, had a share of about 50% in 2007. The main part of MSW is disposed of in sanitary landfills (recycling rate is about 13%) without any further treatment. Landfill gas, produced at the three operating landfills is captured and mainly flared, the use of landfill gas as an energy source is negligible, and therefore the contribution of waste to energy supply for MRS can also be neglected. Within the project 'Climate Adaptation Strategy for the Metropolitan Region of Santiago de Chile (CAS)', which is supported by the Federal Environment Ministry of Germany (BMU), climate adaptation strategies for MRS have been developed on the basis of different explorative scenarios for the year 2050 for the key areas energy, water and land use. In this paper results of the above mentioned study, regarding the contribution of waste management to energy supply in 2050 for MRS, taking into consideration effects of climate change, will be presented. In 2007 electricity demand in MRS was about 17 TWh, electricity generation in MRS was about 4.2 TWh, from which about 50% was produced by hydro-power plants. Due to climate change, temperatures will increase and rainfall rates will decrease, resulting in a decrease of the stream flow of the rivers and therefore in a decrease of electricity production from hydro-power plants. On the other side the energy demand will increase due to rising population and rising living standards. Within the explorative scenarios, it was assumed, that mainly due to an increase in population and in living standards (Gross Domestic Product) electricity demand will increase to 40-50 TWh in 2050 and the production of MSW will increase to about 6,6 Mio tons (2 kg/cap*day). Regarding waste management it was assumed that in 2050 separate collection of a major part of the organic fraction with subsequent anaerobic digestion to produce CH₄ for the production of energy, capturing and using landfill gas for the production of energy as well as the production of a Refuse Derived Fuel (RDF) to be co-fired in cement kilns or in power plants will be common practice. Taking these assumptions into consideration, between 2 and 3.5 TWh of electricity can be produced from waste, which means a share of about 4% to 7% of total electricity demand in the Metropolitan Region of Santiago de Chile in 2050.

How to construct a water shortage, even if you live on a huge river: The case of Shanghai

Michael Webber (University of Melbourne), Jon Barnett (University of Melbourne), Zhong Yuan Chen (East China University), Brian Finlayson (University of Melbourne), Mark Wang (University of Melbourne), Dan Chen (Hohai University), Jing Chen (East China University), Maotian Li (East China University), Taoyuan Wei (East China University), Sarah Wu (East China University), Hao Xu (East China University)

Shanghai is a subtropical city, located on the second largest river (by volume) in the world. Yet it faces the threat of shortages of drinking water. This situation has virtually nothing to do with population growth and economic development, nor yet with privatisation or the commodification of the commons. Instead, many decisions and environmental characteristics have contributed to this threat. First, Shanghai has become dependent on the Yangzi River for its drinking water. The city neither recycles significant quantities of water nor does it store local precipitation. Therefore, it relies on water brought into the municipality by rivers. Second, it has changed its river-borne supply from the Huang Pu to the Yangzi River. This decision has been made in order to control the levels of pollution in the water that enters its treatment plants. China's pollution control regime underpins this decision. Third, for reasons of inter-provincial rivalry and politics, the city has chosen to draw water from the Yangzi through water intakes that are located within the municipality, and that are therefore within the estuary zone and subject to tidal intrusions of salt water. Fourth, the characteristics of the Yangzi itself play a role. At high tide, when the river's discharge is low, salt intrudes into far into the estuary, far beyond the current water intakes. If sea levels rise, these intrusions will become more pronounced. Fifth, large-scale central government infrastructure projects are altering the hydrological characteristics of the river. Dams on the Yangzi, such as the Three Gorges Dam alter the seasonal flow of the river, even if they do not alter the total amount of water discharged annually. The South-North transfer, designed to alleviate water shortages in the great cities of China's north, promises to extract 50 billion cubic metres / year, transferred out of the Yangzi basin. Such projects raise the probability of salt water intrusions into the water intake zone, especially during some periods of the year. The Shanghai and central governments have thus made a series of decisions that, taken together, have forced the municipality to rely on a source of drinking water that is increasingly unreliable (even if its annual discharge is huge and its annual variability small). Why these decisions have been made - and made independently - is an important topic for those who would understand the provision of water for cities and the practical efficacy the Chinese governance systems.

Analyzing Energy Performance of New Quality Building Envelop by Computer Simulation

Kamran Naeiji (TU Berlin), Klaus Rückert (TU Berlin)

'New Quality Building' is a residential building which is built as a pilot for the project of 'Young cities - Developing Urban Energy Efficiency - Tehran - Karaj' in 'Hashtgerd New Town' which is located about 70 km west of Tehran capital city of Iran. The Main goal for implementation of this building was to recognize the potentials, resolve the defects and train the labor in Iran by designing and constructing a high quality residential building according to Iranian national buildings code with the supervision of German side by using existing materials, facilities, labors and etc. The main goal of this paper is to investigate the energy performance of 'New Quality building' during one year and comparing it with a conventional building in Hashtgerd New town. The effect of different component of 'new Quality building' such as envelope insulation, windows etc. on energy demand of this building is also calculated in this paper. To achieve these goals a computerized dynamic energy simulation is performed. In order to simulate the sun radiation and shadings, wind effects, to solve the transient heat transfer equations and to calculate the heating and cooling energy demands of buildings, EnergyPlus software is utilized. According to results, a conventional building in Hashtgerd, consumes nearly 2.8 times higher energy for heating and 1.2 times higher energy for cooling than the 'New Quality Building'.

enough window area, or bedrooms windows dimensions should follow cultural restrictions. 3. The form, size and dimensions of windows of each residential unit (or nonresidential), according to its solar energy demand. The building land piece direction and location have influence on this issue and can provide more or less amount or time duration of solar radiation for a certain window in different urban building location.

Solar Energy Efficiency in Contemporary Architectural Design of Iran's Residential Apartments, Case Study: Hashtgerd

Mohammad Reza Razavi (University of Berlin)

Cold cities of Iran (among them Hashtgerd) mostly located in the mountainside regions around the country. Buildings of these cities use a lot of fossil fuels for heating during cold seasons of the year, which a considerable amount of this need can be provide by solar energy via exposed walls (including windows) or other absorbing and keeping solar radiant energy methods. A factor which has influence on amount of solar energy receiving by each unit of building is the architectural design methods. Since a large number of new urban area buildings are apartments or multi unit residential houses (among them in Hashtgerd), three parameters are influential on taking solar advantages which have examined in this research: 1. The way which land piece is divided between residential units in each floor (for example two or more residential units in a piece). The range of current residential unit area is between 50 to 150 square meters, and in some land division for architectural designing, there is probability of having unit(s) that do not get enough solar energy. Briefly equilibrium establishment in receiving solar energy for all building units is a necessity that should be guaranteed by exact instructions. 2. The internal arrangement of residential unit parts, according to the function and usage of spaces, regarding the size and form of their exposed wall parts (like window). For example stair cases and washing and service spaces of a residential unit could not have

Social and Environmental Impacts of U.S. Oil Boom Economies

Stan Brunn (University of Lexington)

During the past two years the economy, society and environmental setting of northwestern North Dakota has been significantly altered by the development of massive new oil fields open to oil exploration and extraction. According to some estimates, the state is or soon will be the second or third leading oil producing state. The small towns and rural areas in a six county area centered around Williston have been the scene of huge influxes of outside workers living in "man camps" as well as other temporary shelters for this fluid and growing population. Towns have discovered that local planning, health care, and security institutions, as well as retail establishments, have been severely challenged to cope with the new social dynamics of these "outside" workers and unforeseen harmful impacts on the region's transportation systems. The wheat raising and cattle grazing areas are now the sites of hundreds of oil derricks pumping oil for distant markets. The roads are being overburdened with heavy trucks and equipment vehicles supporting this frontier-like landscape. The boom has brought new wealth to some residents and also headaches that were unknown five years ago. The economic and social fabric of rural and small town northwestern North Dakota is being transformed daily as are the human and physical environments. This paper discusses some preliminary findings of a detailed survey we conducted of permanent and temporary residents in the region to measure the social, economic and environmental impacts of the oil boom frontier. These results will be useful to local, regional and state officials as they seek ways to effectively address issues of social and environmental risk, comprehensive local planning, excessive extraregional immigration numbers, and the preservation of local culture and livelihoods. The North Dakota example is but one of a number of "energy boom economies" in North America, and elsewhere, that calls for collaboration by social and environmental scientists.

Microgrids for the Optimal Use of Renewable Energy in Mediterranean Countries

David Chinarro (Universidad San Jorge), Luis Hernandez (El Centro de Desarrollo de Energías Renovables)

The electric power system needs new conceptual paradigms that encourage better control, empower the distributed renewable energy generation, and improve the energy efficiency and the environmental stewardship. Microgrid is not only a small-scale version of the centralized electricity system. In addition, it achieves important goals as the reliability, carbon emission reduction, diversification of energy sources and cost reduction.

In addition, it is a business opportunity to produce a viable business case. A growing number of stakeholders are considering the smart microgrid as an efficient approach toward the grid modernization and an entrepreneurial job creation in the local area. This work shows that the constraint of the smart technology scope, maximizes the service quality, and optimizes the design to supply local energy to meet the exact needs of the customer being served, whether a town, university, neighborhood, business park or industrial area. The study deals with international projects focused to achieve energetic models of industrial areas in the southern Europe, also discusses the conference results celebrated to bring together experts. All issues have suggested the necessary shift towards a new model based on sustainable development, alternatives in the electricity market, and technical solutions based on self-generation of renewable energy and automatic coupling optimization between generation and demand. Mathematical models adjust production to actual demand and ensure to customers the contracted service quality at a competitive price. This justifies the need for the demand forecasting computing with an error as small as possible. Artificial Neural Networks (ANN) as a very effective tool for forecasting electricity demand. The utility of Wavelet afferent cores in the modeling of electricity demand is one of the most used tools in systems analysis in various fields (medicine, glaciology, meteorology, economics, etc.), given its efficiency to extract information from time series and estimate the prediction electricity demand, especially in the novel technique of prediction by SSA (Singular Spectrum Analysis) with Wavelets adapted. The result was calculated on historical consumption data from a working microgrid in Walqa Technology Park (Huesca, Spain). There are some arguments for cases where it is possible to quantify external factors, such as socioeconomic and weather ones, affecting demand, to apply wavelet cross-correlation for detecting the sensitivity and coherence of compared data, and thus, to improve prediction accuracy.

MRP-02 - Towards a democratic Maghreb-Mashrek? Vers un Maghreb-Mashreq démocratique?

Chair: Maria Paradiso, Ali Toumi

Géographie d'une révolution

Toumi Ali (Université de Tunis)

Entre décembre 2010 et janvier 2011, la Tunisie a vu se déclencher une véritable révolution contre la dictature, révolution qui annoncera en fait le début d'un printemps arabe. La Révolution Tunisienne a une géographie bien originale tant au niveau de ses différentes phases qu'à celui de ses origines. Partie des régions intérieures déshéritées, elle n'atteindra la capitale du pays que dans une seconde phase au cours de laquelle elle va s'accélérer et s'intensifier tout en se concentrant dans un espace très réduit avant de faire tomber le dictateur. Il est à constater également que la révolution tunisienne a été celle des citoyens. La ville a été en effet son principal espace catalyseur et ce, dans toutes ses phases. Plus encore, c'est la ville capitale qui, écartée lors de la première phase de déclenchement de la révolution, a fini par reprendre son rôle de leader. Et ce sont quelques unes de ses artères et de ses places principales qui se sont transformées en véritable théâtre de cette révolution dans ses phases cruciales. La présente communication tentera de dresser le décor de cette révolution à travers l'analyse de sa géographie, en fonction de ses différentes échelles tant au niveau national que sur le plan international. On essaiera également d'apporter à cette analyse quelques éclairages d'ordre socioculturel.

Les grandes puissances et le "printemps arabe": analyse de leur rôle et de leurs enjeux en Tunisie, Libye et Egypte

Hilaire de Prince Pokam (Université de Dschang)

Depuis janvier 2011, un ensemble de manifestations populaires d'importance inégale se produisent dans de nombreux pays du monde arabe appelé « Printemps arabe ». Ces mouvements révolutionnaires nationaux sont aussi qualifiés de révolutions arabes, de révoltes arabes ou encore de « réveil arabe ». Outre le départ des dictateurs et l'instauration d'une démocratie, les manifestants exigent un partage des richesses qui leur assure de meilleures conditions de vie, des emplois, et la dignité. Ces mouvements sont soutenus en grande partie par la communauté internationale, principalement les grandes puissances, à l'instar des États-Unis, de la France, de la Grande Bretagne, etc. Cet article se propose, à travers l'analyse stratégique et à partir du cas tunisien, libyen et égyptien, de déterminer non seulement le rôle joué par ces grandes puissances de manière individuelle ou collective dans ce processus révolutionnaire en faveur de l'émergence de la démocratie, mais aussi et surtout les enjeux qui structurent leurs actions et interactions étant donné que ces acteurs sont des acteurs stratégiques

motivés par d'autres enjeux plus ou moins avoués sur la scène internationale. Car leurs enjeux transcendent ceux des acteurs internes dans les pays concernés, la quête et l'établissement d'une véritable la démocratie.

Empowerment and Control: The Evolving Role of ICT in the Middle East and North Africa

Mark Wilson (Michigan University), Kenneth Corey (Michigan University)

The Internet, social networking and mobile telephony have considerable social and political application and influence, but technologies that enable diverse views to be expressed are also a target of control. Through history social movements have actively sought out new information and communication technologies (ICT) to give voice to their concerns, and at the same time authority has adopted technology to silence, control or influence protest. Since the introduction of the printing press, ICTs have been contested technologies for the control of information. Significant in recent political and social movements is the widespread availability of the Internet and mobile phones to facilitate organization and action, which is often countered by government and opponents using the same technologies to limit voice. The growth of information and communication technologies in the Middle East and North Africa (MENA) region provides an important vehicle for communication and interaction; opportunities for both expression and control. ICT is a technological and generational challenge to the hierarchical social order of many MENA societies. The growth of social networking, such as the 2009 introduction of Facebook in Arabic, confronts governments trying to restrict networking activities. The recent experience of democracy movements in a number of MENA countries shows how communications during times of social protest and unrest can be a force for organization and mobilization. Analysis of the scale and scope of ICT use in a number of MENA countries (Tunisia, Libya, Egypt, Syria, Yemen, and Bahrain) illustrates the power available for social and political action by individuals, as well as the role and reaction of the state to ICT use. The paper argues that while ICT is a facilitator of social movements it is also subject to controls and intervention from governments seeking to limit public expression.

North African democratic movements: The role of ICTs in Tunisia Jasmine revolution.

Maria Paradiso (University of Sannio)

The paper presents and discusses the results of a field study carried out at the Italian Lampedusa island in March 2011. The research was aimed at investigating the exposure of migrants to the Internet and to communications technologies while still in their North-African countries of origin, and the influence of ICTs on recent democratic movements. Empirical work proved the use of the social networks and communications as the tipping point to break isolation, to spread information and indignation, to virally coordinate

demonstrations. However, why democratic movements happened there and in that time is due to local geography and changes in information geography.

GCG 01-01 - Analyzing climate change and its impacts via method combinations 1

Chair: Jan Cermak, Jörg Bendix, Monika Steinrücke

Integration of Climate Change Scenario and Geographic Information System for Impact Assessment due to Enhanced Lahars Flooding under Control of Climate Change (Case Study Yogyakarta City, Indonesia)

Andung Sekaranom (Gadjah Mada University)

Yogyakarta City, located in the southern slope of Merapi Volcano, has a big threat comes from the volcanic hazard resulted by Merapi eruption. Merapi volcano is one of the most active volcanoes in Indonesia, where the eruption occurred for each 4-7 years. The eruption of Merapi Volcano is very well-known for its destructive and devastating power towards people and their environment. Material ejected from the eruption is mainly consists of pyroclastic material, which sometimes mixed with ash and hot gases and formed pyroclastic flow. Pyroclastic flow, which categorized as primary hazard, moves from the top of the volcano to the bottom with incredible speed, killing people and animal, and also destroying the building alongside the way. In addition to pyroclastic flow, secondary volcanic hazard comes in the form of lahars flood brings more threats to the city. Lahars flood, which is a mixture of pyroclastic materials and rainwater that falls on the top of the volcano, has caused some problems in the recent eruption in 2010. Great mass of pyroclastic materials ejected, combined with very high intensity of rainfall that rarely occurred, resulted in high volume of lahars flood. The lahars flood not only destroyed infrastructures such as bridges and dams, but also caused the loss of hundreds settlements near the riverbanks. Although the magnitude and volume of lahars flood mainly influenced by volume of pyroclastic materials, the rainfall intensity could generate higher magnitude of lahars flood. The threat of climate change, which might give influence in increased intensity and frequency of extreme rainfall, potentially caused increasing in lahars flood in future years. The purpose of this study was to determine the potential increase in rainfall intensity as a result of climate change and analyzing its impact on lahars flood. To analyze the potential impacts of climate change towards the lahars flood, climate scenarios and model development using Geographic Information System (GIS) has been applied. The results of this study indicate that rivers located on the southern slope of Merapi potentially suffered in increasing extreme rainfall, in which the increasing might reach up to 30% compared to current conditions. This condition implies that settlements located near the riverbank will gain higher threat from the lahars flood, so that mitigation and adaptation to the local communities become very important to be improved.

Modeling the effect of climate change on water supply and the future water demand in Urumqi, NW-China

Katharina Fricke (Heidelberg University), Yuan Yao (Heidelberg University), Olaf Bubenzer (Heidelberg University)

In this study hydrological and socio-econometric modeling was used in order to calculate the water balance for the catchment area of Urumqi City as well as to analyse the water consumption by population and economy now and in the future. The research area is located in NW-China, on a narrow oasis belt between the semi arid Junggar Basin and the Tianshan Mountains. The development depends very much on the water supply from the mountain range, which serves as a meteorological divide and stores precipitation in snow and ice. Over the last 36 years, the area has experienced an increase of 1.7 °C in mean annual temperature. This climate change will also likely continue in the future and change the spatial and seasonal distribution of precipitation type, runoff and water supply. At the same time, Urumqi Region has experienced enormous growth of economy and population. The average GDP growth rate between 1978-2010 was 14 %, while the population increased by 2.4 % per year. Until now, the largest share of water supply has been used by agriculture which is based on irrigation. In the future, however, industrial and domestic water use will be the new drivers of water consumption the water consumption side. For the water consumption of population and economy, socio-econometric modeling was performed. The water demand was coupled with population and GDP growth and additional relevant factors (e.g. urbanization rate, sector specific quotas of water use) controlling the water demand of production, households and the ecological system. Based on national standards and urban master planning, it forecasts the factors mentioned above and the water demand is determined. The hydrological model for the catchment area was calculated raster-cell-based in a monthly time step. Various remote sensing data sets provided the input information for the model: Spatial gradients for the extrapolation of climate station data were based on TRMM and MODIS 11A1, land use and cover characteristics were classified from Landsat imagery, digital surface models and their derivatives were obtained from SRTM2 and ASTER data. A precipitation-runoff model was implemented using a physical model to calculate potential evapo-trans-piration (Penman-Monteith), on the other hand index models for the estimation of snow melt water and runoff generation were used. Based on the distribution of surface runoff and groundwater recharge, areas of 'water production' and 'consumption' now and under a changing climate could be identified. In the end, the results will be compared and the applicability of the methodology to the topic and scope is discussed in order to assess the quality of the model results. This analysis is important to evaluate and confirm the necessity and degree of measures to adapt to climate change and possibly insecure water supply on the one side as well as an increasing water demand by industry and population on the other.

Glaciers Response and climate Change: A Case Study of Sikkim Himalaya

Parvendra Kumar (Jawaharlal Nehru University)

Glaciers being one of the most sensitive parameters of climate change contain huge repository of landforms that can be used as proxy data source to assess magnitude and frequency of processes over time and space. From these glacial landforms, we can reconstruct the paleoclimate i.e. temperature and precipitation. The Himalaya has the largest concentration of glacial mass outside the Polar Regions. Most of these glaciers are not easily accessible. A majority of scientific studies on the glaciers response and climate change is concentrated on the western Himalaya and not on the eastern Himalaya. The present study tried to focus on two important issues, one on the basis of past we can predict our future and can do the best planning, and second is that weather climate change is global or regional. Sikkim, with an area of 7096 km², has a rectangular shape measuring about 114 km from north to south and 64 km from east to west. There is a great variation in altitudes from south to north (300 m to 8500 m), largest relief for any Indian state. A large number of glaciers descend from the eastern slopes of Kanchenjunga into Sikkim where snow-line is found above 5300 m.

Modelling Future Water Availability in the Central Andes under the Climate Change Hypothesis

Maxime Souvignet (University of Bristol), Hartmut Gaese (Institute for Technology and Resources Management in the Tropics and Subtropics), Juergen Heinrich (Universität of Leipzig)

Arid and semiarid areas cover on third of the Earth's surface and estimates for populations living in these regions varies between 1.4 to 2.1 Billions. By 2080, three Billions of people are projected to live in such areas. Mountainous zones, hosting the headwaters of these arid and semiarid basins provide these populations with freshwater. However, these zones are very sensitive to changes in precipitation and in temperature. Consequently, shifts in the regional climate will possibly influence snowmelt processes or foster glacier retreat, and therefore durably introduce perturbation in the local hydrological processes. However, despite their substantial socio-economic relevance, variations in temperature, precipitation and discharge are poorly studied in drylands, and this although they are expected to be among the ecosystems most affected by Climate Change. The Central Andes - of interest in this study - shares all common characteristics

of arid and semiarid mountainous zones, which makes this region an ideal candidate for the investigation of the impacts of Climate Change on water resources. Consequently, the objectives of this work are i) to downscale climate projections in the region, ii) to simulate future water availability in a selected headwater catchment and, iii) discuss the uncertainties linked with the combination of such methods. Projections of future water availability were obtained combining downscaling techniques with hydrological modelling. For climate projections, two different downscaling techniques (statistical and delta method downscaling) were use and were preliminary tested for their accuracy in the region for four different GCMs (CGCM3, GDFL, HadCM3, and MRI). Subsequently, a hydrological model (SWAT) was calibrated and validated. SWAT performance statistics returned satisfactory to good results (ENS>0.71, d>0.89), showing a good agreement between observed and simulated discharge. Finally, downscaled variables (precipitation, Tmax and Tmin) were introduced in the hydrological model. Future streamflow regimes in the Upper Hurtado watershed were simulated at the time horizons 2050 and 2090. Results show a general decrease of the annual water availability. In the same vein, a one-month shift perturbation in the catchment's hydrograph is projected at both time horizons. This indicates a decrease of water availability in summer, when it is most needed. Consequently, agriculture in the region might be seriously challenged in the region. Nevertheless, although these conclusions are in agreement with observed long-term trends in the study area, it is worth discussing if all sources of uncertainties at stake (GCMs, downscaling methods, hydrological modelling) do allow enough confidence in these projections.

Drought characteristics under current and future climates in the Jordan River region

Tobias Törnros (Universität Heidelberg), Lucas Menzel (Universität Heidelberg)

The Jordan River region is one of the most water scarce regions in the world. A combination of methods has been applied to characterise current and future droughts and their impact in the arid/semi-arid to sub-humid region. A well known drought index was applied first on observed precipitation and then on future projected data. Thereafter the irrigation water demand during drought was simulated. The Standardized Precipitation Index (SPI) has been applied worldwide. The drought index can be applied on different time scales (e.g. 3 or 6 months) to assess among others meteorological and hydrological droughts. In this study, the index was applied on spatially interpolated precipitation (1x1 km) with the aim to characterise current and future agricultural droughts. To confirm SPIs performance and to identify the most suitable timescale, correlation analyses were conducted with the Normalized Difference Vegetation Index (NDVI) received from the Advanced Very High Resolution Radiometer (AVHRR). NDVI was used as a spatial estimation of the green biomass. It was assumed that if SPI and the vegetation index would be correlated for the overlapping time period 1982-2002, then SPI would be suitable to assess agricultural droughts. Correlation analyses were conducted for several land-uses, multiple SPI-time scales and for each month of the year. It was shown that in overall, the 6-month SPI had the best performance. The correlation between SPI and NDVI was highest during vegetation peak. Since SPI could explain the inter-annual variation of NDVI, it was assumed that it could be used also under future conditions. SPI was applied on three climate scenarios based on the IPCC emission scenario A1B. The drought index was computed for the years 1961-2060 and thereafter evaluated according to a reference (1961-1990) and future time period (2031-2060). The average drought length during the reference period was 9.5 months. Under future conditions, the average drought is expected to be 1.5 months longer. Future droughts are further expected to become more severe. The number of moderate droughts is expected to slightly decrease and the severe droughts are expected to become more common. The number of extreme droughts is expected to almost double. To better understand

the hydrological impact of the more intense droughts, the physical based hydrological model TRAIN was applied. The model is able to simulate a potential value of the irrigation water demand (IWD). The IWD was simulated for average conditions (1961-1990) and during the longest drought within the reference and future time period. For the years 1961-1990, the annual IWD was 80 mm or about 1810 million m of water for the whole study region. The annual IWD during the longest current and future drought was 122 mm (2770 million m) and 174 mm (3950 million m), respectively. Compared to the average conditions, this implies to an increased demand of 53 and 118%, respectively.

Impact of climate change on water availability of beech stands in Rhineland-Palatinate, Germany

Gayane Grigoryan (Universität Trier), Markus Casper (Universität Trier), Jürgen Gauer (Zentralstelle der Forstverwaltung), Philipp Reiter (Forschungsanstalt für Waldökologie und Forstwirtschaft)

In order to find best silvicultural decisions, foresters need to know how far climate change will influence the water availability of forest sites in the next 50 to 100 years. This knowledge is crucial because water availability mainly determines biomass production of tree species. The foresters in Rhineland-Palatinate, Germany, already have an approach for determining the water availability of forest sites, but it is assumed that under fast changing climate conditions the current (static) approach will be inappropriate. For this reason, the aim of the present study is to find a new approach which objectively detects the impact of climate change on water availability of forest sites; exemplarily beech sites. First of all, the study area is divided into characteristic landscapes using a geographic information system. These landscapes are classified as a function of mean annual precipitation, mean annual temperature, exposition, slope and available water capacity. They represent a bandwidth of potential beech sites in Rhineland-Palatinate. In the following step, hydrological simulations for each of the resulting 156 landscapes are run on plot scale with observed climate data, in order to mimic the hydrological cycle of potential beech sites in Rhineland-Palatinate. Afterwards, simulations for the beech sites are run with projected climate data (WETTREG). After this, the results of the simulations are statistically analysed in regard to water availability and transferred to the 156 landscapes. Based on this, we produce maps which show today's and possible future mean water availability of beech sites in Rhineland-Palatinate. For the near future (2021-2050) the changes of water availability are small, with the biggest changes on the beech sites with small available water capacity. The results for the far

future (2071-2100) reveal considerably larger changes for the whole study area. The largest decrease is expected for today's beech sites with low water availability as well as for submontane beech sites. In summary, the new model-based approach allows detecting the non-linear impact of climate change on water availability of the simulated beech sites. Future work will focus on additional plausibility checks of the simulated water availability. These checks include e.g. the use of remotely-sensed data and simulations with additional time series of climate projections.

Analyzing the impact of climate change on wheat phenology in Iran

Elham Rahmani (University of Bonn), Andreas Hense (University of Bonn), Jan Keller (University of Bonn), Petra Friederichs (University of Bonn)

This study will present a refined model of wheat phenology to be used in regional climate downscaling to study the effects of climate change on wheat phenology and yield in Iran. Local temperature variability being an important factor for phenology is very well represented in the ERA-40 data set. This was found by a regression analysis between ERA-40 grid point based near surface temperatures as predictor and long term observations of 45 years of daily temperatures at climatic stations covering whole Iran as predictand. The results indicate high significant correlations and correlation structures between ERA-40 calculated temperature data and Iran observed temperature data on monthly and daily scales. The seasonality is pronounced and needs to be incorporated into the statistical model. Spatial structures or modes of large scale temperature are well defined in both seasons. These form the basis for the downscaling model by projecting large scale near surface temperature fields from ERA-40 and later from global climate models onto these modes and regressing the amplitude with the local observations. In a second step wheat phenology (ripening date) is compared to GDD (Growing Degree Days) based on the FAO model for several Iranian stations. Instead of a classical regression analysis we took a probabilistic view of the time to ripening. We used probabilistic models from survival analysis to model the probability that after a certain time after sowing the probability of ripening is large. A linear regression between GDD as predictor and the parameters of several classical survival functions as predictand was developed. To assess the probability forecasts, we considered two scores; the Ignorance score (IGN) and continuous ranked probability score (CRPS). We achieved the best model using an exponential distribution for the time to ripening. In the next step we will combine the ERA-40 grid points values and the

correlation modes to develop an optimal wheat phenology model for large scale reanalysis data or global climate models.

The seasonal transition of monsoon in Bangladesh and its association with atmospheric circulation

Roxana Hoque (Tokyo Metropolitan University)

This study presents comprehensive aspects of climatological characteristics of the monsoon seasonal transitions associated with the atmospheric circulation in Bangladesh, focusing on the pre-monsoon, monsoon and post monsoon seasons. In addition, the onset and withdrawal phases were examined using pentad and 20-day mean wind, moisture flux, precipitable water and rainfall distributions. These were obtained from Japanese 25-year re-analysis data from 1979 to 2003 and rainfall data from the Bangladesh Meteorological Department (BMD) from 1948 to 2008. Analysis of the pentad and 20-day mean the horizontal wind at 850 hPa, the total column water vapor flux, the precipitable water and rainfall distribution around Bangladesh showed that, the onset and withdrawal of the summer monsoon seasons in Bangladesh occurred between Panted 31 (May 31-June 4: P31) and P32 (June 5-9) and between P56 (October 3-7) and P57 (October 8-12), respectively. It is worth-noting that during pre-monsoon, southwesterlies wind, and water vapor flux zones are established around (24-29°N, 84-93°E), in P15-18 (March 12-31) over India and Bangladesh. At this time, the precipitable water distribution is found increasing. The rainfall distribution map also has shown obvious change in P15-18, at this time pre-monsoon rainfall observed northeast region at Sylhet station. These criteria indicate that precipitation gradually developing over land and the Bay of Bengal for the monsoon onset process. The dramatic changes have occurred during the monsoon onset period, between P31 and P32. At this time southerly wind, water vapor flux, and precipitable water are shown drastically stronger over the Bay of Bengal and Bangladesh. Drastic changes also have shown in rainfall distribution maps in P31-32, when abrupt increases of precipitation occur. Remarkable changes also have shown between P56 and P57, which is regarded as withdrawal of summer monsoon. At this time southwesterly flow vanished not only in and around Bangladesh, but also in almost the whole Indian Ocean and Indian subcontinent. Eventually the rainfall distribution maps have showed decrease in rainfall in P56-57. The annual cycle of 5-day mean rainfall has shown heavy rainfall occurs in the northeast region (Sylhet) during the pre-monsoon season and in the southeast region (Teknaf) during the monsoon season. The central west region (Ishurdi) receives relatively less rainfall in all

seasons. Cluster analysis indicates that seasonal march of pentad mean precipitation at Sylhet is very unique pattern. Analysis of horizontal U and V-wind components, it has revealed that the V-wind component clearly defines the monsoon onset and withdrawal and very clearly identifies the conditions of pre-monsoon, monsoon, post-monsoon and winter over Bangladesh.

Dynamics of northern treeline in Russia as indicator of climate change: Combining remote sensing and ground research

Olga Tutubalina (Moscow State University)

The dynamics of the northern forest-tundra transition zone is one of the indicators of climate change. This paper reviews the experience of research in the forest-tundra ecotone carried out within the IPY core project PPS Arctic by scientists of the Faculty of Geography, Moscow State University. The forest-tundra transition in Russia is formed by various tree species. Regional differences and variations in data availability led to several research approaches. Initially we tried to use topographic maps of the 1960s and 1980s (1:25,000 and 1:50,000 series) because they exist for the whole of Russia. Unfortunately, a detailed examination of maps for Kola Peninsula has demonstrated that most identified changes were due to map errors. Therefore we switched to change detection at local representative test sites. In Kola Peninsula these were Kanentiaiv (hilly plain, 190-350 m a.s.l., more maritime, unpolluted), Khibiny mountains (200-1,200 m a.s.l., more continental, unpolluted) and Monchegorsk (200-700 m a.s.l., more continental, heavily polluted). For Kanentiaiv and Khibiny we compared airphotos of the 1950-1960s and very high resolution satellite images of the 2000s. We identified, and validated by field data, the altitudinal treeline advance of up to 30 m in Khibiny and advance of dwarf shrub tundra to lichen tundra in Kanentiaiv. Changes in Khibiny are supposedly due to the increase of winter precipitation. At Monchegorsk, a comparison of a vegetation map of 1932 with field data revealed a pollution-induced retreat of altitudinal limit of living trees by over 200 m (i.e. overriding the climate change impact). No old airphotos or maps were available for the North-Central Siberia sites. In general, the approach has been successful for local sites, but is not applicable to large areas, due to high costs and data gaps. The next step was to use imagery from Landsat satellites. We found that the image resolution (30 m) was not sufficient for representation of ecotone structure changes. However, comparison of vegetation index (NDVI) images has worked successfully for a pair of multitemporal Landsat TM images over Kanentiaiv area, and identified regional changes, confirmed by more detailed studies. Future research should include investigation of more local test sites to provide a comprehensive picture of

species- and environment-dependent dynamics and its connection to climate change. The increased availability of satellite hyperspectral imagery (such as EO-1 Hyperion, 30 m spatial resolution) might enable, in the future, the analysis of ecotone dynamics through spectral unmixing. To support such research, detailed ground studies of key sites will be necessary to provide baseline data. This study has been financially supported by the Research Council of Norway (grants 185023/S50 and 176065/S30), the Russian Leading Science Schools Programme, and Russian Scientific Educational Centres programme (grant 14.740.11.0200).

Statistical Downscaling of Regional Climate Models in Bulgarian Mountains

Petar Nozharov (Bulgarian Academy of Sciences)

Air temperature and precipitation data from three high mountainous Bulgarian stations were used. A total of 13 Regional Climate Models (RCMs) for air temperatures and 12 RCMs for precipitation, included in ENSEMBLES project, were checked. Air temperature and precipitation outputs of the IPCC scenario SRES A1B were compared with actually observed values. RCMs with the

Towards integrated climate change vulnerability assessments

Anne Holsten (Potsdam Institute for Climate Impact Research (PIK)), Carsten Walther (Potsdam Institute for Climate Impact Research (PIK)), Jürgen P. Kropp (Potsdam Institute for Climate Impact Research (PIK))

While sectoral vulnerability assessments have become common usage in the climate change field, integrated and standardized approaches are still rare. However, comprehensive knowledge is demanded to concretize and prioritize adaptation strategies, which are currently being drafted at national and state levels. We present a multisectoral analysis where sensitivity is quantified by the physical, social, environmental and economic dimension by means of tailor made approaches for specific sectors. These are directly related to relevant exposure variables defined as relative climatic changes until the end of this century. Aggregation of the sector specific impacts, comprising both sensitivity and exposure, lead to integrated impact measures. These are then combined with the generic adaptive capacity. We exemplify our methodology for municipalities in the German state North Rhine-Westphalia for two regional climate models. Our approach allows for the integrated assessment, while at the same time enabling a sector-specific perspective of risk analysis. However,

various limitations remain, especially regarding the aggregation across sectors. We emphasize the need to consider the aim and methodological advantages and disadvantages before applying any vulnerability assessment.

Towards a methodology to assess the vulnerability of landscape types and their heritage to climate change in Flanders (Belgium)

Tim Van Beveren (Ghent University), Lien Dupont (Ghent University), Veerle Van Eetvelde (Ghent University)

Changes in temperature, precipitation, evaporation and storm events are primary effects of climate change. These cause secondary effects like flooding and drought, which in turn induce tertiary effects on nature and agriculture, e.g. the drought-related extinction of species. The combination of these effects can change landscapes drastically. So far, most studies on the impact of climate change have been sector-oriented and focused on a country-scale. In addition, the impact of climate change on landscapes and their heritage values on a regional and local level has rarely been analysed, although the chain of effects, combined with adaptation and mitigation measures, is causing changes on the landscape pattern and the related functions and services. In previous research, a landscape typology of the present-day landscapes of Flanders has been set up as a reference base, determined by soil properties, land use, elevation and landscape heterogeneity, which are sensitive parameters likely to be affected by climate change. The aim of this paper is to set up a methodology (1) to judge the sensitivity of the landscape types to potentially increasing soil erosion, drought and floods at the regional scale level, and (2) to assess the vulnerability of landscape heritage at the local level. This overall assessment is needed to formulate spatial planning strategies, including future adaptation and mitigation measures to reinforce the resilience of the different landscapes types. The method used to determine the sensitivity of landscape types, combines GIS, spatial and statistical analysis and multi criteria evaluation. Data sources indicating potential soil erosion, drought and floods were selected and reclassified in the GIS-database; variables indicative for environmental changes were derived. Each variable was attributed a weight, calculated by an Analytic Hierarchy Process (Saaty). The weight is depending on the landscape type, since the properties of the types (e.g. soil, topography, amount of build up and paved areas) will be influenced differently by the environmental variables. As a result, we obtained a sensitivity index (very low to very high) per landscape type. For the calculation of the vulnerability maps of landscape heritage and the compilation of adaptation maps at the local scale, a multi criteria evaluation was

compiled in a GIS. Therefore, the sensitivity maps were overlaid with heritage maps (the Landscape Atlas of Flanders) to determine their vulnerability to soil erosion, flooding and drought. In response to this vulnerability, we produced corresponding adaptation maps for case studies. These case studies were selected in different landscape regions to assess the solidity and robustly of the methodology: the Flanders coastal landscape, the basin of the river Dender, the heterogeneous landscape of the sandy region of the 'Kempen' and the hilly loamy agricultural landscapes of 'Haspengouw'.

GCG 02-01 - Bridging the gap? Scope and limitations of practice-oriented development studies

Chair: Juliane Dame, Thomas Lennartz

Contribution from the scientific community to the Brazilian environmental policy regarding the climate issue

Teresa da-Silva-Rosa (Universidade Vila Velha), Gustavo F. Seda (UVV/NEUS-Center for Urban and Socio-Environmental Studies), Priscila Z. Guio (UVV/NEUS-Center for Urban and Socio-Environmental Studies), Joao Paulo Almeida (UVV/NEUS-Center for Urban and Socio-Environmental Studies), Renato Maluf (Universidade Federal Rural do Rio de Janeiro)

The emission of greenhouse gases related to the current development model has compromised the sustainability of the planet and reinforced the socio-environmental vulnerability of populations. This confirms the socio dimension of climate change (CC) and its complex and interdisciplinary character. The mitigation and adaptation measures needed to handle climatic events demand an environmentally-based rationality, placing upon society the challenge of sustainability and of new environmental governance. Aiming at making these measures more effective, the path of constructing a dialogue between the realm of science and that of politics appears as an alternative that should be explored. In this context, the role of the knowledge produced in different scientific areas cannot be underestimated. The scientific community, as knowledge producer and as an actor in the environmental governance, can contribute towards providing the base for public policies, as well as to better inform society in order to lessen vulnerability and help communities facing CC. This paper discusses the contribution of the knowledge produced in different areas in Brazil when a theme as CC is addressed seeing that a dialogue between different areas of knowledge must be prioritized. In order to map the production, the keyword 'climate change' has been used since to 2009 to identify the research groups in Brazil. In April 2011, 146 groups were identified, pointing to a significant increase when compared to the 58 groups identified in 2009. Despite greater interest from groups in the area of SHS, the area of Exact Sciences (ES) remains as the one with the highest representation. The production by the leaders of these groups was categorized using Lattes Brazilian database of academic curriculums, and, then, bibliographical online database. The categories showing the highest number of publications were those which do not presuppose a social concern: 'Agriculture' or 'Water'. Those categories with a social character were

secondary - adaptation, health, vulnerability and housing. 'Amazon' is the most studied biome, while the Atlantic Forest is almost completely ignored. The publications which were identified will be made available online in order to facilitate access to knowledge about the theme. It was observed that (1) fragmented knowledge demonstrates lack of communication between the different areas of science; (2) the recent interest in the climate issue by the SHS compromises its contribution towards understanding CC within a social context. These observations may have implications for decision-making processes, for the design of public policies inadequate to tackle the climate issue, and for the use of knowledge by actors participating in environmental governance, as in the case of the civil society, which could be compromised.

From pilot areas to global awareness: Local flood early warning systems in the Philippines

Johannes Anhorn (Universität Heidelberg)

The creation of the United Nations International Strategy for Disaster Reduction (ISDR) and the incremental implementation of the Hyogo Framework of Action (HFA) shows that Disaster Risk Management (DRM) is increasingly recognised by the "development business". The concept has developed into a broad approach used in several fields of action not only with respect to "natural" disasters, but also regarding a variety of economic and ecological issues. In the light of this evolution community-based early warning systems gained more attention and raised the need for convenient participatory approaches. This paper provides insights into a case study of Local Flood Early Warning Systems (LFEWS) in the Philippines, which were implemented by the German development cooperation (Deutsche Gesellschaft für Internationale Zusammenarbeit, GIZ) and local authorities in the Eastern Visayas. In an extended partnership between the German Aerospace Agency (DLR), Canadian Space Agency (CAS) and GIZ the capabilities of high resolution Synthetic Aperture Radar (SAR) to provide reliable flood extent maps were examined. This was done using field measurements, near-flood-peak SAR data acquisition and the development of an enhanced semi-automatic flood detection algorithm. The advantages of this international partnership were expected to be: better access to ground truth data for the satellite data provider, elaboration of capabilities for near-real-time (NRT) flood processing as a service tool requested by international agencies or networks (e.g. SAFER, ECHO, UN-OCHA, MapAction), and accurate measurement of the flood extent as basis for hazard-, risk assessment or evacuation routing for DRM implementing institutions. Thus to

enhance the positive outcomes of FEWS by narrowing the gap between (political) practitioners, researchers, and (data) service providers at their interrelated levels. The paper gives a short overview of the SAR processing results and shows how effective knowledge transfer can be realized. Such flood inundation maps help local communities to improve the early warning chain and minimize their risks. The transfer of highly sophisticated technology remains challenging if up-scaling from pilot areas to other regions as well as "down-scaling" from international partnership to local authorities is done. One key step is to carefully balance the expectations in an international cooperation to gain good results.

Dealing with the Requirement of Producing Exploitable Knowledge – Differences Between Social and Natural Sciences. Case Study in An Argentinean Peripheral Research Institute

Angelika Hubl (Universität Frankfurt)

For some time past there is a global debate about today's mission of universities and research institutions as providers of education, research and knowledge transfer (third mission). Especially the future orientation of these institutions is hard debated. They have to justify themselves as providers of social benefits for society and economy. Due to globalization this debate was spread from Europe and the United States to emerging and developing countries in the global south. As one of Latin America's economically leading countries Argentina as well takes place in the worldwide discussion. Argentina is a very centralistic state. Therefore the offer and reputation of universities and research institutions is very centralistic as well. That's why especially institutions in rural areas have to justify themselves exceedingly and have to struggle for reputation and funding. The case study will focus on a research institute and its close by university in the north-east of Argentina, which is a region of extremes and contrasts. Especially in population aspects it is one of the regions of Argentina with the highest social inequality and very diverse habitants like little farmers, indigenous people and marginalized people. Since this region is so peripheral, the research institute's task to vindicate itself is very important. The goal of the case study is to examine how the knowledge transfer at the Argentinean research institute CONICET Tucumán works, how the institution and the researchers deal with the requirement of producing exploitable knowledge and what are thereby the differences between social and natural sciences. The field studies will be carried out between February 2012 and April 2012 at CONICET Tucumán. As method semi-structured interviews with the management of the CONICET Tucumán, the

heads of the various research groups, and particularly with selected scientists of innovative research areas in the sense of knowledge transfer will be conducted. The interviews will be evaluated interpretative-reductively. The hypothesis that there are significant differences between social and natural sciences in dealing with the requirement of producing exploitable knowledge will be examined during the field study and will be extended with new insights about the role of research areas for knowledge transfer and adaption in this institute. Therefore it will be an important Latin American case study as an example for dealing with the requirement of producing exploitable knowledge in peripheral regions. Results will be available in June and will be ready to be presented in my master's thesis and at ICG in August 2012.

ForUm – Networking and cooperation for Urban Futures

Christine Knie (Universität zu Köln), Eni Harmayani (Gadjah Mada University)

ForUm – "Forum for Urban Futures" – an international network of urban experts under the leadership of the Department of Geography, University of Cologne, Germany. The program focuses on an active contribution to the North-South-South dialogue in the field of worldwide urbanisation and provides a forum for exchange on concepts, research and application of Southeast Asian and German universities, institutions, private sector, civil society's groups, including local NGOs and non-university partners (www.geographie.uni-koeln.de/projects/urban-futures). Experts from nine Southeast Asian countries and Germany are sharing their experiences and expertise, and discuss challenges and conflicts of urban development. The network is consisting of scientists and researchers as well as practitioners. At present about 150 active members of 9 countries in Asia as well as Germany belong to the network. There is a huge potential of practical experiences and scientific knowledge and we would like to discuss the challenge of common practice-oriented studies as well as the implementation of scientific concepts. The presentation will give examples of good practice and introduce new approaches of interdisciplinary stakeholder oriented projects with a special focus on a recent food safety programme at the Gadjah Mada University in Yogyakarta. Food safety is one of the aspects that give impact on food security in any country. Food safety issues refer to the continued globalization of the food supply, the impact of international travel and tourism, and the impact of food-borne diseases. Food safety crisis has resulted in human morbidity and mortalities, trade disruptions and huge economic losses for all concerned (FAO, 2009). Food-borne illnesses adversely affect the health of millions of people every year. The increasing global demand

for food safety standard has raised concern to local food industries. In attempt to achieve the global food safety standard, Center for Food and Nutrition Studies, Gadjah Mada University has conducted a project to assist small food industries and street vendors in improving their food safety standards. This project involves academicians, local governments, small food industry owners, as well as the local community leaders. The project was conducted in four steps: 1) mapping the existing condition; 2) conducting a workshop to discuss the findings with local governments and the food industry owners; 3) training on food safety and good manufacturing practices; 4) assisting the local small food industries to establish better and safer food processing. The result indicated that this collaborative project was successfully done in achieving its goal when all the stakeholders share a common goal and perspective, and establish a mutual dialogue and directly involve in the execution of the activities.

GCG 03-01 - Central Asian ecosystems under water scarcity 1

Chair: Bernd Cyffka, Yumiti Halike

Water scarcity and environmental change in northern Mongolia: Findings from field research in the Khentii mountains

Lucas Menzel (Universität Heidelberg), Stefanie Minderlein (Universität Heidelberg), Benjamin Kopp (Universität Heidelberg)

Within the project 'Integrated Water Resources Management in Central Asia - Model Region Mongolia (MoMo)' the components of the water balance and their governing factors are studied in the Sugnugur valley, a sub-catchment of the Kharaa river basin in the Khentii mountains, northern Mongolia. The investigations aim at improving our knowledge about the spatio-temporal variations of water availability in a semi-arid environment as well as the impacts of environmental change on hydrological processes and water resources. The Sugnugur was selected as a research basin since it is situated in the transition belt between the taiga and steppe zones and therefore includes a variety of environmental factors, e.g. snow storage, permafrost occurrence or forest distribution, which determine hydrological processes, water quality and water availability. Parts of the region represent a pristine boreal and mountain environment. It is assumed that they act as the major freshwater generating parts of the catchment. However, there are several indicators of direct and indirect human impacts on the ecosystem, first of all human-caused forest fires, leaving extensive areas with burned forest. Observed warming trends may also amplify the degradation of the discontinuous permafrost in the region. Both developments will undoubtedly have consequences for water retention in the headwaters and thus water availability in the dry steppe zone. For a better understanding of the environmental factors and their impact on freshwater generating processes, a small network of hydrological, meteorological and ecological observation sites is in operation in the Sugnugur basin since autumn 2010. It includes a main hydro-meteorological station at the entrance of the Sugnugur valley. In the upper parts of the catchment, three soil moisture transects were installed on dry, south-exposed, forested north exposed and burnt north exposed hill slopes. Two weather stations, river gauges and a high-mountain precipitation gauge complete the observation network. During summer 2011, an intensive field campaign was carried out, including investigations on water infiltration characteristics in soils, the spatial variation of soil temperatures

or the determination of the Leaf Area Index of dominating vegetation cover. The analysis of the data and processes is envisaged to further develop the hydrological model TRAIN which in turn will be applied to study the impact of environmental change on the water systems in neighbouring catchments, including the dry steppe area. Our contribution will present first results from the described activities and investigations.

Integrated Water Resources Management in a water-scarce environment: Experiences from the Kharaa Catchment, Mongolia

Daniel Karthe (UFZ), Dietrich Borchardt (UFZ)

Located to the north of the Mongolian capital Ulanbataar, the Kharaa catchment covers an area of around 15.000 km². The region is characterized by a highly continental climate with warm summers, extremely cold winters and low rainfall (about 300 mm annually). The industrial city of Darkhan in the north of the catchment contrasts sharply with the largely rural character of the region and results into highly disparate pattern of water usage: Surface and ground water generation occurs largely in the upper part of the catchment, whereas water withdrawals are greatest in the lower catchment. The project presented (IWRM MoMo - Integrated Water Resources Management / Model Region Mongolia) aims at the development and implementation of an integrated water resources management for the Kharaa catchment in particular and an investigation of its transferability to other parts of Mongolia and Central Asia in general. For the study region, several key problems have to be addressed: - naturally limited water resources which may decrease due to global change; - degradation of natural water bodies and water contamination due to anthropogenic influences, particularly mining and agriculture; - insufficient infrastructures for water supply and wastewater disposal; - insufficient institutional capacities and legal framework. Spatial disparities related to the present and predicted availability, state and usage of natural water resources further complicate the situation. In this light, a transdisciplinary approach is indicated not only for the investigation of the scientific basis but also the implementation of an integrated water resources management aiming at the protection of water resources and the preservation of the ecological functions of water bodies. Ultimately, such measures would also contribute towards improving local living conditions.

Transnational upstream and downstream water resource analysis at the Zarafshon River with special consideration of land use and climate change influences

Michael Groll (Philipps-Universität Marburg), Christian Opp (Philipps-Universität Marburg), Rashid Kulmatov (University of Uzbekistan), Marieke Lewanzik (Philipps-Universität Marburg), Inom Normatov (Academy of Sciences Republic of Tajikistan)

The Central Asian countries are particularly affected by the global climate change. The cultural and economic centers in this mostly arid region have to rely solely on the water resources of the large streams Amu-Darya and Syr-Darya. Both streams glaciated headwater regions already today respond very sensitive to the increasing air temperature. In the course of the expected climate change, the safekeeping of a sufficient water availability and the sustainable water usage will pose the most important challenge for the Central Asian countries. While the Amu-Darya and the Syr-Darya are well analyzed in terms of their water quality and quantity since Soviet times, the major tributaries have moved out of the focus of the scientific research since the political transformation and the breakdown of the water quality measurement network in the early 1990s. Today, only selective data, if at all, are available for these important rivers. The WAZA CARE project - Water quality and quantity analyses in the transboundary Zarafshon River basin - Capacity building and Research for sustainability (financed by the German BMBF) was conducting essential water quality research at the transnational Zarafshon River in Tajikistan and Uzbekistan in order to fill the existing gap of knowledge for this major tributary of the Amu-Darya and lifeline of the silk road centers Samarqand and Bukhara. The Zarafshon is characterized by significant seasonal fluctuations of the discharge and the water quality. The latter is heavily influenced by inputs from the ore processing complexes, intensive irrigation farming, industrial and domestic waste waters and extensive water withdrawals. The resulting problems of the water availability and quality as well as the impaired functionality (e.g. self-purification abilities or habitat configuration) of the river and its riparian zone are affecting foremost the middle and lower reaches in the Uzbek lowlands. Central aim of the WAZA CARE project was the transnational current state analysis of the water resources as a first step on a way towards an integrated water resources management. This presentation shows selected results from the collected data and own measurements. It gives an outlook of the planned future research under special consideration of the climate change and the very different interests of water users in the upstream and downstream sections of the Zarafshon River.

Water consumption of agriculture and natural ecosystems along the Tarim River, China

Niels Thevs (University of Greifswald), Ahemaitijinag Rouzi (University of Greifswald), Christine Kubal (University of Greifswald)

The man-made ecosystems, mainly cotton under irrigation, and the natural ecosystems in the arid lowlands of Central Asia depend on river water as main water source. Under the arid climate with annual precipitation of less than 100 mm, all agriculture depends on irrigation. Irrigation water mainly is diverted from the rivers, like the Tarim, Amu Darya, or Syr Darya. The natural ecosystems, i.e. riparian forests, grasslands, and shrub vegetation, depend on the groundwater for their water supply. The groundwater is recharged by the rivers. The sources of the rivers are melting water and precipitation in the mountain regions. The Tarim River's headwaters are located in the Tianshan Mountains. Due to climate change and increasing area under irrigation, the water runoff into the downstream parts of the river systems decreases and becomes more and more unreliable for water users. Against this background it is crucial to understand the water consumed by irrigated land and natural ecosystems along such rivers, in order to point out needs for environmental flows or potential for water saving. Along the Tarim River evapo-transpiration (ET) maps were made based on MODIS satellite images from 2009 and 2010. The maps were made after the approach from Senay et al. (2007), which is based on the model of Bastiaanssen et al. (2005). The annual ET of cotton ranges from 700 mm to 1100 mm. At the middle and lower reaches of the Tarim River crop failure is frequent due to water shortage. The riparian forests have an annual ET of 350 mm to 700 mm. Natural stands of *Apocynum pictum* show an annual ET of 200 mm to 300 mm. *Apocynum pictum* is a natural plant along the Tarim River, which can be used as medicinal and fibre plant. Under the conditions of water shortage along the downstream of the Tarim River natural plants like *Apocynum pictum* could provide water saving utilization options. References: Bastiaanssen, W. G. GCG 03-02 - Central Asian ecosystems under water scarcity 2

Chair: Bernd Cyffka, Yumiti Halike

Global Change Impacts on Central Asian water resources

Tim aus der Beek (Kassel University), Marcus Malsy (Kassel University)

Large parts of Central Asia feature arid to semi-arid conditions and are therefore of high interest for hydrological studies, as water scarcity often limits the development of human, ecological, and industrial resources. Within this integrated model study the hydrological and water use model WaterGAP3 is being applied to all river basins located in Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, Uzbekistan, Southern Russia, North-Western China, and Mongolia in five arc minutes spatial resolution (~ 6 x 9 km per grid cell). First of all, water abstractions for the sectors households, irrigation, livestock, manufacturing industries, and electricity production are being computed and fed into the hydrological module of WaterGAP3. Then, water fluxes such as evapotranspiration, soil moisture and routed river runoff, are being modelled for each Central Asian grid cell. The performance of the model is then being evaluated by comparing modelled with observed river runoff for the period 1971 to 2000, which yields good agreement. Also, the Central Asian water towers in the mountainous regions, such as the Pamir, Tien Shan, and Altai Ranges are well depicted by WaterGAP3 with mean annual water availabilities above 200mm. Similar, arid regions, such as the Gobi and Karakum deserts with values less than 10mm are also realistically represented by the model. Human water impacts, especially from the irrigation sector, are high in the Amu and Syr Darya river basins, as well as near densely settled areas. Following the successful validation of the model results, transient bias-corrected Climate Change scenarios are being applied to estimate their impact on the water resources of Central Asia. Therefore, precipitation and air temperature output from the Global Circulation Models (GCMs) CNRM-CM3, ECHAM5, and IPSL-CM4 for the SRES-IPCC scenarios A2 and B1 are being used as drivers for WaterGAP3 to calculate potential changes in future local water resources. Therefore, daily water balances are being calculated for each scenario-GCM combination until the year 2100. Generally, an increase in water availability can be derived for Chinese, Eastern Russian, and Southern Tajikistani river basins, whereas a decrease in water availability can be observed in Northern Kazakhstan and Mongolia, Western Russia, and Eastern Uzbekistan.

Patterns of the Balkhash Lake level change and its climatic correlates during 1992-2010

Pavel Propastin (University of Goettingen), Martin Kappas (University of Goettingen)

The variation of the Balkhash Lake water level over the period 1992-2010 and its relationship with climate dynamics were investigated using satellite altimetry data and meteorological records from climate stations located in the lake catchment basin. The altimetry-derived water level demonstrated a general rise with a mean value of 8.1 cm/yr achieving in July 2005 a maximum value of 342.52 m. We found that the rise of the Balkhash Lake water level was accompanied by an overall upward trend in precipitation and temperature in the catchment basin during the study period. A strong increase of winter and spring temperature was the main contributor to the general upward temperature trend, whereas a significant change of summer and autumn precipitation was the major contributor to the annual precipitation trend. Both precipitation and temperature did not increase uniformly across the entire basin. The results showed that the most pronounced climate change occurred in the mountainous part (> 2000 m above sea level) of the basin, in the upper reaches of the Ili-River, the main contributor to the Balkhash Lake. Statistical analysis indicated that the Balkhash Lake water level is strongly correlated with both precipitation and temperature. Correlations were investigated for three altitudinal strata (below 1000 m, 1000-2000 m, and above 2000 m) corresponding to the lower, middle, and upper reaches of the River Ili. Best correlations were obtained for the upper reaches of the Ili River indicating that changing snow cover and glacier equilibrium are the main factors controlling the trend in the Balkhash Lake water level.

Snow cover variability in Central Asia during the last decade derived from MODIS

Andreas Dietz (University of Würzburg), Christopher Conrad (University of Würzburg), Claudia Kuenzer (German Aerospace Center)

In Central Asia which is characterized by a very dry strongly continental climate water is scarce but highly required for irrigation, power generation, and even pasture. Extensive areas receive less than 200mm precipitation per year generally occurring during winter and spring season in the form of snow. High amounts of snow falling every year in the mountainous regions are essential basis for producing crops along the river systems in the region. But snow cover is susceptible to changes in temperature and precipitation during these seasons

and is therefore reported to be affected by climate change (Foster 1996, Peng 2010). Long term changes in snow cover duration and amount may have profound consequences for the entire region. The vast area and the relatively sparsely distributed climate station network make a detailed observation of these changes difficult. Using remotely sensed data can help to monitor snow cover development at both, high temporal and high spatial resolution. The MODIS (Moderate Resolution Imaging Spectroradiometer) sensor aboard the Terra and Aqua satellites fulfils these requirements, providing two observations per day with a spatial resolution of ~ 500m per pixel. MODIS maps the Earth surface in 36 spectral channels, and offers the opportunity to map snow cover with a reported accuracy of more than 90% under cloud free conditions (Hall 2007). As during winter and early spring clouds often obscure more than 60% of whole Central Asia, the MODIS snow cover products lack the ability to provide an estimation of the actual snow cover condition. We used four successive steps described by Gafurov (2009) and Parajka (2008, 2010) to estimate snow cover conditions below clouds and produced a cloud-free time series of daily data for the years 2000 to 2011 for whole Central Asia. In a next step, snow cover duration information products for each hydrological year were generated which allowed the derivation of further products like mean snow cover duration and anomalies for each year. Onset of snow cover season as well as the beginning of the melting process was examined additionally to snow cover duration and percentage of snow covered area. Furthermore, the analysis that was first applied to all of Central Asia was then performed for single hydrological catchments like Amu Darya and Syr Darya - also including processing of single subcatchments. On this scale, a differentiation between mountainous regions and the flat plains became possible - both regions that behave differently with regard to temperature, precipitation, and snow duration/amount. The analysis of these datasets demonstrated a high temporal and spatial variability of snow cover. We identified regions with more or less stable snow cover conditions during the last 11 years, while for other regions, snow cover stood out due to its high variability.

The dynamics of Aral Sea, Caspian Sea, and Sharda Water Reservoir during the past decade based on MODIS data classification

Andreas Dietz (University of Würzburg), Igor Klein (German Aerospace Center), Ursula Geßner (German Aerospace Center), Claudia Kuenzer (German Aerospace Center)

According to the IPCC (2007) semi-arid and arid areas are particularly exposed to impacts of climate change. Central Asia with its desert and semi-deserts has been facing essential water-related challenges such as water scarcity, water quality degradation, and inefficient water use during the past, and at present. Because water in this region is economically crucially important, particular for irrigation and hydroelectricity purposes, the intense water use leads to conflicts of interests as water resources cut national borders (GFZ, 2011). According to FAO (1998) about 8000 small lakes have disappeared in Central Asia due to overexploiting of water resources in last decades of the 20th century. However, new water bodies arise due to the construction of water storage basins and hydropower dams. 180 water reservoirs have been constructed alone in Kazakhstan in the last ten years. Accurate information on the transformation of small water bodies and the variability of big water bodies is crucial for various applications, including environmental research (e.g. up to date information for modelling) and political decision making based there upon (e.g. hydropower, irrigation). In this study we performed a land cover classification based on 250m resolution MODIS reflectance data for the region of Central Asia and derived annual water masks for the period from 2000 to 2010. Based on water masks results we present the fluctuation of important water bodies in Central Asia, namely the Aral Sea, the Caspian Sea and the Sharda water reservoir over the past 10 years and put the derived dynamics into a geographical context. The examples illustrate that the extents of different water bodies show a completely different dynamic depending on their natural environment (size of hydrological basin, precipitation, land cover, extreme events), and human influences within these regions (construction of dams, political decisions on water discharge, irrigation, oil and minerals exploration). The presented approach allows automatic and accurate derivation of water masks from remotely sensed MODIS data in the region of Central Asia on an annual time scale.

Designing Strategies on Mitigating Climate Change – Towards Development of Wind Energy Potential in The Tropical Region

Andung Sekaranom (Gadjah Mada University)

The use of renewable energy is increasing as one of the strategies in the climate-change mitigation efforts. One of the renewable-energy resources mainly developed is wind energy. Nevertheless, the distribution of wind resources in each region is different, especially the difference between the tropics and subtropics. Wind speed in the tropics tends to be slower, whereas the wind at high speeds only found in certain areas. Thus, the development of wind resource potential as an energy source is only found in certain locations, which have higher wind speed than the average. This paper aims to analyze the wind resource potential in the tropical region with the case studies in southern Java, Indonesia, mainly in the Karst Gunungsewu area. Results of analysis with GIS model indicate that the wind resource potential in this area is high, where the wind flows of about 6-9 m/s at a specific location. This allows the development of windmills on the site. Areas with high potential extend along 12 kilometers on the coastal of Karst Gunungsewu. The area extends from the beach to an area 2 kilometers towards the mainland. Wind resource potential area affected by winds blowing from the Indian Ocean in the south. In addition, hilly karst topography also brings a contribution to the magnitude of the wind resource in the area. Compared with wind resource potential in the flat area over southern of Java, the wind speed is higher karst hills. In the flat areas, the speed is only about 3-4 m/s. This suggests that wind resources in karst areas have a good prospect to be developed as a renewable-energy source. However, at present the development of wind resources in the southern Java coast frequently occurs in areas with flat areas, while in hilly karst areas are still neglected.

Climate change policy in a globalizing world: How the EU is coming to terms with going-it-alone

Yda Schreuder (University of Delaware)

The ambitious energy and climate change policy adopted by the EU has led to carbon-leakage and relocation or a shift in production of energy-intensive

manufacturing to parts of the world where carbon reduction commitments are not in effect. EU business organizations state that corporate strategies are now directed towards expanding production overseas and reducing manufacturing capacity in the EU due to carbon constraints in the EU. Business leaders want the EU to scale back on the Emissions Trading Scheme (ETS) and to permit national governments to provide for compensation for industries affected by competitive disadvantage in the global market place. As the EU has been "going-it-alone" with mixed success in terms of complying with the Kyoto Protocol's binding emissions reduction targets, the paper attempts to address the question of what's in it for Europe and how to weigh the benefits of carbon emissions reduction against employment and business benefits. Until 2005, carbon costs were external to the cost of production in the EU, but under the compliance rules of the Kyoto Protocol and the ETS this is no longer the case. Taking carbon and energy/electricity prices into account, the cost of production - in particular energy costs for energy-intensive industries - are substantially higher in the EU than in most other parts of the world. At the same time, the institutionalization of a global free-trade regime under the IMF, the World Bank, and the WTO induces energy-intensive industries to relocate or shift production to countries where environmental regulations are less stringent and where no carbon constraints apply. Host countries encourage the export of high carbon-content products to developed home markets and have set up free-trade zones or export platforms for that purpose. The combined effect of the EU ETS and the institutionalization of a global free-trade regime is the driving force behind the world-wide increase in the use of fossil fuels - in particular coal - , the increase in carbon emissions, and the development of a fossil-fuel-based infrastructure in developing countries. As the prospects for further economic growth in Europe have dimmed, business leaders and politicians have rallied behind a scheme where national governments are permitted to compensate industries for the impact of the ETS undermining the effectiveness of the ETS in combatting global climate change. The paper will give examples of these strategies and provide evidence of how the EU ETS effectiveness is slowly being eroded. In this context the paper will also try to provide a background and framework for the outcome of the UNFCCC in Durban and a perspective on the way forward in climate change policy in a globalizing world.

Local climate change mitigation between pretension and reality

Fabian Sennekamp (University of Freiburg)

The presentation focuses on the local scope of action and governance structures with regard to climate change mitigation. It is based on a dissertation project. With climate change being a global challenge, mitigation measures have to be implemented not only on an (inter)national but also on a local level in order to achieve the reduction targets imposed by the Kyoto protocol. This means that cities need to find local solutions to a global problem. On the one hand, the local scope of action can be limited due to guidelines imposed top-down, such as national laws. On the other hand, the example of the German Renewable Energy Sources Act shows that national laws can stimulate local climate action. Therefore, local climate change mitigation can be regarded as a multi-level challenge, which means that all scales from local to international are linked up. Particularly important for progress are actors who build up networks aiming to implement local climate change mitigation measures. Typically, environmental activists, local businesses, municipal administration and municipal enterprises are involved. This raises the question which actors play a significant role in local climate governance. The objective is to work out a suitable governance definition. It can be observed that non-public actors get involved in decision-making processes, and the focus is shifted from a hierarchical perspective to consensus-orientated patterns. This theoretical basis coincides with empirical results from the dissertation project, which show that non-public actors play an important role. The contribution and influence of actor networks dealing with local climate change mitigation was analysed in Freiburg (Germany), which is known as a cutting-edge city in sustainable development. Interviews were conducted with all relevant groups of actors involved in local climate change mitigation. Three issues were central: First, the interviewees were asked to indicate which other actors they collaborate with. It can be assumed that pioneers are of special importance as they act as change agents who initiate climate action. Thus, the second aspect was the temporal dimension of climate change mitigation. Finally, the extent of the local scope of action was addressed. It mainly depends on the municipal capacity to act. This point can be generalized because the municipality is an important actor even if the particular surrounding conditions differ. Furthermore, municipal governments have allied in transnational municipal networks to support each other and to lobby for better climate change mitigation conditions on a European level. This way, they bypass the national level so that these networks become an interesting case of multi-level governance. Thus, the role of these networks is a further facet in the

presentation. Putting the different arguments together, the objective is to investigate the extent of the local scope of action to mitigate climate change.

Governing Climate Change in São Paulo, Brazil: Political responses and strategies

Fabiana Barbi (State University of Campinas), Leila da Costa Ferreira (University of Campinas)

Climate change is characterized as one of the most pressing issues in the 21st century. There are still many uncertainties related to the rapidity of these changes and how devastating they will be. It is recognized that climate change poses a major threat to important development issues such as water supply, food security, human health, natural resources and protection against natural hazards. Thus, modern society is challenged to manage growing risks and threats. In terms of responses to climate change, it has been argued that governments are important actors that play a key role setting regulations, institutions and appropriate modes of governance in order to address these risks at different levels and scales. This paper investigates how climate change is being framed by São Paulo State, in Brazil, in terms of policy strategies and instruments and how the responses of local governments in the coastal cities are linked to the Climate Change State Policy. Our findings suggest that this issue is not recent in São Paulo State: the State Program on Climate Change dates from 1995. However, very little was developed under the Program. In 2005, the Climate Change Forum, a civil society initiative, was established in the State aiming at subsidising the state policy. The Forum had a fundamental role in this direction and in 2009 the São Paulo State Climate Change Policy was enacted into law. The international context was also important for this approval, which happened a few weeks prior to the 15th Conference of the Parties to the United Nations Convention Framework on Climate Change in Copenhagen (COP 15). Despite the difficulties of implementing the law, especially regarding energy and transportation, its approval was essential to the national policy on climate change, approved in the same year. One of the flaws of the state policy is the lack of dialogue with local governments. Local responses to climate change are still detached from state actions. One of the highlights of the policy is that it also addresses climate change adaptation, following what the literature on climate policy has pointed out, that is, the growing need for mitigation and adaptation policies synergy. The analysed cities in the coast of São Paulo State do not have specific climate strategies, but the issue has been addressed by local governments in their different sectors of activity. Our findings suggest that the

responses to climate-related risks are blended with the responses to problems typically faced by local governments, such as floods, irregular land occupation, landslides on hillside areas, among others, which can be exacerbated by climate change. Thus, these policy strategies and instruments are not related to the cause of the problem itself but instead to the impacts resulting from it.

GCG 04-02 - Climate change mitigation from global to local 2

Chair: Rüdiger Glaser, Fabiana Barbi

Potentials and risks of REDD+ implementation in indigenous lands in the Ecuadorian Amazon

Toa Loaiza-Lange (University of Goettingen), Udo Nehren (Cologne University of Applied Sciences), Gerhard Gerold (University of Goettingen)

The lowland tropical rainforest of the Yasuní Man and Biosphere Reserve in Ecuador, described as the most biodiverse place in the world and an important carbon sink, is also home of 12 indigenous groups. Oil exploitation, illegal logging and mining have caused major shifts in the landscape and affected the lives of its original inhabitants, resulting in serious social and environmental conflicts. Against this background, REDD+ (Reducing Emissions from Forest Deforestation and Degradation) could be a valuable opportunity not only for climate change mitigation, but also for biodiversity conservation and poverty reduction. In this paper, an analysis of the territorial configuration and the socio-political organization of two indigenous groups, the Shuar and the Kichwa are presented; and compared to a 'campesino-mestizo' group living in the buffer zone of the Yasuní National Park. Using various mapping techniques and workshops with communities, the potential benefits and potential risks of REDD+ were assessed. Communities in this area are highly heterogenic and their social organization is complex. Therefore, a potential implementation of REDD+ needs an approach adapted to the specific local conditions. Insecure land tenure and population development as well as legal uncertainties about carbon property rights should be clarified before entering the national REDD+ scheme. On the other hand, the inclusion of large indigenous territories in REDD+ mechanisms may have a greater conservation impact and lower transaction costs that could enhance the management of forest resources inside communal reserves. Actual governance of common indigenous property could be seriously threaten by external mitigation mechanism rules and should be taken into account along with social and environmental safeguards.

Global overview of local peri-urban food crop production potential

Steffen Kriewald (Potsdam Institute for Climate Impact Research), Anselmo Garcia Cantú Ros (Potsdam Institute for Climate Impact Research), Till Sterzel (Potsdam Institute for Climate Impact Research)

Urban areas are currently the main sources for population, population growth, and GHG emissions. In the light of climate change mitigation and sustainable food production, the scale and rapidity of population growth confronts cities with many problems, such as the highly CO₂-emissive transportation of food to cities. A concentration of food production within or near cities could be a solution, and currently lacks a quantitative general overview of its potential. We provide an overview of the potential of peri-urban agriculture for over 380 cities globally to nourish their populations. Cities are by definition locations where fertility accumulates. As cities are often built along rivers, their soils are often fertile. Furthermore, labour force and the possibility of using fertilizers from human fecal matter within the city promises sustainable cycles. Although urban and peri-urban agriculture can be found in many cities worldwide and already has a substantial contribution to food supply it is considered just little in scientific research. Commonly cited examples of cities with urban agriculture are Havana, Dar es Salaam, and Dakar. Many case studies exist for these and other cities or regions, but all these case studies are not unequivocally comparable. Using high resolution land-use data, global agricultural yield datasets and census population data we evaluate the potential of peri-urban agriculture globally and calculate the fraction of the cities' respective populations which can be nourished by it. Therefore we define urban areas not by administrative boundaries but by connected built-up urban areas, and peri-urban area as the surrounding area with the same size. Only already existing agricultural areas are considered for the food-production. We consider the influences of cropping seasons, national food consumption patterns, and population density. In a review of over 380 cities with populations over 500,000 we find that 4% of all cities are already able to nourish their inhabitants through peri-urban agriculture (e.g. Adelaide, Islamabad, Munich, Novosibirsk), and 25% are able to nourish over 50% of their inhabitants (e.g. Beijing, Budapest, Oklahoma City, Kuala Lumpur). For most cities vegetables are the most calorie-yielding cultivars. With regard to making use of local circumstances, our results of potential peri-urban agriculture for selected cities support the further investigation of reconciling climate change mitigation with sustainable food production in urban areas.

Global forest politics going local. Contingency and power relations in forest carbon projects in Thailand

Annika Mattissek (Department of Geography)

The overall picture of climate negotiations in Durban has been rather disappointing and little progress has been made towards developing effective mechanisms to reduce global emissions. However, one instrument that has gained increasing attention and has been hailed as a glimmer of hope is the mechanism to Reduce Emissions from Deforestation and Forest Degradation in Developing Countries, REDD+. Supporters praise REDD+ as a cost-effective way of cutting emissions that - if implemented appropriately - can have additional positive effects on local populations and ecosystems. Negotiations on REDD+ in the last COP-meetings in Copenhagen and Durban focused on financing and safeguards for the implementation of REDD+ to ensure that forest conservation policies will not have negative impacts on local populations and indigenous peoples. However, opposition against REDD+ has come from exactly these groups. Local and indigenous people associations not only argue that REDD+ will cut emissions in the wrong places, i.e. in the developing world as opposed to in industrial countries. They have also articulated strong concern that the proposed financial incentives for forest conservation will increase pressure on forest-dependent dwellers and, in the worst case, may result in evictions of local populations. Drawing on empirical research on REDD+ and other forest carbon related pilot projects in Thailand, I discuss possible impacts of the implementation of these global political instruments on local contexts. The empirical findings suggest that outcomes of such mitigation instruments depend largely on historically established power relations and conflict constellations. Using the example of Thailand, I show how transferring political instruments designed on the global level to national and regional contexts may lead to new conflicts and shifting power relations. This does not mean, however, that REDD+ or related forest carbon projects necessarily lead to increasing discrimination of local communities. Rather, the implementation of global climate politics in local contexts is both contingent and contested - it has the potential to destabilize long-grown arrangements of resource use and gives rise to new debates about forest governance and appropriate policies.

Local Assessment of Urban Vegetation in the Context of Global Climate Governance

Jan Tigges (Humboldt-Universität zu Berlin), Tobia Lakes (Humboldt Universität zu Berlin), Patrick Hostert (Humboldt-Universität zu Berlin)

To date discussions move ahead on carbon regulation towards mitigation of climate change. To a great extent such global change is analyzed in the perspective of its local effects. Whereas recent research mostly disregards the opposite point of view concerning the importance of local urban vegetation in the context of adaptation and mitigation strategies of global climate change. In the matter of climate relevant functionalities of carbon storage, urban vegetation has recently gained more attention in the role of a regulating ecosystem service. The assessment of such service is challenging as field measurements of vegetation lack up-to-dateness and a consistent area-wide basis. Moreover field measurements do not offer a unique representative value of an ecosystem service as it is manipulated by different stakeholders. Stakeholders differ in their assessment of a service due to individual interests and different scales of acting. Therefore the aim of this case study is to discuss a remote sensing and modeling approach to assess urban vegetation in the city of Berlin (Germany) as a proxy for carbon storage concerning different stakeholders' strategies on climate change. The discussion considers different stakeholders' interests, possibilities and problems of adaptation and mitigation of global climate change, among those are such public awareness, planting strategies, green economics as well as addressing public and private space. A remote sensing and modeling-based approach addresses measurements of carbon storage of urban trees to provide a spatial up-to-date and consistent area-wide basis. This basis of field measurements is confronted with urban stakeholders considering their individual evaluation of urban vegetation as a climate regulating service. Regarding the evaluation is to first say that a high quantity of urban vegetation might act as a global carbon sink itself. The second is to point out that urban vegetation offers various ecosystem services which act as complementary climate regulators, as cooling & shade of trees can reduce energy consumption of urban housings as well. The third is to say that the urban share of total carbon storage of urban vegetation might be low. Nevertheless urban stakeholders can function as a seedbed inducing and diffusing socio-ecological and socio-economic behavior towards climate governance on a global scale.

GCG 05-01 - Critical junctures of globalization – Reshaping globalized living conditions in contexts of rupture

Chair: Sebastian Lentz, Ingo Breuer

Stabilizing everyday living conditions in a place of transition: The changing geographies of the island of Lampedusa

Holger Jahnke (University of Flensburg)

Migration flows between the Global South and the Global North have characterized living conditions at the island of Lampedusa and shaped the island's geography in different ways. For its geographic location in the middle of the Mediterranean, in a triangle between Sicily, Tunisia and Libya Lampedusa has become since the 1990s one of the most important entrance gates for many refugees and migrants from African countries and even beyond. Whereas the island itself has only about 5000 inhabitants, only in 2008 around 30.000 refugees arrived by boat from Libya and Tunisia in the port of Lampedusa. As a reaction, the European Union and the Italian government followed a consequent policy of externalisation which lead to an almost complete decline of arriving refugees, until the Revolutions in Tunisia and Libya finally caused so far unseen migration flows. The presentation will focus on the local geographical, political and social consequences of these external events for the everyday living conditions on the island, and how the inhabitants are trying to construct a future in this context of uncertainty.

Impact of globalization on spatial development and regional peculiarities in Ukraine

Eugenia/Ievgeniia Maruniak (National Academy of Sciences of Ukraine)

Spatial development issues are crucial for any country or region. In Europe it was reflected in a number of resolutions of the Conferences of Ministers responsible for regional/spatial development. Their decisions are being implemented successfully in developed countries, as well as becoming increasingly important for countries undergoing the integration into the EU. The present situation requires that we take into account the growing influence of the external components - global challenges, including those arising from globalization. Well-known concept of space transforms radically and acquires

new dimensions and new differentiation. Changes in mentality, social development mean that approaches to the analysis of space, its organization, processes like homogenization and marginalization should also change. Innovation and the customs barriers disappearance may reduce the costs of moving people and goods; improve management of these flows, especially for multinational corporations. However, such competitive advantages always come at a certain cost to a particular territory, its potential, and usually extrapolate to the global space. The need for changes in Ukraine spatial organization is caused by two groups of factors: internal (structures formed during the 30s-80s of the XX century and the results of inconsiderate decisions after 1991), and external (increased competition, global players, integration processes). In our opinion, main directions of the spatial development in Ukraine and its regions are: 1. Improvement of spatial structure, providing regional cohesion and possibilities, arising from polycentric development. 2. Improvement of accessibility: transport, information technologies. 3. Reduction in the negative impact on the environment, paying careful attention to possible effects of natural and manmade disasters. 4. Improvement in governance and spatial planning quality. Every year the level of country's involvement in the global economy is growing, but the qualitative characteristics of this integration are questionable and they limit opportunities for sustainable development. Export of goods is associated with the production of no more than 3-4 technological modes, and such are the FDI. The overall level of innovation and infrastructural development is low. Aspects of the so called 'shadow' globalization are forming; not to mention their impact on the environment. Regional peculiarities of globalization's impact represent special points of interest. There are substantial differences between directions and intensity of the integration of western and eastern regions, as well as response (reaction) from industrialized and agricultural areas, readiness for the development of tourism, etc. Their assessment is based on the author's methodology and its results should be taken into account when drawing up strategies and plans of spatial development.

The New Rush for Food Security: Globalised Arenas of Land and Water Discourses

Sarah Ruth Sippel (University of Leipzig), Birgit Kemmerling

The conjunction of the world food price and financial crises in 2007/08 in combination with population growth and climate change has led to a repositioning of global food security. We approach food security from a discursive perspective, focusing on its construction in globalised arenas of land

and water discourses within and beyond the Arab world. We consider food security as a concept that is embedded in a broader neoliberal discourse and constantly reconstructing and renegotiating resource distribution and power relations. In a first step, we seek to analyse globalised arenas of land and water discourses using two concrete examples: (1) global investments in land properties coming from the Gulf; and (2) international development assistance in agricultural production and irrigation in Egypt. The Arab Gulf States on the one hand depend on external food supplies, which have become increasingly uncertain and expensive since 2008. Scarce soil and water resources but huge oil and cash reserves have led them to re-examine their food politics, identifying global investments in land as one strategic asset for the future. Government representatives in Egypt, on the other hand, while also facing scarcity of land and water resources and high dependency on staple food imports use different strategies to cope with food insecurity. Without similar cash reserves however high poverty rates and social inequalities, food and agricultural politics concentrate on improving agricultural and water management efficiency. This strategy is endorsed by the official development assistance in order to strengthen national food security. By focusing on investments from the Gulf and official development assistance we investigate how "private" and "state" actors, "official" and "hidden" agendas, "development promoting", "profit seeking" and "Islamic/Arab" rhetorics are overlapping and become sometimes fluid, sometimes fuzzy. In a second step, we assume that the materialisation of food security discourses has an impact on everyday living conditions by shifting existing power relations and altering the social landscapes of rural communities. Drawing on the complementary insights from our case studies, we aim to tackle the following questions: (1) What are the implications of the "new rush for food security" on the local reallocation of the access to natural resources? E.g. does it lead to new empowerments or rather unfold mechanisms of exclusion? (2) How do the political events in the Arab region and the discursive practices of revolution shape local identities? E.g. does it enable a renegotiation of the "local" and local power asymmetries? (3) What are the underlying concepts of spatialities that we can identify in these discourses? E.g. how are new spatial references employed, perceived and constructed? Can we identify a reification of national spatial references?

GCG 06-01 - Current shifts in globalizing logistic networks, importance of distance and spatial implications

Chair: Robert Scholz, Barbara Weig

Ports and urban development: Unpacking the co-evolutionary dynamic

Wouter Jacobs (Utrecht University), Cesar Ducruet (French National Centre for Scientific Research (CNRS)), Peter Hall (Simon Fraser University)

The dynamic relationship between ports and cities has long constituted a rich object of study for geographers and economists alike. This paper builds on these earlier works in which port-city interactions have been considered from various territorial scales and functional specializations. While viewing port and urban development as distinct processes is both theoretically supported and analytically tractable, this detracts attention from the vectors or links through which each system exerts influence on the other. Hence, in this paper we call attention to the co-evolutionary relationship between port functions and the wider urban economic spaces in which they are embedded. Building upon evolutionary economic geography thinking, we address a framework to enrich existing port-city - and wider, urban-regional - analysis. Two main databases on port activities are combined with urban population data for the 1970-2010 period: container throughputs and various centrality scores of port cities in the global shipping network. Such information allows for exploring co-evolutionary dynamics; what is the trajectory of the relationship between port and urban growth over time? Are there regional specificities in the nature, level and evolution of such interactions? Controlling for urban specific variables, we present the results of this preliminary analysis.

Site Generation and Network Integration of New Logistics Hubs Impacted by Globalization: The Instance of Dubai

Rudolf Juchelka (University Duisburg-Essen)

The role of transport and logistics in the globalized world is of increasing importance. Proof of this development are the high growth rates in internet commerce, container circulation, in airfreight and KEP service providers. Apart from the transport-wise dimension of these processes measurable for example

in the shape of worldwide increasing quantities of goods and transport flows - the hierarchic nodes of traffic and logistics networks are assuming a more crucial role. This pertains not only to the operative organization aiming at an augmentation of efficiency for these networks but also with necessary decisions regarding location and the resulting spatial network patterns. At the same time a certain dynamic pertaining the significance of logistics hubs shown for instance in the emergence of new transport and logistics centers. Exemplary for this are transport hubs in the nations on the Gulf, new port locations in China or KEP service provider's hub sites. Taking the Gulf nations as example, and in particular Dubai, the talk aims at illustrating · how the generation of new transport- and logistics sites can be controlled, · how an integration within international transport- and logistics networks runs and · what regional and supraregional site effects and spatial imprinting evolve. Taking the example of Dubai is it possible to show and analyze how a new location of the transport and logistics industry is designed in a multimodal fashion and as an effect draw further related commercial sectors close to transport and logistics. A real logistics cluster will develop based on a transport hub. Through the industry's worldwide networking and integration of these nodes within a globalized system, the logistic site structure will change on a global perspective. The talk is laid out to illustrate in the case of Dubai this metamorphosis of logistics nodes in their global interconnectedness, identify causes and discuss positive as well as negative site perspectives of logistics hubs

Logistics Service Providers and the Transport Geography of Global Supply Chains

Christopher Savage (Namibian German Centre for Logistics), Eric Lambourdiere (Université des Antilles et de la Guyane)

Economic liberalisation of the global economic space has significantly increased the potential sales of companies that have embraced supply chain globalization. The companies that now have the major share of customers are those who, like DELL, ZARA or Wal-Mart, have organized their supply chains so that these potential markets are converted into real ones. In a short time, these companies have surpassed the competition in their respective fields. For example, DELL beat former number one selling computer hardware company, Hewlett-Packard; Wal-Mart overcame Sears in the retail business and Zara surpassed Marks & Spencer in the fashion sector. The success of these transnational companies is based on global supply chain management in which the logistics flow is based on integrated processes. In many cases, they chose to focus on their core

businesses and therefore have entrusted the management of the globalization of their business processes to outside companies. The core business of these companies is the administration of the movement and flow of physical goods and the associated information through space and time. The purpose of these third party companies, known as logistics service providers, is not merely to diminish the unique logistics costs engendered by the mobility of flow. Rather, they must construct global supply chains that are integrated to enable consumers to receive their goods at the right time, right place, as quickly as possible and at the right cost. This article is based on the concept of transport geography; on the one hand it seeks to show the evolution of logistics and transport in the management of the physical flows of goods as well as information in space and time. On the other, the role of support provided by the logistics service providers in the process of globalization of supply chains is highlighted. A case study of the logistics service provider APL Logistics will be used illustrate to this.

Dynamics of transport accessibility of the large cities of Ukraine as an indicator of "compression of space"

Nataliia Pashynska (National Academy of Sciences of Ukraine)

The development of transport and communication infrastructure, of new technologies transportation, integration of transport systems (development of intermodal transport, transport corridors, terminals, hubs) leads to increased speed, reduced costs of communication, increased frequency of movement of goods and people. This increases transportation accessibility, distance transform and the process of "compression of space". At different territorial levels, this process has its own characteristics. For the global level "compression of space" in the first place out factors of technical progress, the development of maritime and air transport, ports, development of international transport corridors. For regional and local levels are important transport accessibility, the development of high-speed transport infrastructure, connectivity and mobility of the transport network. The process "compression of space" flows evenly, it travels at different speeds in different regions and countries and depend on their level of economic development. Dynamics of transport accessibility was studied on the example of changing the transport distance of regional centers of Ukraine. In particular, determined by the difference in time spent on travel by rail in 1989 and 2009. "Compression of space" (average reduction of travel time) was calculated by the formula: $SP = TT/T$, where TT - change of time traveling from one location to another. T - time period for which this process took place.

SP - "compression space" (minutes/year). Analysis of changes in transport accessibility to the regional centers of Ukraine, Kyiv during 1989-2009 was shown that the compression of space occurs between Kyiv and powerful economic centers - the city of Kharkov (-11.46 minutes/year), Dnepropetrovsk (-11, 56), Donetsk (-10.55), Lviv (-15.36), Zaporozhye (-9.51). This is due to the fact that between the capital and cities there are intensive economic, financial, business, information and cultural relations. However, socio-economic relations and transportation accessibility between regional centers of Ukraine is much weaker than the capital. The exception is the Odessa - the largest Ukrainian of port city, which operates as an international transport and logistics center. Thus, the greatest rate of "compression of space" occurs between the capital and powerful economic centers of Ukraine through the introduction of high-speed means of transport (in this case, increasing the movement of rail transportation). In addition to improving transport accessibility, speed compression space between the economic centers of Ukraine depends on their socio-economic development, including population (correlation coefficient is 0,69) and size of GRP (correlation coefficient 0,61).

GCG 07-01 - Digital Earth: An opportunity for spatial citizenship 1

Chair: Karl Donert, Michaela Lindner-Fally

Use of GI technologies in public participation as the key to responsible spatial citizenship – the Geoconsultation+ project for secondary school students

Monika Rusztecka (UNEP/GRID-Warsaw Centre), Elzbieta Woloszynska-Wisniewska (UNEP/GRID-Warsaw Centre)

Spatial management is one of key tasks performed by self-governments in Poland. As all spatial planning decisions have spatial reference, they can be presented with the aid of maps, geovisualization tools and 3D animations. These techniques help understand the concept of planned changes and hence are often used in communication between local authorities and citizens. Especially the young people should get to know them, as in a few years they will be deciding about the future of their "small homelands". Their ability of geo-understanding (including reading maps and geovisualizations, approaching with criticism geoinformation being presented, conducting simple spatial analyses, drawing conclusions and having reflections) is crucial for developing a spatially literate society. Need for rising spatial awareness among Polish youth gave rise to the project addressed to students aged 13-18 (secondary schools) entitled Dialogue, compromise, public participation - school education for sustainable development of local communities within protected areas (in short - Geoconsultation+) conducted by the UNEP/GRID-Warsaw Centre in the years 2010-2011 (<http://www.geokonsultacje.edu.pl>). The main goal of the project was to help students in 50 schools from all over Poland feel the "public spirit" and encourage them to actively participate in the spatial planning process. Each of Geoconsultation+ teams proposed their own "dream investment" to be carried out in the commune, e.g. construction of a new sports and leisure complex or revitalization of an old nature park. Students analyzed data (local spatial management plans, information about protected areas and sites, etc.), chose alternative potential locations for their object, marked them on a map, and created simple 3D visualizations. All these materials were used to prepare meetings with self-government and nature conservation authorities, local community members, etc. convoked to debate about the investment. Public consultation sessions were also conducted using specially developed geoportal (<http://geokonsultacje.edu.pl/geoportal>) with a module for placing "geo-

comments". Each comment could be referenced to a specific object/location - an existing one, or one newly drawn/marked on the map. Using GI tools helped present information in a reliable, comprehensible way, to gather comments of all actors involved in the public consultation process, and to analyze them quickly to avoid potential conflicts. The example of the Geoconsultation+ project showed clearly that spatial thinking and good communication could improve the quality of decision making in everyday life of any local community. During public consultations some of the investments proposed by students were considered to be quite important and feasible, received support from the citizens, and for that reason were brought to life by the local authorities.

Telling Geo-Stories on Spherical Displays

Sebastian Wintner (University of Vienna), Andreas Riedl (University of Vienna)

Globes possess a long tradition in 'narrating' worldwide themes. In particular the information era with its manifold technical possibilities enables an enormous innovation potential for globes. A spherical display fascinates its viewers through its novelty and gives them a better understanding of earth's phenomena. Digital globes as spherical displays are one of the major subjects of research at the Institute of Geography and Regional Research (IfGR) at the University of Vienna. The display format of so-called material hyperglobes is suitable especially for schools, museums, science centers as well as for public relations. We think that it is worthwhile to present global issues in a more 'personal' way, rather than going on in producing them in the currently common manner. Therefore we consider Interactive Digital Storytelling as an eminent metaphor to communicating global themes to a broad audience. Thus, this contribution focuses less on technical preconditions rather than on the types of currently established geo-animations on spherical displays. The adoption of spherical displays as digital globes for knowledge transfer e.g. in education or within scientific public relations (e.g. in research facilities), uses diverse levels of complexity and (didactic) methods to visualize global issues. Besides imparting knowledge about topography, thematic contents play an important role. Their creation has to be based on a didactic concept and their presentation must be as user-friendly as possible. To reach these conditions, an appropriate editorial preparation of geo-data in terms of age group and target audience (to meet the users' level of education and standard of knowledge) is necessary. Furthermore with hyperglobes, in contrast to analogue globes, the opportunity arises to not only depict different static globe images but to show temporal changes in animations. Thus the evolution of spatial phenomena can be visualized

dynamically and leads to new insight. A professional implementation assumed an animated development process facilitates the cognitive processing and interpretation. Furthermore the paper will discuss a classification of Digital Global Stories. In order to ease the users' access to global issues, we developed an extensive system of topics/stories. Global stories exist in a manifold of varieties according to their grades of complexity and interaction. The main focus lies on the connection between Interactive Digital Storytelling and geo-animations in terms of combining different media together with a more emotional way of telling a story. This supports the advantages of digital globes and finally leads to better receptivity and understanding of our 'Mother Earth' amongst the viewers.

Near in the city (NIC) – an exercise package for GIS studies on urban environment

Virpi Hirvensalo (Department of Geography and Geology)

This presentation introduces an empirical work under development; a web-based learning environment, which focuses on themes related to the urban environment. The aim is to produce a flexibly applicable toolkit for geography and sustainable development courses for Finnish students. It is intended for students from the level of secondary school to institutes of higher education, including also subject teacher education. NIC is usable in many kinds of course contexts from 15 minute teaching episodes up to whole courses. It strengthens students' environmental competence by providing guidance to act in various physical and web environments. From the viewpoint of GIS studies, NIC serves best as an exercise package, whose contents can be carried out for example in PaikkaOppi; a web-based learning environment for GIS studies in Finnish upper secondary schools. PaikkaOppi provides technical and methodological competences to process spatial information. NIC provides competence to understand spatial representations of society and a comprehension how to engage actively with the spatial activities of society (cf. Gryl, Jekel & Donert 2010). An understanding of a local environment and knowledge of its central concepts are the premises of an active urban citizenship. NIC provides socially relevant learning materials for students' own research projects relating to physical and social spaces of a city. Practically NIC familiarizes users with various kinds of places in a city, such as suburban area, urban brownfield, park and street. NIC acquaints students with meanings and power relationships relating to them. NIC contains also descriptions of methods which guide students to make field trips and practice various research methods. Finally there are also instructions for students to produce presentations of their practices. An

example of those is a new plan of a using an urban space, being realized with a web-based GIS application. NIC is an application of a progressive inquiry model, a version of a constructivist learning theory. Students are encouraged to find authentic, real world topics for their projects of their own interest. Projects will be realized in a local environment, for example in a suburb by interviewing its residents or by participating an urban planning process by launching an initiative. Exercises realized in everyday places inspire students. In addition to that, local themes bring global phenomena, for example urbanization, near to a students' own world view. Gryl, I., Jekel, T. & Donert, K. (2010). GI and Spatial Citizenship. In: Jekel, T., Koller, A., Donert, K. & Vogler, R. (eds.): Learning with Geoinformation V. Heidelberg, Wichmann.

Forward to Basics. Education for active citizenship in a spatially enabled world

Thomas Jekel (University of Salzburg)

The use of geoinformation (GI) systems at the secondary-school level has been considered mainly as preparation to join the geospatial workforce and as a support tool to encourage spatial thinking. While this approach definitely has benefits in arguing for a wider set of competencies acquired by GI-based learning, it has frequently been linked to instrumental knowledge, and misses out on the societal consequences of GI use. In short, it links GI in secondary education to science education, but lacks reference to basic everyday social life influenced and possibly supported by geoinformation and relevant pedagogies using GI. The concept of spatial citizenship looks to avoid these deficits. This contribution presents a fundamental conception of an education for Spatial(ly enabled) citizenship that is based on the individual and collective appropriation of space and the role GI plays in these processes. This includes processes of consumption and lay production of GI in order to participate in society as well as an awareness of new tools of control and interferences with privacy. Spatial citizenship education is about learning how to navigate everyday life with respect to (a) the physical world, (b) the meanings attached to the physical objects and environment, and (c) the power relations involved in the production of meaning (including GIS instruments to naturalize meaning as well as new forms of collaboration and negotiation of meaning using Web 2.0 applications. Based on Bennet, Wells & Rank 2009, the paper presents an approach to citizenship education that is compatible with the web2.0/geoweb world and goes beyond an administratively bounded conception of citizenship and responds to spatially referenced community cultures. It looks at possible roles of GI in decision

making processes in everyday as well as political environments and develops a rough structure of competencies needed to successfully participate. These are competencies in the fields of: a) technology/methodology to handle spatial information, b) Evaluation, reflection/reflexivity regarding spatial information and representations, and c) Communication, participation, and negotiation with spatial representations. The presentation concludes with various real world examples from secondary schools showing paths towards the participatory and emancipatory inclusion of GI in secondary education based on the basic competence model. Where is the place for GI skills in secondary school education?

Elzbieta Woloszynska-Wisniewska (UNEP/GRID-Warsaw Centre), Monika Rusztecka (UNEP/GRID-Warsaw Centre)

Modern society is fully dependent on information. An increasing amount of spatial information (geoinformation) available for us through different GI tools (geoportals, maps applications, virtual globes, 3D animations) forced the development of a new type of citizens - the "spatially thinking" ones, equipped with the ability of geo-understanding (including reading maps and geovisualizations, approaching with criticism geoinformation being presented, conducting simple spatial analyses, drawing conclusions and having reflections). Needs of this new generation require many changes in the education system - putting more attention to the development of specific student skills (GI skills) that give the ability to find appropriate (geo)information and use it in practice, instead of providing them with ready solutions. However, there are a lot of questions related to this issue. What is the list of needed skills? How and when (in what lesson subjects) the teachers should and can develop those skills among their students? Which GI tools may be used? An attempt to solve these problems gave rise to the project entitled The EduGIS Academy addressed to teachers in secondary schools. The project was conducted by the UNEP/GRID-Warsaw Centre in the years 2010-2011 (<http://www.edugis.pl/en>). The main goal of the project was to popularize the use of information and communication technologies (ICT), as well as geoinformation (GIS), in teaching science and in environmental education in secondary schools. To achieve this goal, the so-called EduGIS Working Group was created. It consisted mainly of teachers and methodological consultants from Regional Teacher Training Centres in Poland. In the frame of the project members of the EduGIS Group with the support of representatives of the Ministry of Education and experts in the field of Geographic Information Systems (GIS) from Poland and Norway: (1) developed their GI skills (use of geoportals, GIS software), (2) prepared a list of GIS skills that should be developed among students in secondary school education, (3) analyzed the place of GIS skills in Polish biology and geography core curricula (finding provisions obliging teachers to pay more attention on geospatial issues), (4) compiled a "GIS knowledge base" - gathered a list of different spatial data

resources to be used by teachers and students, (5) proposed different scenarios and ideas for educational projects showing possibilities of using spatial data and GI tools in the classroom. Ideas developed by Polish teachers were discussed with their Norwegian colleagues invited to take part in the project activities. This helped formulate pros and cons of different approaches to GI education in Poland and Norway, and specify some recommendations for teachers in both countries. All results of the project were also compiled in the guidebook "GIS at school" (available also in English).

Chances of and constraints to GI(S) usage in the classroom – Selected empirical results from a teacher survey

Steffen Höhnle (FAU), Jan Christoph Schubert (WWU Münster), Rainer Uphues (FAU)

In the framework of a larger cumulative mixed-methods approach which aims at improving the implementation of GI(S) in the classroom by developing well-founded implementation strategies and concrete measures for implementation, we surveyed teachers of geography in Germany on the frequency of GI(S) usage, on their point of view of constraints to a wider implementation of GI-applications and the chances they see in the usage of GI(S) in the geography classroom (n = 410 teachers). The study on implementation strategies for GI(S) usage in geography education consists of several empirical partial studies: Partial study I: The frequency of GI(S) usage in German secondary schools was surveyed initially. Partial study II: The results of partial study I revealed the necessity for a follow-up study which deals with concrete implementation strategies for GI(S) usage in schools in a three-step development approach. Initially, the teachers were presented a battery of 21 potential constraints to GI(S) usage in schools which they had to rate individually on a five-level Likert-like scale ranging from 5 = 'true' to 1 = 'not true', as well as sixteen items about chances they see in the use of GI(S). Following a mixed-method approach the second step consisted of a cumulative follow-up qualitative study which consists of six group discussions. Thereby five homogenous groups of four to six participants with a similar background were created and one heterogenous group with different backgrounds. During the group discussions the results regarding the constraints to GI(S) usage of the quantitative survey were presented to the participants. In the course of the discussions, the groups developed concepts and ideas reflecting their perspectives on how to overcome impediments to and promote GI(S) usage in schools. Partial study III: After the end of partial study II another partial study will evaluate the strategies in an

intervention-based approach at various schools. In this paper we will provide a detailed overview of the study approach and of the complete results from the quantitative parts of the study (frequency of GI(S) usage in the classroom, constraints and chances from the point of view of teachers; n = 410 teachers).

PaikkaOppi – a Web Based GIS Learning Environment for Finnish Schools

Jukka Tulivuori (Finnish National Board of Education), Lea Houtsonen (Finnish National Board of Education)

Usually the most important argument for incorporating GIS in the school curriculum has been its ability to enhance spatial thinking skills. It does not only support the students' understanding of the environment and stimulate sustainable ways of living but also develops professional skills for working life and enhances their digital literacy in GIS. In this paper, our aim is to present how a web-based GIS learning environment PaikkaOppi can support learning of spatial information in Finnish schools. Geography is a compulsory subject at all levels in Finnish schools providing general education. At the upper secondary school level teaching should help students to understand global, regional and local issues. They must be able to acquire, interpret and critically assess geographical information, such as maps, statistics and printed, digital and other media sources, and know how to make diverse use of information technology to present this information. All upper secondary schools in Finland should offer an optional course 'Regional Studies', which provides an introduction to GIS methods and their applications. The Finnish solution to offer support for GIS education in schools is called PaikkaOppi, funded by the Finnish National Board of Education. The idea was to combine spatial data of various topics with a pedagogic web-mapping interface. The data had to be so detailed that geographic inspections could take place in the school surroundings. The content had to be thematically extensive to allow multiple inspection angles to the environment. In addition, the service had to support active learning to enable personalized mapping exercises, sharing data and reporting to teachers. The service also had to be easy to use and technically stable to have teachers to adopt it. Data for the empirical part of this study was collected from 40 teachers by a questionnaire in 2011 by Jukka Tulivuori. There were also six thematic interviews to get more detailed and deeper information about the use of GIS in schools. The study showed that the Finnish teachers show high appreciation for a free web based learning environment for GIS. They also think that it is important to teach with GIS, not about GIS. There are also some challenges in

teacher training, both basic and in-service, because they can't really answer the need to train teachers in implementing ICT tools, and the level at which different schools are equipped varies highly. Dozens of schools around Finland have started to use PaikkaOppi to study Finnish geography on their geography lessons. The basics of GIS become familiar when studying the environment: Students work with different datasets, browse through them and their metadata, and using the overlays in the map service. Learning geography through discovery has been the basis for developing PaikkaOppi service for Finnish schools.

GIS teaching in a “junior university” – a report of an experience

Cristiana Martinha (University of Porto)

It is our intention to present an educational project that aimed to introduce pupils (between 13 and 15 years old) to GIS. The project is developed in University of Porto inserted in its project 'Junior University' (see: <http://www.universidadejunior.up.pt/>). The project has the objective of be a practical implementation of the 'digital-earth:eu' network in our university and it has the intention also to give news points of discuss and development to the network, for example, asking about the role that the universities can have in the development of the implementation of GIS in Education not only in the level of teacher training, resources production or curriculum recommendations, but also in the direct action with the pupils through projects like juniors universities that are now very developed in Europe (see: <http://sites.google.com/site/eucunetevents/>). So, because of that, we will focus in some theoretical points: the importance of GIS to development of spatial citizenship and geographical education; the importance on the called 'juniors universities' to geographical education; the role of the universities and R&D centers to development of the use of GIS in Education (with connections with companies). It is our intention to present our activity in the 'junior university project' of University of Porto related to GIS to pupils in the next points: present quickly the project 'junior university' in our university and its internal organization and national impact; planning of the activity since the project submission to rectory to its implementation; obstacles and difficulties in the implementation (software; specific teacher training; computer labs); resources used (its choice and its construction); opinions of the teachers (monitors) and pupils obtained through an opinion survey about the activity. With this presentation, it is also our intention to listen all the comments of specialists in the session of the IGU congress and with them to improve our project to be implemented once again in

the next year. It is also our intention with this presentation to encourage other colleagues of other universities around the world to develop similar projects in their universities in order to improve the importance of the universities to teach and develop the use of GIS in Geographical Education. In conclusion, this project (and this presentation) is already a result of the work in 'digital-earth.eu' in our university and it is, at the same time, a practical product to the network. It is also a contribution to the development of GIS in Education in Portugal and in our university and our R&D center.

GCG 08-01 - Ecosystem services: Its epistemology and relation to geography 1

Chair: Xavier Arnauld de Sartre, Noel Ovono Edzang

Le Millennium Ecosystem Assessment (MA) or the introduction of a scientific concep into political arenas

Monica Castro (SET- Université de Pau/ Centre national de la recherche scientifique), Xavier Arnauld de Sartre (Centre national de la recherche scientifique)

The Millennium Ecosystem Assessment is the result of a science/policy making process of great magnitude, which lead to the widespread use of the concept of ecosystem service (ES) among policy makers, scientists, NGOs' related to biodiversity conservation and climate change. As part of an effort to understand such a process, our study assessed the MA in regard to the science use to justify the arguments it contains. Our aim was to identify the epistemic communities behind the different discourse used for building the concept of ecosystem service inside the MA. Using content analysis and bibliometrics, we build and analyze a data base which relates MA documents with its citations. We compared it with data extracted from a scientific data base. We identify the different actors leading the process and their disciplinary and geographical attachment. As well, we identify the main scientific arguments used to build the MA discourse about ES. Even though the MA was issue of a participatory process, it is a product of northern scientist with particular views of nature. We argue that disciplinary and geographic attachments of MA shaped the actual application of the ecosystem concept all around the globe.

Uncertainties and controversies around ecosystem services: A review

Cécile Barnaud (INRA), Martine Antona (CIRAD)

The concept of ecosystem services (ES) is enjoying exponential success on both scientific and political arenas. However, this concept is increasingly being taken for granted and the strong uncertainties and controversies associated with it are rarely addressed. The objective of this paper is to demonstrate that a constructivist geography could contribute to an innovative approach to the concept of ES that acknowledges, analyzes, and even benefits from these uncertainties and controversies. One of geographers' main interests is indeed

the study of relations between people and nature, and constructivism considers people's perceptions of these relations as a key determinant of their practices. Drawing on a review of the literature, this paper identifies and characterizes five main domains of uncertainties and controversies associated with the concept of ES: (i) the multiple understandings of the concept of ES due to deep differences in the way people perceive the place of humankind in the ecosystems: Is humankind part of nature? Are ES produced by ecosystems or by people? Does the concept of ES contribute to an integrated or a segregated vision of human-nature relations? (ii) the different perceptions of the notion of value of ES : Is a human-based value of ES a non-sense, an ineluctability or a necessity? Should such values be objective and universal or subjective and negotiated? (iii) the scientific uncertainties related to the ecological dynamics that underlie the production of ES : scientists are indeed often unable to establish with certainty a causal relationship between the state of an ecosystem and the effective provision of an ES, either because knowledge is insufficient or because the systems considered are, by their very nature, unpredictable; (iv) the complex social interactions (conflicts of interests, power plays, scale issues) underlying both the valuing of ES (which services do different people value the most who benefits from which services?) and the choice of ES to be preserved in priority (individual, collective or public choices); (v) the controversies around the political tools derived from the concept of ES: Why are most incentives monetized and market-based? Is it inherent to the concept of ecosystem services? The paper also examines how these uncertainties have been dealt with so far. This review allows us to identify the need to develop approaches to ES that take into account the diversity and the complexity of local stakeholders' perceptions, interests and practices around ES, and that allow these stakeholders to exchange and confront their perceptions, i.e. to acknowledge and address collectively the key uncertainties associated to the concept of ES. We argue that a constructivist geography that would reconcile with environmental preoccupations and action-research practices could fill in this gap.

Alien plants in tropical smallholder farming landscapes: Can the "ecosystem services" concept help evaluate their sustainability?

Christian Kull (Monash University)

Smallholding, household-based farm landscapes in the tropics contrast strongly with industrial mono-cropped agribusiness, fenced off protected areas, and state-owned forests. These landscapes contribute to food security, preserve a diverse array of crop varieties, embody local culture, have aesthetic appeal, and

contribute in certain ways to wild biodiversity conservation. A troublesome component of these landscapes, particularly in the eyes of some biologists, is the presence of plants introduced from other parts of the world. These plants can become crop field weeds, lower the water table, or invade 'natural' environments. Yet, alien plants are often the chief source of food, fiber, and construction wood for self-subsistence and cash income in these landscapes. They contribute to soil protection, land rehabilitation, and carbon sequestration, and they add colour, memories, and emotions to rural communities. How does one come to terms with and evaluate their role in the sustainability of these landscapes? One conceptual tool to do so could be that of 'ecosystem services' as popularized by the Millenium Ecosystem Assessment. It analyzes the benefits people get from ecosystems, and could easily be applied to tropical smallholder farming landscapes with alien species. The useful (though not very intuitive) categories direct attention not just at obvious benefits like food, fiber, and forage, but also services like nutrient cycling, water purification, seed dispersal and climate regulation. However, problems with this tool ensue at the conceptual and ideological level. Ecosystem services was originally conceived to describe the benefits humans receive from 'natural ecosystems', and thus the concept tends to be underlain with a neo-Malthusian critique of anthropogenic landscapes and not welcoming to introduced species. The tool focuses on services, but does not explicitly incorporate dis-services like opportunity costs, which would allow for a more balanced view. The concept facilitates an economic, neoliberal model where services rendered can be valued in monetary terms, which may or may not fit with the perceptions of communities living in the landscape. Finally it does not address the political and social consequences of environmental management interventions carried out in its name. The ecosystem services approach, as a result, might end up critiquing tropical smallholder landscapes with alien species, which appears counterproductive in terms of their obvious resilience and contributions to lives, livelihoods, and culture around the world.

Retheorising ecosystem services: A cultural landscape approach

Jessica Budds (University of Reading), Margreet Zwarteveen (Wageningen University)

Originally proposed by ecological economists, the concept of ecosystem services has gained traction in demonstrating the importance of ecosystems for providing goods and services to society since the 2005 Millennium Ecosystem Assessment. Much work has sought to develop and operationalise the concept

as the basis of scientific research and ecosystem conservation. Yet, most thinking and practice around ecosystem services is based on a view of ecosystems as inherently biophysical systems that interact with, yet are separate from, people. In this article, we draw on insights from political ecology and science and technology studies to argue that the ontological separation of nature and society that underpins this conceptualisation is problematic, both in theory and in practice. Such an understanding of ecosystems overlooks the multiple ways in which ecosystems are shaped by social processes over different spatial and temporal scales. This, in turn, produces analyses that ignore the power relations that underpin the (re)production of ecosystems and their human populations, and enables the continued dominance of formal science in producing knowledge. We propose advances in two directions. First, we re-theorise ecosystem services as co-constituted by biophysical and social processes, both materially and discursively, and over space and time, by ontologically redefining ecosystems as cultural landscapes rather than natural environments. Second, we explore the epistemological implications of this re-theorisation: acknowledging that ecosystems are also social implies that human influences and meanings are not external to, but part of, ecosystem services. This raises important questions about the (often implicit) claims to objectivity that continue to characterise much knowledge about ecosystem services, the types of knowledge that are needed to better understand human-ecosystem interactions, and the nature and effectiveness of policy interventions. We suggest that these advances offer a more critical framework for researching ecosystem services and contemplating policy responses.

GCG 08-02 - Ecosystem services: Its epistemology and relation to geography 2

Chair: Xavier Arnauld de Sartre, Noel Ovono Edzang

Contrasting “ecosystem services” with the concept of “landesque capital

Lowe Börjeson (Stockholm University)

This paper will contrast the concept of ecosystem services (ES) and its epistemological foundations (e.g. its association to natural capital), with the concept of “landesque capital” (LC), which was launched into political ecology by Blakie and Brookfield (1987). Both concepts are efforts to approach society-environment relations from an economic angle, manifested by the metaphorical use of “services” and “capital”, and essentially represent counter notions to “land degradation”. They are both used as key concepts in studies of management-environment relations in agricultural landscapes, e.g. to articulate the recursive and dynamic interactions of management and biophysical processes. However, while ES is widely adopted in contemporary research and development projects, the use of LC is contained within a rather specialized field of scientific inquiry, dominated by geographers, anthropologists and archaeologists with an interest in the dynamics, history and intensification of agricultural landscapes. Interestingly, but not surprising given the different academic origins of the concepts, i.e. in ecology/economics (ES) and geography/agricultural economics (LC), there is virtually no reference to or engagement with LC in studies that take an ES approach. This paper aims to look beyond the overarching similarities mentioned above and explore to what extent LC can be useful to critical examinations of ES or possibly add an analytical dimension to studies structured on the concept of ES. This will primarily be done by discussing the analytical strengths/weaknesses, epistemological differences/similarities as well as more pragmatic considerations with respect to the use of these concepts. Since the 1980s, LC (defined by Blakie and Brookfield, 1987, as: “any investment in land with an anticipated life well beyond that of the present crop, or crop cycle”) has taken on a rather precise meaning as physical landscape elements that improve agricultural productivity (terraces, drainage and irrigation channels, stone walls etc.). Non-conspicuous investments in anthropogenic soils has also been conceptualized as LC, while more “green” conceptualisations of LC, i.e. trees and enduring patterns of vegetation and open fields are not as well developed. This clearly stands in contrast to the central role of biodiversity or “natural”

vegetation for the notion of ES, and thus partly explains why LC and ES remains analytically separated. The paper concludes that, unlike ES, the analytical power of LC lies in its ability to transcend the society-nature dichotomy in a productive way, and by doing so set the recursive character of labour-land-ecology relations at centre stage. However, a more explicit engagement with vegetation and biodiversity is probably needed to enhance the usefulness of LC as an analytical concept in studies of agricultural land-use dynamics.

When geography puts people “back in the picture”: Water management and ecosystem services in the Volta Basin

Jean-Philippe Venot (International Water Management Institute), Fred Kizito (International Water Management Institute), Sabine Douchamps (International Water Management Institute)

A growing body of literature identifies Ecosystem Services as an innovative analytical approach that links social and natural sciences to better understand the relationships that societies nurture with their environment, in an era recently qualified as the Anthropocene. The promise for making economic argument about the importance of the environment for people and society as a whole - through for example payment for ecosystem services schemes- has notably stimulated interest among policy makers and researchers alike. But this also marks a tendency towards too great a focus on economic valuation, which could tend to obscure ethical and political issues in relation to the environment and ‘commodify’ nature. In a context of growing uncertainty over environmental dynamics, shying away from the political and social dimensions of ecosystem that are likely to assume greater importance than economic ecological ones has become increasingly untenable. This constitutes an opportunity for human geographers ready to engage with their physical counterparts and other biophysical scientists. This paper highlights the constructive tension that can emerge from considering the dynamics of decision making within an Ecosystem Services perspective, through a case study of water management in the Volta river basin, West Africa. The Challenge Program for Water and Food (CPWF) in the Volta Basin is a research-for-development program which aims, among others, at “enhancing efficient use of water for ecosystem services”. From this anthropocentric, utilitarian perspective, researchers have engaged in characterizing bundles of ecosystem services in relation to water through quantitative tools such as historical perspectives of land use/land cover and spatial hydrological models; these models will serve as a basis for scenario building in the view of the program’s objectives. But, as for landscapes,

waterscapes (i.e. where water is tapped and stored and how it is distributed to the different water users according to socially negotiated rules) have a social and political dimension. The research identifies actors, their values, livelihoods, knowledge, and networks and how these contribute 'and may be shaped by-ecosystem services. This understanding constitutes the first step towards identifying scenarios that are both socially and environmentally acceptable to all stakeholders. As in the field of political ecology where scholars debate on the relative importance of the 'political' and the 'ecological', human geographers have a unique role to play in the field of ecosystem services science, one of highlighting the inherent (rather than emergent) social dimension of environmental decision making and socio-ecosystems.

Mangrove Ecosystem Services in the Mekong Delta: Combining Socio-Economic Household Surveying with Remote Sensing based Analyses

Quoc Tuan Vo (German Aerospace Center), Claudia Kuenzer (German Aerospace Center), Quang Minh Vo (Can Tho University), Natascha Oppelt (Department of Geography)

Mangrove ecosystems along (sub-) tropical coasts are threatened due to the conversion of land cover and land use. In the Mekong Delta - Vietnam, mangrove forests have been cleared especially for shrimp farming due to the high economic benefits of shrimp production. The value of ecosystem services can be quantified in many ways either by statistical methods or modeling approaches. In order to undertake an ecosystem services evaluation - a useful framework and applicable tool for environmental management and policy making - the values of these services first need to be quantified and visualized appropriately. Remote sensing has been widely proven as a useful tool for the derivation of ecosystem services, for example delivering inventory information of forest quality and quantity especially based on high resolution data. The objective of the current study is to design a framework for an economic evaluation of mangrove ecosystem services based on in-situ and remote sensing observations. Based on over 300 household investigations, the direct benefits of different mangrove ecosystems were calculated based on different ratios of mangrove and aquaculture combinations. Landuse classifications supplied the basis to transfer the finding into a larger area. The result shows that the quantitative direct value of different mangrove coverages ranges from 100 USD to 3000 USD a year for one hectare. This does only include direct economic earning from e.g. fish or shrimp production, but not indirect values,

such as storm protection or positive microclimatic influences. It will be discussed how direct ecosystem service value maps can be extended to derived the ecosystem's overarching value, considering different service-value components. This study presents the capabilities to study mangrove ecosystem services based on earth observation data and socio-economic household surveys.

Areas of permanent Preservation and their usage planning in the watersheds context: Methodology for legal pattern adjustments applied in a pilot area in Northwestern Rio Grande do Sul, Brazil

Sidnei Luis Bohn Gass (Universidade Federal do Rio Grande do Sul), Roberto Verдум (Universidade Federal do Rio Grande do Sul)

Land usage and settlement process based on deforestation and unsystematic land management bears conflict between environment recovery and farmer's economic reproduction. This dichotomy is displayed in the effective application of the Forest Law (Federal Law 4.771/65) that deals with permanent preservation areas (APPs) in the marginal strips along water courses. We aim to present a methodology to define the waterside permanent preservation areas using elements of fluvial geomorphology and vegetal cover as an alternative to current legal patterns. We present an historical refurbishment of Northwestern Rio Grande do Sul settlement (Brazil), a theoretical interpretation of nature's conservation and discuss the permanent preservation areas in two analysis levels: the current juridical structure and the area usage in Northwestern Rio Grande do Sul. The discussion of the farm's social function is fundamental because farmers are responsables for preservation. We try to understand the public policies in the official agencies (Ibama, Fepam and Ministério Público Estadual) and how this agencies act. We chose three sectors of the Santo Cristo river to apply the methodology. In each sector, we assigned the floodplains levels and the levees by the cartographic analysis and evaluated the regional structures. As a result, we detected that the river influence areas varies from 20 up to 380 meters and concluded that permanent preservation areas can be 330 meters larger than the legal parameter. This shows the inefficiency of the metric definitions currently used. The main conclusion of the study is the need to take into account other ecological and geomorphological parameters for the definition of permanent preservation areas. We can say that conservation practices made by rural producers should be seen as positive impacts for rural property, as well as for the enrichment of biodiversity in small, medium and large properties.

GCG 09-01 - Financialisation, marketisation and the environment: Towards 'alternative' economic geographies of finance? 1

Chair: Hans-Martin Zademach, Tim Heinemann, Jane Pollard

Exploring sustainable finance in various contexts: Conceptual thoughts and insights from the energy industry

Johanna Dichtl (Katholische Universität Eichstätt)

The energy sector provides a field in which the growing influence of financial institutions and intermediaries on the environment and society become evident in a particular striking manner. Due to the extensive deregulation and privatisation of this industry in a large number of places around the globe, energy services are today mostly tied to market mechanisms, i.e. to the circulation and expansion of financial capital in its various forms. This paper aims to scrutinize this financialisation in light of the paradigm of sustainable development. It pursues a twofold target: First it suggests an analytical framework that enables an encompassing exploration of the interrelations and interrelatedness between financial, natural and social systems in varying geographical contexts, drawing on insights from both the sustainability discourse and the financialisation debate. Second, it presents empirical results gathered in an ongoing research project that illustrate the explanatory power of this framework. These results display the contradictions and potential contributions of the financial industry to sustainable development in a variety of different geographical contexts.

Microinsurance for climate change: Performing risk and forming risk-bearing subjects

Leigh Johnson (University of Zürich)

This paper examines recent efforts to extend weather-based microinsurance products to rural agricultural and pastoralist households in the global South. Such products, which make small financial payouts to policyholders in the event of a prespecified weather trigger, are increasingly championed by development agencies, NGOs, and global (re)insurers as tools to bolster the resilience of households that are highly vulnerable to climate change. The creation of these new financial circuits for risk transfer in economic and geographic peripheries provides an opportunity to reflect on the insurance exchange, which is often

invoked as one of the most quintessential banalities of modern life. The extension of insurance products to households for whom the concept of commercial insurance is quite foreign demonstrates how other subjectivities unsettle the seemingly obvious sets of assumptions, institutions, and relations surrounding insurance. For instance, a number of pilot projects have encountered quite low demand within the target populations for the insurance products offered, despite households' high vulnerability to climate volatility and the apparently careful design of products. Here I consider practitioners' and researchers' explanations for low insurance uptake and their strategies for creating demand in the target populations. This process of market creation highlights not only how specifically bounded climate risks are performed as uniquely ameliorable via financial channels, but also how the economic institution of insurance depends upon the iterative creation of a very particular kind of subject that identifies 'risks' as such, and imagines them as transferable - ergo alienable - by means of a market exchange.

The murky waters of green property investment

Katia Attuyer (LATTS)

In the last two decades, efforts have been made to devise legislative and policy frameworks that encourage the adoption of sustainable development options at all scales. The pertinence of the urban scale to address issues of sustainability is particularly recognized. There is increasing pressure from political circles and citizen's groups to ensure the production of urban built forms that can address both social and economic needs while respecting long-term environmental goals. Yet, the built environment has increasingly become a category of financial asset; and investors are often believed to give precedence to the maximization of return over the integration of social and environmental concerns. This paper will examine how the intensification of the sustainability agenda is impacting on commercial property investors. It will identify the main triggers that have led to changes in behaviour, and what obstacles remain to achieving sustainability objectives. We will show that the fear of financial loss is the main driver of change. The introduction of new legislative requirements and the potential passing of stricter laws in the near future are producing a certain greening of investors' portfolio. Nonetheless, we will stress that we have not yet reached a tipping point whereby green buildings investment would have moved from being a concern for a few to being common practice. The paper will document the variety of behaviours encountered within this industry and will characterize the

discourses and actual practices of institutional investors in the French business property market, by drawing mainly on qualitative data.

Carbon market financialization and time-space compression

Janelle Knox-Hayes (Georgia Institute of Technology)

Countries around the world are developing carbon emissions markets as a governance mechanism to reduce greenhouse gas emissions. By mapping networks, market flows and proximity this article draws on the strengths of economic geography to illustrate the function and meaning of developing climate finance regimes. While climate change is an environmental phenomenon, the processes that drive it are economic. Carbon markets are representative of a growing emphasis on managing social and environmental problems through information governance and must be understood from the standpoint of financialization. This article deconstructs the notion that emissions markets are merely as system of pricing externalities, and considers the dynamics that create and underpin carbon emissions markets. I address two questions: 1) how does the compression of space and time facilitate the financialization of emissions markets? 2) what are the material implications of the financialization of environmental systems? I develop a theoretical framework to explain how financialization divorces resources from their materiality through time-space compression. The separation of resources from material context allows for the creation of distortions of value. I analyze how the architecture (including processes and agents) of the emissions markets contributes to three mechanisms of financialization: ownership, commensuration and mobilization. The article suggests that the architecture of the markets embodies a growing transition from material to information governance. The virtual nature of the markets and their ability to compress space and time enables them to operate globally and instantaneously, but threatens the integrity of natural systems embodied in materiality.

GCG 09-02 - Financialisation, marketisation and the environment: Towards 'alternative' economic geographies of finance? 2

Chair: Hans-Martin Zademach, Tim Heinemann, Jane Pollard

Mind the (financial) gap: Financialisation and the emerging spaces of 'older entrepreneurship'

Thomas Wainwright (University of Southampton), Ewald Kibler (Turku University)

Contemporary research in economic geography and the social sciences has attempted to examine the processes of financialisation, and the permeation of its politics into the 'real' economy, society and households (French, et al. 2011). This paper seeks to contribute to these debates by investigating the emergence of new economic spaces, as a consequence of the shift from defined benefit pensions, to less generous defined contribution pensions. Specifically, the paper uncovers the relationships between financialisation, pensions and their connections to household spaces, to examine how the failure of private pension provisions to meet the needs of older individuals, has begun to displace retirement with a work-retirement balance. This in-depth study of 22 older entrepreneurs, aged 50 years and older, provides new insights into a response to the effects of financialisation, where individuals have created new businesses in their later life, as they cannot afford to retire 'full-time'. While recent critiques of research on financialisation have argued that space is often treated as a passive container, this paper provides a theoretical contribution to financialisation by situating space at the centre of its analysis. Particularly, our paper argues that the household has become a socio-spatial fix of economic production, as older individuals are developing entrepreneurial activities at home, to overcome the inadequacies of an increasingly financialised economy, poor savings and pension returns. In doing so, the paper identifies the emergence of 'reluctant', alternative economic spaces, where households are reconfigured to form hybrid spaces of work and retirement.

From bank- vs. market-based to local- vs. international-oriented financial systems: The case of German saving banks

Stefan Gärtner (Institute for Work and Technology), Franz Flögel (Institute for Work and Technology)

Comparative studies of financial systems often focus on contrasting of bank- vs. market-based systems (e.g. Allen and Gale 2001; Demirgü-Kunt and Levine 2001). In the light of this differentiation some authors view the global financial crises of 2008 as evidence for the homogenisation of the varieties of financial systems under the pressure of financialisation, because bank- and market-based financial systems have alike been affected by the crisis (e.g. Beyer 2009; Hardie and Howarth 2010). Especially the bailouts of some banks in Germany (quoted as typical bank-based system) demonstrate that also banks are highly intertwined in market-based activities. Without doubt international financial integration has reached a high level, but significant spatial differences can be detected by the causes and effects of the crises (e.g. French et al. 2009; Martin 2011), e.g. only some countries have witnessed the emergence and burst of a housing bubble and not all countries were affected by a credit crunch (Gärtner 2011). In spite of existing global trends there seems to be no single financial system, but territorial varieties which are not homogeneous but interlinked to different degrees. We propose a comparison of local- vs. international-oriented financial systems as an alternative approach for comparative studies of finance. Based on empirical material on saving banks and a review of previous studies we will discuss the proposed concept.

Hybrid Neoliberalism, Hybrid Natures: Contested Borders in the Mexican National Payments for Ecosystem Services Programs

Elizabeth Shapiro (Duke University)

First implemented in 2003, the Mexican National Payment for Ecosystem Services (PES) programs pay rural communities for carbon sequestration, biodiversity conservation, improvement of agroforestry systems and hydrological services. The initial design of these programs was decidedly neoliberal, from their emphasis on the superior efficiency of market vs. state led environmental solutions, the attempt to institutionalize new property rights and the explicit goal of commodifying ecosystem functions. This article examines how the neoliberal notions of the programs' designers were hybridized by the intervention of national rural social movements, the inability of the down sized state to intervene at the local level and the continued strength of the rural collective in Mexico. The analysis is based on semi-structured interviews with members of thirty-two communities in which the PES programs had been implemented, intermediary organizations, and the actors involved in the design of the programs. The neoliberal framing of the programs' founders were first challenged and hybridized by members of a national coalition of rural social movements. These

actors introduced a conceptualization of PES as a societal recognition of the value of traditional rural stewardship and a source of funding to ensure its continuance. At the local level, there was a marked inability of the Mexican state agencies, down sized during successive rounds of structural adjustment, to articulate their own policy. Most participants believed that payments were a government subsidy and had little awareness of the intention that markets would be formed. Though true commoditization of ecosystem services rarely occurred, I found that the payments reinforced pre-existing environmental management, with the funds being used to support collective action for forest protection. I conclude that the programs designers' intentions to privatize conservation and commoditize ecosystem services, disentangling nature from its coproduction with rural stewards, were hybridized at multiple scales through the process of implementation.

New alliances against financialisation? The case of the German Mittelstand

Christoph Scheuplein (University Muenster)

Until the global economic crisis in 2008, it could be observed that the coordinated market economies adopted gradually elements of the liberal market economies, particularly from the booming financial sector there. Even though the charges of the financial crisis occur in all economies and the financial market capitalism has not come to an end, new alliances and ways of thinking are observed in the coordinated market economies. German small- and medium-sized businesses, which a few years ago still used new types of finance in order to free themselves from the dependence of the banking sector, are an example for that. The presentation portrays the types of finance of the small- and medium-sized businesses since the financial crisis. According to that, the convergence between market economies appears to be stopped. Instead, a new scepticism of business owners and managers is observed towards financial innovations. Theoretically possible explanations are discussed for this new divergence in the light of the new concept of 'Varieties of Capitalism' and the regulation theory.

GCG 10-01 - Focal points of the past – Historic-geographical dimensions of globalization

Chair: Klaus Braun, Jacqueline Passon

Global Consciousness in the Early Nineteenth Century

Alix Winter (Université de Versailles)

In my dissertation project I attempt to challenge the assumption of a silence concerning global processes among the contemporaries of the early nineteenth century. The consciousness of global connections and dependence is an essential part of globalisation itself and could be considered as the criterion for demarcating epochal change. Given this, it becomes crucial to look at the historical debates about these processes in order to reason out the question of the beginning of globalisation. And I assume the early nineteenth century to be an important period of reflection on the world as a unity, increasingly spreading in the public sphere. One can hypothesise that a significant break in the development of a global consciousness occurred at the beginning of the nineteenth century. Whereas the perception of global commerce in the eighteenth century was above all concerned with theoretical claims for free trade and the contestation of outdated trade company monopolies, the discussion in the early nineteenth century was shaped by ongoing processes of an increasingly economically interconnected world. Accordingly, this discussion thus considerably anteceded the technical global communication boom. The foundation of globe-encompassing telegraph connections and steam ship lines did not give birth to the global consciousness of contemporaries; rather, this consciousness preceded it. A definite turning point relating to communicative interconnectivity can be placed in the mid nineteenth century, but the rise of a public global awareness can be dated back. This timeframe is in accord with theories of leading economic and social historians. Additionally, global political connections came to the realm of possibility by the mid nineteenth century as a result of this logistical revolution. The first three decades of the nineteenth century thus comprise a basic step between these two points of reference of the development of a global consciousness that has rarely been taken note of and that certainly deserves more attention for the sake of the intellectual history of globalisation and for the discussion about the beginnings of globalisation in general.

From Empire to Nation – Egyptian Nationalists in Berlin during the Weimar Republic

Nathanael Kuck (University of Leipzig)

When studying the entanglement of Europe and the Arab world in the 19th and 20th century the attention has been predominantly directed at the imperialist European presence in those regions, less so on the presence of actors from those regions in Europe. Yet, analysing this presence could not only help shedding some light on the early history of migration that has profoundly shaped the diversity we today so commonly encounter in every big city. It can also offer insights into the discursive shifts that pre-dated the disintegration of colonial empires after World War II. In the first few years after World War I, several hundred Arab males, in their majority Egyptians, came to Berlin often to study at one of the city's well-known universities. There they found a capital that had lost its status as an imperial centre and saw its political landscape dominated by sharp social and political contradictions, yet provided a liberal atmosphere that allowed for subversive political activities. Apart from Arabs, Berlin also hosted migrants from China, India or the former German colonies in Africa and all of them started to form political groups to claim independence for their respective countries. This metropolitan anti-colonialism with its calls for self-determination challenged the predominant spatial order. Instead of the dichotomy of the national-imperial world order that divided a great part of the world in either imperial centres or peripheries the anti-colonialists wanted to establish a new territorial regime based on the equal exchange between self-determined nations. Being a part of this political milieu, Egyptian activists also formed political organisations, staged political events and published periodicals for their cause. The biggest journal called *Aegyptische Korrespondenz* was produced between 1920 and 1924 and will be at the centre of interest in this paper. It looks at the publishers, their political practices and alliances, but above all the debates in which they engaged. Of particular interest are the ways in which the articles negotiated national belonging and established a narrative of a national Egyptian history, how the authors conceptualised imperial rule, related to other anti-colonial movements and how they saw the relationship towards their host society Germany. By drawing on the Egyptian activists in Berlin during the Weimar Republic, the paper makes a case study of the early endeavours to dismantle the imperial structures as dominant forms of organising power over space and the demands to replace them with the nationalisation of political forms. The practical consequences of this demand for a comprehensive

transformation of the world were only felt decades later but are still very much reverberating in today's globalised world.

Rural Urban Migration, Maasai Pastoralist Youths and Globalization in Tanzania – Case of Ngorongoro Arusha & Dar es Salaam, Tanzania.

Emmanuel Munishi (Freiburg University), Axel Drescher (Freiburg University)

The Maasais belong to the Nomadic Pastoralist groups in the arid and semi-arid regions of East Africa. Maasais have historically been considered backward, conservative to their cultural practices and thus less responsive to globalization. Studies however indicate that, starting from 1990's Maasai Pastoralists in East Africa and Tanzania in particular began to migrate to cities for wage labour due to intensifying poverty, droughts, and depletion of their livestock herds by diseases. Studies among the Maasai pastoralist communities indicate that Maasais have overtime developed different ways of coping with the changing world. These studies however have not specifically and systematically linked the factors and patterns of the Maasais' rural urban migration with globalization. Based on the various theoretical and qualitative primary data from the field, the present work employs a historical-dialectical materialism approach to establish that various explanations are responsible for the recent patterns of the Maasai youth rural urban migration, identifying that Globalization-related aspects right from the colonial to the contemporary times have significantly catalysed this process among the Maasai youth pastoralists. It therefore reminds various stakeholders to underscore globalization in different policy and development related issues while dealing with the Maasai rural urban migration. The paper first offers a comprehensive conceptualisation of the term globalization and presents a gist of the Maasais socio economic evolution since pre-colonial period. Then it offers a critical review of migration theories and literature to help us capture and analyse a portfolio of factors and specific globalization aspects responsible for the current rural urban migration of Maasais'pastoralsits youth. Later the paper presents, empirical findings followed by a discussion and conclusive remarks that link migration and globalization. Key words: Rural urban migration, Maasai Pastoralist youths and globalization, Dar es Salaam, Ngorongoro.

Sanusiya's and Zaghawa's Trading Networks in Comparison: Past and Present of Trans-Saharan Trade between Chad and Libya

Meike Meerpohl (Ruhr-Universität Bochum)

San's'ya's and Zaghawa's trading networks in comparison: Past and present of trans-Saharan trade between Chad and Libya Dr. Meike Meerpohl Through the centuries the Sahara has never been an impassable barrier separating the shores of the Mediterranean from inner-African societies. In fact, people have crossed the vast, waterless terrains for thousands of years and for various reasons. The fluctuations of power and control often entailed the transformation of trade routes and areas of interest. New regions were discovered, conquered or assimilated and new trade goods rose to prominence while other commodities lost their importance. This contribution pays specific attention to the Wadai-Benghazi trade route, which passes through south-eastern Libya and north-eastern Chad. It will focus specifically on the period between the late 19th century and the beginning of the 21st century. In the late 19th century the Wadai-Benghazi route became the most important long-distance trade route between the Mediterranean and the sub-Saharan regions in East Africa after trade had been disrupted for many years. The extension and growing importance of this route has been attributed to the abandonment of the darb al-arba'n between Darfur and Egypt and of other trade routes in Africa, as well as to the growing control and influence of the San's'ya in the region. The San's'ya brotherhood was established in 1837 and governed from its headquarters in Cyrenaica from 1843 until 1896. The Grand San's' established religious centres along the Wadai-Benghazi trade route, which were also used for commercial exchange. After the fall of the San's'ya, this trade route was abandoned. Crises, war and instability plagued the region for many years. Trade links finally re-emerged in a new form at the end of the 20th century. The semi-nomadic Zaghawa pastoralists managed to diversify their economic activities by entering the trading business. In doing so they could draw upon their wide family networks, result of the tribe's migration across the region. In this presentation I will try to compare San's'ya's and Zaghawa's commercial networks and strategies. Especially the case of Zaghawa's trade management will exemplify how dynamics of globalization have entered the trans-Saharan trade through the use of technical innovations and the integration into international networks at the beginning of the 21st century.

GCG 11-01 - geo@web. Geography production and its lifeworld consequences in the era of the web 2.0

Chair: Inga Gryl, Tobias Nehrdich

Prosuming images in the web 2.0: the end of critical constructivism or its implementation?

Antje Schlottmann (Goethe-Universität Frankfurt)

Recent critical constructivist theories on visual geographies include the idea of perception as a productive practice. In contrast to a mimetic understanding, images are understood as products that come into being (and evolve) in the very act of viewing. They are hence conceived as being continuously re-shaped against the background of a certain cultural context. Images, in this view, are no longer consumed only, but at the same time produced, in other words: they are "prosumed". The new ways of inter-action offered by web 2.0 constitute an interesting situation in this respect: they put theory into practice in consideration that provided maps and images appear explicitly as user generated contents. But what is this practical turn of the theoretical concept of "making geography" about? The paper deals with the question of whether the web 2.0 can be seen either as a new reflective stage of visual practice inasmuch as it discloses the productive part of the consumer, or whether it rather produces "users" instead of prosumers because its tools render any reflections regarding the role (and construction of) the involved subjects obsolete. In this context, the contribution also engages with the educational program of media competence. Critical reflection of the social, i.e. particularly medial, construction of reality has just recently entered educational standards. Arising web 2.0 habits among children and adolescents could lead to either a rather indifferent attitude regarding the programs underlying constructivist criticism ("sure we produce our own world, so what?"), or they could lead to a rather engaged critical attitude and to new movements of empowerment ("now we know that we produce our own world, but how can or should we deal with this responsibility?"). The paper theoretically discusses arguments for both prospects by referring in particular to educational work with geographical images.

Digital geodata traces and locational privacy: New challenges for geographic education

Kim Pascal Miener (WWU Münster), Steffen Höhnle (FAU Erlangen-Nürnberg), Romy Hofmann (FAU Erlangen-Nürnberg)

Young people in modern societies consciously (e.g. Facebook) or unconsciously (e.g. some Google services) produce a vast amount of geodata using web services. In doing so people not only produce their own geographies by attaching meaning to locations and communicating about it, they also often unconsciously produce geographies valuable for other societal actors. Using relational databases it is possible to create very precise profiles of the individual user and his spatial practices from the produced data (e.g. for private companies). This almost inevitably prompts questions regarding data protection and privacy issues. In this paper a conceptual approach is presented on why students have to develop competencies regarding their personal geodata management, how they can do so and which challenges this subject matter implies for research in geographic education.

Mapping together: On Collaborative Cartographies, their discourses and space construction

Christoph Fink (University of Salzburg)

In 2012, maps are everywhere. Web mapping and mobile mapping have become killer applications on smart phones and Web 2.0. Many, and with them the most popular, cartographic tools and widgets were not created by cartographers. Among these 'implicit' or 'undisciplined' cartographies (cf. Hruby & Miranda Guerrero 2008:9; Crampton & Krygier 2006:12f) a special position is taken by community driven projects, and mapping efforts strongly relying on user input. This includes Goodchild's (e.g. 2007) VGI, but also covers 'soft' geographies, such as geo-tagged photos, Facebook comments, Twitter messages, or Wikipedia articles. 'Implicit' cartographies provide distinctly different conditions than traditional mapping environments: They are characterised by a vast absence of the normative standards set out by the cartographic research community over the last century, and typically feature a seemingly Fordist division of labour; traditional cartographic actors are replaced by advertisers planing and deciding, software programmers designing maps (and their looks), and users contributing to the maps's content, to name just a few. Collaborative cartographies above all add a sheer unbelievable multitude of contributors (and opinions) to the discourses of mapping. The research to be

presented approaches the topic from two angles: First, on a meta-theoretical level, the development of implicit cartographies is traced, their importance for a contemporary understanding of cartography is underlined, and reactions of actors of an opposed 'explicit' cartography are discussed. Second, the differences in the conditions of map (and space) production applicable in collaborative cartographies are explicated; consequently case studies are carried out: in great parts following the approaches of Schlottmann (2005) and Gryl (2009), the discourses of 'map edit wars' (cf. Maron et al. n.Y.) in OpenStreetmap are evaluated from the openly available changelog data. -- References: Crampton, J. W. & J. The Neocartography of the Geoweb: On the Pathway to Mapless Locative Media?

Tristan Thielmann (University of Siegen)

Neocartography claims to be the cartography of the everyday person using Web 2.0 techniques to create and overlay their own locational information on media platforms such as Google Maps. Rather than making claims on scientific standards, methodologies of Neocartography tend towards the intuitive, expressive and personal, but may just be idiosyncratic applications of traditional mapping techniques. However, does this also mean that these practices are of no use to the geosciences? Or can we say that the numerous distributed geotagging platforms and applications like Flickr and Google Latitude have given rise to a new genre of 'Maps 2.0'? Will geobrowsers become the basic layer for any kind of information we are looking for, and may thus maps and satellite imagery become a dominant way of interacting with networks as claimed by apologists of the Geoweb? To answer this, we have to be aware that at every major juncture of conceptual or technical geographical breakthrough, the term

Neogeography has been invoked. More than that, many mapping practices now labeled as Neocartography are well represented in pre-literate cartography. As a consequence of that, the map mashup phenomena should motivate the geospatial community to think more deeply and broadly about the true meaning of spatial representations. Therefore, this paper not only gives an overview of apostrophized next generation mapping interfaces, but also how these examples integrate geographic data with non-cartographic interfaces and dynamic data with a static grid. For instance, with augmented reality smartphone applications as Layar or Wikitude, a new generation of users is able to browse data directly as it is represented on the screen within their spatial context off the screen. Mobile locative media converge the practices of touring, tagging and navigation by layering geocoded data onto the grid of tracked video camera images. These developments indicate that digital technologies have reconfigured the experience of mapping into navigational platforms. This has far-reaching epistemological consequences for the geosciences. It was and is always the case that the graticule acts as a sign system that organizes geographical knowledge into visual schemes which depend on culturally accepted misrepresentation of abstracted territory. However, how can the format of the map still shape mobile media and its contents? How do navigational screens fixate the relationship between on-screen and off-screen space? And under which circumstances is way-finding actually mapless? If, as Tim Ingold phrases it, 'we know as we go', and if the basis of all knowing and mapping lies in bodily movement, it might be that we are in the process of moving towards a navigational essentialism. This would imply a fundamental change in the understanding of the Geoweb, with the consequence that we have to think about the mobile Geoweb, and moreover any network, independently of a map.

GCG 12-01 - Geography, complexity, and information dynamics: Addressing real-world challenges of the new millennium

Chair: Cristian Suteanu, Beate Ratter

Complexity, Conflict and Resilience in Climate-Society Interaction

Jürgen Scheffran (University of Hamburg)

With global warming, the world is facing complex interactions between climate stress, environmental change, human responses and social conflicts that could significantly shape the future geography of risk and conflict. Changes in the climate system (such as variations in temperature and precipitation) affect natural resources (e.g. soil, water, ecosystems, forests, biodiversity). Depending on vulnerability, environmental changes will stress basic human needs and values (such as the availability of water, food, energy, health and wealth) which may lead to social disruption through instability events, such as migration, riots, insurgencies, urban violence or war. The stability of this interaction depends on the sensitivities between crucial variables which determine how events spread in the network of interconnections. Due to non-linear effects, an increase in global temperature above a certain threshold may trigger instabilities, tipping points and cascading sequences that could exceed the viability of natural and social systems. Human perceptions and responses shape the evolution of the social networks under environmental change. A key challenge for regional and global governance structures is to develop new cooperative approaches, conflict resolution mechanisms and institutional frameworks that stabilize the interaction. Adaptation and mitigation strategies allow societies to apply technology, physical, human and social capital for adjusting the economy, the energy system and human behaviour. Concepts of adaptive complexity and stability provide guidance to influence the multiple decision points and adjust the actions along the causal chain to protect human security, develop social livelihood and strengthen societal resilience. Agent-based approaches are adequate to analyze multi-level decisionmaking under uncertainty, the micro-macro formation and breakup of coalitions and the transition between conflict and cooperation. The integrated framework will be specified for comparing selected climate hot spots in Africa and Asia.

Utilization of Remote Sensing and GIS for Annual Soil Erosion Measurement In Lake Tondano Catchment Area, North Sulawesi Indonesia

Agus Santoso Budiharso (Nusantara University)

Lake Tondano in North Sulawesi Province has very important role in providing clean water for Manado City, and other purposes for human life. It has been issued that high erosion in the Lake Tondano catchment area is the cause of many problems regarding with the reducing the capacity of the Lake Tondano. Since year 1999 the Tondano Watershed has been designated as high priority watersheds to be addressed. There had been many erosion studies had been done. This paper will present the result of erosion studies in this area by using Hazarika and Honda method to map soil erosion based on Normalized Difference Vegetation Index calculation and Slope parameter. The objective of this research is to predict soil surface erosion in Lake Tondano Catchment Area using remote sensed data especially Landsat imagery and slope. The applied methodology encompasses image processing and calculation of erosion, field observation and secondary data acquisition; GIS analysis and mapping by using ArcGIS software. Field observation was done to verify the tentative land cover map also for recognizing erosion appearance in the field relating to landform and land use. The result shows that land cover from 1991 to 2007 was changed, especially the existence of forest tended to decrease from 3.89% in year 1991 to 2.2 % in year 2007, while dry land farming had tendency to increase from 16.35 % (1991) to become 26.02 % (2007). This causes to the increase of quantity in annual soil erosion rate. In general, the study area has been dominated by very low level of annual erosion rate to low level. In the steep slope area both in the hill and in mountain the erosion from moderate level to very high level become available and tend to increase significantly from 1991 to 2002 and after that decline gradually from 2002 to 2007. The biggest area, where moderate level to very high level of erosion happen taking place in dry land farming and in clove plantation. The biggest percentage area where moderate level to very high level of erosion happen taking place in the landform of upper slope of mountain, The second largest of landform with moderate to very high rate of erosion is in the upper slope of Mount Manimporok .The third rank of medium-eroded landforms occurs in the landform of Lower Slope of Mount Tampusu. All moderate to very high level of erosion were happen in steep to very steep slope where dry land farming and in poorly treated of clove plantation exist. In accordance with management and conservation practice, most the study area has no conservation practice if any only in traditional way.

Thus, in the landform with steep slope occupied by dry land farming and clove must be conserved immediately with contour terraces to prevent the further worsen in the future. Key word: Remote Sensing, GIS, NDVI, Landuse Change, Landforms and Annual Soil Erosion Rate.

Spatial Factors in Planning Mass Events: Planning Pilgrim Flows for the Hajj

Sven Müller (University of Hamburg)

There is a growing number of mass events throughout the world. At the same time these mass events get larger and larger. Typically examples for mass events are the FIFA world cup and the olympic games. The management - particularly in terms of security - of these events become more and more relevant: Crowd disasters as witnessed at the german Loveparade 2010 in the city of Duisburg or at the Great Pilgrimage to Makkah (aka hajj) force authorities towards a security based planning. With more than 3 million pilgrims the hajj is known as the largest pedestrian problem in the world (<http://www.trafficforum.ethz.ch/crowdturbulence/>). During hajj several rituals have to be performed by the pilgrims. One of the most dangerous ritual in terms of crowd disasters is the stoning of the jamarat at the jamarat bridge in the mena valley. In this contribution we propose a management approach based on a mathematical program in order to schedule and assign pilgrims to pre-defined routes. The schedule and the route plan yield a good balance of pilgrim flows in space and time as shown by simulation and revealed data from several years.

GCG 13-01 - Global change, criticality and tipping points: globalised trends, disasters and resilience

Chair: Alexander Fekete, Jörn Birkmann

Criticality of infrastructures: Global changes or local trends? – Assessing the vulnerability of infrastructure systems

Claudia Bach (United Nations University)

Critical infrastructures (CI) and particularly electricity supply systems build the backbone of highly developed societies and have gained importance in a variety of them. Here, they are in general defined as those infrastructures whose disruption would lead to major social consequences. In developing and threshold countries instead, criticality of infrastructures rather defines the importance of certain sectors for development. However, the criticality of infrastructures in the "highly developed sense" plays a major role in the context of infrastructure vulnerability assessments by defining the effects of a potential shortfall. In order to increase societal resilience, it is thus important to assess infrastructure vulnerability towards natural hazards also considering their level of criticality. Accordingly, the physical assessment has to be accomplished by the assessment of infrastructure significance. Whereas in highly developed countries, an almost uninterrupted supply leads to unawareness, thus unpreparedness of the population and a societal vulnerability to such shortfalls that is comparatively high, threshold and developing countries instead, are struggling to increase their supply levels which are close to zero in some areas. The population however, is used to the lack of e.g. electricity, better prepared and less vulnerable to shortages. Vulnerability assessment methods thus have to take into account the vulnerability of the infrastructure system, supply levels as well as the degree of dependency of the population. Resulting, the contribution will outline infrastructure vulnerability assessment methods and the inclusion of secondary effects on society. It will deal with their application to different contexts, including the population dependency on certain services. According to several vulnerability components that will be outlined, potential adaptation and development potentials will be discussed. This is especially important for infrastructures as investment in this field tends to be high regarding amount and persistence.

Assessment of social vulnerability using spatial multi-criteria analysis (SEVI model) and the Social Vulnerability Index (SoVI model). A case study for Bucharest city, Romania.

Alexandru Gavris (Academy of Economic Studies), Iuliana Arma' (University of Bucharest)

This study investigates two vulnerability algorithms through a spatial exploration model of social vulnerability in the city of Bucharest. The research examines social vulnerability in the light of three dimensions: "Social", "Economic" and "Housing quality", obtained by applying the factorial reduction procedure on the 2002 census data at tract level of Bucharest city. The social vulnerability index (SoVI model) followed the steps indicated in 2003 by Cutter et al. Using the spatial multi-criteria social vulnerability index (SEVI model), we aggregated the scores of the indicators in which the selected factors were saturated, and introduced them as multidimensional indicator maps in the spatial multi-criteria analysis (SMCA) module of Ilwis software. The final index score was obtained by weighting sub-indices in a complex social vulnerability index (SEVI). We applied spatial statistics tools of the Open Geoda software for exploring geographic clustering of results. The study highlighted that social vulnerability is a major spatial urban process in Bucharest city, with a tendency toward extending clusters. The main result was a significant clusterization pattern in the 2002 census units, with overlap among the clustering areas affected by high social vulnerability. The results were constrained by some limitations of the methods used, analysed in the last part of the study.

Critical Infrastructures as Hybrid Networks. An Actor-Network Theory Approach to the 'Hybrid Geographies' of Critical Infrastructures.

Florian Neisser (Bonn University)

The discourse about societal security in the context of the general principle of human security and vulnerability established a growing interest in critical infrastructures. The dramatic events and cascading effects of risk in Fukushima, Japan made clear that the topics of risk and vulnerability of critical infrastructures bear central questions for today's society. Although it is a topic which is widely discussed from public and private stakeholder perspective as well as from scientific point of view it is lacking a thorough theoretical foundation. Recent studies addressed the interdependencies of critical infrastructures and the network structure of infrastructures. The notion of increasing interdependencies

between infrastructure sectors is broadened by the acknowledgement of a proceeding interconnectedness within different sectors of critical infrastructures. This raises important questions about the network structure, network security and internal and external risks. In studies about risk, security and vulnerability either a perspective focused on social practices and institutions or a view with a technocratic stance are the prevailing frames of analysis. The conception of infrastructures is predominantly seen as technical structures with humans as builders and consumers. These common categorizations and perspectives imply certain roles and attributions with implications on operation, maintenance, management practices and therefore addressing the question of causality of failures. A new and different approach would mean to avoid these a priori distinctions and dichotomies without focussing on one element of the network. In this regard the Actor-Network Theory offers an alternative view by emphasizing the hybridity and heterogeneity of human and non-human interrelations. In this sense, critical infrastructures are heterogeneous entities, assemblages of the material and non-material. Therefore it is crucial to understand, what Aradau stated, that 'infrastructure plays an agential role, both constraining and enabling' (Aradau 2010: 493). From an ANT perspective, critical infrastructure is at the same time an actor and itself an actor-network consisting of a multitude of heterogeneous elements forming this network. To understand risks and contingencies it is necessary to analyse and understand these assemblages which process John Law calls 'heterogeneous engineering' and the configurations of enabling and constraining. The application of Actor-Network Theory for the observation of the 'hybrid geographies' (Whatmore 1999) of critical infrastructures with its complex heterogeneous constellations and contingencies is a promising, logically consistent and consequent approach which pursues current research and broadens it with a sound theoretical foundation. The speech will elucidate the approach, its concept and benefits for a better understanding of critical infrastructures and disaster risk management.

Continuing Challenges to Quantifying Terrorism Risk Management

David Weinberg (Practical Risk, LLC)

After the attacks of September 11, in an effort to supply resources to the nation as a whole, the US Dept. of Homeland Security created a nation-wide program meant to reach out to states, cities, and various infrastructure sectors in an effort to help them 'harden' themselves against future attacks. A consensus was developed to base the grants on some computation of risk, and the basic formula of risk being the product of consequence, vulnerability, and threat came

into being, and became the foundation upon which several years' worth of grants would be distributed. In the paper, some of the more obvious traits of each of the three variables will be examined, but some of the less obvious and, perhaps, more problematic issues that arise from a careful investigation will also be discussed. Primarily, the importance of physical infrastructure will be addressed and the different kinds of consequences that could result from terrorist attacks on these infrastructures. Some issues inherent in trying to perform geographically-based risk as opposed to simply individual infrastructures will be addressed along with various parameters that were considered and used; some clearly influential in risk analysis, while others being far more esoteric. Having set this stage, some of the less well-understood aspects of risk analysis and management will be discussed, along with the challenges they present to the analyst. Infrastructure interdependencies and second- and third-order effects of attacks in some cases could easily dwarf the immediate impacts of a deliberate act of terrorism. There is a strong caveat for all risk analysts that forces them to take into account the quality and quantity of data needed for reasonable analysis. While the challenges of performing robust quantitative risk analysis and management are considerable, there is much to be gained in the journey. Mathematical approaches force the analyst to appreciate the logic of the assumptions and the methodology employed in making the necessary calculations. It is largely in this often difficult struggle that insights can be gained that would otherwise be simply overlooked or ignored. Analysts must realize that regardless how good the numbers may be, resource allocation decisions in the public sector will always be subject to political wrangling. Final results will always be decided by what is most palatable to the broadest community of politicians, and may bear little resemblance to strict numerical analysis. While often unsatisfactory to the purist, the analyst must understand two absolute realities. First, all models are wrong; some are more useful than others in providing insight into what are largely wicked problems. Second, whenever allocation of public resources is involved, politics must trump analysis. It is in finding the most useful balance between risk analysis and risk management that real progress must be measured.

GCG 14-01 - Global complexity: From theoretical thought to geographical evidence

Chair: Christina West, Heike Egner

A pattern that has passed its sell date

Samir Rihani (University of Liverpool)

In almost all societies a management pattern emerged early in humankind's development and has endured to this day. The pattern is simple: an individual supported by a close-knit elite at the top of a steep hierarchy. In politics as in business the inspired leader; qualified through education, natural talent, auspicious birth, or even divine powers, is seen as the obvious person to manage the affairs of others that circumstances have deposited into their care. There is a technical dimension to the above concept. Hierarchical leadership implies a definite view of how most situations should be managed. The ruthless leader and his or her supporting elite is seen as the ideal shaker and mover that achieves results quickly and efficiently. The picture that goes with this style of management is easy to visualise: end-state plans to be executed successfully according to a set schedule implemented by command-and-control. Those at the top tell others what to do, how to do it, and when. This management style, sometimes referred to as the waterfall, is appropriate for many mechanistic situations such as an industrial assembly line or the launch of rockets into space. If only life were that simple! However, in the distant past and in some primitive societies today politics and business does present "tame" problems for which a steep hierarchical setup might be appropriate. This is of course not the case nowadays as both business and politics become more and more complex over time. Most situations fit into the category of "wicked" problems. Sadly, intentionally or otherwise, most current leaders seem blissfully unaware of the existence of complex adaptive systems and their peculiar modes of behaviour that require radically different styles of management. This disconnect between complex reality and linear fiction is now becoming a major source of instability that is beginning to affect social cohesion and the foundations of consensual democracy. The problem is seen at present in the context of quality of leaders rather than the need to recognise the existence of increasing complexity that requires a radical shakeup of the existing management architecture. Stakeholder engagement and active popular participation are not a band aid that could be simply grafted onto the current model of political and business management.

Phenomenon of geoculture: Interpretation and urgency

Yuri Mazurov (Moscow State University)

The early 21st century was marked by significant development in areas of applied geography, and often - at the junction with the other branches of science or human activities. Among them such active demand in the world practice areas as geographic information systems, global positioning systems, geotourism, geoart, etc. These and many other areas of modern human activity suggest that an adequate level of geographic knowledge and skills or, in other words, geographic competency of their users. Geographic component will play an important role in environmental and cultural policies, in the formation of a "green economy", and so on. The presence of the respective geographical competence of specialists, becomes an important and indispensable factor in sustainable development. Geographic jurisdiction, which together form a professional geographical culture (geoculture, GC) - a culture of professional specialists whose work is related to geographic space. However, the phenomenon of GC manifests itself in everyday life, being an important attribute of the modern lifestyle. Visible manifestation of the GC is the transition from chaos to the spatial organization of the life of society to a more or less orderly fashion. Called the procedure is often manifested in the differentiation of space activity in society, his main functions: residential, industrial, communications, conservation, sacred, etc. The results of this differentiation are functional zones - relatively stable certain areas of specialization. The desire to optimize the functional zoning of the space is a universal attribute of ethnic and inherent in virtually the entire history of human civilization. A striking illustration of this is, in particular, the ancient "ideal city of Adrian" near Rome. In the same series of the British idea of "a "garden city", a brilliantly realized in the projects of the capitals of Australia and Brazil - Canberra and Brasilia. Among the recent examples can be called the project of Hammarby Sjord in Sweden. However, all the above cases as examples of local manifestations of GC are clearly inadequate to address contemporary issues of sustainable development. The urgency of finding these solutions on a global level for the first time was identified in the documents of the UN Conference on Environment in Stockholm in 1972. Even more clearly reflected in the documents it had found the World Summit in Rio de Janeiro in 1992. Period after these two summits convincingly demonstrated that the human race has no alternative other than "fitting in" in a space of our planet. It seems that to solve this global problem will solve mankind by means of a "green economy" in the ideological baggage which must occupy an important

place GC with its potential best organization of life space for the benefit of all countries and peoples.

Critical Infrastructures – reducing hidden societal vulnerabilities towards natural hazards

Claudia Bach (United Nations University)

Critical infrastructures (CI) and particularly electricity supply systems build the backbone of highly developed societies. But not only depends the functioning of societies on these services. Infrastructures such as information and communication technology, water supply, or transport today are so interconnected that the failure of one of them could lead to cascading effects into a variety of sectors. Additionally, the organization of infrastructure sectors is becoming increasingly complex with an increase of actors due to the liberalization of markets and privatization of formerly state-owned companies. Although research on coupled CI-population systems has been conducted, an approach to increase resilience based on qualitative and quantitative assessment methods is still lacking. Besides the growing interdependency of infrastructures in highly developed countries, the level of supply is also increasing. An almost uninterrupted supply security leads to a lack of awareness of potential shortfalls and thus unpreparedness of the public. Nevertheless, in case of disruption e.g. through natural hazards, a lack of supply has secondary effects on society. Critical infrastructures can thus be considered as hidden societal vulnerabilities which need to be considered in comprehensive risk assessments. This includes on the one hand the development of vulnerability indicators of CIs towards different (slow and sudden onset) hazards. On the other hand, the inclusion of hidden vulnerabilities also requires broadened assessment frameworks encompassing several levels to analyze interdependencies of human and infrastructure systems. The contribution will refer to these needs and introduce potential assessment methods towards the vulnerability of critical infrastructures on the example of electricity supply. It will further deal with the idea of hidden vulnerabilities and introduce methodological approaches to feed secondary effects of natural hazards towards society into vulnerability assessments.

Super New Economic Geography: Theory and Possibilities for the Analysis of Global Change and Globalisation

Alexey Skopin (National Research University)

The 90-ties was a period of forming the two types of New Economic Geography. The first type was forming by western scientists: P. Krugman, M. Fujita, A. Venables, etc. It was based on the transformed principles of neoclassical economics. The second type (SuperNEG) was forming in Russia by the author of this article based on his own "Theory of the Earth Existence" (TEE). This theory and its applications were used for research of the problem of Aral Sea (1983-1987), explanation of the strategy of development of Kazakhstan (1987-1993), explanation of the strategy of development of Russia (1994-2005) and the complex explanation of the transformations of the Earth surface (2004-2008). The main results of these investigations were summarized in the monography "Common Geography: Global Synthesis" (in cooperation with Peter Haggett, Pearson Education, 2007). But previously all these materials were published just in Russian. Now it is possible to present them for the global geographic society. The main composite parts of the TEE are: 1. Understanding of the earth surface as the only really limited resource for social and economical activities. 2. Understanding of the complication of the structure and behaviour of organisms, social groups, nations and corporations as the only method of victory in the competition for the spatial resources. 3. Understanding of technics of the territories development (TTD) as: a) the practical result of complication of economical, social and cultural life of societies b) metodological and analytical base for forecasting and proyecting of the development of states and regions 4. Differentiation of nine main types of TTD: 1) Primitive economy (hunter-gatherers, approx. 25 sq. kilometers of territory per person), 2) Nomad economy (pastoral nomads, approx. 2,5 sq. km per person), 3) Nomad plant cultivation (approx. 0,25 sq. km per person), 4) Dryland farming (approx. 0,025 sq. km per person), 5) Irrigation farming (approx. 2500 sq. meters per person), 6) Extractive industry (approx. 250 sq. m. per person), 7) Manufacturing industry (approx. 25 sq. m. per person), 8) Service economy (approx. 2,5 sq. m. per person), 9) Informational economy (approx. 0,25 sq. m. per person). Thus the Informational economy TTD allow to use the Earth surface million times more efficient than the Primitive economy TTD. 5. All the variety of the economical, social and cultural phenomenons on the Earth surface could be explained using nine types of TTD including demographic structure of society, economic development and institutional organisations. 6. We can do rather precise forecasts for the amount of population on the Earth, macro regions, states and towns basing on the

knowledge of TTD used there. 7. Replacement of TTD of the concrete territory allows to do well founded conclusion about the complication or simplification of social economic systems of that territory.

GCG 15-01 - Globalization and the re-making of rural place 1

Chair: Birte Nienaber, Michael Woods

The Impact and consequences of globalization on economic sustainability in urban-rural fringe

Hassan Afrakhteh (Tehran Tarbiat Moallem University)

Globalization is an on-going process by which markets grow and expand into a network that reaches around the world. In this sense, globalization is not new. The process was fairly well developed in the ancient world and has evolved almost steadily since about 1400. But huge drops in transport and communication costs have taken place in the last quarter of the twentieth century, and that has allowed the globalization process to move rapidly in our time. Huge blocks of market information move at the speed of light and at very low costs to any place on the globe. Few places are able to isolate themselves from the impacts of economic change anywhere in the world. Sustainable development is development that meets the needs of present without compromising the ability of future generation to meet their own needs. The goals of sustainability are to enhance people's well-being. Sustainability is a concept allows a comfortable way of living by balancing the resource demand of technological, economical and social requirement with the environment's ability to meet present and future needs. Two terms of urban and rural can and must be treated together because they deal with one single geographic concept. Urban and rural are labels applied to different parts of space based upon its uses. Rural is that space which is not urban. We can define an urban area as being one where the land uses from customary and traditional urban activities produce higher returns than from traditional and customary rural activities. The urban fringe, therefore, is the frontier in space where the returns to land from traditional and customary urban land uses are roughly equal to the returns from traditional and customary rural land uses. In theory, such a frontier should always exist, although its exact location on the ground may not be easily fixed. In times of major economic change, that frontier will be very fluid as changing market conditions cause changes in the returns to land at any given place. Hence, rapid globalization of the sort occurring in the current century must inevitably impact the sustainability of urban- rural fringe. Study area of this research is urban rural fringe of Tehran metropolis. The main aim of this research

is understands the process of globalization, its impact and consequences on rural-urban fringe economic sustainability.

Globalisation processes in the Dry Chaco of Argentina. The expansion of soybean and its human consequences.

Julieta Krapovickas (ISES- Instituto Superior de Estudios Sociales)

Under the influence of globalisation processes, for several decades the Argentine Chaco region manifests intense changes, both environmental and human. Among the former, it should be noted the advance of deforestation and forest degradation, main causes of carbon emissions and global climate change generators. Among the latter, migrations, changes associated with access to land and common pool resources by the local population, and the growth of the productive and business sectors result of global market entry, are the most prominent. In the context of a country clearly urban (according to the latest data available 89% of Argentina's population was defined as urban) the Chaco region represents a unique case of high rurality, isolation, poverty, and high proportion of indigenous people (who still uses the forest resources freely for their survival). The most important territorial manifestation of globalisation in there is the change in land use. High deforestation rates are associated with the expansion of the agrarian frontier, which is resulting from good prices of certain commodities (e.g. soybeans) in the international market. Thus, these globalisation processes have led to the coexistence of two worlds within the rural areas of Chaco: by one side, the local rural population with their traditional lifestyles, and by the other side producers and entrepreneurs often foreign or extra-regional, who used capitalist logics and productive models very different from the local ones. In this paper it is proposed a first approach to the logic and the model of soybean production in localities in the south and north of the Salta province (i.e. Las Lajitas and Joaquín V. González in the South, Orán and Tartagal in the Nord). It will be used primary information from semi-structured interviews with producers, entrepreneurs and with national and provincial production institutions operating in the area. It will be analyzed the incorporation of local labor in soybean production, the role of the activity as a catalyst for the economy in the localities as well as the environmental effects of new production model, specifically its implications for deforestation, always from the perspective of a social actor: the producer of soybeans.

Security of Property Rights and Land Use Transition in Ukraine

Scott Loveridge (Michigan State University), Denys Nizalov (Kyiv Economics Institute), Suzanne Thornsby (USDA Economic Research Service), Mollie Woods (Michigan State University), Olha Zadorozhna

Risk and uncertainty over the results of agricultural production were always considered as impediments for the development of agricultural sector and rural areas. Besides traditional weather and market related sources of uncertainty, agriculture in transition economies has to face one more major factor of risk - changes in institutional protection of property rights. This paper illustrates how such institutional changes affect the land use and crop mix patterns in Ukraine. Ukraine is a country with some of the richest arable land in the world and is among the largest agricultural producers. The country, however, went through the major change in the institutions regulating and protecting the property rights for land. In 1990, at the beginning of transition, all land belonged to the state and was operated by state enterprises. By 1995, the ownership for about 40% of land has been transferred to collective farming enterprises. The individual property right for land, however, was almost nonexistent till 2001. At that time, individuals were granted a right to withdraw their parcels from the collective enterprises. The rental market for land was established at the same time. Over a short period of time, collective ownership has practically disappeared. However, sales of agricultural land are prohibited till now. Establishment of market for agricultural land has been postponed several times. Moreover, the rights of tenants remain uncertain once the free market for land is established. This institutional uncertainty of property rights of tenants vs. owners creates different incentives to invest, particularly into perennial crops. This paper tests the validity of the above statement using annual data on land use patterns of the universe of farming entities in Ukraine during 2001-2010. The identification of the property right effect is based on the differences in the investment patterns into perennial vs. annual crops by owners vs. tenants. The results of this study have important policy implications. First, the uncertainty makes the tenant to deviate from the 'optimal' crop mix reducing the productivity of tenant farms. Taking into account that about 95% of agricultural land is rented in 2010, Ukraine faces significant losses in agricultural production and GDP in a short run. Second, the uncertainty leads to underinvestment into new technologies including adaptation to the climate change. Such underinvestment affects productivity and vulnerability of Ukrainian agriculture in the long run.

GCG 15-02 - Globalization and the re-making of rural place 2

Chair: Birte Nienaber, Michael Woods

The role of tourism in rural economy (case study Harsin, Kermanshah, Iran)

Shahbakhti Rostami (PNU), Amirali Zolfaghari (Bonyad Maskan Kermanshah)

Rural migration is a main problem in Harsin, Kermanshah. To come up with this problem, it is necessary to consider a comprehensive solution. The special attention should be paid to potential possibilities of the region and diversification of rural jobs by planners and relevant authorities. As an option, rural tourism can play an important role to diversify rural economic activities, to introduce rural products to tourists, and to increase in come levels of rural residents. The present thesis is an attempt to introduce rural attractions of Harsin from tourism viewpoint. Then, it discusses the role or tourism in rural economy of Harsin. To confine the study area, eleven villages which have some kind of physical or historical attractions are selected as the case study for this research. Using documentary and field study methods (i.e. interview, questionnaire, observation) relevant data about tourism and rural economy are collected, classified and analyzed. Geographic Information System (GIS) have been applied as a powerful tool to create spatial database and also to map and to visualize the relevant data. As a result, the final analysis of the present thesis shows that rural Harsin has a considerable potential of tourism attractions, however, the role of tourism in rural economy of Harsin is not a reasonable and effective one. Therefore, the public and private authorities must pay more attention to rural programs and different tourism plans.

Individual agency, relational political economy and catalysts for globalization-related restructuring in rural regions

Michael Woods (Aberystwyth University)

This paper will examine the role of individual actors as agents of change in rural regions. Drawing together the relational political economy literature than has emphasized the importance of global relations to regional economies and the rural studies literature on neo-endogenous rural development, the paper argues that greater attention should be paid to the role of individual agents in the social and economic restructuring of regions. Employing an interpretative model

developed through the FP7 DERREG project (Developing Europe's Rural Regions in the Era of Globalization), the paper proposes that individual actors, such as business entrepreneurs, corporate executives and social activists, act as catalysts in converting the potential effects of globalization processes into actual impacts in specific rural regions. Furthermore, individual actors are also important as animateurs in initiating and organizing regional development responses to globalization pressures. The argument will be illustrated by examples from case study regions in Europe, relating to business networks and innovation, international migration, sustainable development and regional learning.

GCG 16-01 - Knowledge, networks and innovation in China's development

Chair: Ingo Liefner, Susan Walcott

FDI Networks, Innovation and Embeddedness in China

Yehua Wei (University of Utah)

This paper analyzes foreign invested enterprises (FIEs) in Suzhou Municipality, known previously for its local state-led Sunan model of development based on township and village enterprises. However, Suzhou has been remaking its development model through state-centered efforts to attract foreign direct investment (FDI) and make itself an innovative place. We argue that the local state plays an important, yet diminishing, role in location decisions of FIEs, while the effects of industrial agglomeration have been increasingly important. However, FIEs tend to network among themselves and remain thinly embedded with local economies, and embeddedness is limited by a series of technological, institutional, and spatial mismatches. Strategic coupling rarely exists between FIEs and local firms. Suzhou's development path requires development of endogenous capacities.

Networking Dynamics and Space: The Case of China's Biotechnology Research System

Arman Peighambari (Justus-Liebig-University Giessen), Stefan Hennemann (Justus-Liebig-University Giessen)

The growth dynamics, reasoning, and spatial organization patterns are strongly related to the structure of the respective industries that cause different regional growth models. Moreover, theory predicts that the collaboration activity is showing distinctive features concerning the resulting network patterns. While the industrial activity and networking in export-oriented industries in China is mainly driven by global production chains with low local network embeddedness (type 1), especially science-driven industries, where basic research and economic application is intertwined, the chance for intra-country networking is much higher (type 2; e.g. public research agents are an interesting cooperation partner for the industrial sector). This has consequences for the potential upgrading paths of the respective industries and the state and prospect for the regional development in China. Industries of type 1, such as the electronics sector, are strongly making use of knowledge from their cooperation with global buyers.

However, they face difficulties of upgrading their low-end activities and move towards higher requirements regarding their capabilities and, hence, a higher value-added. In contrast, industries of type 2, such as biotechnology, are making use of their strong relations with the public research sector in China. They are more seen as equal partners in global knowledge networks. Still, they face difficulties that are related to the immediate economic valorization of their inventions, yet offering a regional growth path of great potential. A survey of 300 PRD-based SMEs from the electronics industry, conducted at the end of 2011, is serving as an example for type 1 industry surveys in China. For the type 2 industries we use a large bibliographic dataset (SCI-Expanded and China's Chongqing VIP) to evaluate the regional collaboration activity in the Chinese biotech system. We will discuss aspects such as the different ability of companies to absorb and incorporate external knowledge into the organization, the willingness of collaboration partners to transfer this knowledge, and the potential consequences from different types of knowledge transfer processes for the regional economic development. Further, we propose a comparison of investigating both industries with different empirical approaches and discuss the necessity for a comprehensive empirical toolset.

The Problems of Beijing in the Process of Striving for World City by Technological Innovation

Jie Fan (Chinese Academy of Sciences), Dong Chen (Chinese Academy of Sciences), Wangshu Hu (Chinese Academy of Sciences)

Beijing is implementing technological innovation strategy to reconstruct itself from an industrial city to a world city with developed service industry. This paper analyzes the changes of employment structure and the population migration in the process. The employees are surveyed in those new urban areas. The result shows that the majority of new jobs are occupied by people from other provinces who have better education and stronger competitiveness than the ones from Beijing. But it is noteworthy that only a few native residents leave Beijing because of the high quality of public services, e.g. the lower test scores required to get into the universities, the convenient access to the best hospitals. For the native residents, the government has to develop some low-value-added industries around the inner city. The agglomeration of the new residents and the non-leaving native residents leads to the increasingly expanding of the city and some serious urban diseases, e.g. the traffic jam, which unfavorably influences the construction of the world city. Therefore, the achievement of upgrading depends on whether Beijing can emigrate the native residents and decrease the

population. Fortunately, the enterprises such as Shougang, a steel company, have started to move out of the city and the workers have also begun to emigrate along with the companies.

Technological Learning, Industrial Catch-up, and the Dynamic Evolution

Changhong Miao (Henan University), Wenying Shang (Henan University)

The fast rising of China is undoubtedly one of the most concerned but controversial academic topics in the rapidly-changing global political and economic system. Through more than 30 years's reform and opening up, especially since China's accession to the World Trade Organization, China has become the world's biggest exporter and second-biggest importer. However, China's economy is also at a significant crossroads, because its long-term sustainable economic growth is faced with increasingly severe constraints such as resources, environment, market demand and social inequality. Thus, building an innovative country, changing from "Made in China" to "Innovated in China" and "Created in China", from a follower to a leader in technology and industry, is considered as the only way of shifting China's mode of economic development. In this process, technological learning and industrial catch-up is the most important strategic issue. Technological learning and industrial catch-up is nurtured, developed and embedded in the "learning field" which is formed by the interaction of technology, organization and territory at a global-local networks, the process of technological learning and industrial catch-up is also the dynamic evolution of the "learning field". In this paper, based on institutional economic geography, relational economic geography and evolutionary economic geography, a dynamic theoretical framework of "learning field" is constructed to analyze the case of industrial development of super-hard materials in Henan Province which plays a more and more important role in the global market. We found that the nature of technological learning and industrial catch-up is the process of relationship-building, institutions-constructing and dynamic evolution of the "learning field". It shows that technological learning and industrial catch-up is driven by the interaction and coordination among companies, governments, research institutions, universities, financial institutions, industry associations and other key actors at local, regional and global scales. The case of Henan super-hard material industry reveals that technological learning and industrial catch-up is a complex dynamic evolution system in which the strength of the collaborative innovation and global-local networks among key actors and the capability of technological innovation of

focal companies are key factors, and the government's industrial policy to promote technological innovation and industrial upgrading plays a very significant role as well.

GCG 17-01 - Labour geography: Workers interventions in the global economy

Chair: Martina Fuchs, Andrew Cumbers

Gender and Fairtrade

Janet Momsen (University of California)

Fairtrade is an alternative trading mechanism for commodities involving the payment of a guaranteed price that covers the cost of production and a social premium to be invested, usually in communities. Fairtrade certification is available for groups of small farmers and for workers on large scale farms. The Fairtrade Labelling Organization (FLO) is currently working to mainstream gender in Fairtrade. Farmers may work with Fairtrade as individuals or in cooperatives. The success of women and men Fairtrade farmers and their attitudes to Fairtrade, in different types of groups, will be assessed from field data gathered in Nicaragua and the Caribbean. The importance of local environmental issues such as hurricanes and droughts and of the global economy on these small farmer groups will also be examined, especially in relation to gender.

Trade unions strategies on climate change: Varities of green new dealism

Romain Felli (University of Manchester)

The paper discusses International Unions' strategies on climate change. Whereas the International Trade Union Confederations, and the various so-called "Global Unions", are relative newcomers to the field of international climate policy, they are developing very specific strategies, focussing on the link between socio-economical phenomena and environmental policies. I analyze some of their strategies (such as the incorporation of the concept of "just transition" in international agreements, or the promotion of "green" or "sustainable jobs") by drawing on the literature on "labour geography" as well as on historical materialist's understandings of international relations. Based on an empirical study, this paper argue that all international unions basically share the same green keynesian vision (or green new deal perspective). However differences in the objectives and the means towards the achievement of these objectives vary widely across sectors, countries and unions. These variations are mainly related, I will argue, to the forms of (class) consciousness embedded in the various unions, and hence in the definition of strategies and tactics. This relation

between consciousness and strategies has been relatively understudied in the "labour geography" literature.

Are financial investors being pushed off the road? Defensive strategies of employees in the automobile industry

Christoph Scheuplein (University Muenster)

In the last decade, the acquisition of industrial enterprises by financial investors has also become widespread in Europe's continental countries. From the outset, employees resisted this because acquisitions often entail a higher pressure on working conditions. In recent years, however, the impact of private equity has been viewed more critically in the discourse of civil society and in legislation. Using the example of the automobile industry in Germany, the presentation shows how the increase of financial investors has been stopped in this branch of industry in recent years. Trade unions and works committees played a significant part in this by establishing information networks and intervening restructuring processes. Gradually, the ideological consensus of the corporate management was successfully separated from the financial investors. Initially, managers thought of private equity as a fitness program for the company but in the meantime negative effects on human resources are being considered. The results of qualitative interviews are represented, which analyze employees' actions based on the branch of industry and on business examples.

The potential of collective power in a global production network: Unicom and Metro Cash & Carry in India

Martin Franz (Fachbereich Geographie)

GCG 18-01 - Management Geography – Embedding COPs in changing global urban networks

Chair: Rolf D. Schlunze, Elmar Kulke

The geography of work in knowledge intensive service firms

Kristina Trygg (Stockholm University)

This paper aims to understand the geography of work in knowledge intensive service firms. Geography of work refers to the location where work is conducted. This can be at the office of the employer, the office of the client firm or in a third place including the home of the employees, meeting places like seminars, restaurants, hotels etc. The empirical data in this paper is derived from nine different firms in management and in PR/ communication consultancy. The firms are knowledge intensive and located in Stockholm. The empirical data is interview data from interviews with nine persons responsible for the Human Resource management of the organization. Most of the interviewees are CEOs, partners or owners of the firms. I have also done interviews, time diaries and questionnaire survey at two of the firms with the employees. This means that the data gives the perspective from the side of management of the firms and from the side of the employees. The results indicate the importance to be at the office for meetings, gain information both informal and formal. This may be interpreted both as, on one hand, an effect of the learning and knowledge and working process in such firms to be strongly relying on interactive communications where face-to-face contact is seen as important. On the other hand, the arguments of the importance of presence at the office can also be interpreted as an effect of power relations and the managements aims to control the main resources of the firms and that is the human capital, i.e. the employees. Physical presence and 'shoulder-to-shoulder' work are important means to support 'team building', sense of belong and commitment to the company's visions. Most of the persons in the management team were reluctant to let employees work at home more then necessarily, for example when the kids where sick but all firms said that the employees hade the opportunity to work from home. The paper considers the role of information technology for the geography of work. It is found that information technology is a tool helping the employees to structure their working life. Here smartphones have been a helpful implement. I have also seen that intranet such as jammer are important for the employees. Technology is used to communicate and coordinate the employee's work, not to make them work from distance.

The location of the creative class and US-subsidiaries in Germany

Moirá Conway (CUNY Graduate Center), Marlies Kluike (University of Tübingen)

Germany is a very attractive target for US-investors for endeavors for which a very specifically skilled workforce is required. However, within Germany there are considerable differences regarding where specific types of workforce reside. Therefore, areas of Germany where foreign subsidiaries could utilize the right local talent, due to its higher concentration, should be especially attractive to certain US-investors. Recurring on Florida's creative class Index applied to Germany, we endeavor to establish whether US-subsidiaries that can draw competitive advantage from the creative class are drawn more to creative locations within Germany and differentiate between specific characteristics, such as subsidiary ownership structure. Focusing on US-subsidiaries that have recently established a presence in Germany to ensure that they have indeed been drawn to the creative class location and not the other way around, we test our propositions with the help of database information regarding US-subsidiaries in Germany, controlling for factors such as subsidiary headcount. From our findings we draw conclusions regarding foreign investors, locational decisions and regional planning initiatives.

Is finance ready for inter-firm collaboration? Insights from the automotive sector in a global production network perspective

Hans-Martin Zademach (University Eichstätt-Ingolstadt), Christian Baumeister (University Eichstätt-Ingolstadt)

The proposed paper is concerned with the circulation of financial capital and cooperative means of firm finance in global production networks. Taking the emerging body of literature in the field of supply chain finance (SCF) as conceptual point of departure, it argues that cooperative forms of firm finance increase the competitiveness and resilience of global production networks towards external shocks as occurred during the most recent financial crisis or due to changing legal regulations (e.g. Basel III). With regard to empirical work, the SCF literature states that the collection and description of more detailed case studies is still an open issue. The present contribution intends to help closing this gap with insights into the concurrent practices and limits of intra-firm finance within the production networks of the German automotive sector. These insights draw on preliminary results from an ongoing research project that aims to explore the motives, success factors and constraints of cooperative finance practices in and between different locations in varying development stages by

dint of both quantitative and qualitative work. The paper concludes with an outlook on the research agenda and a discussion of possible implications for both the firm level as well as regional development. Keywords: Global production networks, firm finance, supply chain finance, automotive industry, Germany

On Management Geography

Päivi Oinas (University of Turku), Lech Suwala (Humboldt Universität zu Berlin)

The emerging research field management geography calls attention to its foundations. Management geography is a new approach which seems to have close connections to three established fields, namely, (1) geography of the firm, (2) aspects of economic sociology with emphasis on embeddedness, and (3) the broad literature of management studies. Nevertheless, the connections between these research fields and their role in management geography remains to be scrutinized and established. Moreover, the precise meaning of the spatial environment of management activities has not been fully elaborated in the various theoretical frameworks. Management geography should not be just management studies attempted by geographers but should be defined as an eclectic framework taking a genuine geographical perspective on studying management. Management is taken as the activities that coordinate the operations of firms towards its goals. Managers - as individuals or in teams - hardly determine strategies alone but they are key agents in the strategy process. Our attempt in this paper is to outline a distinctively geographical perspective on management. This involves, first, distilling the valuable complementary insights from the three research fields mentioned above. Secondly, it involves the introduction of three distinct aspects of the environment providing environmental conditions for management, namely economic conditions, socio-cultural conditions, as well as managerial perception of the environmental conditions. This allows us to focus on how various aspects of the spatial environment influences management as well as how management takes the geographical environment into account in evaluating the external impact of the activities of the firm.

GCG 19-01 - Mapping the emergence of change: Future European perspectives

Chair: Karl Donert, Daniela Schmeinck

Students' perception of Europe and European Identity: PAM-INA Project

Aikaterini Klonari (University of the Aegean)

This paper aims at configuring school-children's notions, feelings and understandings of Europe and at exploring the ways in which these affect perceptions of their identity. We attempt to draw this profile of pupils' European identities through ethnographic research, based on interview questionnaires in schools at eight European countries. The study takes place in the broader context of the PAM-INA European research project, investigating common lay perceptions of European identity. Specifically, the children state that they speak often more than one foreign language, have traveled abroad fairly extensively and carry a sufficient knowledge of Europe through school curricula (with an emphasis on the course subject of Geography). However, they exhibit a rather insufficient knowledge of European geography, history and symbolism and seem to think of themselves mostly as national rather than as European citizens, while exhibiting certain indifference as to their European identities. PAM-INA aims at creating Tool Kits for students in Europe. The implementation of the Tool Kits will enable them to achieve an awareness of Europe in their daily lives, deal with cultural issues and promote an active European citizenship. In order to create worthwhile, up-to-date teaching material, which is relevant to each national context, a scientific approach has been chosen to understand the current situation at schools in Europe. Firstly, school curricula in the 8 countries have been compared to examine how the idea of 'Europe' is manifested and expressed. The data collected has been evaluated to reveal relationships between the teaching of 'Europe' and syllabi goals (book forthcoming). Furthermore, PAM-INA has proceeded with the help of qualitative and quantitative research among students. A questionnaire was developed, critically discussed and eventually filled in by 2080 students. Both the results of the school curricula analyses and the results of the questionnaires enabled the consortium to create a very much needed Tool Kit A ('daily life') in order to fill a gap in the school curricula of the participating countries. Momentarily this first Tool Kit is trialled at schools and evaluated by the local feedback groups of all the participating countries. Each of these Tool Kits (A, B and C) consists of a

teacher manual, a student activity book along with a learning journal as well as the usage of the PAM-INA webpage. At the end of the lifetime of the project all three Tool Kits will be designed in the above mentioned way. Thus the Tool Kits aim at deepening the students' awareness, perception and knowledge of Europe, strengthening media literacy and promoting Content and Language Integrated Learning (CLIL).

The Future of Illegal International migration in Europe

Yilmaz Ari (Balıkesir University)

Migration has emerged as a significant research topic in recent years because of the importance of changes migration causes in both in home country and host countries. Illegal migration raises a number of legal, economic and social issues. Although strict measures have been taken to reduce the illegal migration, estimates show that illegal international migration has increased and there is no indication that this trend will reverse in near future. This study looks at, by using Turkey as a case study, policy issues of international migration and tries to investigate how policies of countries and intergovernmental bodies deal with these migrants. In certain cases the policy aspect of international migration makes it even more complicated to deal with illegal migration. Therefore the policy aspects of migration should be treated seriously to provide a more humane solution to international illegal migration.

Strategic Planning and Sustainable Development in Spanish Cities

María Jesús González González (Universidad de León), María Luisa Lázaro Torres (Universidad Complutense de Madrid)

The paper investigates how decision-making processes relating to strategic urban projects are framed in order to achieve innovative urban sustainable development and contextualize the problems which appear in the ten cities chosen as models (those with the highest populations). A sustainable city is one that has undertaken a coherent path towards not only strictly environmental topics but also themes like economic growth models and citizens' rights, addressing fundamental issues that are interconnected. The aim of this work is to discuss these clearly related themes from a standpoint of sustainable development and strategic planning. In recent years there has been a growing interest in sustainable development as a guiding principle to allow the integration of economic development and the environment within policy and strategy.

Impacts of spatialisation: The sustainability of the dehesa landscape

María Luisa Lázaro Torres (Universidad Complutense de Madrid), María Jesús González González (Universidad de León. Departamento de Geografía y Geología)

The landscape of dehesa is one of the most abundant of the mountain formations on the Mediterranean Iberian Peninsula. In the natural environment of dehesa there is a combination of human use and a difficult environment, both provide the balance of the ecosystem sustainability. Current problems threaten the economic viability of the traditional use of these beautiful landscapes of indisputable environmental and cultural values. As a result, it is only possible to ensure their preservation, if it is still possible, through good management. The sustainability of the dehesa is being threatened by the fact that many of its traditional elements of its environmental balance are now in decline or are non-existent such as extensive livestock, transhumance or the cork working. The high cost of the forestry work adds difficulties for the forest upkeep. There is a permanent fight against the constant threat of fire from the parched pasture (withering of the grass). All products that come from the dehesa are in crisis today. So, the only way to conserve is by avoiding leaving the land. Giving up the land is a traditional fact in Spain, which means the Spanish countryside has been abandoned over the last years. In a landscape, such as dehesa, in which the work done by man is irreplaceable to keep it in balance with the environment, both, neglect and over-exploitation of the land are the two extremes that can make these Mediterranean landscapes disappear. Only proper management of these landscapes can preserve them and contribute to rural development in the area. We are going to research and identify the existent problems in this landscape through fieldwork study of two regions, in Andalusia and Extremadura, that are designated as less-favoured areas by the EU and they are the two Spanish autonomous communities with most extension of dehesa landscapes in the peninsula. Then, we will try to detect those elements that contribute to the environment, economic, social and cultural balance as well as to seek integral and sustainable alternatives of management the dehesa landscape. It is necessary to detect actions that can be qualified as good practices in order to help the Common Agricultural Policy (CAP), the development of the recent dehesa law in Andalusia and rural development. In order to fulfil the objectives of the research, it begins with a brief introduction on the importance, significance and the state of affairs of the dehesa landscape in Spain. It continues by explaining the objectives and the methodology of the work. The methodology intends to make a situation diagnostic in both regions in

order to enumerate the existent problems. And at the end we will give different alternatives for the global and sustainable management of this landscape and finally the general conclusions and the bibliography used.

GCG 20-01 - Morphodynamic response to episodic disturbances of coastal systems

Chair: Max Engel, Hervé Regnaud

Records of Mediterranean tsunamis: The importance of geologic archives to complete historical catalogues based on examples from Cyprus and Mallorca Island

Anja Scheffers (Southern Cross University), Dieter Kelletat (University of Duisburg-Essen)

Historical catalogues of tsunamis in the Mediterranean Sea extent over the last 4000 years and list several hundred events. For only few of those records, coastal scientists were able to attribute geomorphic or sedimentologic signatures with a specific event, excluding the mega-tsunami caused by the Santorini collapse during the Bronze Age. In contrast, research on geologic archives has unearthed tsunami events which were not recorded in historical or archaeological sources. The presentation will concentrate on such geologic evidence for the eastern and western part of the Mediterranean (Cyprus and Mallorca). On both islands the most significant tsunami deposits are coarse clast archives as boulder clusters or ridges. Numerical dating (^{14}C , U-series) of the time of dislocation (= the event date) is often challenging as it relies on the presence of marine or littoral organisms associated with the deposits. Often these organisms are absent and researchers have to apply indirect or relative dating methods to establish the likely time period of the events. The attribution of a geologic deposit to a palaeotsunami event requires a thorough differentiation between other possible depositional scenarios such as storms or the so called 'Medicanes' (Mediterranean hurricanes). On Cyprus, key evidence exists in form of an excellent preserved inundation timeline. On Mallorca, the boulder deposits could be compared with the transport energy of the Medicanes of December 2001, the strongest on record in this part of the Mediterranean Sea. Its transport energy of boulders was about 10-50 times less than that of two palaeo-tsunamis.

Dating tsunami-induced transport of coral reef megaclasts on Bonaire (Leeward Antilles): A cosmogenic nuclide dating approach (^{36}Cl)

Gilles Rixhon (University of Cologne), Helmut Brückner (University of Cologne), Max Engel (University of Cologne), Simon Matthias May (University of Cologne), Tibor Dunai (University of Cologne)

Coastal hazard assessment depends on reliable information on the magnitude and frequency of past high-energy wave events (tsunamis, storms). Thereby, onshore sedimentary records represent a promising geo-archive for the Holocene. In comparison to fine sediments which have been subject of detailed sedimentological studies in the recent past (especially after the 2004 Indian Ocean Tsunami), supralittoral megaclasts are less investigated. Firstly, in most cases, it is difficult to distinguish between tempestites and tsunamites. Secondly, the dating of the corresponding event remains highly problematic. On Bonaire (Leeward Antilles, Caribbean), the transport of huge coral reef debris and boulders (up to 130 t) is, at least for the largest boulders, attributed to Holocene tsunami events. Although a large dataset of ^{14}C and electron spin resonance (ESR) ages shows some age clustering, it remains unclear whether these data reflect the time of the transport event(s). Dating the dislocation of supralittoral megaclasts still is a major challenge in the research on extreme wave events. In this pioneering contribution we aim to apply in situ-produced cosmogenic nuclides in order to date the transport event(s), i.e. the inferred tsunami(s). This dating technique was successfully applied in glacial contexts using erratic boulders as sampling material; however, hitherto it has been disregarded in the coastal environment, particularly in the context of supralittoral megaclasts. Along the eastern coast of Bonaire (Spelonk), megaclast deposits were torn from the cliff edge of the last interglacial coral reef platform (3-5 m a.s.l.) and transported further inland (up to a distance of >100 m) by high-energy waves. Five boulders were sampled for cosmogenic nuclide dating. Analyses are in progress. The following characteristics of the megaclasts are fundamental for the success of the presented approach: 1) Given the material lithology (calcitic/aragonitic coral reef), concentration measurements of in situ-produced ^{36}Cl will be performed; 2) only large boulders (min. 50 t) for which tsunami transport was inferred were sampled; 3) as the boulders stem from the edge of the coral reef platform, they had been exposed to cosmic radiation prior to the transport event(s) and had already accumulated a certain amount of cosmogenic nuclides. To avoid this problem of inheritance, we only sampled (i) the thickest boulders (at least 1.5 m), and (ii) boulders that had experienced a 180° overturn

during transport; thus having exposed a "blank" side to cosmic radiation only since the transport event. The complete overturn is indicated by former surface rock pools, now located on the bottom side of the boulders, and by bioerosive notches, now exposed on the topside of the boulders.

Assessing and evaluating rapid coastal change due to catastrophic events: Key messages for non-academic stakeholders

Adam Switzer (Nanyang Technological University)

The use of coastal geology to reconstruct palaeo-overwash caused by tsunami and storm events now incorporates not only geologists and geomorphologists but scientists, coastal planners and engineers of many disciplines. Coastal sandsheets and other overwash features can be used to define the long-term recurrence interval of catastrophic overwash events. Such studies must always be conducted within a framework of assumptions on the pre-event geodynamics of the system. Recent studies on coastal change and the morphodynamic response and the recovery of coasts from modern storms and tsunamis have provided new insights into how systems respond to catastrophic events. This last decade of work now presents the research community with a good opportunity to reflect on the progress made in the field, evaluate some recent criticisms and highlight knowledge gaps for future study. For example, there remain no globally applicable sedimentological criteria for differentiating between tsunami and storms in the geological record. Although a suite of sedimentary features or commonalities can be compiled such commonalities can only be attributed to an event type through careful analysis of spatial features such as the elevation, lateral extent and run-up of the deposit along with sedimentary features such as grading, the presence of intraclasts, and particle size distribution of the sediments. Such analysis may point to storm or tsunami as the likely depositional agent. This stated, there remain many cases in the literature where a tsunami or storm origin is stated with little consideration given to alternative interpretations or the interpretation of palaeogeography prior to the event. This hinders the usefulness of the field and although work continues on the differences between tsunami and storm deposits, their preservation and recognition in the geological record remains subject to much uncertainty and conjecture. Unfortunately this debate and the uncertainties underlying it can undermine the true take home message for coastal managers. This presentation draws on experiences from Australia and Asia in particular from China, Vietnam and the Philippines where rapidly developing coasts are in areas equally susceptible to tropical cyclones (typhoons) and tsunami.

Geographical variation of the gradient of outer reef slopes and its significance relating to the Quaternary sea level change

Nobuyuki Hori (Nara University)

The author proposed an explanatory model on the formation of coral reefs based on the morphometrical method using by hundreds of charts in the world in 1977. In this paper, the coral reef formation sea is divided into the two type seas. One is the core zone, which was permitted coral reef formation during the glacial age, the other is the peripheral zone, which is permitted coral reef formation during the inter-glacial age. Based on this model, fieldworks were carried out using by the small echo-sounder in Ryukyu Archipelago, Guam, New Caledonia, Indonesia, Tonga, Fiji, Pohnpei, Hawaii, Rarotonga, Tahiti, Port Sudan and Kenyan coast. A number of the echo-sounding data on the outer reef slope were collected. The results of analysis shows the geomorphological importance of outer reef slope to know the process of coral reef formation relating to the sea level changes between the glacial age and the inter-glacial age. Besides, the gradient of outer reef slopes geographically varies from showing very steep slopes in the core zone to showing more gentler slopes in the peripheral zone. The distributional tendency of the gradient of outer reef slope show a geographical rule. The author's explanatory model proposed in 1977 re-proposed as the integrated model adopted the geographical gradient rule of the outer reef slope.

GCG 21-01 - Post-development and postcolonial studies: Research on inequalities as a challenge for Geographical Development Studies (GDS)?

Chair: Martina Neuburger, Tobias Schmitt

Post-Development Methodology

Aram Ziai (University of Bonn)

A part of the resistance that post-development approaches have encountered in development studies can be related to the unwillingness to give up the ideal of ameliorating the misery and inequality in the world which has been closely linked to the discourse of 'development'. How, then, could this undertaking be reformulated without reproducing the Eurocentric and depoliticizing implications of this discourse? The article, building on Gibson-Graham and 'indigenous research', attempts to provide an outline of how the methodology of post-development studies could look like, how we can assess global social inequality and social change and devise policies to overcome it through alternative concepts, indicators, practices and research methods, even alternative epistemology. This entails overcoming the dichotomies between North and South as well as between 'development' experts and laypeople.

Post-Development: Empirical findings from Chiapas, Mexico

Dominik Gilgenbach (Libertarian Deconstructions Corp.), Bettina Moser

Ziel dieses Beitrags ist es, das stark Theorie-basierte Post-Development-Konzept empirisch zu unterfüttern, da dieser nach Alternativen zu „Entwicklung“ suchende Ansatz oft mit der Kritik konfrontiert wird, keine Handlungsmöglichkeiten für soziale Veränderungen anzubieten. Wir haben uns daher mit der zapatistischen Bewegung in Chiapas, Mexiko auseinandergesetzt, um das Verhältnis zwischen der zapatistischen Autonomie und dem radikal-demokratischen Post-Development-Ansatz zu untersuchen. Dem zugrunde liegt die Frage, ob in den zapatistischen Gemeinden in Chiapas eine Alternative zu 'Entwicklung', wie sie vom Post-Development-Ansatz skizziert wird, entsteht. Dazu analysieren wir zunächst, welche konstruktiven Alternativen der Post-Development-Ansatz aus seiner Kritik an „Entwicklung“ ableitet. Weiterhin wird es darum gehen, inwiefern diese in der zapatistischen Autonomie eine Entsprechung finden. Zunächst wird dazu der Entwicklungsbegriff dekonstruiert und die Post-Development-Kritik an „Entwicklung“ nachgezeichnet. Im nächsten

Schritt werden verschiedene Aspekte des zapatistischen Autonomieprojekts untersucht. Zunächst wird die politische Autonomie betrachtet, die sich durch lokale, dezentralisierte und basisdemokratische Organisationsformen charakterisiert. Anschließend untersuchen wir die autonomen Strukturen im ökonomischen Sektor sowie die Wissensaneignung und -produktion, was exemplarisch am selbstverwalteten Bildungs- und Gesundheitssystem nachgezeichnet wird. In allen genannten Bereiche lässt sich feststellen, dass lokale kulturelle Praktiken und indigenes Wissen eine wichtige Rolle spielen, obwohl gleichzeitig stark auf Wissen von außerhalb der Gemeinden Bezug genommen wird und die zapatistische Bewegung ihre Einbindung in globalisierte wirtschaftliche und politische Strukturen als Herausforderung anerkannt hat. Diese Hybridisierung, die ein wesentliches Merkmal des zapatistischen Autonomieprozesses darstellt, wird im von uns untersuchten zapatistischen Diskurs über 'Entwicklung' unterstrichen, der die so genannten Errungenschaften der Moderne nicht per se ablehnt, gleichzeitig aber Universalismus, ExpertInnenwissen und eine lineare Weltauffassung in Frage stellt. Anhand dieser Kriterien soll eine Abgrenzung zum hegemonialen Entwicklungsdiskurs herausgearbeitet werden, die eine Einschätzung des zapatistischen Autonomieprojekts als Alternative zu fremdbestimmter Entwicklung rechtfertigt. Der Vortrag basiert auf einem Artikel, der 2012 im Journal für Entwicklungspolitik erscheinen wird.

„The end of the North-South one-way street?“ – Post-Development and international solidarity

Bettina Moser, Dominik Gilgenbach (Libertarian Deconstructions Corp.)

Wird von Post-Development gesprochen, ist in der Regel - quasi den Entwicklungsdiskurs reproduzierend - der 'Süden' im Blickfeld. Dafür, dass es aber unvermeidbar ist, in diesem Zusammenhang auch den globalen Norden zu betrachten, wollen wir mit folgendem Beitrag plädieren. Wir gehen davon aus, dass emanzipatorische Veränderungen nur möglich sind, wenn diesbezügliche Kämpfe weltweit und vernetzt stattfinden. Daraus ergibt sich auch die Notwendigkeit, den Solidaritätsbegriff neu zu denken. Zunächst muss der Frage nachgegangen werden, welche Gefahren aus postkolonialer Perspektive auch die klassische Solidaritätsarbeit von Nord-Süd-AktivistInnen beinhalten kann. Anschließend soll skizziert werden, unter welchen Bedingungen Solidarität und Kooperation unter postkolonialen, herrschafts- und entwicklungskritischen Vorzeichen realisiert werden kann. Wir plädieren dementsprechend für einen global vernetzten zivilgesellschaftlichen Kampf auf Augenhöhe, der sich gegen

das hegemoniale Entwicklungs- und das damit einhergehende Wirtschaftsmodell mit seinen zerstörerischen Auswirkungen auf die Umwelt, auf soziale Gemeinschaften und alternative Wissens- und Produktionsformen richtet. Die Beziehungen, die die zapatistische Bewegung in Mexiko mit der internationalen Zivilgesellschaft geknüpft hat, sollen uns als empirische Grundlage dienen, anhand derer wir den Rahmen für eine neue internationale Solidarität im Sinne des Post-Developments abstecken möchten. Dabei ist uns bewusst, dass dieses Vorhaben hier aufgrund des begrenzten Umfangs nicht umfassend erfolgen kann. Der Beitrag wird zunächst allgemein das Phänomen der internationalen Solidarität (mit dem Schwerpunkt in den deutschsprachigen Ländern) untersuchen, davon ausgehend wollen wir herausarbeiten, wie diese im Sinne des Post-Developments transformiert werden kann. Anhand verschiedener Beispiele werden wir zunächst das zapatistische Verständnis von Solidarität nachzeichnen und die zapatistische Solidaritätsbewegung in einen Post-Development-Kontext einordnen. Veranschaulicht wird diese neue Form der Solidarität durch die Beispiele des Hamburger Kaffeekollektivs Cafe Libertad und des deutschlandweit organisierten Ya-Basta-Netzwerks.

Postcolonial relations between three continents – lusophony as link between countries in the beginning of the 21st century

Chair: Stefan Hennemann, Franz Huber

Integrated Spatial Network for Sustainable Territorial Development in Romania

Vasile Surd (Babes-Bolyai University), Vasile Zotic (Babes-Bolyai University), Diana-Elena Alexandru (Babes-Bolyai University), Viorel Puiu (Babes-Bolyai University)

The concept of integrated network in spatial planning represents a basic operational component with guiding role in defining and establishing the location of various categories of territorial-geographic systems, whether natural or anthropogenic, current or future. Many theories and reference models have developed as premises for the development of this concept and they all meant to push forward the thinking, understanding and building of territorial structures. Among the classical models we mention those of Von Thünen, Weber, W. Christaller, and V. J. Reilly and the contemporary models of J. Forrester, B. Rodoman, B. Mandelbrot. Contemporary authors have taken over the classical ideas/theories about modelling the territorial structures, which exclusively emphasize the anthropogenic structures and adapt them in the light of modern theories (systems theory, fractal theory, spatial polarization theory, the synergy concept, the chorem-based approach), in order to shape territorially complex geographical systems, mainly determined by the fusion of the natural systems with the anthropogenic ones. We can find several approaches of this concept in the Romanian literature. Some of the most known specialists that have had such preoccupations are G. Gusti (1974), A. Molnár, A. Maier, N. Ciang' (1975), and more recently I. Iano' (1987, 2000), who have developed this concept for the national territory. The authors mentioned above have approached the development of anthropogenic systems, however without carrying out an analysis of the relationships established between natural and anthropogenic systems and how they would spatially develop. Hence, our research tries to attain a fusion pattern in modelling the complex territorial distribution of the two broad categories of territorial systems, natural and anthropogenic, and eventually apply it to the entire Romanian territory. Thus this pattern could represent the operational support for rethinking the spatial planning of the national space in order to identify the most favourable sites for future anthropogenic development, yet without eliminating the natural structures,

particularly the ecosystems, which are now subject of the greatest impact as result of development. Chaotic large-scale spatial development in the absence of long-term basic valid territorial pattern could damage the efficiency of spatial planning at all smaller territorial scales. Romania's integration into the European Union in 2007 and the globalization process involve and require more stringently on the one hand, to increase efficiency of spatial planning and to bring spatial radical alterations of the spatial orientation of the major axes of development on the other hand. All of these conditions require the elaboration of a new basic territorial pattern for long-term spatial planning.

Co-evolution between SCN and TCN of China's biotechnology: Towards open innovation?

Tao Wang (Nanjing Normal University)

In the era of open innovation, the capability to conduct collaborative research and development has become a key indicator of absorptive capacity and innovation competitiveness. However, the literature addressing open innovation has a focus on developed economies. The open innovation process in developing country, such as China, is still unclear. The level of development of science and technology is an important indicator to measure innovation ability, and scientific papers and patents are main output results of science and technology. Therefore we explore the relationships between science and technology through science-based paper and technology-based patent of China's biotechnology. By using papers published in VIP (the Chinese Science & Technology Journal Database/Chongqing VIP (<http://www.cqvip.com>)) and SCI-Extended (the Thompson Reuters' Web of KnowledgeSM database (<http://apps.isiknowledge.com>)) as scientific paper data sources, and patents applied in China intellectual property rights net (CNIPR) as patent data sources, we build scientific cooperation network (SCN) and technology cooperation network (TCN) from co-published papers and co-applied patents in 2000-2009. We take centrality, density, average path length, Gini coefficient and other indicators to analyze provincial cooperation network structure and its spatial-temporal evolution at the macro level, and explore the role and position of different innovation actors at the micro level. Our study shows that: (1) Network structure becomes more complex as the cooperation between provinces increases, but SCN is much more complex than TCN. Moreover, differences among provinces in SCN reduce, but there still exist a huge gap in TCN. (2) Interregional cooperation is much higher than intraregional cooperation in SCN, but this phenomenon is reversed in TCN, which means scientific papers are

outgoing cooperation and patents are introverted cooperation in biotechnology field. (3) The main cooperation is university-university and university-public research institution in SCN. In TCN the main cooperation is firm-university, and firm-public research institution. (4) The correlation of betweenness centrality and degree centrality are higher between SCN and TCN, which suggests that provinces in an higher position in SCN are also important in TCN. In addition to discover the open innovation process of China's biotechnology, our research is also useful for the policy makers to understand the current situation and problems of biotechnology innovation in China, and provide advice for making regional innovation policy.

The heart of a network is regional

Sidonia von Proff (University of Marburg), Anja Dettmann (University of Marburg)

The paper at hand studies the development of innovation networks with a focus on the spatial distribution of the network partners. This dynamic view is rather underexplored in the literature up to now. We combine socio-psychological and economic insights for arguing that innovation networks are not only mainly regional in the beginning but have also a tendency to become even more regional over time. A complex activity like an innovation project is very difficult to carry out over long distance and even though there might be partner anywhere there is something like a regional heart of a network. In the empirical part, interviews with 49 publicly funded innovation networks in the eastern part of Germany are exploited. Data is available for three points in time: the formation of the network, the end of the funding period, and today, i.e. one to ten years after the funding. This unique dataset reveals a lot of insights. First of all, if a network has survived up to now, it has gained new members - regional and non-regional ones. If the networks lost non-regional partners, in half of the cases they state distance a reason for the breakup. Only a part of the network members are involved in concrete innovations projects and these projects have a regional core, i.e. more than half of the project members are located in one region. So, the project groups are more regionally limited than the whole network, which is more loosely connected so that distance may be overcome more easily. Overall, the empirical study supports our theoretical reasoning and gives new insights into the dynamics of innovation networks.

Word city network, change, 2000-2010: A complex network approach

Stefan Hennemann (Justus-Liebig-University Giessen), Ben Derudder (Ghent University)

This is an empirical paper that measures and interprets changes in intercity relations at the global scale in the period 2000-2010. To this end, we draw on the network model devised by the Globalization and World Cities (GaWC) research group, in which intercity relations are inferred from the location strategies of advanced business services firms. The paper has two purposes: first, there is a methodological purpose in that we apply a fully-fledged complex network approach (whereas most previous analyses in this literature have remained at the level of guesstimating network patterns based on mere connectivity rankings); and second, drawing on this refined and arguably more appropriate methodological approach, we aim to enhance our understanding of shifting patterns in the world city network in roughly the last decade.

GCG 23-01 - The emergence of China's regional economies in the global economy: A new perspective on upgrading and innovation in global-local networks

Chair: Daniel Schiller, Javier Revilla Diez

Initial Discrepancy and a Dissimilar Process Become Globalized: A Case Study of Guangzhou

Kai Huang (Technische Universität Berlin), Desheng Xue (Sun Yat-Sen University)

Initial Discrepancy and a Dissimilar Process Become Globalized A Case Study of Guangzhou Kai Huang¹, Desheng Xue² ¹Technische Universität Berlin, Germany ²Sun Yat-sen University, Guangzhou, China Drawing on Manuel Castells' and other scholars' view, their research achievements provide a perspective that globalization can be understood as a process with various "flows" and leads to a modification of certain factors of urban development. Meanwhile, it also has been considered as a process with seldom or no governmental intervention. However, authority can currently play a crucial role in such process under a certain background, especially in the megacities of developing countries. In this article, taking Guangzhou as a case study, it will begin with a review of its urban development history of modern time, especially focusing on the innovations in various spheres (e.g. fiscal system, taxation system and urban land use system). Then, a series of crucial government innovations, which considered as milestones, will be marked and further anatomized. By different research methods, direct or indirect influences and chain reactions from innovation results to urban forms and urban spaces and the results will be highlighted. These specialties of urban development will be further compared and linked with current globalization process. It is proved that a dominant government-oriented development model can equally benefit a city's globalization process. It also reveals how indeed a series of local administrative behaviors contribute to its connection with globalization. Furthermore, it is concluded that the track of globalization could be different from the very beginning. Keywords: globalization, government-oriented, innovation, Guangzhou

Urban Networks from the Perspective of Producer Services Linkages: A Case Study of Guangzhou

Yun Zhong (Jinan University)

Urban networks are mirrored in the linkages of producer services, which means the exportation of producer services from one city to the others can be regarded as an index of urban linkages. To study the urban networks of a metropolis from the perspective of producer services linkages can be helpful to understand the new growth drivers of China's metropolis and provide hints to the impact of producer services on future urban development during globalization. In this paper, the focus is on the exportation of producer services from Guangzhou, a central city in South China and also a most developed city in China. Important facets of this exportation are the range, the strength and the direction of the linkages as well as the factors affecting them. The way to find out the characteristics of the linkages is to analyze the behavior of the producer services corporations located in Guangzhou. Based on questionnaires and interviews, the paper analyzes the characteristics of Guangzhou producer services linkages. As to the range of linkage, it is found that: (1) The spatial linkages of producer service ranges from the hinterland of Guangzhou to oversea markets; (2) The linkages with oversea markets will be extended considerably in the future; (3) The proportion of linkages to the faraway cities will increase faster than that to the nearby cities, which means, along with the increase of exportation capability, the urban network of Guangzhou will also change in the future. As to the strength of linkage, another finding is that: The corporations' managers prefer to devote more energy to exploit one market place than to exploit several. On this basis it can be stated that not only large manufacturing corporations but also large producer services enterprises, will play an important role in the urban network buildup in the future. As to the direction of linkage, it is found that the metropolises are the most tight linkage direction than the medium size cities or the small cities. Regarding the factors affecting the linkage it is found that: '1' Not the distance between two cities, but the client's capacity to pay is the biggest barrier to the linkage;'2'It can be shown that the dominating ways to export the service is by means of business trips by the supplier of services, so a good infrastructure is very important for constructing a larger urban network. As to the characteristics of Guangzhou producer services linkages, several conclusions can be drawn:

Regional Inequality of Higher Education in China and the Role of Unequal Economic Development

Wan-Hsin Liu (Kiel Institute for the World Economy), Frank Bickenbach (Kiel Institute for the World Economy)

In light of increasing global competition and rising labour costs the Chinese government, by the end of the 1990s, recognised innovation and upgrading of production processes crucial for the Chinese economy's ability to sustain its high-speed economic growth in the future. And it also recognised the importance of a highly qualified labour-force for the success of innovation and upgrading strategy. To increase the provision of highly qualified labour, the Chinese government has continuously reformed the higher education system. It attempted to transform the higher education system from the one focusing on elite education to the one promoting mass education through a substantial scale expansion of higher education. Between 1998 the last year before the expansion and 2008 the number of newly enrolled students grew six-fold. Along with the massive increase of higher education opportunities in general, the Chinese government intended to narrow the gap between the differing higher education opportunities across Chinese provinces as part of its regional development strategy. Using a provincial panel dataset from 1997 to 2008, we empirically analyse the level and development over time of the inequality in the distribution of higher education opportunities across the Chinese provinces in general, and across groups of provinces with different development levels in particular. To do so, we calculated a series of generalised Theil indices, which allow us to explicitly consider the heterogeneity in the provinces' sizes and structural development levels. Our empirical analysis shows that, during the period of rapid expansion of the higher education system, the inequality in the distribution of higher education opportunities across different provinces in China decreased, when taking into account the substantial differences in the sizes of provinces. It shows, however, that the inequality in the provision of university places per capita relative to GDP per capita between the poor and rich provinces increased. But this increase was in favour of the poor provinces, which realised an increasing advantage over rich provinces with respect to the number of university places relative to GDP (and a corresponding decline in their disadvantage with respect to the number of university places per inhabitant). These results are largely consistent with the announced (regional) development priorities of the Chinese government, which intended to massively expand the scale at the higher education system and at the same time reduce the inequality of higher education opportunities in favour of backward provinces. The results

may further imply that, assumed human capital is key for further innovation and upgrading activities in China, a more balanced starting point w.r.t. more comparable human capital endowments for sustaining long-term growth for different provinces seems to be better provided now than a decade ago.

The Governance of Economic Upgrading within Textile Clusters in China: A comparative analysis of regional economies in Keqiao and Guangzhou

Michael Waibel (University of Hamburg), Philipp Zielke (Universität Hamburg)

The textile and apparel industry in China was a key sector in the development of the backward Socialist country from the early 1980s to the mid-2000s. Currently, China is the biggest exporting country for textiles and apparel products. Against the background of rising wage levels in China and increasing global competition, however, the exclusively export-driven growth model is no longer valid. Therefore, the national government supports the shift towards approaches that generate more added value: For example, more emphasis should be placed on designing textiles for the domestic and global markets. Finally, 'Made in China' should be replaced by 'Designed in China'. This paper analyses the governance of the economic upgrading policies of the two most important textile clusters in China over time, which are embedded in this structural context: The China Textile City ('??????') in Keqiao, Zhejiang province and the Zhongda Textile district ('????') in Guangzhou. In the past, both regional economies have made significant efforts to re-structure their economic growth models. Within our research approach, governance theory is understood as an analytical concept rather than as the expression of a supposed globally changed reality. Our research is based on recent comparative empirical case studies. We will show that the restructuring and innovation strategies of both clusters are significantly different: Whereas Keqiao is focusing on international textile markets in North America and Europe, textiles from Guangzhou are mostly delivered to mainland China and Southeast Asia. We will show that Keqiao implemented upgrading strategies earlier and served as the role model for the upgrading of the Zhongda textile district. Furthermore, we will demonstrate that the interactions among the spheres of industry and local governments are highly disparate. The adaptation of the China Textile City to global competition is overwhelmingly dominated by a single state-owned enterprise, whereas in Guangzhou, the stakeholder landscape is much more heterogeneous. Here, private company actors are involved to a much higher degree within a specific brownfield restructuring and upgrading process. As a consequence, decision-

making processes in the regional economy of Guangzhou seem less authoritative than in Keqiao. Further, we will demonstrate that in Guangzhou, the transformation of land from urbanized villages to real estate developers and wholesale mall operators became one critical success factor. Finally, we emphasize that while analysing the governance of regional economic upgrading processes in China is a major empirical challenge, it provides complex insights into regional decision-making processes towards upgrading and innovation in global-local networks.

GCG 24-01 - The Land of Indigenous Traditional Knowledge

Chair: Paula Smith, Mirjam Hirsch

Understanding the Geography of Water and Sanitation Health Issues in Nigeria: The Traditional Ecological Knowledge Perspectives

Emmanuel Akpabio (University of Uyo)

For many years, tremendous efforts attempting to link important diseases epidemics to water supply and sanitation practices often mobilize around the strategic disruption, interruption or weakening of the chain of contamination cycles. Such purely scientific logic, largely based on biological and epidemiological understanding of the pathways of disease etiology, do not provide easily grasped and intelligible framework for understanding realities that have deep cultural intersections most especially among indigenous people in Africa. In the research, I am developing a Traditional Ecological Knowledge (TEK) framework as a basis for capturing both the spatial and temporal dimension of cultural, socio-economic and environmental factors that pose heavy constraints to intervention efforts at addressing the water and sanitation challenges in Africa. Through extensive case study in Nigeria, local senses and ideas around water and sanitation were correlated with the various TEK-anchored contextual factors to determine commonalities and differences. The results show that understanding environmental health issues around water and sanitation depend on a range of ecological, socio-economic and cultural factors mostly mediated by the traditional ecological knowledge. The practical implication about the result translates to the need for more place and locally sensitive programme intervention. Given the promise offered by the TEK framework, the paper calls for more empirical studies to validate some of the assumptions discussed.

The tree which is quarreling with the sky: Utilization and spirituality of *Faidherbia albida* in Africa.

Nobuyuki Hori (Nara University)

Faidherbia albida was known as the synonym of *Acacia albida*. This tree is widely distributed through savanna zone in Africa. Farmers in savanna notice of a curious phenology of this deciduous tree which is fallen leaves in wet season, and grow thick in dry season. They call the tree is quarreling with the sky, or the magic tree. The farmer use its phenology to advantage in their agriculture. Fallen

leaves in wet season become fertilizer. The crops around this tree vigorously grow up without shade. Many kinds of insects are existing in the flourishing tree in dry season, and thus various birds are making a nest on thin tree, and producing a lot of droppings around the tree. The shade of this tree is attractive for the villagers and domestic animals seeking for the rest place. Many kinds of organic matter are produced around the tree. Villagers call it the magic tree after the above mentioned phenology. They think and image a kind of spirits living in this tree. Especially the tree experienced thunderbolt is become the sacred tree. Such the tree is called as the special hidden name. These results are obtained from field works in mainly Niger and Cameroon.

The indigenous trap: On the construction of traditional knowledge and the question on modern practices.

Peter Koch (Leibniz-Institut für Länderkunde)

At many past and also present occasions Sámi and environmentalists have supported common goals (e.g., Alta, Nellim). In the recent decade, however, Norway has faced a serious conflict loom over Sámi reindeer herding in newly established national parks. Suddenly two nowadays unquestioned moral values - the preservation of indigenous cultures and livelihoods and the protection and conservation of large natural areas - have come into conflict with each other. First the local Sámi herding cooperatives were in favour of the establishment of national parks on their grazing lands as they could expect other land-use competitors such as mining and forestry companies to be displaced. But soon they found them selves in a less desirable atmosphere in which areas of interest to some businesses have been excluded from the national parks, novel and eventually more restrictive regulations to reindeer husbandry have been implemented, the relevance of local Sámi in decision-making processes has been decreased, and reindeer herders have been blamed for causing damages to endangered vegetations. How did this situation come about? We must consider that reindeer husbandry nowadays is an extensive and efficient industry that both operates with modern technologies and is integrated into the domestic - capitalist - economy. Let us have no doubt about it: The presence of modern practices in Sámi reindeer herding has demonstrated this community's ability to adapt to social, technological, political, economic and environmental changes. However it both challenges the idea of Sámi as the natural people to their homeland in which they live in complete harmony and it contrasts the image of indigenous people and their traditional knowledge and livelihoods as it exists in society. Traditional knowledge - as any other social phenomenon - is not simply

a given truth, unchangeable and incontestable. Instead it is an imagination, something that has been constructed. It is delivered from the elder to the young; it is objective to permanent negotiation in powerful settings; it is of great political relevance; it is by no means static but something very dynamic. At this point we then must critically ask who is in the position to define what indigenous traditional knowledge is, how indigenous communities must act - or do things in a traditional way - in order to be regarded 'indigenous' and what indigenous people in turn shall not do under any circumstances. In this paper I want to unfold these issues and share my material with you. I have gained it from extensive interviews that I have conducted during my various field trips to Norway - especially to the region of Nord-Trøndelag - in the period from 2009 - 2011. I have talked to local reindeer herders and Sámi representatives, local, regional, and national government officials, environmentalists, and members of other interest groups.

**Preserving traditional knowledge against external pressures:
Assessing the opportunities of Ecological Engineering in Ifugao,
Philippines**

Vera Tekken (University of Greifswald), Susanne Stoll-Kleemann (University of Greifswald), Monina Escalada (Visayas State College of Agriculture)

Against the background of global change and globalization unique cultural landscapes increasingly attract the attention of science and nature conservationists. The efforts to preserve these particular socio-ecological systems are reflected in the World Cultural and Natural Heritage list of the UNESCO. Included in this list are the mountainous rice terraces in the Ifugao Province, Northern Luzon, Philippines. The area is characterized by extensive subsistence rice cultivation which is mainly based on traditional indigenous farming techniques with associated rituals applied at each stage of the rice crop cycle. This synergetic interaction has been evolving over the past 2000 years, has until recently represented the main basis of household income, and has been shaping the social structures of local communities. The indigenous land use practices are perfectly adapted to the environmental conditions and due to their multi-functionality they are as well appropriate to partly offset disturbances like, e.g., extreme weather events and pest invasions. However, recent external influences (increasing livelihood costs, climate change) have severe consequences for the social structures of communities. In particular the traditional knowledge preservation and transfer to future generations are at risk. The low opportunity to earn a living in rice agriculture leads to increasing

emigration of young people to the cities. This loss of work force in the rice terraces leads to their abandonment and degradation. But still, the region is dependent on agricultural production which requires a comprehensive knowledge on appropriate farming techniques. In the Ifugao Province, a qualitative data collection was conducted to assess the role of traditional farming methods for the socio-economic development. Traditional knowledge and its role for the cultural landscape was evaluated. With the techniques of Ecological Engineering for biological pest control as an addition to traditional pest management it is tested if rice yields can be stabilized to support the farmers' incomes. The main long-term purpose is to support local livelihoods, to archive traditional indigenous farming methods, and to complement those with environmentally compatible techniques. In search of more sustainable farming methods, traditional knowledge will play an ever more important role. It is important to preserve cultural landscapes as next to being the basis for livelihood they contribute to the heterogeneity of societies.

GCG 25-01 - Urban climate and air pollution in a changing climate

Chair: Christoph Schneider

Investigating spatial variability of urban particulate matter concentrations

Hendrik Merbitz (RWTH Aachen University), Gunnar Ketzler (Geographisches Institut)

The population exposure to air pollutants like particulate matter (PM) remains one of the major environmental challenges in cities. Currently, exposure assessments are rather difficult because they require precise information about the spatial and temporal distribution of these contaminants. The low number of PM measurement locations and the high spatio-temporal variability of particulates make a continuous mapping of the concentration difficult. However, concentration maps are necessary both for the estimation of the total population exposure and for the identification of 'hot spots' with highest pollutant concentrations, which require measures immediately. Due to the anthropogenic climate change, summer heat waves and dry episodes might have additional negative effects on urban air quality. Especially the combination of heat stress and poor air quality impinges on the well-being of urban population groups. The presentation analyses results from studies within the interdisciplinary Project 'City2020+' at RWTH Aachen University covering the field of urban climatology and air pollution. The spatial distribution of PM10 and PM2.5 concentrations in the city of Aachen, Germany (population 250,000) is investigated by mobile measurements. Results from geostatistical investigations are presented which allow the identification of air pollution hot spots and the responsible drivers. A geostatistical model is presented, which creates maps of PM10 and PM2.5 levels over the city area at a resolution <10 meters. Further on, the exposure of vulnerable population groups towards particulate air pollution is addressed, combining the results with other studies from the interdisciplinary project City2020+.

A GIS-incorporated database of urban surface parameters for high-resolution meteorological models

Pavel Konstantinov (Lomonossov Moscow State University), Evgenia Kukanova (Moscow State University), Samsonov Timofey (Lomonossov Moscow State University)

This work presents a universal method of generating the meteorological database using GIS technology designed for detailed description of the thermo-physical characteristics of the underlying urban surface. Some of the characteristics that are most appropriate for this aim have been selected. It has been done according to two principles: universal applicability and frequency of use in studies of urban climate around the world. The chosen set of characteristics includes: · Sky view factor [Proportion of sky hemisphere seen from bottom of the urban canyon.] · H/W ratio [Ratio buildings height to width of streets between them.] · Surface fraction [Proportion of surface covered by construction, impervious, pervious materials.] · Albedo · Thermal admittance [Ease with which zone takes up and releases heat.] · Anthropogenic heat flux [Heat flux density from combustion processes.] · Geometric average, expectation function and standard deviation of height. It is proposed to carry out the calculation of these characteristics within each cell of regular grid covering the study site. This allows providing data that can be easily assimilated by any atmospheric boundary layer model. Also this allows changing the size of grid cell during investigation. In other words, universality of the calculation method will be ensured. Our study area for testing universal method of generating the meteorological database is Moscow, Russian Federation. GIS (Geographical Information System) extension is created for calculating all thermo-physical characteristics based on ESRI product - ArcGis 10. GIS technology is used in order to ensure flexibility and efficiency method. Also the advantages of GIS technology provide a wide range of tools for spatial and mathematic analysis and results visualization. Nevertheless, the two values of characteristics set (thermal admittance and anthropogenic heat flux) are currently difficult to assess even within well-studied cities in developed countries. In Russia these estimates have not been carried out yet. In order to solve this problem, study area has been zoned using newly created classification by Stewart and Oke. (Stewart I.D., Oke T.R., 2010) Also the applicability of the local climate zone classification for East-European type of building has been assessed.

Urban climate mitigation strategies in a regional climate modelling context

Matthias Demuzere (Katholieke Universiteit Leuven), Andrew Coutts (Monash University), Nicole P.M. van Lipzig (Katholieke Universiteit Leuven)

Urban climate models provide a useful tool for assessing the impacts of urban land surface modification on urban climates. It provides a mechanism for trialling different scenarios for urban heat island mitigation. Only recently, urban land surfaces have been included in global and regional climate models. Often they represent a trade-off between the complexity of the biophysical processes of the urban canopy layer and the computational demands in order to be workable on regional climate time scales. This study employs the Community Land Model (CLM) which was recently extended with a single layer urban canopy scheme (CLM-U). And although it is primarily developed as a tool for regional climate scales, we intent to extend its reach and use it for local (neighbourhood) scales in a changing climate context. Hence, an off-line validation is performed using meteorological observations for Toulouse (France) and multiple medium density urban areas in Melbourne (Australia). Model results are evaluated against observations of the surface energy balance from flux towers, including evapotranspiration, and show that the model is able to correctly address (urban) energy partitioning including high urban heat storage, and low evapotranspiration rates. Furthermore an investigation was undertaken to explore first of all the capacity of the model to incorporate Water Sensitive Urban Design (WSUD) features, mimicking vegetated and non-vegetated infiltration systems, open water bodies and other green infrastructure. In a second step, the effectiveness of WSUD integration scenarios are also compared with other common mitigation strategies such as increasing albedo and controlling urban morphology.

Effect of Air Pollution on Human health & Urban Management system in Tehran, Iran

Gholamreza Taleghani (University of Tehran), Seyed Esmaeil Asgharpour (Islamic Azad University Shahre Rey)

The biggest environmental problems which occur in metropolitan area of the world is air pollution. It is a global tragedy for human society .A large number of people are being died by air pollution in the megalopolis every day. Rapid population growth and urbanization which associated with industrialization has caused environmental problems, especially, in the metropolitan cities of the less

economically developing countries ,in the recent years. Tehran, the capital city of Iran located between 35 to 36 degrees N. latitude and 51 to 52 degrees E. longitude over 10 million populations ,is one of the most polluted cities in the world. Recently, air pollution has been getting worse annually .A great mass of pollutants are emitted to the atmosphere by motor vehicles, and different factories. It is a very serious and lethal crisis. Hadi Heydarzadeh director of Tehran clean air committee stated that Tehran's environmental situation as a 'collective suicide'. 'Air pollution has killed more than 3600 people in just last month October 23 to November 23, 2010. Tehran's air pollution is made even worse by geographic location which surrounded by Elborz mountain range in the north, causing the increasing volume of pollutants to become trapped. About 1.5 million tons of pollutants are produced in Tehran annually, carbon monoxide from car exhaust making up a large percentage of these pollutants. When high level of carbon monoxide and other pollutants engulfed Tehran for several weeks, it resulted a cloud of smog hovering over Tehran. It happens when the blowing of wind is not strong enough to take pollutants far away .The combination of natural and man made factors has caused this city to be counted one of the most polluted metropolitan cities in the world, ranking with Mexico city ,Beijing, Cairo, Sao Paulo, Shanghai, Jakarta and Bangkok [3]. So, governmental authorities and urban managers have to put a lot of effort in dealing with this crisis. It is a good idea to use experiment of other countries in this field and contribute and cooperate in activities to fight against air pollution. The recent pollution crisis in Tehran forcing governmental authorities to take serious actions in protecting the health of its citizens .Tehran's air pollution is a complicated issue, so it needs that new strategies to be taken before this increasing environmental problems reaches to a critical stage .The study based on collected data which were analyzed to reach a favorable result. Key words: pollution, urban, industry, smoggy, strategy, metropolitan, global, transparent, environment

GCG 26-01 - Vector-borne diseases and climate warming

Chair: Carl Beierkuhnlein, Markus Neteler

The vector, the landscape, the ecosystem: the multiscale character of vector-borne diseases

Sophie Vanwambeke (Université catholique de Louvain)

Vector-borne diseases and zoonotic diseases are well known for the complexity of their transmission systems. These systems are influenced by a broad spectrum of environmental factors. However, these environmental factors influence the spatial distribution of the disease at various scales. Climate, for example, essentially homogeneous at a broad scale, affects the distribution essentially at the regional scale. Locally, a number of global change-relevant factors are also significant. Land cover is an important determinant of habitat suitability for vectors and hosts. Land use in fine determines areas of contact between vectors and humans, by favouring or limiting access to areas with high densities of infected vectors or host. Land cover and land use can be highly spatially heterogeneous at a fine resolution. Geographers are well equipped to document these spatial heterogeneities at multiple scales, and to collaborate with biologists, epidemiologists and other disciplines involved in understanding the spatial heterogeneity and multiscale character of vector-borne disease transmission systems. Results of such successful collaboration will be presented, emphasizing the multiscale character as well as the efforts on bridging methodological approaches that have remained essentially separate in the field of disease ecology, i.e. empirical-statistical and process-based approaches. Cases presented will cover tick-borne diseases in Europe and mosquito-borne diseases in the tropics.

Water-related vector-borne diseases in eastern Africa: Present and future risks

Stefan Kienberger (University of Salzburg), David Taylor (University of Dublin)

Environmental change, such as climate change, will affect and impact human health, which is a major concern for the global community. The effects will however be felt most acutely among the poorest members of society. Much concern has focused on the future distribution and spread of infectious diseases, and in particular the negative health impacts of changes in transmission and outbreaks of vector-borne diseases (or VBDs) as a result of

climate change. The impacts may be direct, in terms of outbreaks of disease among human populations, or indirect, in the form of outbreaks of diseases that affect domesticated animals or plants, and therefore jeopardise food security, agriculture-based economic activities and trade. Activities and preliminary outcomes relating to the HEALTHY FUTURES project, funded under the EC FP7 research program, are the focus for the presentation. The HEALTHY FUTURES project, which started in January 2011, is motivated by concern for the health impacts of environmental changes. HEALTHY FUTURES aims to respond to this concern through construction of a disease risk mapping system for three water-related high-impact VBDs (malaria, Rift Valley fever and schistosomiasis) in Africa, accounting for environmental/climatic trends and changes in socio-economic conditions to anticipate future risk. Concentrating on eastern Africa as a study area, HEALTHY FUTURES comprises a comprehensive, interdisciplinary consortium of health, environment, socio-economic, disease modelling and climate experts in addition to governmental health departments. To achieve its aims, HEALTHY FUTURES deploys a bottom-up, end-user/stakeholder-focused approach combining field-, laboratory- and library-based research. Within this paper results of the first one and a half years of the project are presented, especially first insights on disease-environment relationships in the study area, disease outbreaks in the historic past, and a preliminary risk-vulnerability framework and associated mapped hot spots for eastern Africa. Additionally, results from down-scaled climate models will be presented and their integration into disease models will be discussed. Given these first results, the way forward to integrate relevant risk information within a Decision Support Tool in the context of climate change adaptation will be outlined.

Transmission of Schistosomiasis in Africa and its vulnerability to climate change

Yvonne Walz (University of Wuerzburg), Martin Wegmann, Stefan Dech

Schistosomiasis is a chronic human disease caused by parasitic worms and affects approximately 800 million people worldwide. 90% of the 250 million infections are currently concentrated in sub-Saharan Africa. The transmission of the disease requires the presence of specific freshwater snails as intermediate host to release human pathogen species. In Africa, the presence of *Bulinus* spp. snails is necessary to shed *Schistosoma haematobium* parasites and *Biomphalaria* spp. to shed *S. mansoni*. The potential spatial distribution of freshwater snail species can be described by environmental factors such as

temperature, soil moisture, vegetation density, water bodies and water flow velocity, which are to some extent related to the risk of acquiring the schistosomiasis disease. Scenarios of global climate change predict warmer temperatures and are further accompanied by perturbations in precipitation, hydrology and water availability. The major question associated with global climate change and schistosomiasis is whether temperature, water, and other conditions adequately support the snail and the schistosome parasite. However, the nature and extent of climate change on the transmission of schistosomiasis remain still poorly understood. The spatial distribution of schistosomiasis shows a very heterogeneous pattern, both on the continental scale of Africa and on the local scale. Disease prevalence can vary between neighboring villages and between regions. In this research, remote sensing data with different spatial resolutions (Rapid Eye, Landsat, MODIS) are investigated for hot spots of disease transmission in different ecological settings to assess the effect of environmental factors in relation to the disease distribution at different spatial scales. The study area in Burkina Faso represents savanna, which is predominantly infested by *S. haematobium* infections, whereas the study area in Ivory Coast represents tropical rain forest that hosts mainly *S. mansoni*. Following a field trip to the study area of Burkina Faso, bi-temporal analyses of high resolution Rapid Eye data showed that very small potential snail habitats are heterogeneously distributed in the study area and represent different suitability as snail habitat. Whereas differences in temperature have no relevance on the local scale, this heterogeneous pattern of disease transmission sites is not captured by large-scale analyses using moderate resolution data of the MODIS sensor. Furthermore, potential snail habitats in the savanna region of Burkina Faso are predominantly man-made water reservoirs versus natural ponds in the tropical rain forest of Ivory Coast. We could show that remotely sensed environmental factors provide valuable information for disease mapping and prevention and that the spatial distribution of the disease at different scales and in different ecological settings are fundamental to assess disease transmission vulnerabilities with respect to climate change scenarios.

The potential effects of climate change on malaria in tropical Africa using regionalised climate projections

Volker Ermert (Institute of Geophysics and Meteorology), Andreas H. Fink (Institute of Geophysics and Meteorology), Heiko Paeth (Univ. of Würzburg), Andrew P. Morse (Department of Geography)

The projected climate change will probably alter the range and transmission potential of malaria in Africa. The potential impacts of climate change on the malaria distribution is assessed for tropical Africa. Bias-corrected regional climate projections with a horizontal resolution of 0.5° are used from the Regional Model (REMO), which include land use and land cover changes. The malaria models employed are the 2010 version of the Liverpool Malaria Model (LMM2010), the Garki model, the *Plasmodium falciparum* infection model from Smith et al. (2005) (S2005), and the malaria seasonality model (MSM) from the Mapping Malaria Risk in Africa project. The results of the models are compared with data from the Malaria Atlas Project (MAP) and novel validation procedures for the LMM2010 and MSM lend more credence to their results. For climate scenarios A1B and B1 and for 2001-2050, REMO projects an overall drying and warming trend in the African malaria belt, that is largely imposed by the man-made degradation of vegetation. As a result, the malaria projections show a decreased malaria spread in West Africa. The northern Sahel is no more suitable for malaria in the projections. More unstable malaria transmission and shorter malaria seasons are expected for various areas farther south. An increase in the malaria epidemic risk is found for more densely populated areas in the southern part of the Sahel. In East Africa, higher temperatures and nearly unchanged precipitation patterns lead to longer transmission seasons and an increase in the area of highland malaria. For altitudes up to 2000 m the malaria transmission stabilises and the epidemic risk is reduced but for higher altitudes the risk of malaria epidemics is increased. The results of the more complex and simple malaria models are similar to each other. However, a different response to the warming of highlands is found for the LMM2010 and MSM. This shows the requirement of a multi model uncertainty analysis for the projection of the future malaria spread.

Society & Environment

SE 01-01 - Analysis of linked social-ecological systems 1

Chair: Tillmann Buttschardt, Anna-Katharina Hornidge

Institutional change and transformation of water governance regimes in South Africa: The role of fit and interplay

Elke Herrfahrdt-Pähle (German Development Institute)

Since the end of the apartheid era South Africa is undergoing a comprehensive political and economic transformation. Among other things the water legislation has been completely revised, featuring goals such as equitable access to water, sustainable water use and the introduction of basin management. The latter represents an effort to align the spatial fit of the boundaries of the water body and the social institutions and organisations administering it. It requires the introduction of new management units. This paper seeks to examine the issues of fit and interplay arising between the ecological system and the old and new management units of the social system and their influence on the resilience of the social-ecological system. It examines mismatches arising through new institutional arrangements and governance structures at various levels of the spatial, jurisdictional and institutional scales. A possible result of such mismatches is the mismanagement of natural resources and a subsequent loss of adaptive capacity and resilience in the social as well as in the ecological system. The paper firstly develops a framework which allows integrating different scales and levels of analysis both from the ecological and the social system. This framework allows identifying mismatches within and between scales. Secondly, the framework is applied to water governance reforms in South Africa. The example of the introduction of basin management illustrates the advantages of hydrological boundaries for adapting governance structures to ecological conditions but it also highlights some institutional mismatches and trade-offs. The paper concludes that even though aligning water governance institutions to the biophysical system and thus increasing their fit produces frictions within the social system, basin management has the potential to improve water management outcomes. However, it suggests that in addition to a static understanding, the concept of fit should be framed in a dynamic sense. An institutional setup which fits the biophysical conditions such that it is similarly flexible and able to adapt to ecosystem dynamics would probably benefit the resilience of social systems more than merely a focus on mimicking ecosystem properties at a certain point in time.

Rural-amenity landscapes: Social-ecological interactions shaping private land management

Benjamin Cooke (RMIT University)

Rural landscapes in many parts of the post-industrial world have become increasingly multifunctional in recent decades, as people with lifestyle-orientated land use objectives migrate to regions once the domain of productive agriculture. In parallel to this phenomenon has been an increasing interest in private land as a site of biodiversity conservation, to complement the protected area system. As land use transitions have gained pace, debate has emerged as to whether rural-amenity landscapes present an opportunity or a challenge to biodiversity conservation on private land. Despite the increasing awareness of conservation value in these regions, we have little knowledge of what actually influences the biodiversity management practices of landholders. This research aimed to explore how landholder interactions with the physical landscape and with other social actors might shape their management. The site for this study was the hinterland regions of Melbourne, Australia. An ethnographically influenced methodology involving in-depth interviews with 24 landholders was the primary source of data collection. A key component of the process was walking the properties of participants with them during the interview encounter, allowing the physical landscape to elicit past management interactions and contextualise their ecological knowledge. This methodology was inspired by a desire to explore conservation behaviour at the site at which human-nature interactions occurred, to better understand how practices emerge. Interviews were also conducted with five extension staff involved in the delivery of private land conservation schemes, to provide an external, institutional perspective on landholder management practice. This methodology brought to light a number of social-ecological interactions that influenced how landholders pursue management. The landscape often served as a dwelt-in-ecosystem that embedded knowledge of ecological processes to the place and duration of residence. Also pertinent was the process by which management practice passed between generations of property owners in the form of social-ecological legacies. Material nature like trees or the artifacts of abandoned agriculture embodied a history of practice that influenced the actions of current landholders. This research highlights the potential contribution of fine-grained qualitative research in contributing to understandings of landscape management across regions of dynamic land use transition. This is especially pertinent for informing policy interventions for biodiversity conservation in such a context. Exploring management practice at the site of human-nature interaction can prove

beneficial in determining the relationships between social and ecological phenomena in preserving, creating and re-creating landscape ecologies over time.

Frameworks for the analysis of coupled social-ecological systems

Claudia Binder (University of Munich), Jochen Hinkel (Potsdam Institute for Climate Impact Research (PIK))

The growing relevance of complex environmental problems, such as climate change, bio-diversity loss, and resource scarcity and degradation (e.g., water, energy, minerals), have led to the insight that these problems have to be dealt with in an integrative, inter-disciplinary way that takes into account the interaction between social and ecological systems. Within the last decade significant progress has been made with respect to interdisciplinary investigation and modeling of coupled social-ecological systems (SES). While a great number of studies on SES have been conducted, the comparison of results, and the derivation of general implications are difficult not only because case studies are conducted in regions having different cultural, environmental, and behavioral structures, but also because of the diversity of the methods and concepts applied. In this contribution we compare 11 established frameworks for analyzing social-ecological systems. We limited ourselves to frameworks that were explicitly designed to be used by a wider community of researchers and practitioners. Although all these frameworks seem to have emerged from the need for concepts that allow for structured, interdisciplinary reasoning about complex problems in social-ecological systems, they differ significantly with respect to contextual (e.g. time, space specification, disciplinary background, theoretical foundations) and structural (e.g. conceptualization of social, environmental system and their interactions) criteria. It appears that three main aspects suffice to produce a classification of frameworks that may be used as a decision tree when choosing a framework for analysis. These criteria are (i) whether a framework allows for static or dynamic analysis; (ii) whether it takes an anthropocentric or an eco-centric perspective; and (iii) whether it is applicable to any social-ecological system or only to specific ones. Finally, we discuss to which extent these frameworks might contribute to managing complex social-ecological systems.

Nulture: Conceptualising the mutual nurturing between nature and culture

Janet Stephenson (University of Otago)

There is abundant evidence that both indigenous and non-indigenous communities engage in stewardship practices crafted to support the wellbeing of local ecologies. The benefits however do not just flow one way, and human interactions with natural systems can be highly influential in personal and collective wellbeing. Such two-way flows have resulted in a wide variety of locally distinctive nature-culture interrelationships. These coupled human-ecological systems can be rich in both cultural and ecological diversity (Pretty et al. 2009). From a resilience perspective, such heterogeneity offers a better basis to respond to future shocks than one-size-fits-all management systems. Stewardship of the local environment is crucially important in helping to realise a sustainable future, and can help achieve a 'reduction of moral distance between actions and consequences' (Adger et al. 2010, p 547). Awareness of the contribution of natural systems to personal and collective needs is also crucially important in creating environmental citizens who will 'care for the earth' (IUCN 1991). There is clearly great benefit to be had from heightening awareness of the confluences between nurturing of the environment and nurturing from the environment. Western discourse largely couches this relationship using terms such as conservation, environmentalism or guardianship - concepts that suggest nurturing is a one-way flow. In contrast, the mutually supportive relationship between nature and culture is overt in the worldview and language of some indigenous cultures: in M'ori for example, one is genealogically related to all parts of the environment; whenua means both 'earth/landscape' and 'placenta'; and kaitiaki (environmental guardians) can be both human and non-human. While various aspects of dual-direction nature-culture flows have been explored in western scholarship, a mind-map or model that presents the mutuality of these relationships is lacking. Social-ecological systems approaches have begun to explore the 'cross-sphere linkages that constitute the core of human-nature relations' (Glaser 2006, p131) but I argue that a more intimate framing of human-environment interactions is also needed - one which highlights the existence and possibilities of the mutual nurturing between nature and culture at a locally specific level. This paper introduces the concept of 'nulture' to describe this set of relationships. By giving prominence to locally distinctive and mutually nurturing interactions, nulture aims to promote wider consideration of the possibilities inherent in sustained, located, nurturing and mutually interdependent nature-culture interactions.

Urban watercourses as key socio-ecological link in Santiago de Chile?

Alexis Vásquez (University of Chile), Ulrike Weiland (University of Leipzig)

Urban watercourses such as streams, canals and rivers are structural components of the Santiago landscape. Our hypothesis is, that they have the potential to serve as key links between urban social and ecological natural systems and to provide environmental services, helping to reduce socio-environmental problems and to stabilizing the link between social and ecological systems in an urban setting. Analyzing environmental characteristics and functions of riparian zones as well as exploring opportunities and constraints to develop multifunctional riparian greenways, helps to assess their potential to serve as key link between social and ecological dimensions - as multifunctional riparian greenways - and to set priorities in urban decision making. For two watercourses - Mapocho river and Zanjón de la Aguada' integrative analyses of the socio-ecological systems have been carried out. As key features for the analysis social pattern, transport infrastructure, flood risk, land use/cover, public green spaces, native woody species distribution as well as air temperature and wind patterns have been addressed. Local stakeholders were interviewed to identify opportunities and constraints to develop multifunctional riparian greenways. Zanjón de la Aguada and Mapocho rivers have been heavily affected by the urbanization process that has a much higher impact close to the stream. More than 50% of riparian zone population lives in the flood prone area. The most important opportunities to develop multifunctional riparian greenways are related to: -These watercourses flow through 12 and 9 municipalities, they have the potential to link the social and urban fragmented landscape. -In some segments they still are providing cooling effects, harbouring native woody species and acting as wind corridors. -An increasing number of social movements strive for urban greening, agriculture, and ecology. On the other hand, the most important constraints are: More than 20% of Mapocho and Zanjón de la Aguada riparian zones are covered by dense residential areas. There is a high administrative spatial fragmentation due to a missing authority for the metropolitan area. Awareness of the complexity and necessity of greenways on the part of political actors and the local communities is missing. In order to link better the urban social and ecological systems, to benefit the

opportunities and to overcome the constraints mentioned above at the best, a 'Riparian-Zone-Multifunctional-Greenway-Strategy' should be developed covering the built-up areas as well as the catchment areas of the watercourses investigated. In this contribution, 1) an integrative socio-ecological system analysis of the selected urban riparian zones will be presented. 2) Opportunities and 3) constraints to develop multifunctional riparian greenways will be discussed, and finally 4) conclusions how to link better the socio-ecological system will be drawn.

Zoning of Regional Environmental and Socio-Economic Systems of Ukraine

Anatoliy Kornus (Sumy State Pedagogical University), Olesya Kornus (Sumy State Pedagogical University), Vladimir Shishyk (Sumy State University)

Socio-ecological-economic zoning of Ukraine can be attributed to the scientific search for ways and mechanisms for solving problems of regional development. Given the incomplete readiness of socio-ecological-economic zoning of large areas, it is important to find effective approaches for its implementation. This determined the aim of our study, which was making such zoning for the North-Eastern region of Ukraine. Implementation of socio-ecological-economic zoning took place in several stages. The first phase was carried out analysis of natural resources, demographic and economic potential of the administrative districts of the North-Eastern part of Ukraine. At the second stage of our study was the estimation of the balance of resource potential administrative districts, which are a North-Eastern region, which allowed based on an index of socio-economic sustainability and ecological sustainability index to identify the most problematic areas and regions as socio-economic and environmental development, and rank all the studied region for tension problems in their development. Administrative districts of the North-Eastern region of Ukraine where there are major regional industrial, organizational-economic, cultural and living centers usually have complex environmental problems and the peripheral territory have problems mainly in the socio-economic terms, that each region can be seen as problematic territory. Number of districts where there are no pronounced problems of socio-economic and environmental development is minimal. In the third stage of our investigation, based on the spatial distribution of above mentioned sustainability indices, was carried out the socio-ecological-economic zoning of the North-Eastern region of Ukraine. Each socio-ecological-economic area (SEEA) - this is not virtual space design, but real space systems are closely intertwined and interacting nature, economy and population. Each such system

performs certain functions that are entire system configurators. Village periphery provides the industrial centers of raw materials and foods, urban centers provide the periphery of industrial goods and serve as social and cultural services to the population of the province. Thus, the pattern within the SEEA is reproduction of socio-economic, natural resources and the demographic potential of the territory. In Ukraine there are no administrative units that could perform similar functions; the municipality (administrative districts and cities of regional subordination) is very small such purposes, and administrative regions or economic areas are very large and spatially heterogeneous. But each SEEA in perspective can be considered as a potential unit of administrative-territorial division designed to ensure the successful implementation of regional strategies for sustainable development. Such a strategy should have each region, as sustainable development of any country provided by sustainable development of its regions.

How social aspects need to be considered in small-scale ecological research projects

Jenny Schmidt (Institut für Landschaftsökologie)

Mankind is facing increasing challenges with sustaining a healthy living environment on planet earth. While many phenomena like climate change, scarcity of water, soil erosion, desertification and the finiteness of natural resources are well known, the need for rapid action seems overshadowed by political, social and economic constraints. If scientific research in the field of landscape ecology and physical geography wants to produce applicable results, scientists need to inform themselves about linkages between the ecosystem and the society they work in and how the interaction of people with their natural environment works. Using an example of a small-scale research project on pollination of rooibos in South Africa, it is shown, how knowledge exchange can be successfully incorporated into the research setup without the need of additional resources. The benefits for local stakeholders and the scientist are laid out. A few general considerations about knowledge exchange and how we use it is provided. Also, some insights are given into the discussion about a paradigm extension which is taking place within the discipline of landscape ecology. While some people are looking to extend pattern and processes with design, others are emphasizing place and people to be included. The presentation aims to encourage scientists' reflection on their self-concept and their professional relationship to society.

Landscape Ecological Assessment of the Bakreshwar River Basin, Birbhum District, West Bengal, India: A Micro-Level Study

Druheen Chakraborty (Visva- Bhatari, Santiniketan)

Landscape ecology relates the relationships between sustainable development and ecological processes in a particular ecosystem. Landscapes are spatially heterogeneous geographic areas characterized by diverse interacting patches or ecosystems, ranging from relatively natural terrestrial to human-dominated environments including agricultural and urban settings. It is measured within a variety of landscape scales, spatial patterns, and organizational levels of research and policy. The landscape ecology includes ecological flows in landscape mosaics, land use/land cover change, scaling, relating landscape pattern analysis with ecological processes, and landscape conservation and sustainability. Land use planning based on the landscape ecological approach and design can be effectively used as most appropriate method to restore the landscape ecologic equilibrium in degraded land for solving the society's sustainability problems. In this paper, an attempt has been made to identify the patches and analyse the patch dynamics. In fact, patches are the basic unit of the landscape that change and fluctuate (horizontal and vertical processes). The Bakreshwar River Basin, located in the south western part of the Birbhum District, West Bengal, has been selected for the present investigation. Topographical sheets (1970-71) and Satellite Imageries (IRS-P6, LISS III of 04 December 2006 Precision Geocoded FCC), field information and GIS techniques have been used to analyse the patch dynamics of the study-area. Each micro-level Landscape Ecological Units (LEU) have been assessed in this paper. Some specific remedial measures have also been suggested for the management and planning of land resources in the study-area.

The Social Ecology of Californisation & Littoralisation in Mediterranean France

Christophe Neff (IFGG, Karlsruher Institut für Technologie), Julia Baum (IFGG, Karlsruher Institut für Technologie)

Both californisation and littoralisation are two of the main drivers of landscape changes in Mediterranean ecosystems (Neff & Frankenberg 1995, Neff & Scheid 2005). These processes can also influence the quality of ecosystem services of Mediterranean ecosystems. In Mediterranean France - the littoralisation of coastal areas has widely changed the coastal geography - "real wilderness" is restricted to very small parts of the coastline (Calanques coast, part of the Camargue, coastline between la Clape Massif and Cap Leucate). Furthermore, the californisation of the coastal hinterland - the term californisation as used in francophone geography describes the process of suburbanization of large landscapes - provokes a new frontier line of urban/forest interface, which in case of forest fire can create a tough challenge for firefighters. The progression of settlements into the "wild" - and the progression of the wild into settlements can create a new social ecological system, with changing ecological service capacities. In a case study (Masterthesis J. Baum, Baum 2011) we analyzed how these processes actually restructure the landscape cover/geography of the Leucate area - one of the remaining rare areas of wilderness on the french Mediterranean coastline (Neff 1998) - and how these processes influence (reduce or reinforce) local ecological services. This study, which is one of the first studies analyzing ecosystem services in a spatially explicit approach in Mediterranean terrestrial ecosystems, provides some interesting "insight views" of connectivity of local & regional societal systems and local & regional land cover dynamics. We also try to show how to integrate the results of the Leucate case study in a large theoretical framework - using the approach of G.S. Cumming (2011a+b). Literature: Baum, J. (2011): Land Use Change causing local Land Cover Change in mediterranean France and its Impact on Biodiversity and Ecosystem Services. Unpublished Masterthesis, IFGG-KIT. Cumming, G.S. (2011a): Spatial Resilience in Social - Ecological Systems. Dordrecht. Cumming, G.S.

Knowledge of adaptation – Adaptation of knowledge. Mapping the adaptive capacity of a social-ecological system.

Simone Beichler (HafenCity Universität Hamburg), Maria Hagemeyer-Klose (HafenCity Universität Hamburg), Sonja Deppisch (HafenCity Universität Hamburg)

How can adaptive capacity of an urban region be characterized and evaluated in the face of climate change? The authors present conceptual considerations about adaptive capacity in social-ecological systems emphasizing the handling of correlated, highly dynamic and fast changing variables, in particular knowledge. A case study in Germany investigates such correlations via vulnerability analyses combined with scenario planning as an integrating inter- and transdisciplinary method. In climate change research, adaptive capacity is seen as a key element of vulnerability besides sensitivity and exposure (IPCC 2007). There is an increasing demand for tools that allow spatial representation of vulnerability to implement adaptation measures, to inform actors and to prioritise actions. Knowledge as basis for decisions and actions in adaptation to climate change is the crucial prerequisite for all adaptation efforts. Therefore knowledge can be seen as one decisive variable of adaptive capacity (Berkas et al. 2002). Mapping vulnerability, possible consequences of measures and resulting interventions need to be considered. Hence, clear cause-effect relations should be taken into account, but the correlations between sensitivity and adaptive capacity measures and their dynamics are still under acknowledged. Moreover, a social-ecological system permanently transforms its structure, dependencies and feedbacks, because the system incorporates properties like knowledge alongside with social networks and communication practices, which are permanently changing. Consequently, the overall results suggest that the adaptive capacity of a social-ecological system is highly dynamic, contrary to the fact that a spatial explicit evaluation of adaptive capacity can only show a snapshot at a given time. In order to cope with these challenges the case study of our project plan B:altic firstly uncovers correlations and dynamics of adaptive capacity in vulnerability assessment. Here, interactions between humans and their environment are presented. On the one hand, society depends on ecosystem services especially in the face of climate change. On the other hand society takes actions that influence ecosystems. Secondly, the paper presents an integrated approach using scenario planning, which consciously incorporates change.

Participant observation as a tool for holistic agroecosystems research

Imogen Bellwood-Howard (Kings College London)

Social and ecological concerns interact nowhere more than in agroecosystems. It follows that agricultural research must use interdisciplinary methods. This paper assesses the benefits of participant observation, an ethnographic technique, in agroecosystem analysis, illustrating its use in soil fertility management (SFM) research in the Ghanaian savanna. The research used qualitative and quantitative methods to explore how farmers' socioeconomic assets influenced their access to environmentally appropriate SFM techniques. Soil nutrient and moisture tests on 59 farmers' fields found that the water retention qualities of composts added to the sandy soils raised maize yields. Yet farmers explained how financial constraints limit their access to vehicles with which to convey compost to the field; also to fertiliser and to traction for early ploughing that allows them to benefit from the first rains of the short farming season. To tackle this they used and compared, through assay, survey and interview, six compost carriage methods. Participant observation was invaluable in identifying the institutions and management practices they developed to work within social and ecological boundaries. Accompanying farmers as they carried compost to the farm, I observed synergy resulting from their use of multiple vehicles to maximise labour efficiency in the limited time they had with a hired or shared donkey cart. Using the donkey allowed them to get compost to the fields on time, as it had more stamina than the more traditional and expensive bullocks. When labour for compost carriage was unavailable, other locally developed methods, such as double ploughing and coppicing, maximised the amount of organic matter incorporated into the soil. Living in the community, I observed unreported examples of hire, borrowing and sharing. These illustrated how institutions acting at individual, household, community and national scales governed access to resources, especially the carts used to carry compost. Participant observation gives researchers insight into participants' worldview. Farmers' holistic view of agroecosystem functioning led me to describe it and the management practices within it as a complex, self-defined system rather than an arena where discrete social and ecological processes collide. Participant observation is not, however, infallible. An extended period in the field is necessary to appreciate the importance of seasonality. Linguistic fluency elucidates the nuances of actors' practice; in its absence good working relationships with participants and interpreters are essential. Finally, researchers' positionality prevents them becoming full 'participants'. Participant observation

must therefore be triangulated with qualitative and quantitative methods. Together they constitute a powerful set of tools for understanding local management practices and developing them for resilience to environmental change.

Socio-ecological resilience and vulnerability in the high Andes – a bio-cultural approach

Dorothea Hamilton (Universität Marburg)

The antagonisms resilience and vulnerability are concepts that require a more systemic and holistic approach towards the human-environmental interaction. That the holistic nature requires seeing the worldview as the fundamental bases of the system is obvious. The bio-cultural approach includes all tangible and intangible aspects for understanding the resilience, seeing spirituality as one of the aspects in understanding the system. The Andes region is a highly fragile ecosystem with high climate variability. The human-environmental co evolution has created a place-based system that has shown to be resilient to the social and environmental shocks it has been exposed to. The base is a bio-cultural system which links traditional knowledge on the ecosystem with everyday practices and spirituality. The knowledge of the interlinkages with spiritual beliefs and values has to be seen as the bases for the continued existence of the socio-ecological resilience of the area. In the Andean terminology this system is called Ayllu, meaning the interaction and interchange of all beings as the principle for survival. As the Andean worldview is cosmocentric, therefore the realms of exchange include as well the exchange of goods between the people as well as the exchange with other living beings and nature itself by ritual acts. The principle of exchange is the bases of the traditional Andean landscape management and implies the continued respect of all beings and a non-exploitive view on nature. Nonetheless the traditional Andean resilience is being threatened by many aspects, turning it into a vulnerable area. So-called development projects are threatening to destroy the bases of the Andean bio-cultural system by undermining the fundamental principles of their worldview. At the same time ecological threats such as the increase of extreme events need a stable human-environment-interaction in order to continue to be resilient. This study focuses on results of an action research conducted in six Quechua communities near the city of Cusco, Peru. Together the communities form the Potato Park, a project to strengthen the traditional Ayllu system in order to increase resilience. The human-environmental linkages in this bio-cultural system are explored as well as the impact of actual tendencies on this, giving insights

into the resilience and vulnerability in the high Andes. Empirical evidence shows that there are effective measures in order to support the traditional Ayllu system in order to enforce socio-ecological resilience.

Potential economic interest for urban future in Hukawng Valley, Kachin

Seng Aung (Myitkynia University)

Aloe (local name is Thithmwe and Mura Hpunsau in Kachin), plant by Lord (Number 24:6), which can be studied as many names for the resinous, fragrant and highly valuable plant species in Kachin State. It is known as tropical plant, Aquilaria and it occurs in 16 countries from Bhutan and northeastern India across to southern China through Southeast Asia and as far as the Papua New Guinea. A shade-tolerant under evergreen and semi-evergreen forests, Aquilaria occurs throughout Myanmar from Tanintharyi rain forests to hill evergreen forest of Putao with exception of the central dry zone. According to Aquilaria hunters, species grown naturally in Hukawng Valley is the best quality resin in the whole Myanmar. These natural non-timber trees were overexploited due to attractive price of its resin as illegal trade since 1970s in Kachin State and also in the whole Myanmar. The natural growth in the wild of Aquilaria is getting rare and endangered throughout its range in Kachin State and also in Myanmar. Aquilaria had been almost neglected in forest and distribution status of the wild agarwood species is very little. Aquilaria reflects its widespread and varied use as medicinal products, cultural and traditional and it is used as a perfume has been recorded in the Old Testament and uses continue today. According to interviewed local Aquilaria hunters, agarwood oil and incense are used for their fragrant properties, notably in the Middle East. Nowadays, Aquilaria domestication and plantation is being carried out in Kachin State and also in Myanmar from 6 years ago. Sustainable use not only emphasizes sustained yield, but also embraces sustenance of ecological, socio-economic and cultural services of the species. To achieve sustained yield, and the regeneration characteristics of the Aquilaria, sustainable socio-economy for urban future population under different ecological setting and environmental position, it is important to study for development of long-term objectives of eco-based farm research and technological development and seeking local people' participation and international networking in Kachin State. Aim and objectives Major aim of this study is development of sustainable socio-economy for urban future population by means of non-timber forest resource management in Hukawng Valley, Kachin State. Objectives - to seek the way of poverty of local people - to develop

sustainable livelihood - to cooperate in the fields of research and technology for Agarwood plantation toward urban future development in Kachin State

Capturing a multidisciplinary approach – Integrating ecosystem services and social impact analysis for sustainable land use management in Krummhörn (German North Sea coastal region)

Leena Karrasch (Universität Oldenburg), Thomas Klenke (Universität Oldenburg), Johan Woltjer (University of Groningen)

The coastal lowlands and estuaries of North-West Europe are particularly vulnerable to climate change. The need for adaptive strategies leading to a more sustainable development and focusing on human well-being to meet the changing conditions is obvious. Related informal processes on regional climate adaption strategies and schemes have started in the area of Krummhörn (Northwest Germany). Here, stakeholders want to cover the structures of both, the community and the ecosystems, in a process dealing with the development of new options for sustainable land use management. There is, however, a lack of knowledge concerning the relationship between ecosystem services and social impacts in particular. Decision-makers together with scientists have to deal with the challenges of an integrative approach. We developed and applied a method for participatory planning based on an integrated assessment of the ecosystem service approach in combination with a social impact assessment. Both concepts constitute the foundation to analyze complex socio-ecological systems and activities within the regional society. Capturing the knowledge of local stakeholders and using the multiple trade-off analysis from other scenarios, ecosystem services are evaluated in a socio-economic and socio-ecological framework. Indirect and direct social impacts and ecosystem services are included in the strategy development. Putting the method into practice of planning sessions, stakeholders express their experiences and needs in social terms without the need to understand the scientific background of the ecosystem service approach which is often not easy to communicate. E.g., the provisioning service "green energy production using crops" is determined by the direct social impact "fear of increasing monocultures". In addition, indirect social impacts strengthen the ecosystem service, like the dependence on market prices or the fear of competing land use. Another example is provided by the cultural service "recreation and tourism". This service relates directly to indicative landscape impacts and indirectly to the security of income or the economic prosperity and resilience of the region. The combined framework optimizes decision-making as well as evaluation processes and leads to a better

understanding of human well-being. It reduces complexity and encourages stakeholder participation. Scientific and practical implications contribute to new courses of action leading to a sustainable and multi-functional land management. This provides a trans-disciplinary approach of natural and social sciences negotiating the separation between humans and environment.

Wetlands of Göksu Delta: History, Problems and Policy

Murat Karabulut (Kahramanmaraş Sütçü İmam University), Mehmet Gürbüz

Wetlands are ecosystems with high ecological and economic value. Among other wetland ecosystems, deltas are the ecosystems with the most dynamic and complex relations. This study comprises of wetlands of Göksu Delta which is located in the Mediterranean region of Turkey. Göksu Delta have one of the most important international wetlands that provide reproduction, nutrition and accommodation facilities for delicate, rare and in danger of extinction of many species. This area is also located on the one of the world's important bird migration route. In Turkey, approximately 450 bird species have been identified and 332 of them have been observed in the Göksu Delta. Globally, 12 endangered bird species out of 24 were also found in the Göksu Delta. Flora of the area consists of 384 taxa and among these, 5 of them on a global scale, 3 of them on the European scale and 43 which are rarely found species across the country are under threat. As a result of the hydrologic interventions and several human activities in Göksu Delta, the wetlands of Göksu Delta have been changed, many wetlands have extinct and Akgöl which was a temporary lake has been turned in to a permanent lake. This alteration has changed the cultural structure in the area totally and resulted in new settlement, production and consumption trends. The cultural life that emerged as a result of these alterations has also changed the way people utilize wetlands forcing people to adapt themselves to environmental conditions that have changed as a result of hydrologic intervention. Because of the cultural and biological values that the delta possesses, the area has been granted various protection statuses such as becoming RAMSAR site. Two different management plans also were prepared and work is currently underway as part of these plans between 1999 and 2009. However, the work currently underway is focused on the physical structure of the delta with the work related to the cultural qualities of the people living around the delta remaining limited. Thus, analyzing natural environment and human activities which are two interactive properties together would allow the protection activities to be carried out more effectively.

Addressing the information needs of farmers in North Rhine-Westphalia can help to promote sustainable land-use in overused landscapes.

Jenny Schmidt (Institut für Landschaftsökologie)

A research project about the ecological, economical and political information requirements and perceptions of farmers in the Region of North Rhine-Westphalia in Germany is used to evaluate the success of incentives to promote biodiversity in a highly agriculturally industrialized environment. Topics addressed within the project will include: · - Do farmers have sufficient knowledge about the advantages of biodiversity for their own fields? · - What does biodiversity mean for farmers? · - Are state-promoted programs providing credible and understandable information about the benefits? · - Is the financial incentive the main reason for farmers to take part in the programs? · - How do scientists communicate their findings to the general public and potential users? · - Are there incentives for scientists to engage with the civil society? Lessons learnt from other countries, especially so-called third-world countries will be adopted and applied to a Western society. The methodology will be chosen with emphasis on a two way flow of information and knowledge between farmers and scientists.

SE 02-01 - Border Water Scarcity

Chair: Matthias Moeller, Hermann Klug

Trans-boundary flood monitoring in Namibia using automated sensor web infrastructure

Jan-Peter Mund (University of Eberswalde), Joerg Szarzynski (United Nations University Bonn)

The paper presents an international multidisciplinary initiative's Namibia Sensor Web Pilot Project that represents a testbed for evaluating and prototyping main technologies for distributed data processing: sensor web, Grid and clouds. Like many other regions on planet earth the Southern African Development Community (SADC) region is threatened by several severe disasters in terms of floods and droughts in close connection with water borne diseases. Trans-boundary river systems in Namibia's northern areas are characterized by strong seasonal flooding of ephemeral drainage networks in a semi-arid environment. Exceptional floods, such as those occurred in 2008-2010, caused emergency disaster conditions for the local population and infrastructure development. Increased climate variability is currently discussed as one of the major drivers for such events. In addition, vector- and water-borne diseases and epidemics of weather- and climate-sensitive infectious diseases, including malaria, meningitis, and cholera, cause massive disruption to societies and put a heavy burden on national health systems. The Sensor 'Web Pilot project aims at developing operational trans-boundary flood management decision support system for the Southern African region to provide useful flood and water-borne disease forecasting tools for local decision makers. The effort consists in identifying and prototyping technologies which enable the rapid acquisition and dissemination of both space-based and ground sensor data and geospatial products from risk assessment for the purpose of flood disaster management and water-related disease management. An integrated Disaster Management System (DMS) is proposed to allow governmental and non-governmental organizations to handle the changing conditions and resulting threads. The overall system needs to combine real-time and near-real time sensor information on several physical variables necessary for flood and disease early warning and disaster response with pre-computed multi-risk assessment information based on geospatial and geo-statistical base data. To encounter these requirements the proposed overall framework consists of two core components: a Flood Sensor Web and a Hazard Monitoring and Mitigation System. The Pilot will support the deployment of

services as well as the development of a virtual infrastructure to support such services. The Pilot Project is established under the auspices of the Namibian Ministry of Agriculture, Water and Forestry (MAWF) Department of Water Affairs, and the Committee on Earth Observing Satellites (CEOS) - Working Group on Information Systems and Services (WGISS), and is moderated by the United Nations Platform for Space-based Information for Disaster Management and Emergency Response (UNSPIDER).

Integrated Water Resources Management and the Challenges of Action Plans in the Hadejia-Jama'are -Komadugu-Yobe Basin, Nigeria

Haruna Kuje Ayuba (University of Maiduguri), Mala Mohammed Daura (University of Maiduguri)

In recent times, the Federal Ministry of Agriculture and Water Resources (FMAWR), Nigeria and the European Union (EU) are partnering to support the piloting of Integrated Water Resources Management (IWRM) project in the Hadejia-Jama'are-Komadugu-Yobe (HJKY) Basin of Nigeria. The IWRM Project is part of the Water Supply and Sanitation Sector Reform Programme (WSSSRP). The IWRM Project aims to improve water governance in the basin. However, various institutions and organizations within the basin have developed many action plans, cutting across a wide range of environmental issues. In addition, not only are the institutions and organizations involved often uncoordinated, the action plans developed by them have not been integrated into a single and more comprehensive action plan. New developments within the basin also demonstrate the need for an updated action plan to take account of progress made and to ensure integrated water resource management (IWRM) and the conservation and sustainable use of natural resources within the economic and social development frameworks of the basin. This paper synthesized all the water action plans developed over the past 15 years in the HJKYB into a single, updated and more inclusive action plan for the basin to guide policy makers and the basin stakeholders. The plan consists of three major components, each of which is divided into sub-components: Development of the socio-economic and institutional resources in the basin, comprising the policy, planning and legislative framework, and capacity-building of the stakeholder organisations; Sustainable management of the basin's natural resources, comprising water and ecosystem resources; Increasing the knowledge base, comprising data, research and communication strategies. It builds on the present situation in each of these components to identify actions in

the short-term (~2 years), medium-term (2~5 years), with some actions for the long-term (~25 years). The emphasis is on specific and practical actions which can be undertaken by basin stakeholders. The plan proposes stakeholder responsibilities for implementing the various actions, and presents an outline budget. An updated and integrated action plan in the HJKYB will among other things provide solutions to the institutional problems which have hampered previous efforts at sustainable water resource management and integrated ecosystem management within the basin, establish a coherent basis for undertaking physical interventions and pilot projects in the basin and set a rational basis for data, research and communication strategies. The paper concludes by making some recommendations concerning dissemination of the plan.

Water-ecological aspects of transboundary cooperation in Continental Asia

Bella Krasnoyarova (Siberian Branch of the Russian Academy of Sciences), Yuri Vinokurov

Water resources are called the primary resources of the third millennium. Their availability and quality in many regions is a limiting factor for their development and a reason for interregional and international conflicts. In general Asia can be referred to the territories of water-ecological risk. Here, water resources are characterized by nonuniformity. The relationship between the North and the South is a problem of today taking into account the issue of water supply. The north possesses sufficient amount of water resources, while in Central and South Asia water resources are severely limited. It results in the outbreak of diseases and sometimes the risk of conflicts associated with water-related problems. In recent years, China being a peculiar kind of 'hydro-donor' of the region, finds itself in the center of water-ecological conflicts occurring within the Continental Asia. Here, such rivers as Brahmaputra (Matsang Tsangpo in Tibet), Hongha'RedRiver (Lishekhe-Yuantian in China) etc. originate. The most part of territories in Central Asia is provided by as many as half of water resources from abroad. Kazakhstan takes as much as about one-third of water from transboundary rivers rising from China. Thus the development of these countries directly depends on the economic and geopolitical behavior of China. Water-related interests of Russia and China intersect mainly in the basins of Irtysh, Ili and Amur rivers. Even with sufficient water supply of the Russian regions the issues of water apportioning and water quality are of great importance due to the increasing demand of population and expanding economy. In these

circumstances, the situation in the Irtysh basin becomes aggravated because of the presence of the 'third' countries when Russia is the 'second' user and gets water last after China and Kazakhstan without any participation in the agreement with these countries. Russia gets to choose between the passive participation in water management of the basin and the dynamic policy oriented to the conservation of water resources and the maintenance of the Irtysh status of significant artery. In Russia, water-related issues can be solved by two ways, namely, the construction of a dam near Omsk city and the construction of a reservoir for runoff retention. One more option is the construction of underwater artificial bars which allows the water level rise due to the reduction of flow rate. In our opinion, the second project is more preferable taking into consideration the water-related and ecological aspects. However, more conservative project on the construction of the low-head dam and a reservoir near Omsk city has been approved. The implementation of any of these projects deals with water management of Omsk city but not with sustainable water use in the basin. For this purpose more effective technological, technical and institutional efforts of three countries are called.

Drought management in transboundary river basins: An Iberian feasibility assessment on the Guadiana

Afonso Do Ó (Universidad de Sevilla)

Over the past several decades, increasing economic integration and the impacts of climate hazards, which know no boundaries, have brought transboundary environmental issues to the forefront of international political debate. In semi-arid regions, water risks and conflicts are of major concern, and call for a shared multilateral approach, particularly during water-stressed periods such as droughts. Shared river basins of the Iberian Peninsula, and particularly the Guadiana, are of major interest for Mediterranean Europe, because of its significant dimension, aridity, water scarcity, and drought risk. A political agreement (the Albufeira Convention) regulates water issues between the two riparian countries (Portugal and Spain), but an exception regime is applied under drought conditions (when the conflict potential is higher), water planning remains strictly at the national level, and the hydro-hegemonic position of Spain dominates negotiations. This paper seeks to identify the potential and constraints for an effective transboundary drought management for the Guadiana river basin. To achieve such goal, a preliminary SWOT analysis was conducted on each country's drought management framework, based on 24 criteria grouped into four major categories: Institutional Cooperation,

Environmental Protection, Social and Economic Dimensions, and Planning System. Secondly, ten key decision-makers were interviewed in both countries, allowing to: i) validate the preliminary SWOT analysis; ii) identify competences to be shared for mutual benefice (win-win situations); iii) define the best level of competence for drought response measures; and iv) identify risks associated to transboundary competences, thus setting a business model framework to be used on a joint process of river basin planning. General results show that the Portuguese situation is quite fragile when compared to Spain's, because of its downstream position, weaker social, economic and negotiating capacity, and poorer governance conditions. On the other hand, Spain faces greater internal challenges, due to an excessive irrigation demand, and increasing political power fragmentation. Interviews point to a 'depoliticised' transboundary model of river basin management, mostly restricted to technical competences, and identify several risks related to the implementation of such competences at the transboundary level - namely loss of sovereignty, excessive costs, poor communication, and mismatching planning structures between riparian countries.

SE 03-01 - Can we manage human-nature interactions?

Chair: Beate Ratter, Kirsten v. Elverfeldt

On the potential in a relational arena perspective for understanding landscape dynamics

Marie Stenseke (Human and Economic Geography)

Culture's importance to maintaining natural diversity and vice versa is widely acknowledged. Furthermore, it is recognised that the management of our physical environment has to be considered within a multi-dimensional framework embracing societal values such as human well-being and cultural heritage. Theories, concepts and methods to explore and explain the integrated relationships between the human sphere and the non-human have evolved in various disciplines. A number of scientific approaches with holistic ambitions has been presented, and these have to some extent also been applied in various contexts. There are, however, shortcomings related to these approaches, evoking the question if an integration of nature and culture in environmental planning is possible? This paper elaborates on the potential in a geographical relational perspective in addressing this issue. It relates to empirical cases in Peak District, England, the Cevennes, France and Kinnekulle, Sweden. A prerequisite for landscape research is the acceptance of some fundamental differences between studies of plants and animals and studies of the human society and human actions. Recognizing these differences implies for example that it is highly problematic to apply analytical concepts developed in biology on the human sphere. One complication for the commonly used system perspective on people and nature as well as for mapping are the diverging scales for ecological relations and human societies respectively, where the first have remained fairly stable over time, while the latter has expanded and new land use demands such as tourism and recreation have evolved. In the paper, it is suggested that an arena perspective, related to time-geography and its core aspect 'thereness' helps to capture human intentionality and improve the understanding of the inherent character of landscape dynamics.

State of Ukraine's socio-environmental system: Issues in striking the balance between development objectives of their components

Sergiy Lisovsky (Ukrainian National Academy of Sciences)

Ukraine's challenges to optimize the interaction between society and environment, to solve conflicts, aroused during formation of its integral socio-environmental systems in the process of socio-environmental interaction, represent crucial conditions to guarantee country's transition to sustainable development. At the dawn of the third millennium, irrational approaches to nature management in Ukraine resulted in national economy to become the most nature intensive in the world and all components of country's environment under powerful anthropogenic pressure. At the same time enormous scale of natural resource exploitation held back country's economic development and prosperity. Transformational processes which began and have been developing under the conditions of deep national and regional socio-environmental system crisis during 90's of the XX century and first decade of XXI century, aggravated the magnitude of old problems, and gave rise to new obstacles in the attempt to strike the balance between socio-economical development and environmental protection within the territory. We developed our own methodology for conducting multilayered (from global to local levels) comprehensive research on balanced development issues of environmental and social components within socio-environmental systems. To implement the methodology we developed and tested integrated benchmark indicator of the balanced development. We compared level of balance in development of some countries and territories in the world with Ukraine in within global commonwealth. The results we found allowed us to determine the Ukraine's position in balanced development among other countries, uncover and analyze resources and possible approaches to resolve the conflicts in Ukraine's socio-environmental systems and find ways for country's transition to sustainable development. We also conducted the research on regional differences in the levels of socio-environmental development balance. Based on the results we developed recommendations for country and its regions' smooth transition to the sustainable development. The main resources and potentials for Ukraine's balanced development implementation are human, farmland and natural resources, geographical position, socio-economic, scientific and know-how, historical and cultural resources. Implementation of transition to the sustainable development requires from Ukraine utilization of all its resources and application its full potential based on co-evolutional development, as well as resolution of all internal conflicts in the country's socio-environmental systems.

Managing river and floodplain interconnection: Can we turn back time?

Bernd Cyffka (University of Eichstätt-Ingolstadt), Florian Haas (University of Eichstätt-Ingolstadt / Aueninstitut Neuburg), Barbara Stammel (University of Eichstätt-Ingolstadt / Aueninstitut Neuburg), Peter Fischer (University of Eichstätt-Ingolstadt / Aueninstitut Neuburg), Gerald Blasch (University of Eichstätt-Ingolstadt / Aueninstitut Neuburg)

The Upper Danube has been embanked and straightened, and hydropower plants have been built on it since the 19th century. River and floodplain became disconnected, the hydromorphological situation changed dramatically and typical floodplain habitats, such as softwood and hardwood riparian forests, have been suffering and diminished nearly. The presented project aims to restore the former river-floodplain interconnection by bringing back water and sediment dynamics via technical measurements to the riparian forest. Three measures were implemented, notwithstanding the still existing dams. At first a new river on the floodplain, permanently flowing, was created to bring more water to the soil and groundwater body. Then, two or three times a year, water will be diverted for ecological flooding, and at last the constantly high groundwater level will be drained from time to time. To improve the measures, an extensive monitoring program was installed and should support an adaptive management. All these measures are controllable, but only possible if they are sustained by human engagement. The question is how intensive the human action must be, and how long the situation will be stable. At present it is something like 'faking nature', but of course the hope is that the system will become more and more self-sustaining. Is it really possible to manage this human-nature interaction? Can we turn back time and correct our mistakes?

Self-assessment tool on management effectiveness for UNESCO-biosphere reserves to manage human-nature interactions more successfully

Clara Buer (University of Greifswald), Susanne Stoll-Kleemann (University of Greifswald)

UNESCO-biosphere reserves are examples to manage human-nature interactions. Per definition, these model regions try to create and implement approaches for sustainable development while conserving natural and cultural diversity. In reality, its management bodies face various challenges by trying to achieve these aims. A self-assessment can help to reduce the gap between

concept and implementation. Therefore, this contribution addresses the following question: How can self-assessments on management effectiveness of UNESCO-biosphere reserve administrations help to improve the adaptive capacity? Instruments for a socioeconomic monitoring have been designed and tested in the context of a research project on societal processes in four German UNESCO-biosphere reserves (2009-2012). One of these instruments is a self-assessment tool on management effectiveness which is based on the WWF's Management Effectiveness Tracking Tool. In 2010 this tool has been tested with each of the four administrations. During a one-day workshop, 4 - 10 staff members joined an external moderated group discussion to assess their management effectiveness. The discussions were structured through a questionnaire divided into two parts: the valuation of 50 different external threats and the self-assessment which consists of 71 questions about e.g. management competencies, equipment, activities, and cooperation with stakeholders. The group discussions have been recorded and transcribed verbatim. Using the software tool ATLAS.ti, the data were interpreted according to a SWOT-analysis. The results show that most efforts of the administrations concentrate on conservation measures. Thus, to improve the implementation of the biosphere reserve concept, other aspects such as sustainable regional development, education, research, and monitoring need to be extended. In general, the self-assessment tool can foster adaptive management through: - Controversial discussions during the workshop which help to explicate different perceptions among staff members from different departments, e.g. about management priorities. This can firstly lead to strengthened mutual understanding and secondly, to a common identity of the management body. - The results can be communicated to the public and thereby increase transparency of management activities. - A comparison of the results with further monitoring results which directly detect environmental and societal changes allows explicating gaps between perception and reality. Direct actions can be derived from these findings to increase the adaptive capacity. If repeated biannually, this tool could be an essential part of an integrative monitoring programme for UNESCO-biosphere reserves. All in all, this self-assessment tool helps to identify concrete measures to improve adaptive management and to take on the challenge to manage the interaction of the society with its natural surroundings.

SE 04-01 - Capturing imagined invisibility: How to analyze social representations of climate change?

Chair: Lutz Meyer-Ohlendorf, Diana Reckien

Visions of climate change: reconstructing images of an invisible threat

Eva Noethen (Goethe-Universität Frankfurt), Antje Schlottmann (Goethe-Universität Frankfurt)

During the 1970ies a scholarly discourse emerged, and quickly gained popularity, that was concerned with the idea that a continuous growth of world population and its encroachment on natural ecosystems would result in global warming. Simultaneously, global warming as a threatening scenario became a major issue in mass media coverage. Today, according to omnipresent images such as thawing glaciers, shrinking polar ice masses, decreasing permafrost etc., it seems as if there is no doubt about global warming as a fact anymore. Recent approaches in cultural geography lead to a critical reflection of such discourses. In this context not only the social construction of global warming was emphasized, but also a simple understanding of the interplay of physical events ('nature') and their representation was questioned and re-theorized. However, emerging critical research focuses first and foremost on verbal discourse of climate change. This is remarkable given that contemporary communication processes are increasingly visual and assuming that visual communication is strongly related to the formation of collective knowledge assets. Moreover, visuality of any kind works in a direct and immediately affecting powerful way. Images work on the mind as well as on the body, evoking both emotions and motions. Though these latter effects remain often inconsiderate, it must be presumed that there is a strong interrelation of the body-related somatic work of images and social action. In our paper, we address questions of how and to which extent images of climate change in, predominantly western, mass media can be related to an everyday individual risk assessment and how visual representations are involved in confining scopes of action as a result. In this respect, we develop an action-oriented theoretical and methodological approach to the effects of visualities as well as to their modes of operation concerning required sustainable practices. In doing so, we compare examples from images of regions in the developed world to those in underdeveloped countries that both are obviously affected by climate change and that implicitly or explicitly appeal for taking action, although in different ways.

Today's life in the so called "developed world" is affected by a high level of technological development and an omnipresence of multimedia communication technologies. As a consequence, individuals are confronted with images of places or regions from all over the world. The globalization of information, however, of course also reaches the so called underdeveloped world. An unequal distribution of visual information derives from the power structures of stock photo agencies, rather than from territorial power structures. Beyond the geographical classification of a developed and an underdeveloped world, we thus call attention to the effects of the representation of development and underdevelopment in the discourse of climate change.

The Invisible as Event: Social Memory and Climate Science

Arne Harms (FU Berlin)

While anthropogenic Climate Changes are largely predicted for the future, they already do unfold in the present and have so in the recent past. Some of its effects – large or small, unexceptional or dramatic – fit uneasily into broader patterns of environmental hazards and changes. They are, therefore, not only challenging livelihoods, but also culturally mediated perceptions, cosmologies and interactions. Climatic changes, therefore, unfold against the background of ever-evolving natures, as well as ever-evolving societies and are deeply enmeshed in these. In more than one sense the roles and uses of the past therefore hold important clues for the socially bent climate sciences. Drawing on the dynamic field of inquiry which evolves around the concepts of landscape, environmental hazard and social memory, I will highlight in this paper the usage of remembrance as an analytic tool to understand environmental changes and related social adaptations or dislocations. This, I believe, might be helpful in many ways. Among others, it will allow for a better identification of social vulnerabilities and resiliences; to address pervasive issues of power; or to analyze culturally mediated and contested interpretations of (environmental) changes. Fundamental to these (and other) analytical trajectories is, I believe, an attention to varying temporalities. Related to Climate Change, two basic modes of social remembering will be distinguished. That is, on one hand, a remembrance of large scale disasters, that is often institutionalised and on a grand scale. This will be contrasted, on the other hand, with the socially structured and culturally mediated remembering of processual, but dramatic changes that amount to forms of 'slow violence' (Nixon 2011). While the former often play a decisive role in global mediascapes, it are the latter that do and might further endanger lifeworlds in large parts of the Global South without much public notice. The

attention to varying temporalities, to the eventfulness of the uneventful and to politics of remembering might help to better understand how largely invisible changes are perceived and related to by vulnerable populations. I will illustrate these considerations through findings from my own fieldresearch in coastal/deltaic West Bengal (India).

Participatory Mapping of local knowledge about climate-change related natural disasters

Christian Reichel (Freie Universität Berlin)

This article examines ways to complement the dominant normative and technological practise of catastrophe management by using local knowledge to improve the resilience against to climate-related risks. Based on comparative examples from Indonesia and Switzerland, it will be questioned how local perceptions and handling strategies of climate-related risks may be integrated within the politics of catastrophe managements in an effective way. Technical prevention strategies and local knowledge will be juxtaposed to examine their potential for contributing to improved resilience to climate-related catastrophes. In particular, it is shown in what ways an integration of local knowledge into catastrophe management contributes to effectively responding to the expected cultural, political, economic and environmental transformations which are caused by climate change. Participatory GIS mapping (PGIS) is the chosen method utilised in this research. It is a relatively new cartographical approach which includes local perceptions and handling strategies. It enables an improved communication of policy advice, thereby helping to implement an interdisciplinary cooperation within the academic world. Moreover, the approach fosters an active participation of local people in the process of catastrophe management.

Peasant perception and adaptation to climate change in the Sudano Sahelian zone of Cameroon

Marcel Nkoma (Ministry of Planning and regional development)

Climate variability continues to weaken the economies of African countries and threatens the security of the poorest. They suffer the impacts of many extreme weather events such as -floods, droughts and reduced rainfall. Climate variability and climate change are phenomena of concern, mainly because as Cameroon (occupying the 157th position in the human development index), part of which consist of a sahelian zone. Agricultural productivity is strongly linked to rainfall.

Indeed, the unevent distribution of water resources, 72% are located in the southern part of the country while in the north and far north water resources are limited. This situation reinforces the negative impact of drought periods. As a proceed longer, a result the desertification in this part of Cameroon. This are caused a fall in agricultural production is observed, especially for some crops like sorghum and long cycle maize. Despite continuing threats due to climate change, the country has not yet gotting and operational contingency plan to deal with these situations. Faced with these situations, a perception rather based on the qualitative elements, brings farmers from sudano sahelian zone to do a reading of climate change, including: (a) the constant uncertainty about the continuity of the vegetable cycle, (b) the repeat of the seeding over a year, (c) the rains do not mean the beginning of the growing season, (d) uncertainly about the end of the rainy season, (e) the decrease in performance. As a matter of fact, the perception of climate change by farmers from the plains of the far north of Cameroon is based on rainfall variability. Faced with these risks due to climate variability, vulnerable populations have no choice-they must adapt. Adaptation is not yet an alien phenomenon in the area. People have historically developed adaptation strategies. In this study, we identified seven key strategies to climate variability: (1) the predisposition to suffer losses (they are psychologically prepared to face the worst), (2) the constitution of emergency stocks, (3) the development of traditional cultural practices, (4) the change in cropping patterns, (5) the use of new plots, (6) the date change for some operations (sowing date) and (7) the counter-season cultivation of lowlands and irrigated crops (case of Mouskouari). Thus, before analyzing the various response strategies of the northern populations associated to climate disturbances, we will go through a preview of the peasant reading of climatic changes based of a perception of qualitative elements. The methodology used in this paper results from the combination of different aspects of empirical evidence and literature review unable to gather accurate statistical data for the study, we had to resort at times to extrapolation techniques.

SE 05-01 - Climate change – indications, dynamics and regional perspectives

Chair: Heiko Paeth, Dieter Anhof

New assessments of areas and equilibrium line altitude of Chukotka glaciers and their development projection for the near future

Maria Ananicheva (Institute of Geography RAS), Gregory Kapustin (Institute of Geography RAS)

New assessments of glacier areas were received by ASTER and World View-2 images for Meynypilgynsky Range (South-East of Chukotka), which was divided into 6 glacier systems. The difficulties and peculiarities of practically manual deciphering (processing of the images) are discussed. These areas were compared with the data of the Glacier Inventory compiled for this regions in 1980-s (Sedov, 1991). The areal reduction of the range on average is ~ 25% as compared with Sedov data. It is relatively large shrinkage among the glacier systems of the NE Siberia and northern Far East, the new areal estimates for which will be presented as well. Our areal estimates and use of DEMs and some assumptions made possible to construct the spatial patterns of the contemporary equilibrium line altitude (ELA) for the studied region. The map of the ELA allows defining sites of enhanced glacio-nival hazard risk besides the new evidence about meso -climatic features of the mountain glaciated region of the Meynypilgynsky Range. The ECHAM5 as a climatic scenario was used for projection of the glacier systems development in near future (2049-60). The method was described in some publications (Ananicheva et al. 2008, Ananicheva et al., 2010, The Cryosphere). It consists basically of construction of vertical profiles of accumulation-ablation for each glacier system by weather stations data and ELA patterns plus construction of hypsographic schemes (distribution of ice via altitude in the system) based on topography data. The results of the projection for the region studied is 17% reduction, it is quite modest retreat despite the 'warm' scenario. The main controlling factor is lack of precipitation caused by warming taking place there in present.

The seasonal transition of monsoon in Bangladesh and its association with atmospheric circulation

Roxana Hoque (Tokyo Metropolitan University)

This study presents comprehensive aspects of climatological characteristics of the monsoon seasonal transitions associated with the atmospheric circulation in Bangladesh, focusing on the pre-monsoon, monsoon and post monsoon seasons. In addition, the onset and withdrawal phases were examined using pentad and 20-day mean wind, moisture flux, precipitable water and rainfall distributions. These were obtained from Japanese 25-year re-analysis data from 1979 to 2003 and rainfall data from the Bangladesh Meteorological Department (BMD) from 1948 to 2008. Analysis of the pentad and 20-day mean the horizontal wind at 850 hPa, the total column water vapor flux, the precipitable water and rainfall distribution around Bangladesh showed that, the onset and withdrawal of the summer monsoon seasons in Bangladesh occurred between Panted 31 (May 31-June 4: P31) and P32 (June 5-9) and between P56 (October 3-7) and P57 (October 8-12), respectively. It is worth-noting that during pre-monsoon, southwesterlies wind, and water vapor flux zones are established around (24-29°N, 84-93°E), in P15-18 (March 12-31) over India and Bangladesh. At this time, the precipitable water distribution is found increasing. The rainfall distribution map also has shown obvious change in P15-18, at this time pre-monsoon rainfall observed northeast region at Sylhet station. These criteria indicate that precipitation gradually developing over land and the Bay of Bengal for the monsoon onset process. The dramatic changes have occurred during the monsoon onset period, between P31 and P32. At this time southerly wind, water vapor flux, and precipitable water are shown drastically stronger over the Bay of Bengal and Bangladesh. Drastic changes also have shown in rainfall distribution maps in P31-32, when abrupt increases of precipitation occur. Remarkable changes also have shown between P56 and P57, which is regarded as withdrawal of summer monsoon. At this time southwesterly flow vanished not only in and around Bangladesh, but also in almost the whole Indian Ocean and Indian subcontinent. Eventually the rainfall distribution maps have showed decrease in rainfall in P56-57. The annual cycle of 5-day mean rainfall has shown heavy rainfall occurs in the northeast region (Sylhet) during the pre-monsoon season and in the southeast region (Teknaf) during the monsoon season. The central west region (Ishurdi) receives relatively less rainfall in all seasons. Cluster analysis indicates that seasonal march of pentad mean precipitation at Sylhet is very unique pattern. Analysis of horizontal U and V-wind components, it has revealed that the V-wind component clearly defines the

monsoon onset and withdrawal and very clearly identifies the conditions of pre-monsoon, monsoon, post-monsoon and winter over Bangladesh.

On the recent upturn in precipitation north and south of the Sahara and its potential causes

Andreas H. Fink (Institute of Geophysics and Meteorology), Malvin Schneidewind (Universität zu Köln), Samo Diatta (Universität zu Köln), Julie Berckmans (Universität zu Köln)

Based on a comprehensive rain gauge data set for tropical West Africa and subtropical Northwest Africa, standardized precipitation indices have been calculated. Stations are sampled into rainfall regions that show coherent low frequency rainfall fluctuations. For Northwest Africa, the three regions selected are the 'Atlantic Region (ATL)', mainly comprising the area to the northwest of the High and Middle Atlas Mountains, including the Rif Mountains, the 'Region South of the Atlas Mountains (SOA)', and the 'Mediterranean Region (MED)', encompassing parts of northwest Algeria. In tropical West Africa, the 'Guinea Coast (GC)', the 'West Sahel (WS)', and the 'Central Sahel (CS)' regions are considered. For Northwest Africa, the hydrological years Sep./Aug. 1900/01 through 2010/11 (base period 1961-1990) and for West Africa the rainy season from June-September 1921-2011 (base period 1950-1990) are considered. For the GC, the entire year as well as the two rainy and dry seasons will be analyzed separately. In the two Sahelian regions, the 11-year running means of the precipitation index indicate average rainfall conditions in the early and mid 2000s for CS and WS, respectively. The recovery from the drought in the 1970s and early 1980s started in the late 1980s, but was sustained not until the late 1990s, with the upturn occurring earlier in the CS when compared to the WS. As is well known, the GC exhibits stronger interannual than decadal rainfall fluctuations. However, a recent decadal wetting trend is also evident for the climatologically wetter southern part of West Africa. In this region, rainfall in the large dry season (December-February) and the stronger first rainy season (May-June) show the most pronounced decadal moistening trend in the recent decades. Overall, Northwest Africa also exhibits wetter conditions recently. In the ATL region, several wet years occurred in the last two decades, interspersed with single drought years, such that a sustained long-term upward trend is yet uncertain. A clear moistening trend is seen in MED that shows some coherence with the Sahel time series. In the SOA, recent years have been almost exclusively wetter than normal. Potential causes are discussed that are mainly concerned with changed patterns in Atlantic sea surface temperatures (e.g. the 'Atlantic

Meridional Mode' and 'Atlantic Multidecadal Oscillation'), variability in tropical extratropical interactions, and the occurrence of upper-level troughs over Northwest Africa in relation to the phase of the North Atlantic Oscillation (NAO).

Climate driven changes for food- and waterborne diseases

Christoph Höser (University of Bonn), Jan Semenza (ECDC), Thomas Kistemann (University of Bonn)

The focus of the ongoing research topic described in this presentation covers food- and waterborne diseases like Norovirus infection, Salmonellosis, Cryptosporidiosis and Campylobacteriosis. The seasonal outcome of incidences covers a dense spatial and temporal variability. A close examination of weather conditions has been applied on each of the 30-day-periods preceding each of the reported incidences, based on a spatial resolution of a grid of 0.25 x 0.25 degrees in Germany. Due to the different incubation time and infection pathways the pathogens have been treated separately. Aspects of weather examined are precipitation, air pressure, maximum temperature, minimum temperature and mean temperature, all on a daily basis. The time span covers years 2001 to 2011. The resulting database has been visualised in interactive 3d animations. The visualizations show the pathogen-specific weather circumstances which do precede elevated incidences. Elevated incidences are preceded by a characteristic 30-day-weather-history, which is significantly different from lower incidences of the very pathogen. While each of the weather aspects do show its incidence- and pathogen-characteristic outcome in general, especially the precipitation-pattern shows up a day-to-day history of dry and rainy days within the 30-day-history examined. The results have been tested by Median-Test, Siegel-Tukey-Test and Kolmogorov-Smirnov-Test to determine the significant days within the characteristic weather history and again have been rechecked by the results of an extensive literature research. Thus a pathogen-specific weather-setting can be described which is pathogen friendly and may be followed by elevated incidences. But again pathogen-friendly weather conditions may support the incidence outcome but will not be able to force infection in an imperative way. Therefore the predictive quality has been checked by historic data, to achieve sensitivity and specificity and at least an impression of uncertainty. Regarding climate change the long-term scenario A2 has been taken into account to check the probability of the identified weather conditions for the next decades to come. Several climate change scenarios describe general settings for climate variables which may take place within the next decades to come. The resulting effects of changed variables have been

examined on a local scale and a dense time-resolution to cover the pathogen's opportunistic flexibility. Infections from food- and waterborne related pathogens do profit from pathogen-friendly weather conditions which are presented. The probability of these weather conditions within climate change scenarios may be an indicator for future outcome of incidences, thus adding a piece into the puzzle of a comprehensive picture of the future climatic conditions and its effects towards human health on a regional basis.

SE 06-01 - Contextualising gender and climate change

Chair: Kim Philip Schumacher, Astrid Ulloa

Climate justice and gender justice: Women in the climate trap

Sybille Bauriedl (Universität Kassel)

There exists no gender-neutral climate change, mitigation or adaptation. As climate change is an issue of ecological and social relations, the impacts and origins of climate change are always gender relevant. 'Climate change' is a powerful discourse with implications for gender hierarchies. The sustainability discourse of the 1990s constructed woman as environmental protectors and experts of local resource managers. With the climate discourse women lost this active role and got the role as victims of multiple vulnerabilities. Within climate studies of the last decade woman became objects of risks and vulnerability analysis, and at the same time they were excluded from local and international climate policy. Climate mitigation and adaptation are political projects and as so they reproduce, stabilize and intensify gender hierarchies - even though climate researchers recognize social justice as important element of adaptive capacity. Statistical data prove the argument of women as more vulnerable group, if women and man are observed as homogenous groups. Women are not more vulnerable as men because of natural hazards but because of socio-economical inequality. Some people are more vulnerable because they do not get access to land, education, income, political participation, knowledge. But they are not vulnerable because of their biological gender. Women are acting subjects of climate change - and gender hierarchies. White, middleclass men of the north should not be the unquestioned standard category of mitigation and adaptation, if climate researchers want to create efficient strategies for a sustainable and low carbon society and economy. I will summarise the main debates on gender relations within climate studies for the issues of gender specific vulnerability, perception of climate risks, involvement in climate change, adaptation, burden of mitigation, and participation in climate policy. The paper offers a theoretical contribution for a gender sensitive climate research with approaches of a feminist political ecology and intersectionality. These approaches helps to deconstruct the narrative of a poor rural woman in undeveloped countries as climate victim and its implications of a north/south and women/man-dualism.

Adaptation to climate variability in small holder irrigation farming: A component of the gender contract

Martina Angela Caretta (Stockholm University)

'Gender contract' is defined as a set of power structures creating relations among men and women (Forsberg, 2010). These contracts constitute gender regimes where women face several constraints in terms of labor and decision making processes (Chant, 2007). The articulation of the gender contract into labor division shapes the attainment of knowledge for both men and women and determines their perceptions and responses to climate variability. The terminology of 'climate variability' takes into account both singular weather events and extremes, which farmers seem to remember better. Moreover, climate predictions for Eastern Africa, where the study was conducted, are not conclusive, while the existence of long term climate variability, possibly part of more complex process of climatic change, has been assessed (IPCC, 2007). This paper presents the findings of a multiple case studies investigation carried out in small holder irrigation farming communities in drylands in Eastern Africa. These locally developed irrigation systems are managed through a complex gender contract. Women, prohibited from irrigating, carry out soil and crop management, while men irrigate, clear out and fence plots of land, when needed (Watson et al., 1998). The division of labor reflects itself on the distinctive local division of knowledge. Women discern the characteristics of seeds and crops in relation to different climate conditions and are aware best practices to maintain and improve soil fertility. Men are involved with the construction and reparation of the furrows, which entail knowledge on erosion management and efficient irrigation distribution. Despite the fair amount of literature devoted to the analysis on the social organizations of irrigation systems in drylands in Eastern Africa (Davies, 2009; Östberg, 2004; Watson et al., 1998; Adams et al., 1997), the attention paid to gender relations has not gone beyond a mere descriptive approach. Especially it has not been studied how the local gender contract manifests itself, is articulated and negotiated. This is crucial in relation to adaptation to climate variability. Indeed, findings show a mismatch in the practice and knowledge divide: whereas men are officially recognized as climate predictors, women farm and depend on climate conditions. Nevertheless, women pragmatically assert their knowledge by making autonomous soil and crop management decisions and negotiating communities' decisions through self-organized groups. Participant observation, in-depth interviews and focus groups with both men and women resulted in narratives of gender specific memories and perceptions of climate variability. This shows that adaptation to climate variability in relation to

soil and crop management is a critical aspect of the gender contract and is constantly re-negotiated to bear for instance, periods of hardships or to turn an extreme weather event, as unexpected rains, into an opportunity to produce cash crops.

Gender Justice in Climate Change Politics and Research: Perspectives from Latin America

Dörte Segebart (Freie Universität Berlin)

The paper applies the concept of environmental justice for analysing aspects of gender justice in climate change politics and gender-specific impacts of climate change in Latin America. As environmental justice analyses aspects of distributive and of procedural (participative) justice, the paper focuses on aspects of gender-specific natural resource use, on the distribution of environmental costs and risks referring to the impact of climate change and is therefore analysing gender specific vulnerabilities. Gender-specific possibilities adopting adaptation as well as mitigation strategies will be assessed. Recent policy processes, regulations, political participation and ongoing struggles in Latin America referring to gender and climate change issues will be critically reflected and evaluated. The paper expounds the problems of uncertainty, of gender-blindness in climate change research and political processes, as well as of exclusion mechanisms in global climate change discourses and practices affecting most vulnerable groups. Based on the Latin American experiences, the paper concludes with general recommendations towards more gender justice in climate change politics and research.

Implications of global climate politics on Indigenous women in Colombia

Astrid Ulloa (Universidad Nacional de Colombia)

This paper presents the effects of the discursive formation and ecogovernmentality related to climate change in the local context. One of the strongest criticisms of global politics related to climate change is the lack of inclusion of other knowledges, notions of nature and gender perspective. Measures to control climate change have focused on commitments and agreements related to the reduction of greenhouse gases, and less into consideration of different cultural conceptions and local environmental realities. Similarly, there are few references of the relationship of both indigenous men and women with nature and the effects of climate change in their cultural

practices. This paper specifically focuses on the territories of indigenous peoples and the social implications of these processes in indigenous women lives. At the same time, it looks for local proposals and alternatives to face climate change. The proposals of indigenous women have shown the existence of border thinking, other positions towards climate change, which express a different logic related to territory and nature, which have generated specific use and appropriation of natural resources. Finally, it will present the indigenous women demands related to the recognition of their rights of self-determination, access and control over their territories and resources, and the right to participate on equal political conditions at the time of making decisions about actions required to mitigate the effects of climate change.

SE 07-01 - Crossing boundaries in human-environment-system research: Exploring transdisciplinary approaches 1

Chair: Ulli Vilsmaier, Daniel Lang

The 'Lifeworld' and Transdisciplinary Development Research between different Knowledge Paradigms

Anna-Katharina Hornidge (University of Bonn)

Within ongoing debates on transdisciplinarity and transdisciplinary approaches in the addressing of 'real-life' problems, the inclusion of local lifeworlds in the research process to facilitate the local fit of the research outcomes is repeatedly stressed. While sharing this conviction, the here proposed paper aims to discuss the role of all lifeworlds involved in a transdisciplinary research experience, including besides 'the local lifeworlds' additionally 'the lifeworlds' of the often not-local researchers and representatives of funding institutions. It is therefore the aim of this paper to shed conceptual and empirical light on the notion of the 'lifeworld' in transdisciplinary development research by (a) discussing the concept of the lifeworld, as originally developed and defined within the phenomenology of knowledge and especially by Alfred Schütz (1932), as well as later further deepened by Schütz and Thomas Luckmann (1979), with reference to ongoing discussions on transdisciplinarity; and (b) assessing the experiences of a German-funded, three year transdisciplinary, development oriented innovation research in Uzbekistan[1] with regard to the interaction and close cooperation of three different types of lifeworlds: foreign researchers, Uzbek researchers and local Khorezm water users and managers. The paper thus hopes to contribute to an increasingly growing body of scholarly work on transdisciplinary research, empirically by offering further insights into the role of lifeworld interpretations of reality of foreign and local researchers as well as local stakeholders in processes of transdisciplinary interaction, and conceptually by bringing some of the original thoughts on the notion of the 'lifeworld' by Schütz and Luckmann back into ongoing discussions on transdisciplinarity. [1]Precisely the 'Follow-the-Innovation' experience conducted in the realm of the interdisciplinary research project 'Economic and Ecological Restructuring of Land- and Water Use in the Region Khorezm (Uzbekistan)', funded by the Federal Ministry of Education and Research of Germany and implemented by the Center for Development Research, University of Bonn.

What role for scientists in transdisciplinary approaches?

Michael Stauffacher (ETH Zurich Institute for Environmental Decisions (IED))

Scientists involved in transdisciplinary (td) research can jeopardize their societal role: abandoning the classical role of 'speaking truth to power', scientists may end up as 'political activist'. Such peril is not unique to td research, but common in many applied, commissioned research or sustainability transition setting. To critically review td approaches, I present some conclusions from the perspective of the sociology of science. In essence, these views point to the development of role conflicts for scientists involved in transdisciplinary projects. In addition to soundness of science, scientists are as well responsible for the usefulness of their results. Some scholars argue that transdisciplinarity cannot be understood as science but rather as policy advice or even more bluntly even as policy itself. It is as well argued that quality of its output cannot be guaranteed as peer review only functions in a precise disciplinary context. In contrast, I stress that (i) transdisciplinarity is a scientific activity not 'just' policy advice or politics, (ii) a balance between soundness of science and societal usefulness of its results is possible (and without promoting neo-liberalism), and that (iii) scientific quality of research within a transdisciplinary setting can still be evaluated based on disciplinary standards (but not alone). To justify these claims I will refer to several necessary characteristics of a td approach: (i) the need for the translation of a real-world problem into one or more epistemic objects and as such being able to integrate and contribute to disciplinary knowledge bases, (ii) the careful reflection on the broader societal decision process(es) the td project is embedded in and the different roles scientists can and must not take over, (iii) the importance in this respect of a functional perspective of transdisciplinarity (i.e. why do we need whom, when and for what purpose contributing to the project?), (iv) the distinction between different discourses/processes on going in a td project (epistemic, value, interest) and the respective responsibilities. With respect to the role td can play in the science system, I argue that in fact td is a promising approach for disciplinary researchers to formulate innovative research questions and as such can have a much broader impact. In fact, the relation between disciplinary research and td research will be in my view decisive for the success of td in our present science system. I will conclude by pointing out, how crucial it is to combine this rather instrumental view of the role of science in transdisciplinary projects with a more reflective and critical stance towards present societal developments.

Mixing and modifying methods for the generation & integration of knowledge

Renate Renner (University of Graz), Ulrich Strasser (University of Graz)

TOURIEN Liezen is a transdisciplinary (td) research project that aims at combining tourism and sustainable energy production. Liezen is an alpine region in Styria, Austria and its citizens strongly identify with and gain an important income by tourism. In terms of the regional development different stakeholders from Liezen pursue diverse and on the first sight conflicting future aims. Some are interested in the enlargement of sustainable energy production by, for instance, using wind power and by building hydropower stations and photovoltaic parks. Others think this would destroy the unspoiled countryside, which is very important for tourism. Td research anticipates to have the capacity to solve complex life world problems and to achieve consensual solutions by those involved (cf. Pohl and Hirsch Hadorn, 2007). In order to allow those involved to define their 'life world' (ibid) problem, we did not apply for a clearly defined research project but integrated a pre-phase (1 year) that includes the development of a stakeholder network, generation of system knowledge and structuration of the research problem. Besides, we will meta-analyse the need for different methods, regardless of whether these are approved td methods, disciplinary methods or suchlike, that will become modified within our research for the requirements of transdisciplinary research. Ergo, we focus on the first phase of this td research project and observe the impact of applying and mixing certain methods for the generation of system knowledge and for the integration of scientific and societal knowledge. Experiences within this first phase of research will be documented and critically analysed for consequential learning. Beyond, we will compare our results with data from selected td research projects for the purpose of developing a deeper understanding of methodological requirements for knowledge generation and integration in td research. Pohl C. and Hirsch Hadorn G. (2007) Principles for Designing Transdisciplinary Research - proposed by the Swiss Academies of Arts and Sciences. München: oekom.

Transdisciplinary co-production of strategies for sustainable water use

Flurina Schneider (Institute of Geography of Berne), Stephan Rist (Centre for Development and Environment (CDE))

Both climate change and socio-economic development will significantly modify the supply and consumption of water in future. Consequently, regional development has to face aggravation of existing or emergence of new conflicts of interest. In this context, transdisciplinary co-production of knowledge is considered as an important means for coping with these challenges. Accordingly, the MontanAqua project aims at developing strategies for more sustainable water management in the study area Crans-Montana-Sierre (Switzerland) in a transdisciplinary way. It strives for co-producing system, target and transformation knowledge among researchers, policy makers, public administration and civil society organizations. What kind of research design is needed in order to achieve this goal and how can academic and non-academic knowledge be related in this endeavor? In the MontanAqua project, the process of collaboration between researchers and scientist started when the research proposal was elaborated in order to achieve sound life-world orientation. Later, it was centered on a process of participatory scenario development where the stakeholders' visions of regional development (target knowledge) are linked to the scientists' models on water resources, distribution and use (system knowledge). This step lays ground for jointly assessing the consequences of the stakeholders' visions of development in view of scientific data regarding governance, availability and use of water in the region as well as developing necessary transformation knowledge. The aim of the talk is to evaluate potentials and constraints of the applied transdisciplinary approach regarding the joint production of strategies for sustainable water management.

Participatory strategy development to increase renewable electricity production – a transdisciplinary process

Meike Düspohl (J. W. Goethe University), Petra Döll (J. W. Goethe University)

The stability of our climate system is in danger (IPCC 2007). To stabilize the system, CO₂-emissions from fossil fuel use quickly have to be reduced. Also in view of the recent incidence in Fukushima, a transformation of the energy sector to a sustainable supply system based on renewable energy is essential. Transformation of the energy system of a region requires a region-specific strategy that is supported by a broad range of stakeholders. The county Groß-Gerau in the German state of Hessen aims at covering by 2020 30% of its energy consumption (without traffic) out of renewable energy. For reaching this goal in Groß-Gerau a transformation-process in the county and its communities has to be set up. To tackle the transformation process with the right strategy different forms of knowledge (academia and non academia) has to be generated and integrated into this process of strategy identification. The different types of knowledge for the transdisciplinary approach are system knowledge, transformation knowledge und target knowledge. Therefore different stakeholders have to participate in the strategy formation. However, there is no well-established standard design for a successful participatory, transdisciplinary process. We will present the concept and tools that support the process for the elicitation and integration of stakeholder perspectives in the problem field of sustainable renewable energy use. In this paper, we aim at presenting the concept and tool that enable participatory process for the elicitation and integration of stakeholder perspectives in the problem field of sustainable renewable energy use. Preliminary results will also be included. Actor-based modeling (ABM) and Bayesian Networks (BNs) are adopted in this study. ABM is performed by the software DANA (Dynamic Actor Network Analysis) and BNs by the software Netica. For initiating the process, a total of 15 most relevant institutional actors, inter alia, energy sector, financial sector, public decision makers, and NGOs are identified. The representatives have been interviewed individually and invited to participate in the first workshop. A total of four

workshops is planned throughout the study period. The problem perceptions and the goals that guide the actions of the representatives are depicted in causal networks. Subsequently, these networks are discussed and exchanged in workshops. Apart from eliciting problem perceptions, alternative actor-based scenarios of the development and implementation of renewable energies will also be developed. In this study, the impact of the applied participatory method on social learning of the involved actors will be evaluated.

Participatory regional scenarios: Serving scientific and applied purposes

Jennifer Hauck (Helmholtz Centre for Environmental Research - UFZ), Jörg Priess (Helmholtz Centre for Environmental Research - UFZ)

The use of the limited resource land for one purpose often excludes other uses. Trade-offs may be complicated under conditions of Global Change and increase the complexity and uncertainty under which land use decisions have to be made. In the context of the research topic 'Land Use Options - Strategies and Adaptation to Global Change' of the Helmholtz Terrestrial Environment Programme we address this complexity and uncertainty by developing land use-scenarios with two different stakeholder groups. One group consist of scientists including social, economic and natural science disciplines. The other group comprises representatives of different groups of practitioners from regional NGOs, planning and state agencies. Participatory scenario development combined with rigorous quality control measures is considered a process suitable to develop scenarios serving not only scientific purposes, but also practitioners. Repeated reviews and other feedback mechanisms ensured relevance for scientists and practitioners, legitimacy and scientific credibility of the scenarios.

A transdisciplinary approach to the evaluation of coping and adaptation in the context of changing water-related hazards

Maria Schwab (UNU-EHS)

Water-related hazards threaten a high number of people in the world; these risks take on even greater importance in the light of rapid social and climate-induced changes often observed in the most vulnerable regions. The actual implications of the prevailing risks for both the people and the environment depend crucially on the capacity to act sustainably. It is therefore important to gain a better understanding of coping and adaptation in the light of a changing social and

ecological system, their limits and opportunities and, in particular, each strategy's value for different stakeholders. This demands for integrative transdisciplinary approaches in order to not only grasp the tangible effects on society and the environment but to see their dynamic interplay and the actual value of these effects for the stakeholders. Coupled social-ecological system theory and especially the related vulnerability research provide a basis for such an analysis and evaluation of coping and adaptation strategies. It can convey a better understanding of system dynamics, tipping points and transformations doing justice to the complexity of an action's implication for nature and society. Nevertheless, a mere system-based approach neglects the perceptual dimension of the research problem. A more actor-centred view can, in this regard, convey a good intuition of how people perceive their environment, how they act and how these actions as well as changes are valued. This transdisciplinary concept demands for a mixed-method approach when taking this lens to look at the real world. It is necessary to not only follow a single methodological paradigm but to apply qualitative, participatory and quantitative research in a complementary way. Participatory group discussions and role playing games, for example, can facilitate an understanding of priorities and perceptions whereas secondary data and a semi-structured household surveys can provide the foundation for quantification and validation. In consequence, this approach can show the differences in the actions of groups confronted with different hazard and vulnerability patterns, especially in regard of their adaptive capacity. For some stakeholders, appropriate informal individual and formal governmental strategies might keep on being just an option whereas others have the capacity or access to actually benefit from their implementation. These benefits as well as the costs can affect both nature and society. It can be shown what the actual social and ecological outcomes are and reveal why it is not only them but also individual priorities which make a strategy a 'good' or rather a 'bad' one. Having found how people act and value actions allows depicting the sustainability of coping and adaptation and may also provide a basis for predicting future sustainability when applying the concept in the context of hypothetical actions in different scenarios.

Transdisciplinary Evaluation of Alternative Adaptation Strategies – Value-Tree Method as a Tool to Integrate Multiple Values of Science, Practice and the General Public into Decision-Making

Anke Schmidt (Leuphana University Lüneburg), Meinfried Striegnitz (Leuphana University Lüneburg), Mirjam Willert (Leuphana University Lüneburg)

Coastal protection strategies increasingly have to take into account the effects of climate change. At present, engineering and natural science models that assess the impact of global climatic transformations on regional coastal zones remain rather detached from societal bodies of knowledge. Various adaptation options may conflict with value-based interests and priorities of different actors. This paper argues, that innovative coastal protection requires not only inter- but transdisciplinary research that takes into consideration the whole array of actors involved in regional coastal protection. The findings presented in this paper result from the 5-year research project A-KÜST "Changes in the Coastal Climate: Evaluation of Alternative Strategies in Coastal Protection" that was launched in 2009 in the context of the Climate Impact Research Programme (KLIFF) of the German federal state of Lower Saxony. The transdisciplinary project is structured into natural, engineering and social science subprojects. In addition, the project comprises an advisory board with all relevant actors participating in coastal protection in the project region (Ems-Dollard estuary, Southern North Sea). The findings are based on an evaluation study -conducted within the social science subproject- which focuses on disclosing and structuring latent value-based interests and objectives of different actors and integrating those into a multi-criteria evaluation of alternative adaptation options in coastal protection. Therefore the value-tree method was applied during moderated group discussions with representatives from institutions that are concerned with and affected by coastal protection, to identify different value judgments. In a second step the evaluation criteria against which different alternative adaptation options are to be evaluated were developed. The main objective of the value-tree method was to create a comparable and sound framework of evaluation patterns of all relevant actors related to regional coastal protection. This analysis reveals a heterogeneous picture of areas of consensus and of striking differences that may have many implications for the collective strategy development process. The extracted evaluation criteria broadened the catalogue of criteria against which alternative options for adaptation are evaluated. The value-tree analysis turned out to be a promising methodological approach that can be embedded in transdisciplinary research contexts, by meeting the requirements of integrating the whole array of societal and scientific actors, their

knowledge and interests in a transparent procedure. Reflecting the diverging or resembling interests, objectives and perceptions fosters the communication and common understanding among science and practice and finally fosters the societal anchoring of adaptation strategies within the governance network of regional actors.

Transformations in spatial meaning production of public space: A perspective on GeoWeb users as agents of change

Florian Fischer (Alexander von Humboldt Institute), Robert Vogler (Austrian Academy of Sciences/Institute for GIScience)

The GeoWeb (i.e. the convergence of geospatial technology, mobile web and social media) recently enabled an environment for participation in the production and distribution of geographic information. A vivid mash-up culture let emerge a variety of geomedia, promoting space to a new paradigm for online search, communication and interaction. Geomedia provide a way to recollect physical location in today's networked and multiplexed spatialities. While everyday life is shaped by physical nomadism, flexibilisation, fragmentation and global flows of goods and services, geomedia facilitate new relationships between people and places far beyond a filtering by physical proximity only. New forms of spatial augmentation inherently transform the publicness of space, as the debate about Google StreetView shows. Current research depicts that social location services serve a consumer society for mastering urban heterogeneity and are used to facilitate new forms of empowerment in the appropriation of public space. Contributing users become new gatekeepers who mediate between local businesses and customers. Thereby new modes of spatial meaning production emerge, including partial publics with the capability to contribute. Hence users of these services can be considered as agents of change in networked urbanity. However there are substantial indices for the exclusion of potential users. The platforms are shaped through functionalities by their providers and the intentions of contributing users who need to hold certain means of production in order to become new gatekeepers. Hence the emerging reassemblies of meanings on physical space are not comprehensive or neutral, but biased by intentions of portal operators and practices of contributing users. Furthermore users produce information that assist for social and spatial sorting and is valorized by platform providers in commercial relations with third parties. At the moment we just started to understand how digital citizens perform public space in the context of its transformation by the GeoWeb. Consequently, it is uncertain how users will deal with the extended publicness and what tactics will emerge to appropriate it. It is unclear what ethics will arise for practices of companies in the GeoWeb, and

how they will be able (or have) to adhere to them in future. Nevertheless, in a democratic society it is crucial that citizens are aware of these new modes of spatial meaning production regarding both empowerment and exclusion. This awareness can be mediated best through education. In consequence and based on the premise that its aim is to foster 'actualized citizens', future (spatial) citizenship education has to enlighten about these new phenomena arising out of the (Geo)Web. Based on examples and results of empirical research, this presentation will reveal the transformative capacity of the GeoWeb for the becoming of public space and sketch the consequences for (spatial) citizenship education.

GIS education on the test: Findings from a systematic review in GIS education research

Uwe Schulze (University of Koblenz-Landau), Detlef Kanwischer (University of Koblenz-Landau), Christoph Reudenbach (Philipps-University Marburg)

Due to the increasing relevance of digital geodata and various GIS applications as smart tools in everyday life, the experienced handling of geoinformation and communication technology (geo-ICT) has not only a high meaning in professional fields, but also for the individual's communication and participation in social contexts. Since generally the role of GIS as a supportive tool for students competence development in the classroom has been recognized in recent years, a more specific question arises for the different levels of education: which competences must be considered essential for a successful application of GIS and geoinformation? While the identification of professional competences depends on the needs of specific domains, the redefinition of generic skills occurs mainly due to societal pressure. Under the phrases of 'information based society' and 'lifelong learning' a harmonization of key competences takes place on an international-scale. Particularly the outcomes of the ICT driven Assessment and Teaching of 21st Century Skills project evolves an interesting framework for the discussion on competence orientated GIS education, because it can serve as a basis for a conclusive connection between the demands of an ICT related education of the 21st century society to the development of GIS curricula. Our research addresses the interplay of three competence dimensions that gained importance to GIS education and training: problem-solving, spatial thinking and procedural KSC in GIS&T. Based on our qualitative content analysis of international documents on GIS curricula, we hypothesize that problem-solving capabilities have a fundamental impact on the development of spatial thinking skills and technical as well as methodological

KSC in GIS. However, it is unclear how these core competences are distinct from each other and how they interact, especially under conditions of domain-specific technology - like GIS. Therefore, and to arrive at empirically validated evidence for the development of GIS curricula standards, effective assessment tools and test designs are needed. But, which are they? Against this background, our contribution focuses on the question which methodological approaches are currently used to investigate and assess student learning with GIS? We therefore conducted a systematic review of primary studies in GIS education from 2006 to 2011, using pre-planned methodologies and statistical analysis. Our population relates to peer-reviewed articles in relevant journals and publications, e.g. *Journal of Geography in Higher Education*, *Journal of Geography* as well as the proceedings of the annual forum *Learning with Geoinformation*. Introducing our results, we focus on the foundation of a consistent research framework for GIS education, discussing the scope of the used research questions, the survey instruments as well as the value of the obtained findings of these studies.

Expanding AND shrinking worlds of geo-communication: Spaces of complex technology and the geographies of common lifeworlds

Tilo Felgenhauer (Friedrich-Schiller-Universität Jena)

Late modern societies tend to develop many different specialised and mutually opaque contexts of knowledge and action. For example, technology-driven expert systems stand in a deep contrast to the lifeworlds of lay users. Thus, everyday routine action (such as mobilities of people, things and symbols/communication) requires the constant translation of technological 'geo-codes' into everyday geographies of the individual's home, of place, region and national territories. From the understanding of postal codes to the use of satellite navigation - both expert and lay competences are necessary to carry out successful interactional routines. Especially, current innovation in interface design shows remarkable changes in the way geo-information is managed and in the way its diffusion is supported. Given this background, the question arises, how these manifold routines of interaction and translation (especially, its ambiguities) can be interpreted in a cultural geography perspective. Focussing the lay user's position, two concurrent trends will be identified and discussed: Firstly, the offering of unprecedented possibilities to gather geo-information and, secondly, at the same time, the release from the necessity of comprehending and reflecting on geo-information in order to make use of (geo-)technology. On the one hand, formerly opaque and highly complex technological systems seem

to become transparent for a more and more sensible audience of lay users. On the other hand, examples from interface design reveal a general tendency to 'lifeworld-simulation' by replicating the individual's spatial perception (such as in augmented reality applications for smart phones which reduce geo-information to the user's actual surrounding).

Professional GIS Training programme at Universities in Cambodia

Jan-Peter Mund (University of Eberswalde)

This paper presents the development, implementation and lessons learnt about a new professional GIS education programme in Cambodia and document a critical geography approach to solving a geographic, environmental and GIS education problem. Land management and land administration are defined as a system of planning, management and administration methods and GIS based techniques that aim to integrate ecological with social, economic and legal principles in the management of land for urban and rural development purposes. The main objective is to meet changing and developing human needs, while simultaneously ensuring long-term productive potential of natural resources together with maintenance of inherent environmental and cultural functions. In the wake of social and political turmoil in Cambodia's recent history in the late twentieth century, there is rising demand for transparent land management and land administration that paves the way for economic development in the country. This results in demand for educated young professionals in Cambodia in the related areas of Geomatic and GIS training courses for land management, land administration, surveying and remote sensing. Therefore, the Cambodian Ministry of Land Management, Urban Planning and Construction in collaboration with the Ministry of Agriculture, Forestry and Fisheries initiate a long term capacity building process for GIS based land management in Cambodia. Subsequently the Royal University of Agriculture in Phnom Penh was given the task in 2002 to set up an undergraduate programme and a GIS short training course leading to a Diploma Degree for continuous education of ministry staff. In Cambodia, no such education was ever offered until the establishment of the new Faculty of Land Management and Land Administration within the Royal University of Agriculture. Consequently there was a deficiency in human resources to develop the new curriculum and to establish the faculty at the national level. While geographic education in schools will provide this pool of human resource in the long term, the immediate needs can only be met through professional development and GIS teaching for existing workers and officers in these areas. It is also through professional development that education for

sustainable development (ESD) will have the farthest reach in society, in this case. In addition to providing the empirical evidence for the lack of professional GIS education, this paper describes how the researchers are agents of change in creatively solving the problem through adopting a professional development approach. It also assesses the present status of professional GIS technology development as the mode of ESD in Cambodia and provides a framework for using GIS based professional development as a continuing educational mechanism for other developing countries.

SE 09-01 - Geomorphic systems under pressure – anthropogenic forces in a changing environment

Chair: Thomas Glade, Gary Brierley

Why do we persist in ignoring the fate of Earth's surface?

Olav Slaymaker (University of British Columbia)

Much has been written and huge resources have been channeled into research into atmospheric and oceanic system changes. This is appropriate given the urgency of understanding the behaviour of our planetary system which is enclosed by the atmosphere and whose surface is 71% ocean. But humankind is located on the terrestrial surface and civilization depends heavily on the top few metres of regolith and on the ecosystem it nurtures. By comparison, few resources have been made available for research into the degradation of the terrestrial surface environment. But both biogeochemical and social systems are built on soils. 15% of global soils have been removed and an unknown, but significant, percentage has been degraded. Remediating degraded soils may take hundreds of years, but reconstructing soils requires thousands of years. Global soil degradation and accelerated erosion are critical components of global change. The most important drivers of land degradation and land transformation can be summarized as running water and human activity. Case studies from Ethiopia and Nunavut, Canada confirm the conclusion from the Millennium Ecosystem Assessment that consistent monitoring systems for terrestrial energy and water flows are weak, especially in the less developed world. The general question that arises, and which is addressed in this paper, is "what critical measures or indices adequately reveal global conditions and trends in terrestrial geomorphic systems under pressure?".

Soil erosion and sediment transportation in the Mora Dhansiri River catchments in Assam, India

Rana Sarmah (Pandu College)

This study aims at establishing an equation between soil erosion and sediment transportation in the Mora Dhansiri River catchment in Assam, India. Magnitude and rate of soil erosion, mostly triggered by anthropogenic forces, from land use / land cover areas is estimated using a proposed relationship of discharge, sediment concentration, time, and land tillage frequency. This relationship is also applied to estimate magnitude and rate of sediment transportation through the

river excluding the land tillage component. Discharges are measured at water-sediment flow outlets of various land use / land cover areas in the field, and three discharge measurement sites of the river. Sediment concentration data are generated by analysis of sediment samples in the laboratory collected from various water-sediment flow outlets of land use / land cover areas and at three discharge measurement sites of the river. Magnitude of soil erosion, mostly triggered by anthropogenic forces, from built-up land, agricultural land, forest land, and waste land are estimated to be 3767, 39824, 534, and 1952, tonnes respectively in 2009; 4674, 56704, 624, and 1664, tonnes respectively in 2010; and 5646, 45369, 1258, and 3422 tonnes respectively in 2011. Rate of soil erosion from built-up land, agricultural land, forest land, and waste land are estimated to be 2.00, 3.09, 1.10, and 1.85, tonnes/hectare respectively in 2009; 2.39, 4.61, 1.30, and 1.87, tonnes/hectare respectively in 2010; and 2.83, 4.23, 2.60, and 3.73 tonnes/hectare respectively in 2011. Average magnitude of soil erosion from built-up land, agricultural land, forest land, and waste land during 2009-2011 are estimated to be 4696, 47299, 805, and 2346 tonnes respectively. Average rate of soil erosion from built-up land, agricultural land, forest land, and waste land during 2009-2011 are estimated to be 2.41, 3.98, 1.67, and 2.48 tonnes/hectare respectively. Rate of soil erosion from the catchment of the Mora Dhansiri River is estimated at 3.67 tonnes/hectare/year.

Morphological Influences on Fine Bedload Distribution of Initial Streams in Extremely High Rainfall Region: A Case Study of Um-U-Lah Watershed, Cherrapunji, India

Hiambok Jones Syiemlieh (North Eastern Hill University)

Initial streams in high rainfall regions carry a lot of load because of large volume of runoff and variable slope. Such streams, though initial in nature yield discharge up to 4.103 m³s⁻¹ from an area of 103.4 ha and measuring a length of about 2 km. This discharge is very high at global scale due to heavy precipitation (averaging around 11,000 mm y⁻¹). Because of the influence of Monsoon, the winters are dry and the flow is scanty in the streams. In order to study the nature of fine bed load, the main stream was divided into different sections. Spot visits during winter were made to the site and samples of fine bedload were collected from dry stream beds. These samples were oven dried, sieved, segregated and weighed to understand their textural characteristics associated to different slope and drainage length conditions. This paper tries to understand how in such extreme conditions along with anthropogenic interferences, fine bed load is distributed within short distances over varying

slope conditions and how varied is the transported material which ranges from pebbles to clay particles are influenced by morphological conditions of the stream. It was found that clay particles are negligible while pebbles dominate the upper parts of the catchment. At about 2 km from the source coarse sand is found to be more abundant.

Confection of Thematic Chart and Geomorphological Mapping of Barra De Mamanguape 1:25.000, Topographic Chart, Eastern Border of The State of Paraíba, Brazil

Wesley Ramos Nóbrega (UFPB), Maria Emanuella Firmino Barbosa (UFPB/IFPB), Diego Nunes Valadares (UFPB/IFPB), Alexandre Santos Souza (UFPB)

This work aims realize a geomorphological study in region comprehended by the topographic chart Barra de Mamanguape, between geographic coordinates 35° 07' 30" / 35° 00' 00" of longitude west, and 6° 52' 30" / 6° 45' 00" of latitude south. The study area covering by this coordinates is located in north coastal of Paraíba state, Brazil, comprehended a portion of the Paraíba area where such studies have been poorly developed. Thus, analysis of the relief is of fundamental importance for understanding the environmental context, since their comprehension will enable the planning of the use and occupation of space through the interpretation of cartographic products generated. For the developed of this research has been initially used the topographic chart Barra de Mamanguape in scale of 1:25.000 with equidistance of level curve from 10 m, from which it possible for the production of thematic maps, hypsometric, Declivity and roughness of the relief, which was made possible through the development of the geomorphological map with the same scale as soon as this scale allows to analyze the geomorphological peculiarities present in the study area. Besides the production of the maps mentioned above, was made a map of use and occupation of the land using satellite image HRC / CBERS 2B. The software utilized in production of all cartographical material is the Georeferenced Information processing system (SPRING 5.1.8). Thus, the whole process undertaken during the research supports the importance of digital products in the study of geomorphological features of the study area, providing information relevant to the reading and understanding the geomorphological peculiarities of the chart studied, so that from this understanding of the relief, the relevant knowledge about this area, serves as an indispensable support for the application of any environmental planning in this area of study.

SE 10-01 - Global challenges & local responses: The mitigation of climate change by travel behaviour change

Targeting Sustainably Aspiring Motorised and Active Travellers or Environmentally Apathetic Motorised Travellers? Reducing unsustainable travel behaviour through segmentation.

Candice Howarth (Global Sustainability Institute)

Greenhouse gas emissions from the transport sector continue to grow demonstrating that political, technological and economic measures are not delivering the required reductions. Strategies aimed at reducing CO2 emissions centred on behavioural changes are increasing in popularity to fill the gap left by technological and political measures. In spite of this, statistics show that travel behaviour remains unsustainable and due to its perceived indispensable nature, shifts to more sustainable practices remain a challenge. This paper establishes the extent to which population segmentation and the use of climate change information can lead to sustainable travel choices. Postal questionnaires and focus group results identified three clusters according to attitudinal traits and travel behaviour. Three behavioural clusters were identified: Sustainably Aspiring Motorised Travellers (43.9%) are environmentally-focused, feel morally responsible and obligated to change their travel behaviour and understand the benefits this would have, yet travel principally by car. Sustainably Aspiring Active Travellers (29.8%) characterised by sustainable attitudes and marked active travelling (i.e. by non-motorised modes). Conversely Environmentally Apathetic Motorised Travellers (26.3%) express little concern about the implications of their own personal behaviour and see no point in changing it, further highlighted by their heavy motorised travel patterns. These results highlight the existence of an attitude-behaviour gap. Perceived barriers to behaviour change identified within each group depended implicitly on perceived personal gains and losses as well as a lack of awareness on the availability of options to facilitate changes. Habit, misperceptions of modal emissions and environmental impacts of travel, cost, convenience and lack of incentives to change were all significant determinants of sustainable attitudes. Findings from focus groups highlighted the need for a positive approach to instigate travel behaviour change led by incentives rather than penalties: demonstrating the ease of change, highlighting the benefits and

ultimately promoting transparency of peer, social and government action. Climate change information was found to successfully reduce perceived barriers to change and increase willingness to engage in sustainable travel when tailored to specific clusters identified and highlighted the personal benefits of travelling sustainably. Respondents also highlighted a need for clear and transparent information on peer, political and industrial engagement in order to alleviate fears of free-riders and encourage widespread changes. By segmenting travellers based on their attitudes and perceived barriers to behaviour change, this paper demonstrates how targeted climate change information can influence sustainable travel choices and can support transport infrastructure in facilitating a shift to more sustainable practices.

Can cycling mitigate climate change? – Understanding and explaining the behavioral change of cyclists in German cities.

Martin Lanzendorf (Goethe University Frankfurt), Annika Busch-Geertsema (Goethe University Frankfurt)

In many cities worldwide cycling related policies are an important tool to achieve a more sustainable transport system and, among other goals, to reduce greenhouse gas emissions. However, in the literature surprisingly little is known on the travel behavior change of individuals from other modes to the bicycle. Some research refers to the relatively high speed of bicycles in urban areas compared to many other modes, to its little operating costs and the convenience of parking the bicycle close to any destination in the street or close by. Other researchers refer to the experience of physical exercise, independency or, additionally symbolic-emotional aspects related to cycling. However, these benefits of cycling are not perceived by all travelers similarly, since other travelers claim unsafe aspects and vulnerability of cyclists by being exposed to car traffic or other discomfort aspects of cycling like for example the exposure to bad weather. For the purpose of this paper we ask what the reasons for this increase of bicycling on an individual's level are and if, ultimately, cycling can mitigate climate change. As travel behavior research and theories like the mobility biographies research suggest, travel behavior is frequently a routine and does not change easily. Thus, we expect that the travel behavior change towards more cycling will not be observed for the whole population of an urban area uniformly. Instead we expect that the routines for certain travel purposes are weaker or that people affected by key events in their life course will be more open to travel behavior changes than others. For the empirical analysis of these hypotheses we employed the German national travel survey 'Mobility in

Germany' from the years 2002 and 2008. Our bi- and multivariate analysis of mode choice draws mainly on the regionally extended data sets of Frankfurt Rhine-Main, Berlin, Hamburg and Munich and the travel behavior changes observed between these two years in each of the cities. The empirical results suggest that individuals in a life phase after major key events (e.g. children in the household, moving) are more likely to increase their cycling shares than others. Moreover, general socio-economic factors like age, gender, and income affect the likelihood of increased cycling as well although the interaction of these variables with other key events in the life course is possible. Even, the travel purposes show significant differences between each other. Ultimately, the effect of bicycle infrastructure and marketing policies are hard to assess from the available data set since they might be perceived as a key event for travel behavior change.

The role of global challenges for the usage of electric cars: An empirical study about commercial users of electric cars

Jessica Stock (Technische Universität Berlin), Christine Ahrend (Technische Universität Berlin)

Electric mobility is regarded as an important element in the transition to sustainable, post-fossil mobility. The scarcity of energy sources is attended by a rising societal awareness for climate change and environmental problems. Therefore alternatives to the internal combustion engine and new mobility concepts are gaining in importance. In this context the Federal Government of Germany has set the goal that by 2020 one million electric vehicles should drive on German roads. A successful diffusion of electric cars presents major challenges not just to politics and economies, but also to the users. They are encouraged to integrate the electric car in their daily lives. The focus of this paper is the user analysis as a part of the subproject 'user behaviour analysis and spatial planning regional infrastructure'. The results refer to the target group of commercial users. Regarding the electric car this group already shows a strong acceptance. But such acceptance is not to be equated with the willingness to integrate the electric car in daily routines in the long run. Acceptance represents an important basic condition for a successful integration into daily mobility, but doesn't automatically lead to a reconsideration of private and commercial mobility routines. The user analysis aimed at the identification of current requirements for electric vehicles. Electric car users are often associated with a strong environmental awareness. But are they also willing to accept changes in their mobility routines and to implement them permanently? What do

we even know about the use of electric cars? An answer shall be given to the question of whether the promotion of electric cars is a suitable measure to reduce greenhouse gas emissions. For this, one has to ask for the potentials of electric cars to reorganize mobility routines. In this context we have identified two user perspectives: the substitution and the innovation perspective. Both perspectives include their own specific ways of thinking and lead to differing perceptions and evaluations of electric cars. The substitution is the dominant perspective on electric cars and their use. In our paper we want to show how the great white hope electric car is actually used. Subjective user experiences must be taken seriously. The users make diverse demands to their means of transportation and their routines illustrate large inertia effects in everyday life. A new transportation technology must be seen as beneficial compared to the existing one. But is the zero emission trait of the electric car sufficient to accomplish this?

An estimation of the interaction of gasoline prices and entropy on transit ridership: Evidence from vector auto-regression and multi-stage least squares analysis

Bradley Lane (The University of Texas at El Paso)

Gasoline prices are one type of cost that can influence travel behavior. Amid notable fluctuation, real US gasoline prices rose approximately 300 percent between 1999 and 2008. Despite their presence in the public consciousness, relatively little work has examined the role of gasoline prices in influencing travel behavior. Both research and public policy have focused on measures such as purchase taxes and roadway tolls to influence travel. Public transportation constitutes one particularly unexplored component of travel behavior influenced by gasoline prices. Increasing the cost of travel through fuel price could lead to a reduction in automobile usage. However, other transportation modes such as public transit must absorb some of this displaced travel. The relationship between a reduction in auto usage and modal shift is particularly relevant in the US, where public transit is relatively limited and excessive levels of automobile driving have negative externalities contributing to the unsustainability of transport. Previous research has established the presence of a significant, inelastic effect of gasoline prices increasing transit ridership. This relationship appears to contain temporal components and works in tandem with other socio-economic characteristics and transit deployment. These relationships have been established through case studies with complex modeling structures and inter-urban analyses with more simple statistical models. There appears to be

geographic and temporal variability in the magnitude of the relationship, as well as interrelationships among the independent variables including gasoline prices, but thorough examination of these facets is lacking. This paper advances this knowledge by using more recent data and employing a more complex modeling structure to further explain the influence of gasoline prices on public transit. Vector auto-regression and multi-stage least squares models are applied to gasoline price data as well as data on other economic and demographic factors for a set of 42 cities in the United States. Discontinuity effects are also tested to identify potential changes in the relationship over the time period. The vector auto-regression and multi-stage models allow for the testing of simultaneous effects among socio-economic characteristics that influence travel behavior as well as to estimate the lagged nature of those effects. Data are measured in monthly intervals between January 2002 and December 2011 and comparisons are made among different types of bus and rail systems. The results indicate a consistent effect of gasoline prices as a component of a set of economic characteristics which, working together over time, suggest the potential for large changes in urban travel behavior. The results are discussed for their implications toward transit and price mechanisms in transport sustainability.

Commuting travel behaviour and polluting emissions in suburban north-west Milan: Which role for travel demand management?

Giulio Mattioli (Università degli Studi di Milano-Bicocca), Mario Boffi (Università degli Studi di Milano-Bicocca), Matteo Colleoni (Università degli Studi di Milano-Bicocca)

Policy approaches to sustainable transport can be seen as located on a theoretical continuum: at one extreme, "technological fix" solutions (alternative fuels, etc.) aimed at reducing transport emissions without challenging trends towards ever-increasing travel demand, motorization and suburbanization. At the other end of the continuum, many scholars and policy-makers see reductions in travel demand and changes in travel behaviour (such as modal shift away from the car) as the only way to achieve a reduction in greenhouse-gases emissions. In this second field, a further dividing line can be traced between approaches that target individual behaviour directly (such as travel demand management) and planning interventions aimed at changing the spatial structure in which transport choices are made (Transit Oriented Development, urban densification, etc.). The paper addresses this policy dilemma, by presenting the results of an exploratory survey on the commuting behaviour of the employees of public and private firms in suburban north-west Milan. The survey has been carried out by the Department of Sociology and Social Research of the University of Milan-Bicocca in May 2010, in the context of a travel demand management initiative that has involved both local governments and private firms. The collected data allow an estimation of the PM and CO₂ emitted during the daily commute, making it possible to assess the environmental impact of work-related travel. The findings show the existence of two main types of employees: a relatively old, mostly female public-sector workforce, who lives in the local area and has low environmental impact; a group of private employees who is younger, more educated and lives further away from the workplace, and is thus responsible for a much larger amount of emissions. The data also allows for the appraisal of the environmental impact of three extreme policy scenarios: a "technological fix" scenario, where all the

vehicles are replaced with less polluting ones; the implementation of a successful travel demand management strategy, which considerably reduces the modal share of the car; an urban densification strategy, that reduces the commuting distances. This mental experiment leads to the following conclusions: first, the social and spatial trends of the last decades are clearly the main driver behind the dramatic rise in transport-related polluting emissions; second - and consequently - the potential impact of travel demand management policies and technological fixes appears limited, especially in comparison with densification strategies.

Suburban daily mobility – between freedom and sustainability

Cornelia Rahn (German Aerospace Center (DLR))

In Berlin, an increase of multi-modal mobility is observed based on urban lifestyles combined with the availability of alternatives to the private car such as public transport, bicycle rental systems or car sharing. To examine the influence of travel behaviour on the mitigation of climate change in developed countries, it is important to consider not only urban but also suburban areas since the suburban population in western countries has been growing over the last decades. Due to limited facilities of surrounding communities, daily car trips of suburbanites account for a substantial share of all-German traffic. Only if motives for suburban travel behaviour are known, changes in the perception of transport modes can be induced aiming at a more multi-modal mobility. Hence potential savings regarding energy consumption can be identified. Against this background the question arises if daily mobility of persons living in the suburban fringe of Berlin is influenced by urban 'sustainable' trends or if suburban residents remain with their 'traditional' mobility. Different assumptions exist: On the one hand they do stick to their cars which results from their chosen 'suburban way of life' with the car as the ultimate symbol of freedom. This car-affinity is strengthened by the suburban built environment and infrastructure. Contrary to that new research shows that the dichotomy of place related urban and suburban lifestyles renders obsolete based on observed urban attitudes of suburban residents and vice versa. This presentation aims to address the question if suburban residents in the Berlin area tend to show rather urban than suburban mobility patterns. Special attention is given to underlying motivation which shows the awareness of risks of climate change by GHGE and the possibility to contribute to the mitigation by individual mobility behaviour. The knowledge of the specific reasons influencing suburban mobility will help to identify potentials to reduce the overall energy consumption. Analysis is based

on a quantitative household survey (n = 1,135) that was carried out in 2007 by the Geographical Institute of Humboldt-University of Berlin. On base of this data, mobility patterns of the suburban residents can be shown. The survey was complemented by a sample of qualitative interviews (n = 20) in 2008. Through the analysis of interviews underlying motives and reasons for the discovered travel behaviour become clear. The majority of the surveyed residents had lived in Berlin before they moved to the suburbs in the mid-1990s. Therefore they were able to compare their former urban with their current suburban travel behaviour. This comparison provides an indication of the influence of urban respectively suburban lifestyles and built environment on mobility.

Changing travel behavior requires understanding travel behavior - The impact of preferences towards land use for travel behavior

Julia Jarass (German Aerospace Center (DLR))

In order to reduce greenhouse gas (GHG) emissions by changing travel behavior it is necessary to better understand the key drivers of travel behavior: various studies have been conducted analyzing the impact of socio-demographics, land use and lifestyles on travel behavior. However, taking these factors into account still does not explain travel behavior to its full extent. In this context the question arises as to what extent preferences towards land use influence travel behavior. Are there differences in the travel behavior of residents with preferences towards urban or suburban land use and do people use specific transport modes according to their land use preferences? Finding answers to these questions will enable transport and urban planners to better understand the key drivers behind travel behavior. Ultimately, this knowledge will help to change travel behavior and improve the acceptance for sustainable transport modes. Using data from the "StadtLeben" project it is possible to provide an insight into the issues raised above. The survey conducted in 2002-2004 examined different land use structures in the region of Cologne assessing travel behavior, living environment, every day activities, lifestyles and socio-demographics. Since reducing car dependence, and therefore emissions, is especially problematic in the disperse land use structure of suburban areas, in the session of IGC 2012, I intend to focus on a suburban area: analyzing the data illustrates that travel behavior here differs distinctively between residents with urban preferences and those with suburban preferences. Moreover, more than 50 % of the residents have urban preferences, but they live in a suburban area. What does this mean for their travel behavior? This mismatch bears at the same time potential and challenges for more sustainable travel behavior: On the one hand, residents with urban

preferences tend to have a rather urban travel behavior, namely they walk, bicycle and go by bus more often than residents having suburban preferences. On the other hand, they still do not walk, bicycle and use public transport quite as often as residents living in urban areas. Hence, in my presentation I intend to provide a closer look at the impact of preferences towards urban and suburban land use on travel behavior. My presentation will address the type of preferences that lead to a rather "urban" and more sustainable use of transport modes and the socio-demographics by which the residents having urban or suburban preferences can be described. This knowledge can provide an important basis for promoting sustainable travel behavior, since stimulating an already existing preference is a promising approach to changing travel behavior.

20 Years of Semester Tickets in Germany – A Success Story with a Significant Contribution to Greenhouse Gas Reductions: An Evaluation of the NRW-Semester Ticket

Miriam Müller (Wuppertal Institute for Climate, Environment and Energy)

20 years ago, the first semester ticket (ST) was introduced at a German university. Invented and demanded by student initiatives, STs are special tariffs for students to use public transportation in the area of their university. Price, geographical reach and terms of a ST are subject to negotiations between student representatives of a university and their respective local and/or regional public transportation companies. If a ST model is introduced to a university, it has to be purchased by all students at a contractually agreed solidarity contribution, leading to very low prices compared to regular tickets. The introduction of STs in Germany has positively influenced the student's travel behaviour towards more sustainable modes of transport. For example, after introducing a ST in Duisburg, the student's use of public transportation increased by 27%, while the use of motorised private transport diminished by 28% (from 1991 to 1996). Similar effects could not be identified for universities not having a ST. Students having expenditures for a car diminished from 53% (1991) to 34% (2009). Since the 1990s, the geographical reach of STs has undergone a remarkable development: While the first STs were valid only for public transportation within a city, some STs of today give access to the public transportation system in the entire federal state. Since 2008, the ST for North Rhine-Westphalia (NRW) extends the geographical reach of the still valid regional STs to state level. NRW has 18 million inhabitants, extensive agglomeration areas and an efficient public transport system. In 2010, 48 universities have introduced the ST NRW for more than 370.000 students, which equals 18% of

all students in Germany. Within a diploma thesis supervised at the Wuppertal Institute, the ST NRW was evaluated in an online survey at the University of Bielefeld in 2010, regarding acceptance, utilization and impacts. 4.500 students (25%) took part by self-selection. The survey revealed that the ST NRW is broadly accepted by the students, although approval differs depending on the students' regional provenance, age and car ownership. 80% graded the ST NRW as 'good' and 'very good'; 76% wish to retain it. Car ownership could be reduced by 10%, the acquisition of a car could be prevented by 26%. Of the trips travelled with the ST NRW, 28% would not have been travelled without the possession of the ST NRW; 18% of the trips would have been travelled by car. Roughly estimated, this shift from car to public transportation equals CO₂-reductions of about 3.000 t/a at the University of Bielefeld. The ST NRW can be considered a good approach to help develop a sustainable mobility culture at a young age. However, the unidirectional extension on the Federal State of NRW is capable of improvement. The options to further disseminate the tariff model within Europe and beyond should be examined.

SE 11-01 - Globalisation of trade and production and (ecological) sustainability

Chair: Amelie Bernzen, Peter Dannenberg

Globalization and its impact on sustainable development opportunities

Eugenia/Levgeniia Maruniak (Ukrainian National Academy of Sciences), Sergiy Lisovsky (Ukrainian National Academy of Sciences)

At the turn of XX-XXI centuries, the international community realized the growing interdependence of countries and regions, as well as global problems, unfolding against this background. The contradiction between the high intensity of end-use of natural resources, formed in most developed countries of the world, and the high level of environmental degradation in developing countries (in which extraction and primary processing of the resources occur) permanently increases. Inadequate assessment of different types of resources takes place, new conflicts appear, the activity of TNCs growth. For Ukraine, the main problem, that arises due to the influence of globalization processes, is its 'object's reality' in the modern system of international relations, which identifies a whole number of problems of internal development in social, economic and environmental spheres. Some risks arise: polarization of regional development; increasing poverty and income differences; utilization of human, industrial and natural resources in the interests of other players; homogenization of the ethnic and cultural space; further environmental degradation; biodiversity loss; illegal migration; transnational crime; spread of diseases. To prevent such risks, to overcome their consequences, complex methods, which include research, management and monitoring for all levels, should be developed and implemented. Due to the significant potential of geographical science in this area the authors have made certain steps which could be presented in the report. Therefore, particular attention should be paid to the study of such major aspects of the impact of globalization on the possibility of attaining sustainable development, as follows: 1. Globalization is a factor to be taken into account when developing plans for transition towards sustainable societal development at all levels. It influences the features of interaction between society and nature, the scope and territorial features of anthropogenic impact. 2. Globalization affects the nature of usage by the community of the natural resources capacity of the globe (territorial features, the scope and directions) as well as the possibilities of population of certain regions to gain access to certain types of

resources. 4. Under globalization, for certain countries and governments of certain countries it is becoming more difficult to implement their policies to ensure sustainable development within their own territory. So, the state must pay special attention to conservation and development of the socio-economic potential of its own territory as well as to preserve cultural diversity. 5. The phenomenon of globalization requires to join efforts of all mankind and to raise society's awareness in each country and region in order to ensure coordination of efforts to realize the transition toward sustainable development within the whole planet.

Corporate Social Responsibility in Developing Countries - The impact of CSR on sustainable regional development

Peter Jakob Fürmaier (Universität Erlangen-Nürnberg)

The planned contribution has the intention to show how companies get socially and ecologically involved with developing countries in accordance with the concept of Corporate Social Responsibility and with this action going beyond minimum statutory requirements. The first step is to ask for the intention that lets the companies become engaged in an ethical aware manner. A general distinction is made between institutional, economical and moral approaches. The main focus of the contribution first of all lies on a description of connections between corporate social commitment of companies active in developing countries and a sustainable regional development in the respective area. In addition correlations between corporate social commitment and a sustainable regional development are derived by development sensitive growth parameters including income, human capital and social capital. The measurement is based on the classical 'Input-Output-Outcome-Impact' ('IOOI') approach. The 'Input' is represented by the companies' investment of money and resources, the 'Output' by the CSR measures taken instantaneously. The effects achieved for the target groups (employees, residents, etc.) are the 'Outcome', the additionally effected impacts on civic concerns are referred to as 'Impact'. The case study for the acquisition of an empirical basis was conducted on the cut-flower industry situated north of Quito, canton Pedro Moncayo in the Pichincha province of Ecuador. Thirty-one percent of the 33,000 inhabitants of canton Pedro Moncayo are employed in the cut-flower industry which amounts to 80 farms and a land coverage of 968 hectares. The farms of the case study that are certified according to the CSR tool 'Environmental and Social Certificate' of FLP, Max Havelaar (Fairtrade), Global G.A.P., Veriflora, MPS, Rainforest Alliance and Florecuador show an additional commitment regarding social and ecological

concerns defined by an own Code of Conduct compared to a control group of flower farms without any certification. The planned contribution will describe the 'FLP-Flower Label Program' certificate in detail. Currently 23 flower farms are certified according to the FLP. Preliminary results of the study demonstrate a positive effect of the certifications on regional development indicators such as human capital, social capital and income. The main motivating factor for obtaining a certification seems to be the fear of losing the respective 'license to operate'. Neither economical advantages of the FLP certification nor institutional pressure by the government are shown to be the reason for such a commitment. As additional reason a philanthropic, altruistic thinking is suspected to make the companies act as Good Corporate Citizens in the region.

Agri-food globalisation and governance for environmental sustainability: Challenges and opportunities of a global commodity chains approach

Edward Challies (Leuphana University Lüneburg), Jens Newig (Leuphana University Lüneburg), Andrea Lenschow (University of Osnabrück)

This paper discusses the conceptual implications of a relational view of globalisation for environmental sustainability, and suggests that the increasing predominance of cross-scalar, relational networks in the organisation of global production and trade demands new approaches to environmental governance in theory and in practice. With reference to contemporary globalisation in the agri-food sector, we consider the challenges posed by increasing global interconnectivity and interdependence - between distanced regions, populations, and social-ecological systems - for the conceptualisation and operationalisation of governance for sustainability. We reflect on the case of intersecting commodity chains for animal feed and factory-farmed meat, and consider the ways in which a global commodity chain approach may offer insights into the current and future governance of environmental impacts across geographically remote, but increasingly mutually dependent, socio-ecological systems and communities of producers and consumers. Drawing on insights from recent literature on global commodity chains and production networks, coupled social-ecological systems, and global environmental governance, we identify a need for special attention to scale, and a critical re-examination of concepts such as resilience, vulnerability and sustainability as they are commonly applied to social-ecological and agri-food systems.

L'essor maritime et portuaire balte face à la nécessité d'un développement durable des transports

Arnaud Serry (Université d'Orléans)

La Baltique présente des particularités uniques. C'est une mer jeune, qui, avant de devenir une mer intérieure fut tour à tour détroit, vaste baie, et enfin lac. Peu de mers au monde sont aussi vulnérables que la mer Baltique dont l'environnement maritime et les régions littorales sont au cœur de problématiques fort différentes. La pression résultant des activités des populations qui vivent et travaillent dans le bassin de la Baltique commence à se faire gravement sentir et les façades sont exposées aux pollutions d'origines diverses.

L'essor important et récent du transport, surtout maritime, dans la région renforce les interrogations quant à l'avenir de cette mer fermée. Le développement d'un système de transport durable et de qualité s'impose comme une obligation pour les Etats Baltes mais l'articulation du binôme transport/développement se trouve complexifiée par les externalités négatives, notamment environnementales, des activités de transport. Le transport, en tant qu'activité économique, participe incontestablement au développement des Etats Baltes. Au cours des deux dernières décennies, l'espace balte a, en effet, vu s'y multiplier les flux, principalement ceux de marchandises. Or, c'est surtout en matière de fret que les enjeux de durabilité sont les plus élevés. Les avantages économiques et sociaux de cet accroissement des trafics sont difficiles à concilier avec les coûts environnementaux élevés. Ainsi, le transfert progressif d'une partie des volumes vers des modes plus polluants comme le transport routier, l'omniprésence de marchandises à risques dans le fret sont autant d'éléments à prendre en compte dans l'appréhension de la durabilité du développement dans les Etats Baltes.

Cette communication met en évidence les spécificités de cet espace balte et les difficultés d'y concilier développement du transport, secteur omniprésent dans les économies, construction régionale et impératifs de développement durable. Il s'agit de plus de révéler le rapport entre développement et durabilité des transports dans les Etats Baltes, en rappelant l'organisation et les mutations du système de transport et les stratégies et les jeux d'acteurs mis en place afin de réaliser l'objectif de durabilité..

SE 12-01 - Green economies: A business, society and policy approach 1

Chair: Brita Hermelin, Grete Rusten

Public Transportation Geographies in New York State: Using Data to increase utility of Transit

Richard Quodomine (New York State Dept. of Transportation)

In the USA, development over the past 50 years has encouraged urban sprawl, or more accurately, increasingly urbanized suburbs as economic hub activity was moved out of prior-existing core business districts. At first, there was the use of lower, wider buildings and more extensive use of land, rather than intensive use of land. Then, the spaces between villages and cities became planned suburban areas. Most famous is Levittown, Long Island, New York, but there were many others who emulated a similar style of planned community. However, over the last 10 years, this growth has subsided. Middle class growth from manufacturing has declined and these communities and housing stock have aged significantly. This creates a conundrum: the more a population ages, the less income it produces, the more tax dollars it utilizes and the more public transportation of some sort is needed. When most people think 'public transportation', they presume it to mean buses. In the United States, however, tax dollars support 62 different types of publicly-supported transportation, from large buses and rail, to veterans' transportation, to Medicaid and Medicare service, even on cars. With shrinking public tax bases to support these options, new ideas are necessary to deliver public transportation. In the USA, this has come under Coordinated Transportation, with an emphasis on Mobility Management, otherwise known as, 'How do you get multiple government agencies unused to talking to each other to share costs and burdens wisely and still maintain a system that caters to the needs of customers'? Compounding this issue has been a law that protects equal access to public services for people of any race, socio-economic circumstance, or nation origin. This includes providing as much as access as is reasonable to those with Limited English Proficiency (LEP). In the last 50 years, immigration into the US has been by people who do not speak English well, and can come from anywhere in the world, making the US the destination for over 150 different languages. Identifying where concentrations of LEP populations are is a new point of emphasis in public transportation. All of this data can be best accessed and publicly understood by Geography. Specifically, using Census data to show

aging populations, lower socio-economic status populations, and limited English proficiency populations that identify likely 'need users' of public transit. In concert, utilize data where new densities are located that may get choice commuters, i.e. those who utilize public transportation and choose to do so. In New York State, I and my colleagues have identified these populations through an Environmental Justice project that focuses on identifying those populations. This paper will show some of the results of this ongoing project and how it can be important to better utilize precious tax dollars in an era of difficult budgets.

Are companies concerned about sustainable transport ? Results of a qualitative research in a french mid-sized city.

Patricia Lejoux (Transport Economics Laboratory)

In a globalized world, transport plays an important part in companies functioning through the delivery of goods and services, employee travel and employee commuting. But transport has also significant impacts on the environment, accounting for 50 % of global oil consumption and 23 % for carbon dioxide emissions. This can become a problem for companies which are faced with demands for increasing ecological sustainability. The aim of this paper is to know if companies are concerned or not in sustainable transport and if that is the case, to answer two questions. The first one is : why companies develop strategies to promote sustainable transport - Is it for economic reasons - For example, the implementation of sustainable transport measures can be a way for the company to cut costs, particularly if fuel prices rise. Is it for environmental reasons - The company can be interested in implementing sustainable transports solutions because the company head is very sensitive to environmental issues or because the company cares about its corporate image and wants to communicate about its corporate environmental responsibility. Is it for social reasons - The company can be aware of the difficulties of its employees to come to work by car (traffic jam, fuel prices increases?) and wants to implement sustainable transport measures to solve the problem. The second question is : what kind of sustainable transport measures are implemented by companies - For example, they can decide to buy green vehicles which are more fuel-efficient. They also can reduce business travel by improving meeting management, by using new technologies (e.g. videoconferences), by encouraging car pooling? Then, companies can also decide to implement a mobility plan for their employees or to increase telework? In order to answer those questions, we will submit results of a qualitative research based on in-depth interviews of companies heads. These companies are specialized in

industry, transport and logistics and are located in the periphery of a french mid-sized city (160 000 inhabitants).

Knowledge dynamics in a green economy

Margareta Dahlström (Karlstad University)

This paper aims to develop the understanding of knowledge dynamics processes developed in the European research project 'Regional trajectories to the knowledge economy' (EURODITE) applied on knowledge dynamics processes in a green economy. Demands for conversions into ecological sustainable production of goods and services calls for the generation and processing of new knowledge. To address the challenges of an ecological sustainable production, the furthering of knowledge within single scientific disciplines is not sufficient for driving innovations to tackle these challenges. On the contrary, different types of knowledge such as analytic, synthetic and symbolic, as well as knowledge from diverse disciplines have to come together to develop new knowledge needed for solving problems to advance a green economy. Hence, the generation and development of new knowledge takes place in complex relationships between different types of actors located in different places. Actors involved in knowledge generation and development range from micro businesses to transnational firms, higher education and research institutions and public actors and agencies of different kinds. Increasingly, also users and consumers are identified as playing important roles with regards to knowledge dynamics. Knowledge interactions across sectors, scales and actors can be called knowledge dynamics. An important aspect of knowledge dynamics is that changes in knowledge are driving innovation. In addition, policy actors can play a role in taking action to promote and support knowledge dynamic processes and remove obstacles obstructing such processes. The paper explores knowledge dynamics in a green economy with an empirical focus on Lake Vänern in western Sweden. Lake Vänern is the largest lake within the EU and with its surrounding area provides a multifaceted region where many of the green economy challenges and opportunities are present. The lake has a unique fauna and flora and is the fresh water source for the 300 000 inhabitants in the region. It is also Sweden's largest hydroelectric power dam and is used for transportation, commercial fishing and recreational purposes for the local population as well as for the tourism industry. With regards to local planning, the lake provides an attractive setting for waterside developments. Lake Vänern administratively affects thirteen local and two regional authorities, in addition to regulations at national and EU levels that are

affecting the lake and its surroundings. Through the many competing demands on the resource of Lake Vänern, the region provides a valuable case to study knowledge dynamics in a green economy.

Eco-networks for eco-innovations and a green economy

Brita Hermelin (Stockholm University)

This paper aims to analyse the development of eco-innovations through composite knowledge in eco-networks. Eco-innovations may be defined in terms of innovation processes toward sustainable development and a green economy. Innovations, knowledge and learning are closely related concepts and in this paper the aim is to understand how these develop in a number of cases of eco-networks for eco-innovations. There are many types of innovations involving organisational, product, market, process and input innovation. Innovations have also been categorized in terms of radical or incremental. The discussion in this paper proposes a broad and encompassing understanding of innovations. The paper aims a particular interest towards eco-innovations through cross-sector knowledge interactions and which are closely related to composite knowledge, i.e. the processes of developing new knowledge through combinations of knowledge from different knowledge fields. The empirical data in the paper is derived from the mapping of a selection of projects for eco-innovations. These are projects developed in Sweden and which involve actors from different organizations and industries and from the public and the private sectors. The paper describes and discusses how the selection of eco-networks develops across sectors and also across space in multi-local structures and processes. The aim is to advance the understanding how eco-networks generate learning, knowledge and innovation processes and also how discourses and institutional settings means hindrances for knowledge dynamic processes in network relations.

SE 12-02 - Green economies: A business, society and policy approach 2

Chair: Brita Hermelin, Grete Rusten

Changing energy geography of North Eurasia: Regional impact of global policy, technology, and market shifts

Vladimir Litvak (VTB Capital)

Traditional energy geography of Russia and other CIS countries is changing, both structurally and spatially. Spatial changes involve both location and configuration of energy production, processing, and transportation facilities, and the patterns of energy trade. A variety of drivers are in play: from global, regional and national climate change mitigation policies to market shifts, from technology-driven transformation to regional integration, from energy security considerations and efficiency gains to policy impacts of natural disasters and industrial accidents. The above cause changes on the national and subnational public policy levels and in the behavior/response of government agencies, energy companies, financial institutions, expert community, and civil society. Although "greening" of the region's energy sector has been slower than in the other regions, virtually all countries adopted national goals and policies related to green growth, achieving greater energy and resource efficiency, and development of renewable energy and started moving to implement the above. The paper will highlight the impact of selected global change factors, mediated by regional and national policies and practices, on energy geography of North Eurasia (Russia and other CIS countries), with focus on development of sustainable ("green" energy) and spatial changes in conventional energy. It will, inter alia, address the following cases: (i) impact of regulatory and market changes on geography and structure of the Russian power and heat sector; (ii) changes in geography of the Russian energy exports due to the EU energy policies, development of Asian energy markets, and technological changes in gas industry; (iii) policy and market-driven development of renewable energy in the CIS countries: case studies of Armenia and Ukraine; (iv) urban energy; (v) associated gas utilization in Russia, Azerbaijan, and Kazakhstan; (vi) regional and local sustainable energy finance influenced by targeted interventions by the international financial institutions (vii) subnational energy policies and practices in Russia

Maritime cleantech entrepreneurship in Frederikshavn, Denmark: Exploring the role of intermediaries on information and competence provision

Roberto Rivas Hermann (Aalborg University), Jeanne-Christine Lunde-Christensen (Maritime Center for Operations), Henrik Riisgaard (Aalborg University), Arne Remmen (Aalborg University)

The demand on maritime cleantech may increase as result new regulations on maritime source air pollutants by International Maritime Organization and the European Union. As result, the demands will also increase for ship retrofit and cleantech installations. Such opportunities may be triggered by frontrunner shipyards and its interlinked maritime-servicing clusters and networks. Yet, in order to exploit these opportunities, conventional business literature usually refers to information availability and competence building. Yet, in the blossoming literature of eco-entrepreneurship both topics are barely discussed. This paper aims to fill this knowledge gap by studying the case of Frederikshavn district in Northern Denmark. This district can be considered as a paradigmatic case, from which generalizations can be made to other harbors in Western Europe. The article departs from the following research question: What is the current role of brokers and intermediaries in facilitating information concerning green shipping practices? The paper's main argument is that information availability, facilitated by public and private networks is a requirement for potential maritime cleantech eco-entrepreneurship. In this article, eco-entrepreneurship is understood as offering new services and products (either by an existing firm or by a start-up). Such services and products may address an environmental externality. The following are the case study's main results:- Two broker/intermediaries contribute to information flow between information rich domains (maritime associations, conferences, etc) to end users: Frederikshavn's district government (Kommune) and Frederikshavn Business Council (Ehrvervshus Nord). - "Information" in the Frederikshavn's context implies: new shipping environmental regulations, air and water pollution control technology specifications. Besides, information encompasses maritime staff competences on how to service new air emission control technology (e.g. scrubbers, SCR, etc...), as well as alternative energy sources engines (e.g. LNG, hydrogen fuel cells). The case may provide insights on how eco-entrepreneurial opportunities are recognized with intermediaries' support. According to Baron (2010, 124) a key question in entrepreneurial recognition is 'Why are some people and not others able to discover specific opportunities'? This author considers that an answer to this question resides in access to and best use of information.

Furthermore, access to information can result from active search, alertness to opportunities, and entrepreneur's previous experience. The Frederikshavn case study may add a fourth element: access to information can result from the facilitation provided by intermediaries.

Sustainability and competition: The role of management consultancies in the embracement of eco-innovations in production systems.

Grete Rusten (University of Bergen), Silja Kristiansen Bruland

Eco-innovations can be understood as a technological move for development of eco-efficient product and processes leading to efficiency and value creation. This may involve a whole range of actors, in-house or external experts, firms and policy makers that are engaged in developing tools, giving advice, organising procedures and evaluating and regulating sustainable developments. This research focus on what role external consultancy services play in providing knowledge in these projects. The theoretical approach in our study combines literatures within technology development, management, innovation and industrial design. The basis for this research is to investigate the supply and demand side of eco-innovation projects through empirical evidence that combines updated company information from a systematic analysis of the consultancy service company database with a sample of 50 service management companies and 50 industrial design service companies operating in Norway. Firstly we analyse occurrence and details around eco-innovation advice and projects. Secondly, we combine this with an electronic survey among businesses demanding these services. Major sectors including marine resource industries, maritime industries and petroleum industries are of particular focus.

SE 13-01 - Integrative approaches to water resource management in times of global change 1

Chair: Flurina Schneider, Olivier Graefe

Enhancing Stakeholder Involvement in Water Management Schemes of the Heihe River Basin (China) - A Theoretical Outline Based on the Greifswald Approach

Lilin Yu (Universität Greifswald), Jan Felix Köbbing (Universität Greifswald), Niels Thevs (Universität Greifswald), Konrad Ott (Universität Greifswald), Stefan Zerbe (University of Bozen-Bolzano)

Managing freshwater has gained a broad attention in our public debates. The uneven natural distribution of water resource and diversified socio-economic conditions make it highly challenging to formulate a standard package of solutions. How could we establish an integrative approach, which is sustainable and embedded in local socio-economic reality? Upon the Heihe River Basin case, we propose a holistic approach that regards the whole river basin as a unit in social-scientific analysis. The Eco-system services approach, multi-criteria valuation and adaptive management are three important components in our framework. Within the Greifswald Approach, we understand water as a non-living fund with a zero rate of substitutability. To solve hydro-logical problems, it is vital to grasp an in-depth understanding of hydro-logical problems from within user's perspectives. Those perspectives include, above all, "water cultures" like history, perception, economics, schemes, and institutions as well as water ethics in the contemporary times. A "Universe of Discourse on Water-Related Practical Problems" (UoDW) could then be established, consisting of discourses from stakeholders. Presuppositions of parties concerned in UoDW should be reflected, ambiguity be dissolved and arguments be reconstructed. In our study site, there are four types of stakeholders: the locals (S1), farmers (S2), entrepreneurs (S3), and government agencies responsible for managing conserves, e.g. Mt. Qilian, various wetland parks and the tugai forest (S4). Reluctance of stakeholders to participate in water management schemes is largely a result of (1) unawareness of the issue actually at stake and its weight; and (2) failure to reach compromises in face of conflicting interests. For the first point, we suggest start with Ecosystem Services evaluation. In our view, each stakeholder pays for various ecosystem services (ES) from the River to sustain their existence and enhance the quality of life. Different ESs are categorized as: provisioning (E1), regulating (E2), supporting (E3) and cultural

(E4) services (The Millennium Ecosystem Assessment 2005). A matrix can be then established as $[SE]_{i,j}$ where $i,j=1,\dots,4$. The values of Ecosystem Services should then be conveyed to each stakeholder and their opinions be gathered. Nonetheless, there is potential risks in applying the ES approach; therefore, local resource managers should take deeper considerations as to the validity of stakeholders' argumentation. "Validity" here is rooted in the Habermasian Discourse principle (D). A map of multi-criteria is inferred from arguments deemed as valid. Subsequently, an appropriate management proposal can be drafted, which is expected to encounter least objections (the second point), and hence enhance stakeholder involvement. This draft, again, should be able to withstand public scrutiny.

Water research in South Africa: Knowledge and adaptive capacity

Raymond Siebrits (University of Cape Town)

The coupled human-environmental system of water resources in South Africa is seen by many as approaching or already in a crisis but solutions can and must be found. This paper therefore proposes to identify and understand the past and present paradigms of water related research in South Africa. It then proposes to critique this water related research endeavour through theoretical and contextual debates of sustainability, appropriateness and relevance in research. It is stressed that this paper focuses on a macro understanding of the past, present and future of water research activities and questions and does not attempt to answer whether the research is aiding sustainability, is relevant or appropriate. A contextual narrative will be created using meta-data from all peer-reviewed scientific publications related to water in South Africa since 1971. This will be strengthened by interview data and narratives with key persons who are and were engaged in water related research. Discussions around the role of knowledge and science in society will also be presented to this narrative. The final analysis will represent the categories and themes in matrix form that many thousands of publications apply to and possibly identify areas of research focus or neglect in the past. Paradigms and changes thereof in the past research will be identified and discussed. This narrative will then be used to invoke thought and debate amongst a diverse array of water research stakeholders in South Africa. These stakeholders will be invited to participate in a horizon scanning endeavour using comprehensive online surveys at its core. This undertaking will generate categories and rankings of priority water research questions in South Africa that are being asked or should be addressed. A few hundred robust, achievable and structured research questions will be presented to the water

research community. Coupling the contextual narrative and horizon scanning results will then allow the current state and direction of water research to be critiqued. This will be performed in the theoretical context of the requirement of adaptive capacity for greater resilience to enable a more sustainable path to be attained. This paradigm will be critiqued amongst the complexity, debate and challenges that exist in sustainability science as well as assigning appropriate notions towards research. This critique does not aim to definitively answer whether research is sustainable, whether it contributed/contributes towards sustainability or whether it is relevant, but rather wishes to identify and critique current and past paradigms identified in the data analysis within these theories.

Modeling of the human-environment interaction: Conflict and cooperation over water resources in the Nile River Basin

Peter Michael Link (Universität Hamburg), Jürgen Scheffran (Universität Hamburg), Franziska Piontek (Potsdam Institut für Klimafolgenforschung)

Recent studies suggest that climate change can aggravate environmental degradation and resource scarcity, which may contribute to violent conflict in a number of ways, including resource captures, mass migrations, and conflicts over the distribution of risks and costs between countries. However, it is also possible that addressing the problems and risks might lead to more cooperation instead. In the context of the overarching subject of the session, we focus particularly on water as an essential natural resource. A conceptual framework of conflict and cooperation is applied that assesses the link between environmental factors, human security and societal instability. A macro-level analysis of regional impacts of climate change is combined with a micro-level analysis of potential environmental conflicts, regionally focusing on the Nile River Basin, which can be considered a potential climate hot spot. The aim is to provide a deeper understanding of the climate-society links and the potential for destabilizing cascading effects and tipping points. The analysis of impacts and responses provides a basis for developing and testing strategies and policies for adaptation, stabilization, cooperation and conflict resolution in the Nile River Basin in light of a possibly significantly altered water availability due to changing environmental conditions. It is expected that the Mediterranean region will be severely affected by global warming. Rising temperatures and changing precipitation patterns exacerbate existing problems of desertification, water scarcity, and food production. Based on data of key countries in the Nile River Basin regarding various economic, environmental, developmental, and political dimensions, an analysis of the potential regional security implications and

conflicts is conducted that may arise if the influence of climate change alters the current status quo. In the past, Egypt has established itself as a water hegemon that controls a majority of the water resources of the region. This status has been recently challenged by developments and alliances of the upstream countries, increasing the tension between Egypt and some of its neighbors. Unfavorable shifts in precipitation patterns can augment the pressure on the downstream countries, causing them to consider shifting towards strategies that are based on threats rather than on cooperation. A computational modeling framework is introduced to outline the complex interactions between the most important variables of the climate system and fundamental socio-economic quantities in the upstream and downstream countries of this region. It is used to assess the dynamic interactions between countries which invest into different action paths to improve water availability. Recent developments and different scenarios are discussed, alternative strategies and cooperative approaches are considered that enhance conflict prevention and governance structures to address security risks.

Best practices for community-based environmental assessment – Promoting learning and sustainability in Kenya and Tanzania

John Sinclair (University of Manitoba)

This paper establishes best practices for community-based environmental assessment (CBEA) in Kenya and Tanzania and examines what participants in community-centered approaches to environmental assessment have learned. Three CBEA cases involving water supply projects were studied using interview methods and action research. Findings show that best practices for encouraging meaningful community involvement include providing access and adequate notice to participants, fairer cost sharing, broader representation of women and youth, participant understanding of the CBEA facilitator and culturally appropriate sharing of findings. Learning outcomes attributable to the CBEA process included technical skills for erosion control, new information about EA regulations and shared values of environmental sustainability and community unity. An application of selected best practice approaches in a test case in order to encourage greater participation and learning had mixed success. For example, attempts at providing early notice still resulted in it being far too late for most participants and only about one-third of the participants were women. However, a pictograph functioned as an effective tool for reporting CBEA results to the community and demonstrating learning outcomes.

SE 13-01 - Integrated water resource management and land use change in South America

Chair: Rene Höfer, Carsten Lorz

How to balance urban and agricultural water related needs under changing conditions in the Maipo catchment, Chile?

Laura Simon (Karlsruhe Institute of Technology), Helmut Lehn (Karlsruhe Institute of Technology), Melanie Oertel (Karlsruhe Institute of Technology)

The Central Valley in the metropolitan region of Santiago de Chile (MRS), located in the Maipo Catchment, is the most densely populated area in Chile, with all the main economic, social and technical functions of the country and therefore especially vulnerable to the impacts of climate change. Already today 100% or even more of the available water resources are allocated as private water rights leading to competition for water among agricultural, domestic and industrial purposes. The available renewable water resources of the Central valley are composed of 1) precipitation and 2) inflow of surface water from the Andes via the rivers Maipo and Mapocho. Precipitation shows considerable variations within a year and even stronger between different years. This precipitation pattern leads frequently to droughts, increasing the risk of a growing competition between agriculture and urban water demand. Due to low average annual precipitation and its concentration in winter months most water-related needs in the rest of the year are highly depending on melt water from glaciers and snowfields of the High Andes (McPhee et al. 2011). The regional impacts of global climate change will noticeable influence the future water availability in the MRS, leading to an increase of temperatures and a decrease of precipitation up to 10-30 % but with higher variability and intensity. Downscaling of climate models predicts reduced run-off of the Maipo River in summer months up to -40 %. Facing the shrinking water resources the elaboration of suitable measures for climate change adaption is a pressing need. The CAS-Project combines downscaling of global climate change models for the supply side with two socio-economic regional scenarios in order to address possible developments on the demand side in the region. Two plausible future storylines Business as Usual and Collective Responsibility have been developed, based on assumptions of the key socio-economic relationships and driving forces of change. On the basis of the outcomes of both scenarios in a participation process adaptation measures have been developed with relevant institutional stakeholders of the region. These measures include both the supply and demand side. While supply

side adaptation options involve, inter alia, increases in storage capacity, rain water harvesting or making other water resources available, demand side options focus on increasing efficiency and sufficiency of water use. There are large potentials given for reduction of water demand and increased water use efficiency within the city and the surrounding agricultural belt. Besides technical aspects, institutional/policy-based matters are considered.

Analysing the Relevance of Urban Structure Types for an Integrated Water Management Using Remote Sensing

Linda Firmbach (Helmholtz Centre for Environmental Research - UFZ), Rene Höfer (Helmholtz Centre for Environmental Research - UFZ), Michael Thiel, Carsten Lorz (TU Dresden), Holger Weiß

The rapid urban growth in the recent decades mainly concerns areas of developing and emerging countries. Urbanization, i.e. mostly surface sealing, higher water consumption, and waste water production, is likely to have substantial effects on water resources, e.g. reduced groundwater recharge, shift in infiltration-runoff ratio, waste water collection (treatment and drainage), and water quality issues. The analysis and prediction of effects of urbanization is a major challenge for applied research. The study is part of the IWAS ÁGUA DF project - a German-Brazilian cooperation which is funded by the German Ministry of Science and Education (BMBF) and Brazilian Partners (CAESB, UnB). In the scope of the general project aim of developing an Integrated Water Resources Management (IWRM) for greater Brasilia region, analysing and predicting the effects of urbanization are major challenges of the project. Remote sensing techniques can be used for urban monitoring and save time and costs. The Distrito Federal do Brasil (DF), planned for approximately 600,000 inhabitants, is situated in the tropical savannahs with pronounced dry and rainy seasons. Since its foundation in 1960 the population has been increasing to more than 2.5 million in 2010 (IBGE, 2011). The main objective of this research focuses on the importance of the urban structure types (UST) for an IWRM derived from remote sensing data. UST are units of physiognomically homogeneous urban areas. They are used as spatial indicators that help to divide and differentiate the urban fabric into open and green spaces, infrastructure, and building complexes so that their typical characteristics such as physical, functional, and energetic factors can be identified. Study area of this research are two sub districts of the Distrito Federal do Brasil, characterized by high urban dynamics over the last decades. The methodological approach is interdisciplinary using remote sensing and census data. First socio-demographic

and socio-economic information from recent census are analysed according to their relevance of an IWRM. Second UST will be derived from very high resolution satellite images (Quickbird 0.6 m pan, 2.4 m in the multi-spectral) using an object based image analysis approach (OBIA). OBIA is based on image segmentation approaches which generate areas by referring to one or more homogeneity criteria. The segments have additional spectral information (mean values, median, min, max, ratios) and spatial information (distances, neighbourhoods, topologies, etc.). Furthermore, supplemental information e.g. from GIS data can be included in the classification process (Blaschke, 2010). Finally, the derived UST are compared with the results from the census analysis to demonstrate their relevance for an IWRM.

The impact of agricultural conservation management practices on simulated water balance and sediment loss in a Central Brazil catchment

Michael Strauch (TU Dresden), Jorge E.F.W. Lima (Embrapa Cerrados), Albano Araújo (The Nature Conservancy), Franz Makeschin (TU Dresden)

Fast growing population along with urban sprawl and intensification in agriculture has drastically increased the pressure on water resources of the Federal District (DF), Brazil. Serious conflicts arise in rural areas of the DF, where water is used for both public supply and agricultural production. The problem is aggravated by the lack of efficiency in controlling irrigation and avoiding soil erosion. In order to study the impact of conservation management practices on catchment hydrology as well as sediment generation and sediment yield, we utilized the Soil and Water Assessment Tool (SWAT) for the intensively cropped catchment of the Pipiripau River. The SWAT model was successfully calibrated and validated against measured streamflow and turbidity-derived sediment loads. Model calibration was conducted with particular consideration of precipitation uncertainty. Finally, the model is supposed to be used for scenario simulations with changed management practices that are currently being discussed as useful measures to reduce surface runoff and hence soil erosion. These measures include (i) the implementation of terraces on agricultural land, (ii) sediment basins along roads, and (iii) the conversion of soybean and corn monocultures into diversified crop rotation systems. The study is part of the IWAS-Água-DF project that aims at contributing to an Integrated Water Resources Management for Brasília, DF. Using SWAT as a simulation tool for the Pipiripau River Basin is also a useful complement to the Water Producer Program ('Produtor de Água') established by the National Water Agency (ANA),

because it allows the evaluation of management practices that are supported by the program in form of 'Payments for Environmental Services'. Our research depicts critical issues of watershed modeling, such as model calibration, uncertainty analysis, and the representation of conservation practices within SWAT. Despite numerous uncertainties, we expect that this study will provide useful recommendations for water resource managers especially in the Pipiripau River basin, but also in similar catchments.

Towards cost-effective watershed management in the Brazilian Atlantic Forest: Valuing forest ecosystem services related to water quality in the Guapi-Macacu watershed

Vanesa Rodriguez (Institute for Technology and Resources Management in the Tropics and Subtropics), Udo Nehren (Cologne University of Applied Sciences), Jan Boerner (CIFOR), Juergen Heinrich (Universität of Leipzig), Rachel Bardy Prado (Embrapa Solos), Hartmut Gaese (Institute for Technology and Resources Management in the Tropics and Subtropics)

The Brazilian Atlantic forest is considered a global biodiversity hotspot, harbouring a large number of endemic species, and providing essential watershed services to millions of urban water users. However, agricultural expansion and urban development have reduced the forest area to less than 8% of its original size. Multiple pressures on the Atlantic forest ecosystem continue. Payments for environmental services (PES) schemes are increasingly proposed by local initiatives and supported by international cooperation to manage the trade-offs among agricultural uses and watershed services in a cost-effective manner. Studying the provision costs of as well as the demand for watershed services can help decision makers to evaluate the scope and economic feasibility of PES and alternative management options, such as regulatory measures and land purchases. The Guapi-Macacu watershed in the state of Rio de Janeiro supplies water to 2.5 million inhabitants within five municipalities. Water resources are of utmost importance for agriculture and industries, such as water bottle companies, breweries and the biggest Brazilian petrochemical complex COMPERJ. Our study concentrates on valuing watershed services in terms of controlling nutrient and sediment loads under different land-use systems. Nutrient loads include Nitrogen and Phosphorus found in surface water, whereas sediment loads are measured in terms of turbidity and total solids. Replacement and avoided cost methods are applied focusing on the local water treatment facility to estimate demand for service maintenance and improvement. To provide empirical evidence of the link between land use/land

cover and water quality indicators, we rely on water quality modelling and monitoring specifically adapted to this area. This takes place within the framework of the multi-disciplinary German-Brazilian cooperation project DINARIO/MP2. Spatial conservation opportunity cost modelling is used to study the costs of watershed services maintenance and improvement and derive implication for cost-effective management on the basis of scenario analyses. Early results suggest that aggregate water quality demand justifies investments in watershed conservation initiatives, but PES may not generally be the most cost-effective intervention option vis-à-vis strategic land purchases and regulatory measures.

SE 13-02 - Integrative approaches to water resource management in times of global change 2

Chair: Flurina Schneider, Olivier Graefe

One Scale, Multiple Loci: The Shaping of Water Resources Policy in West Africa

Jean-Philippe Venot (International Water Management Institute)

From the 1990s onwards, the river basin has invariably been singled out as the cornerstone of Integrated Water Resources Management (IWRM) and the sole and 'natural' scale for the planning and the management of water resources. This paper opposes this monolithic and rhetoric vision of the river basin to the multiple loci where water resources policies are shaped by investigating the case of Burkina Faso in West Africa. IWRM policies in Burkina Faso meet global calls of international organizations and the institutional arrangements that are devised appear to echo those observed in the West 'notably in France, not the least because of donors' support. However, the agency of local and national actors clearly expresses itself during implementation processes. Watershed committees appear to be embedded in the socio-political reality of Burkina Faso where a strong bureaucracy disputes decision making to newly formed decentralized government structures. This is for example illustrated by the inherent tension characterizing local watershed committees that are alternatively seen as consultation platforms to vet decisions taken at other scales and true management bodies with the power to implement an action plan. The trajectory of IWRM policies in Burkina Faso and more generally in West Africa frame the river basin as a social and political space. Institutional arrangements for basin management need to internalize discontinuous political processes and the flux of power and influence that span multiple scales. This re-scaling process, embodied by development brokers, is more likely to allow for the engagement of local actors towards sustainable water resources management.

The contested waterscape of Khartoum: Between neoliberal reforms and Islamic discourse

Detlef Müller-Mahn (University of Bayreuth), Anne-Sophie Beckedorf (University of Bayreuth)

The paper presents findings of an integrative study on the water supply system in the Sudanese capital and its recent transformations in the context of

neoliberal reforms, rapid urbanization and local discourses. Using a politico-ecological approach, the case study interprets the current condition of water management as both an indicator for and a result of ongoing socio-political changes. It shows that due to water's specific socio-physical characteristics, water management is more difficult to commodify than other public services, such as electricity. The paper explores the epistemological potential of political ecology for the study of water management in this particular case. Special attention is given to the institutional setting within governmental organizations and the way how they manage, modify and renegotiate water related services in day to day practices. On the basis of observations and interviews at the empirical micro-level within governmental institutions, the paper will discuss the question how and why governmental organizations responsible for water supply implement, modify, negotiate, and contest specific reforms in specific historical contexts; how and why governmental organizations responsible for water supply navigate between different ways of water management; and how and why the government employees involved in these operations form alliances, take decisions, and create different logics, practices and narratives. With respect to Khartoum's waterscape, the paper refers to organization sociology to show how the analysis of internal processes within the main governmental water supply body helps to explain aspects of governance at various scales. In the case of Khartoum, these aspects are closely connected to the transformation of water sector institutions. While these transformations are induced by global models of neoliberal water management, they are modified, partly rejected, partly accepted and adjusted to local contexts, which in turn results in parallel and partly even contradictory ways of water management. In sum, the paper argues for a combination of approaches from both political ecology and organization sociology in order to grasp the complexity of water management and to develop a more integrative perspective on current changes.

Bridging the gap between hydrosystems and hydropolitics: A comparative study of two key concepts in water management

David Blanchon (Université Paris Ouest Nanterre)

Two major concepts have emerged in water sciences in the 1980s. On the « environmental » side, the concept of hydrosystem has profoundly renewed our view of the continental hydrology. On the « socio-political » side, understanding hydropolitics has become the focal point of scientific controversies. These concepts have not only shaped academic debates, but they have also influenced water policies and the implementation of the Integrated Water

Resources Management (IWRM) paradigm. Although they are widely discussed in several academic disciplines, 'hydrosystem' and 'hydropolitics' are seldom studied together. In this presentation, I would like to examine how it is possible to bridge the gap between the two approaches. After a short description of the genealogy of the two concepts, I will focus on the theoretical difficulties which prevent us from using rapid shortcuts. For instance, the use of a systemic approach in hydrology is one major obstacle to its inclusion in research partially based on Actor-Network Theory often used in hydropolitical approaches by authors such as E. Swyngedouw, J. Budds or J. Linton. In the second part, I will see how the use of hydrosystem and hydropolitics conceptual frameworks could change our way of analysing particular issues, such as the implementation of IWRM in South Africa.

SE 14-01 - Localising climate change in a development context: Adaptation to what?

Chair: Detlef Müller-Mahn, Chinwe Ifejika Speranza

Climate Change, perceptions and vulnerabilities: a case study in Brazilian biomes

Teresa da-Silva-Rosa (Universidade Vila Velha), Renato Maluf (UFRRJ- Universidade Federal Rural do Rio de Janeiro), Andrea Vanini (Campus FIOCRUZ da Mata Atlântica), Michelle Bonatti (UFSC), Kamila Mynssen (Campus FIOCRUZ da Mata Atlântica), Catia Zuffo (Universidade Federal de Rondônia), José Carlos Lopes (Universidade Federal do Mato Grosso do Sul), Francisca Gonçalves (Universidade Federal de Rondônia), Larissa Homem (Universidade Federal de Santa Catarina), Luiz D'Agostini (UFSC)

Taking into consideration the impacts caused by climate change (CC) and by extreme weather events, the question of assessing vulnerability becomes crucial in the context of scientific research and development of adaptation strategies and public policies. Based on the assumption that the vulnerability condition is socially constructed, and that it may, as such, change according to transformations in human action, it appears necessary to take the matter to the core of studies on the social aspect of CC, risk level and the prevention of disasters. The social nature of vulnerability is determined by elements such as poverty, inequality, exclusion and access (or not) to sanitation, to water, to food, and to education among other factors. Those factors should be the main focus both in field work and in projects that map vulnerabilities and enable the development of skills in order to identify the most vulnerable members of society and their perception with regard to the climate question. In 2010, a study was undertaken, in the ambit of the project 'Climate Change, Social Inequalities and Vulnerable Populations' (by the Brazilian Network for Social Mobilization/COEP and the Reference Centre of Food and Nutrition Safety/CERESAN/UFRRJ, Brazil), on the perception of CC and on vulnerability assessment. Information was gathered through interviews which consisted of structured questionnaires administered in communities in three Brazilian biomes: the Atlantic Forest, the Amazon and the Cerrado region. 115 low-income families in rural and urban communities who were frequent victims of floods or draughts were interviewed. Issues that emerged in association with each biome and the different populations interviewed, rural riverine communities (Porto Velho, RO) and quilombolas (Campo Grande, MS), as well as communities in the urban

periphery of Florianópolis (SC) and Rio de Janeiro (RJ), were discussed taking into consideration the local aspects of the results. To conclude, at least two points in common must be highlighted. (1) The residents of the communities studied do not have plans or actions to adapt to the natural variability of the climate, and by extension, to CC. This makes the communities more vulnerable and unprepared to act with protective or reactive preventive measures. (2) Thus, it is important to consider the process of developing skills training aiming at the elaboration of a future action plan to include measures that tackle the identification of climate change as an environmental problem with direct causal effects on the development of communities. Likewise, it is important to develop actions that address the practice of organised irresponsibility, here understood as a network of mechanisms which keep environmental problems in a state of normality, or regarded as being of governmental responsibility alone.

Adaptation in the face of socioeconomic transformation: Differing impacts and drivers of formal and informal adaptation strategies to urban flooding in the Mekong Delta

Dunja Krause (United Nations University)

The rapidly developing Mekong Delta is often described as one of the world's most vulnerable regions when it comes to climate change. Facing the multiple water-related hazards climate change might have in store for the region the need for adaptation becomes evident. Yet, many non-climatic drivers, such as the socioeconomic transformation or large-scale development projects influence local realities and interact with natural changes creating a high-risk environment. Considering the speed and scale of ongoing development processes including their local impacts, adaptation should be evaluated from a development perspective and aiming at more than climate change scenarios. Analyzing the public discourse on climate change, it is argued that in order to adapt successfully a stronger focus is needed on the notion of 'adaptivity' and flexibility in (spatial) planning thus also questioning of current approaches and evaluating strategies against the background of potential secondary impacts and cross-scale effects. Using the example of relocation versus in-situ adaptation in urban Can Tho City, Vietnam, this paper traces the information base and guiding principles that shape adaptation endeavors of formal institutions versus flood-affected households. It is argued that the gap between technocratic planning approaches and local perceptions, traditions and beliefs leads to different, partially conflicting assessments of the situation. A prevailing idea of technocratic progress and pursuit of a modern lifestyle following Western or East Asian

examples thus somewhat clashes with the local reality and perceived capacities of many: Whereas formal strategies often focus on engineering solutions and large-scale infrastructure, individual households are affected more by secondary effects and development projects than primary impacts caused by environmental or climate change. This divide may lead to divergent evaluations of options which exacerbate integrated approaches to adaptation. Open and semi-structured interviews as well as group discussions build the basis for analyzing drivers of people's agency and pointing out key evaluation criteria. Understanding the information base and drivers of people's decisions is thought crucial for the inclusive evaluation of adaptation options. It is needed to juxtapose differing principles, to understand value judgments and facilitate dialogue between local stakeholders. Overall, the identification of evaluation criteria and gaps is intended to point out leverages to overcome current limits in adaptive capacity.

Seeing like the Karrayu: Adapting and Securing Livelihoods under Climate Change and State Policy Encroachment in Central Ethiopia

Girum Getachew Alemu (University of Bayreuth)

Local livelihoods in dry land areas in Ethiopia in general have been challenged by extreme weather events such as drought and flood. However, those who primarily inhabit such environments have been practicing their everyday livelihoods not only as the sole actors in such a context but also interacting with other actors that may or may not share similar goals and objectives with their livelihoods. The presence of multiple actors in a local scenario has presented multiple options that entail various decisions as well as strategies to deal with the respective decisions. In many cases agro-pastoral households employ different strategies of dealing with livelihood insecurity ranging from adaptation, appropriation and buffering. However, all these strategies do not come out of a blue-rather they are embedded in the social fabric of that particular community as manifested in livelihood decision making process and the associated power struggle within and across households that share the same resource base. Another peculiar character of households in dry land parts of Ethiopia is the flexible nature of their strategies that are tailored to specific problems in order to secure livelihoods. Despite the flexibility of strategies, Karrayu agro-pastoral households also clearly delineate their own boundaries and define the roles and responsibilities of members and non-members. On the other side of the story, the state is yearning to deliver development to the local community by implementing sedentarization programs. The justification for state intervention is

mostly the failure of the local strategies to respond to the frequent drought in that particular area. Here, drought is used as an escape goat to materialize the state policy in the local domain and the solution is mainly based on 'thin simplifications' of the local context and standardized planning and implementation. Under such scenario, I argue in this paper that a localized approach to both climate change and development is important in order to understand the spaces of strategic maneuver for livelihood adaptation and security by various actors and hence to point out the specific strategies that are tailored to particular objectives so as to tackle the important and recurring question "adaptation to what?". In this paper, based on a total of twelve month field research among the Karrayu agro-pastoral communities of upper Awash valley in Ethiopia, I discuss the dilemmas that households are presented with while both dealing with climate related extreme weather events such as drought and state policy encroachments through sedentarization schemes.

Adapting to climate change? The Kenyan agricultural extension services

Boniface Kiteme (Centre for Training and Integrated Research in Arid and Semi-Arid Development (CETRAD)), Chinwe Ifejika Speranza (University of Bern)

Climate change is adding to the various factors constraining public extension services from continuing to play a key role in improving agricultural production in Kenya. This paper examines how the public extension services is adapting to climate change and what structural or institutional reforms are necessary to enable it to effectively promote farmer adaptation practices. Data was collected through a review of public extension services and empirical studies in three contrasting agricultural production areas of Kenya - agro-pastoral Embu and Makueni districts and fishing in Bodo district. Results show that among others, extension officers know little about the effects of climate change on fish farming compared to crop and livestock production. The study discusses policy and structural linkages between climate research and extension services, extension services content and message on climate change adaptation. While extension officers have knowledge of climate variability and climate change, inadequate government funding, dominant extension models and the socio-economic conditions of their mainly poor clientele limit their actions and effectiveness. Various options are discussed on how to improve the content and messages on climate change including the exchange of knowledge with farmers and researchers in ways that foster adaptation to climate change in the smallholder agricultural sector of Kenya.

SE 15-01 - Man and environmental change: Progress in geoarchaeological applications

Chair: Helmut Brückner, Kosmas Pavlopoulos

The aftermath of flood: Geomorphological evolution of the Danube Delta after reconnecting Black Sea / Mediterranean and its implications on eneolithic settlements location

Jean-Michel Carozza (University of Strasbourg), Laurent Carozza (GEODE - UMR 5602 CNRS), Christian Micu (Institutul Cercetari Eco-Muzeale), Albane Burens-Carozza (GEODE - UMR 5602 CNRS)

Lower Black Sea coastal plain are a key-zone in the understanding of neolithic sprawling during the 7th millennium bc and metallurgy spreading during the 5th millennium bc. The core of this process is the Romanian Dobroudja and particularly the lower Danube delta. Until recent progress, the Danube delta was supposed void of any human occupation as late as late Iron Age. The discovery of a first Eneolithic occupation in the heart of the delta provides a better constraint on paleogeographic evolution and the formation process of older phase of the Danube delta related with the final sea level rise in the Black Sea. If the question of the Black Sea / Mediterranean reconnection is still debated, a consensus seems to emerge to consider it as early (~ 8,4 ky BP) and limited amplitude (~ 40-30 m) phenomenon. After the reconnection occurred, the delta show two major step of evolution : 1) The 'blocked phase' during witch the delta remains confined behind the Letea-Caraorman spit and is dominated by fluvial processes. This stage is poorly documented and constrained. 2) The open sea phase, wave dominated delta type is much better well know as well on chronological and palaeogeographical point of view. Data collected on and around the eneolithic site of Taraschina allows us to document the last evolution phase of the blocked delta and its transition to open delta stage. After the Black Sea reconnected to global ocean, the Danube delta grows within fresh water lagoon developed in context of sea-level rise. Evidence from former drilling and new palaeoecological data support this scenario. Between the reconnection phase around 8.4 ky BP to 6.0 ky BP, aggradation has domined the delta evolution, controlled by rapid sea level rise. Danube delta evolution could be regarded as a « bay head transgressive delta ». From 6.0 ky BP, decrease in sea-level rise rate initiated a stage of rapid progradation of the delta and the beginning of St George lobe formation. This phase is well documented by a series of coring around the eneolithic site of Taraschina and have huge influence

on human settlement occupation. During 6.5 ky to 6.0 ky BP rapid aggradation occurred in the lagoon and stops abruptly. This period corresponds to the occupation of Taraschina settlement now wildly silted. We proposed that the site was built at the edge of a loessic terrace recognized in core and correlated with other Pleistocene deposits within the delta. This terrace probably constitute the southern extend of the Bugeac plateau. During 6.5 to 5.9 ky BP interval high variability in fluvial regime is observed. Two phases of high fluvial regime (Flood Dominated Regime like) are recorded between 6.4 to 4.3 ky BP and 4.1 to 5.9, separated by hydrological quiescence (Low Water Regime like). Synchronicity between hydrological regime and settlement occupation is point out, implying rapid adaptation of eneolithic societies to environmental variability.

Geochemical investigation of palaeo-pollutions in sedimentary archives of the ancient harbour of Rome (Tiber delta, Italy)

Hugo Delille (UMR 5600), Jean-Philippe Goiran, Janne Blichert-Toft, Francis Albarède, Jean-Paul Bravard, Simon Keay

Important pollutions were generated during the Antiquity. Our study focuses on the analysis of palaeo-pollutions in Portus, the Tiber delta, downstream of ancient Rome. The hypothesis is that harbour basins had the ability to integrate pollutions by heavy metals originating from local economic activities (proximal pollutions: foundries, fulling, tanning), as well as from activities related to the upstream development of Rome (allochthonous pollution). Discharges of waste water from Rome concentrated into the Tiber were forwarded to Portus through a network of canals connecting the river to the sea. In this manner, harbour basins accumulated both allochthonous and autochthonous heavy metals. Three sediment cores have been selected from the Portus area. The characterization of contaminants is carried out by high-resolution polymetallic concentration analysis of Pb, Cu, Sn, Zn, As, Cd, Ni, Ag, P, S, etc. followed by statistical treatment of these data (PCA, HAC). We are focusing in particular on Pb, which were widely used by the Romans during the Antiquity, especially in buildings, hydraulic structures, food, etc. The simple measurement of Pb concentrations, however, is insufficient for deltaic environments, where mineralogical variations of sediments take place extremely rapidly. These variations influence the concentrations of Pb in the sediments as a function of the intensity of detritism. We therefore also measure the Pb isotopes, which are unaffected by textural variability. An additional strength of Pb isotopes is their ability to discriminate between proximal lead (variations from one core to another attesting to their nature and origin) and distal lead (no isotopic variation between

cores). We have also implemented multi-elementary tracers (Ca, Mg, K, Al, Ti, Na, Sr, Mn, etc.) for a better discrimination between local and/or regional origin of pollution and sedimentary deposits. The behavior of combined elements and the preservation of their relationship over the entire height of the core can be interpreted as the result of environmental changes through time. This behaviour results in chemically defined lithofacies.

Pollen and sediment evidence for the influence of late Holocene climate change on chestnut cultivation at the Seonam-dong archaeological site, Gwangju, Korea

Jungjae Park (Seoul National University)

We present pollen and sediment evidence for the influence of late Holocene climate change on chestnut cultivation from the Seonam-dong archaeological site in Gwangju in southwest Korea. The relationship between the environment and agricultural activities has not been properly investigated in Korea using a paleoenvironmental approach due to the lack of undisturbed samples with high sedimentation rates. This study clearly shows climate-induced changes in chestnut production, which was contemporaneously recognized by the Chinese as an important and unique local food source. It is also shown that the people's adaptation to climate change resulted in both the degradation and the recovery of the local forest ecosystem in the study area. The evidence from the Seonam-dong site supports the following three conclusions. 1) Chestnut cultivation was enhanced to compensate for the decreased crop yields due to the climatic deterioration between 1100 BC - 500 BC and between AD 200 - AD 800. 2) Chestnut cultivation declined between 500 BC - AD 200 and between AD 800 - AD 1600 as crop production increased sufficiently to sustain the population due to the climatic amelioration and/or agricultural improvements. 3) The increased chestnut cultivation led to forest disturbance and increased flooding, whereas the forest staged a recovery during the periods of decreased cultivation.

Environmental change and its impact on human culture in the Central Peloponnese – a comparison of two ~8 ka lake records from Stympthalia and Asea, Greece

Ingmar Unkel (Kiel University), Helmut Brückner (University of Cologne), Walter Dörfler (Kiel University), Timothy Filley (Purdue University), Jeanette Forsén (University of Gothenburg), Christian Heymann (Kiel University), Haydn J. Murray (Indiana University), Oliver Nelle (Kiel University), Arndt Schimmelmann (Indiana University), Christine Schriener (Indiana University), Eleni Zagana (University of Patras)

Sediment cores from inland lakes typically express a more constant sedimentation, thus providing a more continuous archive than alluvial or near-shore sediment archives. The central Peloponnese has been lacking detailed reconstructions of the palaeoenvironment, although a direct comparison of sedimentary and other geoarchives of climate and environmental changes against the rich archaeological and historical records of ancient Greek societies may shed new light on human-environment interactions. In 2010 we recovered four sediment cores from a former lake bed in the valley of Asea near Tripolis. In particular, one of the cores, the 8 m long core Asea-1, covering the last 17 ka, has the potential to provide detailed information about the palaeoenvironment. In the same year, we also retrieved a 15.5 m long core (STY-1) at the center of Lake Stympthalia, the only remaining natural lake on the central Peloponnese, which seems to have recorded the entire Holocene and Late Pleistocene back to 40,000 years BP, based on our ¹⁴C chronology. Two supplementary cores (STY-2 and STY-3) of 10 and 6 m length were taken in Lake Stympthalia in 2011. The first step of our research focuses on sedimentological and geochemical proxies of the last ~8 ka. High-resolution AMS-¹⁴C dating and Bayesian age-depth-modeling was used to establish time series of climatic and environmental variables. We attempt to correlate our records from the Peloponnese with (1) other Mediterranean and global patterns of Holocene climate change, and (2) with archaeological and historical information for this region. While there is a profound archaeological record of cultural changes in mainland Greece that have their climax at around 4200 cal BP (2200 BC), there is still a lack in linking this record with natural archives recording climatic and environmental changes. Many studies dealing with this issue agree that these changes might have influenced cultural development. Going into more detail, we shall focus on the balance between sustainability and exploitation, trying to answer questions like: How did the different ancient cultures manage their water resources? How sustainable was their agricultural land use? So far, our

geochemical analyses of sediments from Lake Stymphalia have shown that the water supply in the region fluctuated over time in response to changing climate. The Rb/Sr ratio as a proxy for changes between dry/warm and wet/cold conditions indicates pronounced humid phases around 6800, 4000'3700, 3500'3000 and 500'200 cal BP, partially corresponding to known phases of rapid climate change. Together with the geochemical analyses from Asea, which were still in progress when submitting this abstract, we are going to present the first steps towards a detailed and comprehensive environmental reconstruction of the central Peloponnese.

SE 16-01 - Palaeoenvironmental reconstruction along the corridors of modern human dispersal from Africa to Europe

Chair: Frank Schäbitz, Henry F. Lamb

A 200,000-year record of climatic change from Lake Tana, source of the Blue Nile

Henry F. Lamb (Aberystwyth University), C. Richard Bates (University of St Andrews), Sarah Davies (Aberystwyth University), Dei Huws (Bangor University), Michael Marshall (Aberystwyth University), Tony Prave (University of St Andrews), Helen Roberts (Aberystwyth University), Harry Toland (Aberystwyth University)

Seismic and core data from the deep sedimentary infill of Lake Tana, the source of the Blue Nile, provide the first continuous ca. 200 ka palaeoenvironmental record from continental NE Africa. Chronological constraints on the 92 m core are from polymineral fine grain IRSL dating combined with radiocarbon analyses of the younger sediments. Within the limits of resolution, the seismic data show: (1) horizons between 200 ka - 93 ka to be relatively conformable (no major erosion events); (2) two phases of shallow-water prograding wedge construction between 93 ka - 61 ka, separated by erosion at 87 ka and terminating with a prominent unconformity at 61 ka; (3) a seismically transparent unit between 61 ka and 52 ka interpreted as recording high sedimentation rates and terminated by an inferred desiccation event; (4) a decrease in sedimentation rate between 52 ka and 17 ka, punctuated by a cut-and-fill sequence and a short period of increased sedimentation between 40 ka - 34 ka; and (5) a previously reported desiccation event at 17 ka with subsequent cut-and-fill facies, contemporaneous with the Younger Dryas, followed by drape fill to present day. Geochemical data from high-resolution XRF scanning support the seismic interpretation. Interpreted wet and dry intervals in Lake Tana correlate well with Gulf of Guinea sea-surface salinity, and correspond to run-off and dry episodes reported for the Nile Delta. Correlation with NW Indian Ocean sea-surface temperature is less consistent, but offers a plausible explanation for the change from high to low sedimentation rates at 52 ka. The record also aligns well with the marine isotope stage chronostratigraphy, but does not readily manifest individual Greenland stadial - interstadial cycles, or most Heinrich events. The correlations with global proxies suggest that NE African climate change over the last 200 ka is primarily

linked to millennial-scale high-latitude northern hemisphere changes. The most prominent environmental change appears to be at ca. 61 ka, marking the end of wedge progradation followed by a major dry phase that lasted throughout MIS4. Environmental pressure over this sustained dry period may have influenced the size and distribution of early modern human populations.

Humid corridors across the Sahara and the origins of the Aterian

Nick Barton (Institute of Archaeology), Mike Rogerson (University of Hull), Tim Brücher (Max Planck Institut f. Meteorologie)

MSA (Middle Stone Age) Aterian assemblages are found over a vast geographical area of North Africa extending from the Maghreb to the Western Desert of Egypt. Re-dating of sites in Morocco suggests that some of the earliest evidence for this technocomplex occurs in the Maghreb in late MIS 6 and MIS 5 thus implying a more complicated pattern of early modern human dispersal within Africa than is traditionally accepted. The new dates also suggest that re-thinking is necessary of population and cultural histories in North Africa immediately before the proposed last out-of-Africa exodus at 70-60 kyr. Moreover, a new generation of climate and hydrological models means that the past surface conditions in North Africa can be elucidated in unprecedented detail. In this paper we review the different potential dispersal routes across the 'green Sahara' and consider alternative theories about corridors and hydrological processes that may have given rise to the early appearance of the Aterian in the west. Barton, R.N.E.1, Coulthard, T.2, Rogerson, M.2, Ramirez, J.2 and Brücher, T.3 1 Institute of Archaeology, University of Oxford 2 Department of Geography, University of Hull 3 Max-Planck-Institut für Meteorologie, Hamburg

Cave and rockshelter deposits of the Western Mediterranean – Records of Last Glacial cultural and environmental change

Martin Kehl (University of Cologne), Jörg Linstädter (Institute of Prehistoric Archaeology), Klaus Reicherter (Institute of Neotectonics & Natural Hazards), Gerd-Christian Weniger (Neanderthal Museum)

Marine and limnic records suggest that Heinrich stadials were the driest and coldest climate phases during the Last Glacial in the Iberian Peninsula (IP) and, probably, Northern Morocco. Heinrich stadials also left imprints on sediment sequences of caves and rockshelters which include most of the palaeolithic sites and, therefore, are of utmost importance for analyzing the response of

palaeolithic hunter-gatherer communities to climate change. We analyzed archaeological and geochronological data of Iberian caves and rockshelters and discussed a possible correlation of Heinrich stadials 3 and 2 with the end of the Early Upper Palaeolithic and Gravettian technocomplexes, respectively (Schmitt et al., accepted). In Morocco, similar correlations between cultural and climate phases are indicated, but evidence is limited, particularly for Middle Palaeolithic to Iberomaurusian time (Linstädter et al., submitted). Here, we examine the sedimentary records of Iberian and Moroccan sites in order to evaluate their stratigraphic consistency and possible imprints of climate change focusing on the period from Mousterian/Middle Palaeolithic to Solutrian and Iberomaurusian times, respectively. The sites are mostly located in carbonate rocks within the Alpine fold belts and few are found in Tertiary Basins and the Iberian Massif. The sedimentological information reported varies to a large extent related to the time of excavation, the complexity of the analytical approach and the reliability of geochronological frameworks. Overall, few detailed sedimentological studies are available. Also, some long stratigraphies of well known sites, such as El Pendo or Cueva Beneito, have recently been challenged. The review reflects the still limited knowledge on sediment properties of Iberian and Moroccan cave sites. The idiosyncratic nature of these deposits requires detailed sedimentological descriptions for understanding site formation processes, enable sound stratigraphic correlation and deduce palaeoclimatic information. These will strengthen the significance of cave and rockshelter fills as archives of climate and cultural change in the Western Mediterranean. Schmidt, I., M. Bradtmöller, M. Kehl, A. Pastoors, Y. Tafelmaier, B. Weninger, G.-Chr. Weniger (accepted): Rapid climate change and variability of settlement patterns in Iberia during the Late Pleistocene. - Quaternary International Linstädter, J., Eiwanger, J., Mikdad, A., G.-Chr. Weniger (submitted): Human occupation of Northwest Africa: A review of Middle Palaeolithic to Epipalaeolithic sites in Morocco. - Quaternary International

Sodmein Cave, Eastern Desert, Egypt – A key site for investigating Northeastern Africa as a possible modern human dispersal route out of Africa

Olaf Bubenzer (Heidelberg University), Philip Van Peer (Katholieke Universiteit Leuven), Mathias Ritter (University of Cologne), Karin Kindermann (University of Cologne), Alexandra Hilgers (University of Cologne)

Understanding the movement of modern humans through and out of Africa from the centre of origin into Northeastern Africa and to Europe is a major research

issue in palaeo-sciences. It is thought that the habitat expansion, accompanied the interglacial period of OIS 5e, relaxed ecological constraints to such a degree that the movement of modern humans through the Eastern Desert of Egypt towards the Levant became feasible. Interdisciplinary geoarchaeological research as part of the German Collaborative Research Centre 806 'Our Way to Europe: Culture-Environment Interaction and Human Mobility in the Late Quaternary' (www.sfb806.de) in the area of Sodmein Cave, situated in an isolated Tertiary limestone complex (Jebel Duwi) of the Egyptian Red Sea Mountains, around 30 km west of the seaport Quseir, provides the opportunity for the integration of the archaeological data and the geo-archives within a stratified context. Besides the extraordinary archaeological sequence of the cave, the research shows that the topography (e.g. wadis, basins) and the palaeo-environment (e.g. climate, vegetation) could have played an important role in the dispersal of modern humans out of Africa.

SE 17-01 - Plants, play and place: Green Environments as a contribution to children's healthy development

Chair: Silvia D. Schäffer, Christina R. Ergler

Observing children's play in Naturescape: Key findings relating to social and environmental interaction

May Carter (PlaceScape)

Research undertaken in 2010 by Centre for the Built Environment and Health (CBEH) at The University of Western Australia (UWA) for Kings Park Botanic Garden and Parks Authority (BGPA) explored child and parent perceptions and preferences relating to outdoor play environments. This research demonstrated strong support for play areas within the urban landscape that can reconnect children with nature and nature-based play and opportunities. Following this preliminary research, BGPA commissioned an observation study of the newly constructed nature-based play area (Rio Tinto Naturescape Kings Park). Over two days during spring 2011, the behaviour of 372 children (accompanied by adults in either family or school groups) was observed within six Naturescape activity areas. Quantitative and qualitative data was collected by a team of trained observers using a data collection instrument developed specifically for this project. Particular attention was paid to: observation of the type and frequency of children's interaction with different activity elements within Naturescape; positive/negative environmental interaction by children; positive/negative social interaction between children; sizes of groups playing together; and adult involvement in play. In addition, children, parents and teachers were surveyed to gauge children's perspectives of specific activity areas; adult overall perspectives of Naturescape; and identification of potential safety issues by parents and teachers. Data collected was used to develop strategies to maximize play and educational opportunities within Naturescape. Several areas of beneficial experience for children visiting Naturescape were identified and include: enabling contact and experience with nature and fostering future environmental care; providing opportunity for creative, imaginative, non-adult directed play and for interactive play, team building and cooperation; developing problem solving skills; promoting physically active play; and complimenting child development and learning outcomes. These findings resonate within current literature suggesting that nature-based activities for children can have beneficial effects on children's personality development, cognitive functioning, attitude and school behaviour. Playing in natural

environments can assist with building children's motor skills and play in natural settings is associated with increased intensity of physical activity. Our research findings provide some unique observational data not previously captured in published studies. This presentation will provide an overview of the research methods used and discuss key findings, particularly those relating to social and environmental interactions. Authors Dr Karen Martin, Assoc. Professor Lisa Wood, Jacqueline Samson, Centre for Built and Environment and Health, The University of Western Australia Dr May Carter, Executive Director, PlaceScape

Urban children's perception and experiences of nature in their neighbourhoods: A case study from 'clean and green' New Zealand.

Robin Kearns (The University of Auckland)

While New Zealand projects a 'green and clean' image internationally and its citizens regard themselves as outdoor people, there is limited knowledge of its children's environmental awareness. Recent urban intensification and declining parental license to explore local environments independently has potentially reduced children's knowledge of the natural environment. We consider how children (8-10 years) resident in inner city apartments and suburban housing in Auckland (population 1.4 million) conceptualize nature in research that used child-led neighbourhood walks. While urban compaction is deemed more sustainable, we found that apartment-dwellers were divorced from knowledge of, and activity in, natural settings. We reflect on the impacts of this 'retreat from nature' and argue that, in order to exact positive change, policies should not only focus on the maintenance of healthy environments but also enable children to rediscover 'the local' through promoting the therapeutic effects of engagement with the 'natural' world for benefiting a healthy development in times of obesity and associated health risks.

School gardening, a safe alternative for outdoor play and access to the natural environment? A critical review.

Liz Trenchard (Coventry University), Moya Kneafsey (Coventry University), Michelle Newman (Coventry University), Gemma Sutton, Elizabeth Cheese (Coventry University)

There is a common sense view that contact with the natural environment improves children's general health and emotional well-being and may also improve academic attainment. Despite this common sense view, children in the developed world today have restricted opportunities for outdoor play and

interaction with the natural environment. Children now lead more sedentary lives compared to previous generations, and this lack of physical activity is thought to be one of the reasons for the increase in childhood obesity and other diseases. The barriers to outdoor play may be physical, a lack of green space in urban environments, or busy traffic which makes play unsafe. But equally a child's ability to roam freely may be restricted by their parent's concerns about their children's safety, fears of predatory strangers who may lurk in playgrounds or unsupervised green spaces such as woods and the urban fringe or exposure to the 'harmful' rays of the sun. In the UK there has been a recent rapid growth in the number of schools undertaking gardening and food growing activities. Initially, the focus of these initiatives was mainly on healthy eating. Nevertheless, if children have restricted access to green space, could school gardening programmes provide alternative opportunities for outdoor learning and safe supervised outdoor play? The main aim of this paper will be to produce a critical review of the literature available, to determine if there is evidence that school gardening programmes have a positive impact on children's health and well being and understanding of the natural world. The review also aims to determine if there are barriers to implementation, or opportunities for increasing participation and does the evidence confirm the commonsense view that contact with the outdoors 'natural' environment improves emotional well-being, general health and academic attainment for many children. Whilst locating our review within the context of international interest in improving children's access to green spaces through schools, our paper will take the United Kingdom as a case study and focus on the recent policy and initiatives which aim to encourage school growing. The paper will also highlight the challenges involved in 'measuring' the impacts of school growing programmes. These include uncertainty as to how to assess impacts quantitatively, difficulties in comparing qualitative data in a meaningful manner, and challenges in comparing analyses from the many different disciplines which have contributed to knowledge in this area so far. Initial research suggests that children are very rarely included as stakeholders when the success of such programmes is evaluated, the paper will also investigate ways in which this can be addressed.

SE 18-01 - Protected areas and tourism planning – preparing for global challenges 1

Chair: Susanne Becken, Hubert Job

Use of spatially explicit annealing techniques for ecotourism planning- a case study from Manas Tiger Reserve and World Heritage Site, India.

Sonali Ghosh (Aberystwyth University), Richard Lucas (Aberystwyth University)

In this paper we discuss the application of Marxan a decision support tool for conservation zoning in Manas Tiger Reserve, India. Manas is a UNESCO designated world heritage site and is well known for its outstanding natural beauty and rich biodiversity. The site has however, witnessed major upheavals including significant destruction of ecosystem properties in the mid 1990s that was mainly attributed to armed conflict and civic unrest that led to general disruption of law and order. The protected area (PA) has since been revived and is currently on a path to recovery with some proactive conservation measures such as reintroduction of locally extinct wildlife species; rebuilding of infrastructure and public support by promoting community-based ecotourism and livelihood activities. At present there are more than thirteen local ecotourism centres that assist the PA authorities in protecting the buffer. These ecotourism centres are usually run and managed by trained local youth and surrendered poachers who are also expert wildlife trackers. The key tourist attractions include wildlife viewing of rare and endangered species such as the Golden langur, Bengal florican along with Rhino, Tiger and Elephants. We used Marxan with Zones (V1.0.1) to analyse whether the eco-tourism centres had adequately represented the area and biodiversity values of the PA. Marxan uses spatially explicit annealing techniques to allocate planning units to multiple configurations such as tourism and core zones. The purpose is to assign each planning unit in the PA to a particular zone in order to meet a number of ecological, social and economic objectives at a minimum total cost. The resultant maps depict the gaps and potential of augmenting the tourism network and suggests suitable areas for wildlife management planning including the designation of multiple use areas in the buffer region. Preliminary results indicate the need for including local communities along the western periphery of the National Park into the tourism and multiple use areas. The techniques developed here demonstrate the need to include computer automated spatial zoning techniques into existing PA

management plans and ecotourism planning in India. Key words: Marxan, community based Eco-Tourism, Manas,

Vulnerability of Nature Based Tourism to Climate Change: Grassroots Perspectives from the Nepal Himalaya Protected Area, the Annapurna Conservation Area

Anu Kumari Lama (Lincoln University)

Nature based tourism is a major incentive for nature conservation and the contributor to the local economy of Nepal Himalayas' most popular protected area - the Annapurna Conservation Area (ACA). In recent years, the global environmental changes pose significant challenges for the nature based tourism system (NBTS) with the potential to negatively impact its key resources (natural, human and tourism) and the livelihood of the people residing in the mountain regions of the ACA. This paper provides the first 'on-the-ground' perspectives on the vulnerability of the NBTS of the lower Mustang region of the ACA, which is experiencing a phenomenal phase of social change driven by multiple stressors of the global environmental change. The dynamics of changes brought about by these stressors and especially climate change are important vulnerability contexts for the tourism stakeholders of this region. Using a case study approach and a mix of qualitative methods, the paper portrays the stakeholders' perceptions on their understanding of climate change, its impacts on the NBTS and their capacity to respond to such impacts. The paper also presents an approach to assess the vulnerability by applying the vulnerability assessment framework model tailored to the characteristics of the NBTS and by framing the responses of the stakeholders into an impact pathways framework developed specifically for the region. The study found that the NBTS is exposed to both climate variability and change. From the impact pathways framework, climate variability is perceived to have affected all three key resource bases of the NBTS, indicating that more systemic change in the climate could pose significant threat to the sustainable development of tourism in the region. However, it was also evident that the context for stakeholders' vulnerability to climate change and their adaptive capacities are multidimensional as they are shaped by wider perceptions and knowledge of climate change. In turn, these perceptions are likely to influence the NBTS itself and its vulnerability to climate change. The paper finally provides briefing on the implication of the findings for sustainable NBT management in the lower Mustang region of the ACA.

Natural landscapes appreciation: Outcomes for protected areas and tourism (comparison between Russia and Japan)

Elena Petrova (Lomonosov Moscow State University), Yuri Mironov (Russian Academy of Sciences)

Up-to-date urbanization, increasing in industrial, transport, and other man-made load as well as other challenges threaten natural landscapes at different levels; from local to global one. When revealing areas for special care and protection one should take into account not only objective appraisal of their natural peculiarities, significance, and usefulness but also their aesthetic originality, because it is very important to preserve beautiful landscapes for the next generations. At the same time, the beauty and attraction of a landscape play the most important role in choosing natural objects for tourism and recreational purposes too. The scenic beauty and high aesthetic value of a landscape is for example one of the key prerequisites for giving a National Park status. People belonging to different cultures differ by their landscape preferences due to a number of ethno-cultural, historical, social, and environmental factors. Thus, the 'outside view' of another culture representatives allows us to see unusual in usual, to assess originality and beauty of familiar landscapes, and to find out new aesthetic features. The purpose of this study is to find out new criteria for revealing of valuable natural objects for protected areas and tourism, using a cross-cultural analysis of landscape preferences in Russia and Japan, in two countries with deep-rooted traditions of landscape appreciation. The photo database of landscapes both similar and unique for Russia and Japan was created. The respondents in both countries are suggested to classify and group photo images of different landscapes according to their personal perception as well as to estimate the attractiveness and exoticism of given landscapes images. Using elementary and multi-dimensional statistics methods we revealed some common features of emotional and visual perception of landscapes, and the main points of differences between the Russian and Japanese cultures, as well as between groups of Russian respondents from different regions (Moscow, Siberia and Kamchatka). While grouping landscapes the most important feature appeared to be the presence/absence of water and type of water basin. Topography is also important for the Russians, while both visual and seasonal characteristics are significant for the Japanese. Russian and Japanese respondents generally agree in assessing the attractiveness of different landscape types, but evaluate their exoticism differently. It was revealed that for Russian respondents the most exotic landscapes are the most attractive, although we can't see such a tendency for Japanese respondents. Despite all

the differences, the most attractive for both Japanese and Russian respondents are mountains, mountain lakes and waterfalls. These landscapes are the most suitable for development of ecotourism. Ecotourism is the form of land use that can reconcile such conflicting goals as of nature conservation, tourism and regional development.

National parks and tourism labor markets in Arctic Sweden

Dieter Müller (Umeå University)

Sometimes seen as location for residual capitalist activities only, peripheral areas in industrialized countries have particularly suffered from globalization and subsequent economic decline for a considerable time. In this context national parks have been considered a tool for regional development. Thus instead of focusing environmental protection only national parks are increasingly seen as potential tourism destinations. Growing employment in adjacent communities induced by tourism to national parks is the major expected economic impact. Recently this assumption has been challenged frequently. A growing number of national parks and other protected areas implies that national park status does not guarantee tourist arrivals. Moreover several studies indicate local resistance against further nature protection and thus further restrictions. This is particularly true for peripheral locations where alternate land uses include mining and forestry promising employment, in-migration and high income-levels. Consequently it can be argued that national parks in cases where they fail to deliver the expected economic impacts are contested and challenged. Hence, a successful tourism development becomes increasingly crucial for justifying nature protection not least in the eyes of the local community. Against this background the purpose of this paper is to analyze the geography of labor market change in the World Heritage Area Laponia, Sweden, containing several major national parks. This is facilitated by a dataset on labor market change in the area. Mainly descriptive statistical methods are used to analyze the patterns of change. The core objective is to assess the consequences of a turn towards tourism for employment and economic well-being in the destination communities. The paper departs from theories on restructuring and peripheral tourism development. Accordingly nature-based tourism at least theoretically offers alternatives for people who lost their employment owing to de-industrialization in the primary industries. The jobs that are an outcome of this process are however hardly suitable for substituting incomes from industrial jobs. Thus the tourism labor market seems to be isolated from other sectors of the labor market and hence attracts incoming labor mainly. Therefore the recent

interest in natural resources like biomass, oil and gas and mining products, redirects focus back to the primary industries. Thus tourism appears not to be an end in itself, but rather a way of hibernating economic decline in other sectors. To accomplish wider reaching economic impacts linkages to other economic sectors have to be established. Otherwise there certainly is a risk that national parks and other protected areas are threatened by competing land-use interests promising desired impacts that tourism fails to provide.

SE 18-02 - Protected areas and tourism planning – preparing for global challenges 2

Chair: Susanne Becken, Hubert Job

Tourism, sustainability and governance in National Parks – the case of the Peak District National Park, UK

Nora Mehnen (University of Groningen), Ingo Mose (University Oldenburg), Dirk Strijker (University of Groningen)

In the UK National Parks are major tourist and recreation destinations, but with increasing numbers of visitors, problems according to 'mass tourism' emerge. Recently initiatives of the national government (e.g. the Sustainable Development Fund of 2002) are promoting sustainable development in National Parks. Pilot initiatives will be given support to sustain biodiversity, adapt to climate change, consider demographic change etc. and thereby make National Parks 'models for sustainable development'. The purpose of this paper is to describe and evaluate the governance structures and the decisive role of networks, tourism partnerships and schemes in the light of the above challenges in a systematic way by the example of the Peak District National Park (Peak Park). The Peak Park is an outstanding example for National Park development in England, because it is the oldest park, and because it is one of the most popular National Parks in the country. Tourism is one of the main industries in the Park with more than 8 million visitors every year. Whilst the Peak Park has only 38,000 residents, it is surrounded by the cities of Sheffield, Manchester, Leeds and Nottingham and thereby easily accessible to more than 20 million people. Although tourism does make a significant contribution to the quality of life of local communities in the Park, the industry tends to offer part-time, low paid and seasonal work, and local people have little say in how tourism develops in their area. 85% of visits to the Peak Park are made by car. Traffic congestion has all kinds of negative external effects, for the residents and for the tourists. Other problems include footpath erosion, damage to wildlife habitats and farmland. Although most of the land is in private ownership, the National Park Authority is responsible for drawing up policies for planning and managing the National Park. It has developed different policies on recreation and sustainable tourism. These strategies and schemes are implemented in partnerships with the tourism industry, local authorities and other agencies to provide a 'high quality visitor experience'. The National Park Authority aims to resolve potential conflicts through good management, discussion and dialogue, with priority on

conservation. So, the Peak Park illustrates the development of a diverse system of governance structures which has major relevance for the design of future pathways in sustainability. Especially the role of networks in the National Park comprising public, private and civic actors is significant. We conclude that National Parks such as the Peak Park, presently facing major future challenges, provide a specific testbed to observe governance structures and their relevance for tourism planning. As experiences in the Peak Park advice, negotiation, dialogue and discussion for reaching agreements and consensus are crucial for the design of future pathways in sustainability.

Economic value of National Parks as rationale for conservation? – The case of Bavarian Forest National Park, Germany

Marius Mayer (Julius-Maximilians-Universität Würzburg)

German National Parks (GNPs) are under pressure from differing and conflicting policy goals and land use trends. As per the National Biodiversity Protection Strategy, until 2020, 2% of Germany has to be under strict protection. This requires the banning of traditional land uses in the existing parks to the greatest possible extend. Similarly, two radical government decisions, such as stopping the use of nuclear power in 2011, and promotion of renewable energy (to fulfill the Kyoto Protocol commitment) are leading to higher wood prices. As most GNPs consist of forests, there is a considerable demand to continue traditional land use practices. In addition to this, the ongoing financial crisis and the resulting budget cuts means that the willingness of decision makers to allocate money for conservation, specifically in compensating the opportunity costs of traditional land use in national parks, may be limited. These backgrounds set the need for conducting economic valuation of National Parks so as to provide objective information, enabling policy makers to deal with these land use conflicts. Till date a complete cost-benefit-analysis of a German National Park does not exist. This study tries to close this research gap through a case study from the oldest and most well-known protected area of Germany. The research aims at clarifying some specific fundamental questions such as: (1) Is the designation of National Parks economically justified? (2) Can revenue from park tourism compensate for the termination of forestry in protected areas? (3) Which stakeholders profit from national parks and who bears their costs and at which geographical scales? The analysis was carried out using the value-added analysis, travel-cost model and contingent valuation, economic impacts of park tourism, its recreational value and visitors' willingness to pay were measured. The productive use value of the park in terms of timber sales and the direct

costs of park were obtained from the Park Administration and the Ministry of Finance. The opportunity costs of forestry use and wood processing industries and indirect costs of the park were modeled, the former, using the actual market-price based data of the park, commercial and state forestry units as well as sawmills, and the latter, with the help of GIS applications and the results of an opportunity cost analysis. Results suggest that National Parks cannot be seen as economically unfavorable land use options in any case. At a national level, half of the scenarios show a positive cost-benefit-ratio (CBR) for the Bavarian Forest National Park whereas half show a negative CBR. This variation stems from differing assumptions and methodological rigidity. At the regional scale, the National Park can be definitely regarded as a tool for economic development because it generates net monetary gains for the surrounding counties.

Tourist town on the edge: Marginality and resilience at Franz Josef Glacier, Westland National Park, New Zealand

Stephen Espiner (Lincoln University), Susanne Becken (Lincoln University and Griffith University)

Protected Areas (PAs) serve multiple functions and provide a useful focus for regional development. Significant relationships exist between protected areas, neighbouring communities, tourism interests and land management agencies, creating complex alliances which sustain the whole. The social-ecological system that includes the network of relationships around PAs is also subject to multiple internal and external factors, some of which threaten the integrity of PAs and the futures of communities that rely on them. For some PAs, geographic isolation and particular environmental conditions contribute to their marginality as destinations - potentially compromising community lifestyle, business profitability and visitor safety. In destinations such as these, emergent global climate trends and predicted energy crises may be the difference between survival and collapse. Situated adjacent Westland National Park, on a narrow strip of land between the Tasman Sea and New Zealand's Southern Alps, the tourist town of Franz Josef is 'on the edge' in many respects. A tectonic plate boundary runs down the main street and major rivers carve out the boundaries of the town. There is a single road running north to south, and no rail or sea access. The town is almost completely dependent on tourism and especially reliant on nearby Franz Josef Glacier as a tourist attraction. Issues associated with geographic isolation are compounded by major threat of flooding and earthquake, sensitivity to fluctuating fuel prices, and climate change scenarios which imply that the region's glaciers that have lured visitors for well over a

century may be melting into the background. In partial response to the latter, tourism stakeholders have attempted to diversify the town's attractions, ironically developing a new focus on the world's rarest kiwi - itself perhaps irredeemably threatened. Drawing on a series of interviews with tourism stakeholders, this paper explores dimensions of Franz Josef's marginality as a tourism destination, and seeks evidence of the community's resilience to current and future conditions. Early analysis suggests a high level of inherent adaptive capacity, with a well-organised community focussed around a 'pioneer spirit', disaster management strategies and other initiatives to counteract vulnerability. The paper also considers the relationship between the concepts of marginality and resilience, and discusses the extent to which this destination is equipped to tolerate future social, economic or environmental perturbations such as predicted changes in climate and increases in fuel costs; and what adaptations might be possible to sustain Franz Josef in coming decades. The paper concludes by contemplating the future of remote protected area tourism destinations in the context of rapidly changing social, economic and environmental conditions.

Assessing the Tourism Potential of the Lake Bosomtwe Basin of Ghana

Emmanuel Mensah (University of Cape Coast), James Kweku Eshun (University of Cape Coast)

In rural areas with declining agrarian economies, tourism provides diverse opportunities for rural dwellers to empower themselves and improve their well-being through the acquisition of jobs, income and information gained through the inflow of tourist and the development of rural resources to support tourism. In such rural areas, it is important that the potential for tourism be assessed by examining the interactions between recreational resources preferences of visitors and the supply of rural resources which can be used to support tourism development. It is also important to seek the views of rural dwellers in order to gain a holistic view of the potential within a destination. This paper examines the tourism potential within rural lake side communities administered by the Bosomtwe-Atwima-Kwanwoma District Assembly of Ghana. An inventory of tourism and recreational resources was conducted using Geographic Information systems (GIS) and Remote sensing (RS). This was followed by a survey of visitors to the lake side and focused group discussions with residents of six communities around the lake. The study found out that, the population of visitors to the lake side was composed of a large segment of young domestic

visitors. A smaller percentage of middle aged local and foreign visitors both male and female were also present at the destination. Terrain based activities such as viewing the scenery and relaxing on the water front, took precedence over other activities such as swimming and the enjoyment of cultural displays. Factor analysis of visitor preferences indicated a four factor solution in visitor recreational resources preferences. Groups of resources which correlated with the identified factors at eigen values of 0.45 and above were: facilities and services, natural resources, cultural resources and accessibility. Existing and potential recreational resources were found to be accessible, nature based and consisting of a series of swimming, boat landing and open recreational areas. Viewshed analysis of communities showed that Abono, the main tourist town had a better viewshed than all other lake side communities in the district. Residents of sampled communities, perceived a linkage between tourism development and the well-being of their communities. Community support for tourism did not differ with distance from the main tourist town. Based on the profile of visitors to the lake side and the distribution and accessibility of rural nature based resources as well as community support for tourism, it was concluded that, the potential for community based nature tourism exists within lake side communities of the Bosumtwé-Atwima-Kwanwoma District.

SE 19-01 - Senses of identity and belonging in coastal regions in transition

Chair: Beate Ratter, Tialda Haartsen

Watchman or Retreat? Local Meanings of the Dutch Wadden Sea Dike

Tialda Haartsen (University of Groningen), Henry Bos (Groningen University)

Future growth and development of rural regions is increasingly dependent upon the 'amenity' of their local physical, social and economic environments. In most coastal regions, this amenity follows a gradient from high to low according to distance from the coast. In the north of the Netherlands, this is the other way around. The Dutch Wadden Sea coast is not generally perceived as attractive landscape. It is commonly known that this has to do with the construction of a high dike at Dutch Delta height, which created a barrier between the sea and the land. Access to the dike and to the coastal zone is very limited, and the dike-landscape hardly has any variation. Before the dikes were built, the relationship of the north-Netherlands people with the sea was much more natural and self-evident. In the (near) future, it will become necessary to adapt the Delta dike to global sea level rise. It may be possible to improve the accessibility and attractiveness of the north-Netherlands coastal landscape in the same movement. In order to be able to connect to potential local wishes considering landscape improvement, knowledge of the local meanings of the Dutch Wadden Sea dike is necessary. Which role does this dike play in the everyday life of inhabitants of local coastal villages? What defines the perceived qualities of the dike, and what could be added to improve these? This paper intends to answer these questions by using survey data (N=200) from four coastal villages in the province of Groningen, The Netherlands.

Wadden Sea Survey – The Dutch View. A comparison of peoples perception in the Northern parts of Germany and the Netherlands.

Katharina Philipp (Helmholtz-Zentrum Geesthacht)

What role play social and physical coastal landscapes in the ways the inhabitants identify with their region? In how far does peoples view on their surrounding influence the perception of renewable energy installations? Are they conscious of climate change and its impacts? And what does this mean to their personal life? In order to get insight into these topics, there is a necessity to

analyse the perception of the coastal population and ask people: -> Where do they come from and what do they associate with the region they live in? -> What are their perceptions of the sea and the coastal landscape? -> How do local residents see nature? -> What are their opinions on offshore wind farming and the believed impacts of offshore wind farming? Former surveys among the inhabitants of German North Sea coast revealed in a great enthusiasm for and attachment to Northern Germany coastal areas. Interviewees perceived their region as unique. They were proud of their home county and wanted to preserve it. Connotations of the sea ('seascape') such as wilderness and freedom and values assigned to offshore wind farming turned out to compete in terms of acceptance or rejection of offshore wind farming. There was considerable emotional attachment to these values. The German North Sea coast is part of the Wadden Sea, which embraces also Dutch and Danish sections. This offers the opportunity to investigate the question 'What is more formative: space and nature or nationality and the respective history of a people'? In comparing surveys around the southern North Sea we want to find out whether people feel in a similar way or whether there are differences. And, if the latter was the case, what are the differences and how could they be interpreted? In 2011, a survey on landscape perception and sense of place in coastal communities was conducted in the Dutch Wadden Sea area. Results from this survey will be presented and potential differences in perception between Germany and The Netherlands will be outlined and discussed.

Participatory evaluation of landscape perception and regional identity in German coastal regions

Elke Wegener (University of Greifswald), Anne Cristina de la Vega-Leinert (University of Greifswald), Susanne Stoll-Kleemann (University of Greifswald)

Sea level rise and higher frequencies of extreme weather events as a consequence of climate change will lead to severe impacts on Germany's coastal zones. The BMBF-project "Sustainable Land Management - Trade-Offs in Ecosystem Services" (COMTESS) addresses the question of necessary adaptation of future land use strategies. Damages caused by extreme weather events indicate that current land use management strategies are partly inappropriate and need to be adapted. However, the change of current land use induces modifications of the landscape; thus cultural ecosystem services, such as landscape aesthetics, are affected. The study focuses on the question how changes in land use influence people's landscape perception and thus their sense of regional identity and place. To approach this complex process three

land use scenarios are evaluated. Scenario one focuses on the maintenance of current coastal protection and land use strategies. Scenario two focuses on the change of land use by concentrating on flood tolerant vegetation in order to prepare farmers for changing climate conditions. In scenario three the dike lines are partly removed to retain low land areas free of land use for renaturation and further for carbon sequestration. Two case study areas in Germany were selected: the Baltic Sea region (the peninsular Fischland-Darß-Zingst, Mecklenburg-Vorpommern) and the North Sea region (the north west of the county Aurich, Niedersachsen). In order to appraise local people's perspectives and to acquire a broad spectrum of research data a participatory approach was applied. People's perceptions about different potential future land uses are evaluated based on photographs taken in the study areas. These show single landscape elements which are presented to selected audiences in World Café meetings as a set of ten pictures for each of the three land use scenarios. Participants are given the opportunity to make statements on the particular appearances of the landscape and whether they feel comfortable with such scenery. Further, the participants are invited to compose their preferred future landscape scenario. The underlying hypothesis is that the participants compose their future land use scenario based on one's own perception and affiliation to landscape and nature. For example, it is assumed that regional farmers have a high interest in retaining the existing coastal dike line and land use strategies, as they directly profit from coastal protection measures in terms of their livelihoods. Land loss, however, does not only lead to a loss of livelihoods but possibly to the loss of regional identity and belonging. Therefore it is assumed that for different stakeholder groups various factors can be identified that influence the landscape perception and thus the sense of regional identity. The consideration of such factors supports decision makers to integrate adaptation strategies into future land use planning.

The German North Sea Coast as a Place of Identity/"Heimat"

Daniela Siedschlag (Helmholtz-Zentrum Geesthacht)

The German North Sea coast is a unique natural landscape which is affected by falling and rising tide, maritime climate and continuous storm surges. It is also an inimitable cultural landscape - enclosures for land reclamation reflect people's struggle against the sea in the past and today. And of course the German North Sea coast is also a place of social interactions. The paper deals with the following research question: - What role do the natural landscape, the cultural landscape and the social interactions play in how people - living on the German

North Sea coast - identify with their region? Or in other words: - What does 'Heimat' mean to the people living on the German North Sea coast? The research is embedded in the theoretical concept of 'Heimat'. In this context 'Heimat' is determined by spatial components (natural landscapes, natural phenomena, special places ...), social components (family, friends, ...) and emotional components (language, intimacy, traditions, ...) (Schwineköper 2005). The empirical case study is a quantitative household-based survey on the island Pellworm (500 households) and the North Friesland mainland (200 households) (Germany) and additional qualitative in-depth interviews. First results of the ongoing research will be presented. These show that the people are bound to this region and feel connected to the sea in their everyday lives.

SE 20-01 - Soil erosion and terrestrial carbon cycling

Chair: Verena Dlugoss, Nikolaus J. Kuhn

The magnitude of agricultural erosion and its impact on the global terrestrial C cycle

Sebastian Doetterl (UCL), Kristof Van Oost (UCL - TECLIM), Johan Six (UC Davis - Department of Plant Sciences)

The effects of erosion resulting from agricultural land use on the soil-atmosphere carbon exchange have recently received growing attention. Large scale assessments are needed to understand its global significance, but reliable global scale data on the extent and rates of soil erosion are scarce and large uncertainties remain. The main objective of this study was to test the assumptions underlying existing assessments and to reduce the uncertainty associated with global estimates of agricultural soil and SOC erosion using a hybrid approach: We used the extensive plot based USDA National Resources Inventory [NRI] to identify the key controls on accelerated erosion at the continental scale for crop- and agriculturally used grassland. We then parameterized a simplified erosion model driven by coarse global databases and calibrated using the empirical NRI database. The agreement between our model results and empirical estimates indicates that the approach presented here captures the essence of agricultural erosion at the scales of continents, and that it may be used to predict the significance of erosion for the global carbon cycle. However, the validation of our estimates using several independent assessments of soil water erosion outside the data cloud of our model calibration (Non-US crop- and grassland) and the results of a sensitivity analysis reveal an uncertainty of 30-70% on the total estimates. This means that even though our model can predict spatial patterns of erosion well, there is still considerable uncertainty in areas of specialized land use systems and/or extreme environmental conditions, mainly due to the lack of model testing in (sub-)tropical regions. We obtained a global soil erosion rate of 10.5 Mg ha⁻¹ y⁻¹ for cropland and 1.7 Mg ha⁻¹ y⁻¹ for pastures. This corresponds to SOC erosion rates of 193 kg C ha⁻¹ y⁻¹ for cropland and 40.4 kg C ha⁻¹ y⁻¹ for eroding pastures and results in a global flux of 20.5 (±10.3) Pg y⁻¹ of soil and 403.5 (±201.8) Tg C y⁻¹. Our estimates are significantly lower than former assessments based on the extrapolation of plot experiments or the global application of erosion models. Our approach has the potential to quantify the rate and spatial signature of the erosion-induced disturbance on the C cycle at continental and global scales. Linking our model

with a global soil profile database, we estimated soil profile modifications induced by agriculture. This showed that erosion-induced changes in topsoil SOC content are significant at a global scale (an average SOC loss of 22% in 50 years) and that agricultural soils are highly dynamic systems influencing the spatial distribution of C in the landscape. Therefore it is crucial that future C models can integrate lateral soil fluxes as an important modifier when assessing the vertical C exchange.

Topographic variability influences the carbon sequestration potential of arable soils

Ngonidzashe Chirinda (Aarhus University), Lars Elsgaard (Aarhus University), Ingrid K. Thomsen, Mette Lægdsmand (Aarhus University), Goswin Heckrath (Aarhus University), Bjørn M. Petersen (Aarhus University), Jørgen E. Olesen (Aarhus University)

There is presently limited knowledge on the influence of field spatial variability on the carbon (C) sink-source relationships in arable landscapes. This is accompanied by the fact that our understanding of soil profile C dynamics is also limited. This study aimed at investigating how spatial variability along a short catena influences C sink-source relationships and temporal dynamics of CO₂ concentrations in soils. In spring 2011, soil samples were collected from topsoil (2-5.5 cm) and subsoil (38-41.5 cm) horizons at upslope and footslope positions in a Danish winter wheat field on a sandy loam soil developed on glacial till. Bulk densities and C concentrations of the soils were characterized. From June 2011, gas samples were collected at least bimonthly from the same slope positions in four spatial replicates using stainless steel needles that were permanently installed at 5, 10, 20 and 30 cm soil depths. Concurrently, gas was sampled from 40, 50, and 80 cm depths using steel rods connected to a sampling port. Concentrations of CO₂ in the gas samples were analyzed by gas chromatography. The results show that at the upslope position, soils from the topsoil horizon clearly had higher C pools (5.2 Mg C ha⁻¹) compared to those from the subsoil horizon (1.0 Mg C ha⁻¹). At the footslope position, however, C pools in topsoil (6.9 Mg C ha⁻¹) and subsoil (7.0 Mg C ha⁻¹) horizons were similar but higher than those at the upslope position. The gas monitoring study is still ongoing, but preliminary results show that CO₂ concentrations generally increased with depth. At the upslope position, CO₂ concentrations ranged between 800 and 24000 ppm and were generally lower than the concentrations observed at the footslope position (3000-42000 ppm) for similar soil depths. The upslope position has been subject to soil erosion while the footslope position

has been a depositional site; thus the subsoil at the footslope position was to a large extent a buried topsoil horizon. The topographic relationship between the upslope and footslope position made the latter a sink for soil C transported through processes such as tillage erosion. This led to the presence of higher C pools and CO₂ concentrations at the footslope compared to the upslope position. Despite the fact that higher CO₂ concentrations with depth may be influenced by the relationship between CO₂ production and transport, our results indicated that variability across arable landscapes makes footslope soils both a larger sink of buried soil C and a bigger potential CO₂ source than upslope soils.

Fire impacts on landscape dynamics in Cyprus – Is black carbon qualified for tracing soil erosion?

Jens Brauneck (Universität Würzburg), Manfred Lange (Energy, Environment and Water Research Center, Cyprus Institute)

A series of both natural and anthropogenic factors has led to severe land degradation on Cyprus in the past. In the forested areas of the Troodos mountain range, wildfires and post fire erosion exacerbate this situation by reducing the groundwater recharge rate of the aquifers located in this region. Additional exploitation of these resources for agricultural irrigation permanently lowers the water table. This leads to contaminations by saltwater intrusions into the coastal aquifers that affect the population of Cyprus in terms of extreme water shortage during the summer months. Due to the high amount of orographic precipitation, more than 100 dams and reservoirs were constructed in the foothills of the Troodos to maintain the islands water supply. The overall objective of this project is to investigate functional relationships between erosion processes and fire sites in the mountainous regions of southern Cyprus. A combined approach of terrain mapping and chemical characterization of black carbon will permit the classification of hazardous locations in terms of potential fires and erosion processes. Additional data will be provided by surveys of the APAESO project (Autonomous Flying Platforms for Atmospheric and Earth Surface Observations), conducted by members of the Cyprus Institute. There, UAS are used to generate high-resolution multispectral remote sensing data. The emphasis of the upcoming survey is concentrated on the investigation of exemplary catchments that are connected to one of the numerous valley dammed reservoirs. There, the use of macroscopic black carbon as an erosion indicator will be examined to enable a reconstruction of historic process dynamics and local fires. For this purpose, NMR (nuclear magnetic resonance)

spectral analysis of primary and secondary charcoal is used to draw conclusions on the fire conditions and to eventually trace the paths of eroded material inside the watershed. The results of this study may be used to improve water and sediment flow modeling for the eastern Mediterranean, for decision support and to develop further recommendations for action in terms of fire and erosion protection.

Model based analysis of soil carbon fluxes induced by soil redistribution processes

Verena Dlugoss (University of Cologne), Kristof Van Oost (UCL - TECLIM), Karl Schneider (University of Cologne)

Soil redistribution on arable land significantly affects lateral and vertical soil carbon (C) fluxes caused by C formation and mineralization and soil organic carbon (SOC) stocks. Whether this serves as a C sink or source to the atmosphere is a controversial issue. In this study, the SPEROS-C model was modified to analyse erosion induced lateral and vertical soil C fluxes and their effects upon SOC stocks in a small agricultural catchment (4.2 ha). The model was applied for the period between 1950 and 2007 covering 30 years of conventional tillage (1950–1979) followed by 28 years of conservation tillage (1980–2007). In general, modelled and measured SOC stocks are in good agreement for three observed soil layers. The overall balance (1950–2007) of erosion induced lateral and vertical C fluxes results in a C loss of 4.4 g C m⁻² a⁻¹ at our test site. Land management has a significant impact on the erosion induced C fluxes, leading to a predominance of lateral C export under conventional and of vertical C exchange between soil and atmosphere under conservation agriculture. Overall, the application of the soil conservation practices, with enhanced C inputs by cover crops and decreased erosion, significantly reduced the modelled erosion induced C loss of the test site. Increasing C inputs alone, without a reduction of erosion rates, did not result in a reduction of erosion induced C losses. Moreover, our results show that the potential erosion induced C loss is very sensitive to the representation of erosion rates (long-term steady state versus event driven). A first estimate suggests that C losses are very sensitive to magnitude and frequency of erosion events. If long-term averages are dominated by large magnitude events, modelled erosion induced C losses in the catchment were significantly reduced.

SE 21-01 - Sustaining ecosystem services in cultural landscapes: Analysis and management options 1

Chair: Tobias Plieninger, Dan van der Horst

A framework for landscape services tested in urban open spaces. A comparative study in Ghent (Belgium) and Valencia (Spain).

Maria Vallés (Universidad Politécnica de Valencia), Francisco Galiana (Universidad Politécnica de Valencia), Floris Moerdijk (Ghent University), Veerle Van Eetvelde (Ghent University)

The ecosystem services approach has proved to be successful to measure the contributions of nature and greenery to human well-being. But not only ecosystems have an effect on the quality of life, also place or landscape, as a broader concept, can be responsible of providing people with a sense of well-being. Landscape is about the relationship between people and place, which also includes the built environment. The concept of landscape services, as compared with ecosystem services, involves the consideration of the spatial pattern resulting from both natural and human processes in the provision of benefits for human-well being. The focus on landscape, as defined in European Landscape Convention, also implies a balance between its material and immaterial dimension, and the consideration of people's perceptions of landscapes and its services. The aim of this paper is to propose a framework for the classification of landscape services and to test its suitability in urban open spaces at the local scale (case studies in two cities). The presented framework is built on the Common International Classification of Ecosystem Services (CICES) and existing literature on ecosystem services, landscape sustainability, social landscape value and quality of life. Three themes of landscape services are defined, each divided into several groups: provisioning, regulation and maintenance, cultural and social life fulfillment; the latter focusing on health, enjoyment, personal and social fulfillment. For the case, four types of green areas and public spaces are analyzed in two European cities: Ghent (Belgium) and Valencia (Spain): peri-urban parks, local parks in a living area, multifunctional city parks, special public places (station, university campus). The landscape services of the areas are mapped in both cities, combining expert knowledge and user's perceptions of landscape services. To collect the user's perceptions, enquiries were held in the parks. Results highlight the need of different knowledge - expert and stakeholder approach - for the identification of the different types of services, especially for the social and cultural services. The

adequateness of the typology of services proposed and the method applied in terms of difficulty for implementation, spatial representation and different source data integration are discussed.

Adequate communication of appreciated ecosystem services can enhance the local support for cultural landscape protection

Franziska Solbrig (University of Greifswald), Susanne Stoll-Kleemann (University of Greifswald)

The protection of cultural landscapes is an important focus of UNESCO-biosphere reserves and consequently, many of the necessary protective measures are carried out close to human settlements. Therefore, managers of biosphere reserves need to integrate the local population in the management process. To achieve this, it is helpful to know which specific ecosystem services are appreciated among the local population. Based on such a characterisation of relevant ecosystem services, strategies to foster adaptive biosphere reserve management can be derived. Consequently, it is necessary to find answers to the following questions: Which ecosystem services - explicitly and implicitly - are perceived and appreciated among the local population? Do these ecosystem services reflect biosphere reserve aims and measures focusing on cultural landscape protection? And if so, can they contribute to communicate current biosphere reserve achievements as well as to foster future efforts? In a telephone survey conducted in autumn 2010, the inhabitants of four German UNESCO-biosphere reserves were asked to assess their particular region, landscape and biosphere reserve. In total, 1429 interviews could be analysed with the help of the computer program IBM SPSS Statistics. The 30 closed and 9 open survey questions did not explicitly ask to assess cultural landscapes and their services. Therefore, it is particularly remarkable that many of the appreciated aspects of both the region and its landscape actually represent a variety of ecological and cultural ecosystem services. Many of the identified cultural ecosystem services relate to different aspects of recreation, to the inhabitants' sense of place and identity as well as to cultural heritage values. Apparently, the local population appreciates several ecosystem services that often coincide with benefits from cultural landscapes preserved by UNESCO-biosphere reserves. Thanks to the personal relevance of ecosystem services (e.g. recreational values), the benefits of these services are self-evident to the people. This provides the management bodies with valuable arguments to promote cultural landscape protection. Those arguments can be more convincing than general claims for species protection, especially in cases of

non-charismatic ones. Although in the end the necessary conservation measures might be the same, people will be more ready to support them if they see a personal relevance. As a consequence, it must be discussed how the management bodies can properly communicate these benefits in order to raise the local support for cultural landscape protection. Since the ecosystem values and services were mentioned implicitly in the answers, the management bodies should try to use a language close to the expressions of the inhabitants. Here, surveys of this kind can provide valuable proposals and finally they can contribute to successful adaptive management of cultural landscapes.

Beyond Production: Multifunctionality in Australian agriculture

Robyn Bartel (University of New England), Elaine Barclay (University of New England)

Productive land management in Australia has had a long history: from Aboriginal firing and production practices to modern industrial agriculture. The resultant landscape is a patchwork of intensive and less-intensive management, with so-called pristine ecosystems preserved in public reserves but also extensively on private land, usually agricultural land. The future productivity and sustainability of agriculture is dependent upon widespread adoption of sustainable production practices, but also multifunctional beyond-production practices. A nationwide survey of 5000 Australian farmers revealed that almost all farmers had implemented some type of sustainable management practice. The majority were deeply concerned about environmental degradation and recognized weeds, pest animals and water availability as their primary environmental concerns. Barriers identified to addressing these were a lack of time and money, and drought. Many were involved in Landcare or other informal groups concerned with natural resource management at the community level. More than half had preserved an area on their land just for its environmental benefits. Engagement in this beyond-production activity was based on landholders' subjective perceptions, namely place attachment and moral agreement with environmental laws furthering multifunctionality as well as the objective factors of community activity and experience of environmental problems. Subjective perceptions were more important than objective factors. Policy-makers are advised to support community initiatives, be cognisant of place attachment factors and provide financial assistance to hasten the adoption of beyond-production practices. These will not only assist in preserving ancient ecosystems but promote new agroecosystem management and conservation practices.

Perceptions, use, and management of biodiversity and ecosystem services in California's working landscapes

Tobias Plieninger (Berlin-Brandenburg Academy of Sciences and Humanities and Humboldt-Universität zu Berlin), Shasta Ferranto (University of California), Lynn Huntsinger (University of California)

It has long been acknowledged that protected areas are too few, too isolated, too static, and not always safe from over-exploitation and therefore have to be linked with adjacent landscape units to increase the survival chances of plant and animal populations. Therefore, biodiversity conservation strategies need to be broadened to include private lands, but these remain widely understudied by conservation biology. Based on a California-wide survey of private forest and rangeland landowners conducted in 2008, we investigated whether landowners that are engaged in commercial livestock or timber production appreciate biodiversity and ecosystem services on their land in different ways than purely residential owners. Both specific uses and management practices and underlying attitudes and motivations towards biodiversity and ecosystem services were assessed. All landowners value intangible ecosystem services like natural beauty and way of life derived from owning forest and rangeland. More synergies than trade-offs among ecosystem services were expressed. In particular, correlation analysis showed one bundle of ecosystem goods and services (livestock, timber, crops, and housing) that are supported by some landowners at the community level. Another closely correlated bundle of ecosystem services includes recreation, hunting and fishing, wildlife habitats, and fire prevention. Perceived incompatibilities also became visible between some resource- and amenity-based uses of ecosystem services: Respondents that expressed demand for more livestock, timber or housing provision in their community do not support management for wildlife and more areas for recreation, and vice versa. Producers were more likely to ally with the first bundle and residential owners with the second. However, producers were much more active in management for habitat improvement and other environmental goals. With a diversity of uses and public benefits provided, California's forests and rangelands come close to the ideal of a working landscape. However, the viewpoints that landowners expressed in this survey reflect that tensions between natural resource extraction and conservation of intangible ecosystem services and biodiversity continue to be 'the overarching political and cultural struggle in much of the rural American West today' (Walker 2006), with competing visions for the future of rangelands and forests. Commercial livestock and timber producers show little preference for wildlife and other ecosystem

services beyond natural resources extraction, while residential landowners are supportive of conservation, but often do not provide the active work input that working landscapes require to be maintained or restored. This finding indicates that promotion of the idea of conserving multifunctional forests and rangelands and enhancing joint production of commodities and ecosystem services requires diverse strategies.

SE 21-02 - Sustaining ecosystem services in cultural landscapes: Analysis and management options 2

Chair: Tobias Plieninger, Dan van der Horst

Exploring the role of cultural ecosystem services for the preservation of terraced rice cultivation in the rural landscape of Ifugao, Philippines

Vera Tekken (University of Greifswald), Susanne Stoll-Kleemann (University of Greifswald)

The approach of Ecosystem Services is well suited to analyze the complex interlinkages and feedback processes of human-environment systems. In this context cultural ecosystem services often recede into the background, as due to their particularity they are less easily to analyze, generalize and applicable to other local contexts. So far, there is a lack of insights into social and nonmaterial functions of nature. However, cultural landscapes have been historically shaped by human activities under specific environmental conditions. Further, non-materialistic cultural ecosystem services such as religious rituals and cultural identity are key part of human well-being. Thus, next to ecological and economic drivers, socio-cultural drivers have an immense influence on ecosystem services of cultural landscapes. The uniqueness of cultural landscapes is reflected in the World Cultural and Natural Heritage list of the UNESCO. Adopted in this list are the traditional rice terraces in the Cordilleras (Northern Luzon) of the Philippines, the Ifugao Province, which are characterized by extensive subsistence rice cultivation over a period of approx. 2000 years. For the assessment of the role of cultural ecosystem services in the context of sustainable land management a participatory approach was chosen for the socio-cultural data collection. Next to semi-structured interviews on household level with regional farmers, participatory rural appraisal methods (i.a. focus group discussions) were applied to gain insights into traditional land management and socio-cultural drivers of change in the Ifugao Province. Historically, annual rice cultivation cycles have been synchronized to local environmental conditions as well as to social life cycles of the population. The conservation and the passing on to further generations of traditional agricultural cultivation techniques is an essential prerequisite for sustainable land management in the area. Recently, financial revenues from rice agriculture are almost exclusively insufficient to cover livelihood expenses for the local population. This leads to an emigration of labor force and a serious decrease of workers in the rice production, and thus to the abandonment and

degradation of the rice terraces. Cultural archives of traditional ancestral techniques of rice cultivation are getting lost, as well as the particular local identity. This loss of cultural values, and in particular of rice rituals has a negative influence on nutrient cycles and biodiversity, thus on provisioning and regulating ecosystem services. Results show that socio-cultural drivers of change currently outbalance other drivers, e.g. regional impacts of climate change. Further, findings point towards a substantial risk for the traditional rice production in the region due to the loss of traditional farming knowledge and a decrease of cultural identity, thus endangering the preservation of this unique cultural landscape.

Promoting cultural embeddedness: Cultural and social capital generation in result-oriented agri-environmental schemes

Rob Burton (Bygdeforskning), Gerald Schwarz (Johann Heinrich von Thünen-Institut)

Despite over two decades of operation, action-oriented agri-environmental schemes (AESS) across Europe have broadly failed to induce the expected attitudinal or cultural change within farming communities. Recent research has suggested that the reason for this may be that, in failing to allow innovation in environmental provision, such schemes are unable to generate embodied cultural capital (skills and knowledge) which, in turn, restricts the development of social capital (networked access to shared group resources) based around environmental provision. By following an almost exclusively economic logic, conventional AES scheme design thus neglects the cultural value of agricultural landscapes and makes the cultural embedding of new environmental meanings difficult. In this paper we present a theoretical perspective on how result-oriented agri-environmental schemes may help resolve this issue. By allowing farmers to innovate, such schemes are likely to make the associated knowledge/skills developed economically valuable and, consequently, farmers who are knowledgeable/skilled in environmental provision valuable inclusions within social networks. Rather than simply rewarding prescribed behaviours with economic payment, the result-oriented approach may thus also reward culturally and socially and, critically, enable new behaviours and values to become embedded within cultural notions of 'good farming'. We contend that this should be an important consideration in result-oriented approaches and discuss some implications for scheme design.

Farmers management and their perceptions of trade-offs of ecosystem services and disservices from forest, trees and shrubs in an agricultural landscape in Southwestern Ethiopia

Tola Gemechu Ango (Stockholm University)

In recent years, a growing number of studies have looked at agroecosystems and their contributions to biodiversity conservation. Despite this, there is a lack of a more detailed understanding of how farmer's decision processes and practices interact with local ecosystem functions. This study, which is part my PhD research, investigates small holder farmers' decision processes and practices with regard to trees and shrubs in agricultural land and in nearby forest and to what extent they target the management of these ecosystem components with respect to their associated ecosystem services and disservices. The research is underway in four purposively selected villages of Gera district in Southwestern Ethiopia. Most parts of the district have a long history of coffee based agricultural practices. Twenty households living in those villages were selected strategically. Empirical material has been collected through participatory field mapping, semi-structured interviews and focus group discussions. To understand farmer's knowledge regarding insects and their relation to agriculture, six different types of insects that include honeybee and ant were collected and used as interview material. The results of the study have showed that farmer's decisions and practices with regard to trees and shrubs in agricultural land and nearby forest are mainly based on the evaluations of the 'immediate' and observable pros and cons of the ecosystem components in relation to agriculture. Trees and shrubs were mostly retained in coffee fields, grazing lands and home gardens for shade and to meet households' wood demand for various purposes. In croplands, trees and shrubs were largely limited to field boundaries, and those retained inside arable fields were heavily pruned to reduce their impact on crops. On the other hand, most farmers have not recognized the link between the insects used as interview material and agricultural production. Whereas pest mammals such as baboons, bush pigs, giant forest hogs, monkeys and warthogs from nearby forest were reported as severe ecosystem disservices to agriculture. The types of pests and the severity of the damage they cause significantly diminish as one move away from forest edges. Pests have brought economic costs by damaging crops and requiring labor for protection and also led to more deforestation as early settlers have frequently welcomed migrants to settle at the forest edge. Hence, the study tentatively concludes that farmers' decisions and practices related to the studied ecosystem components are geared towards reducing their disservices to

enhance agricultural production. This may in the long-run reduce the availability of these ecosystem components and the services they supply. Further studies, however, are required to deepen our understanding on the use and management of ecosystem services and disservices from trees, shrubs and forests in agricultural landscapes.

It is not a paradox that shepherds and farmers do not work together: Power, trust and land degradation in two neighbouring areas of southern Crete

Thanasis Kizos (University of the Aegean), Theodoros Iosifides (University of the Aegean), Helen Briassoulis (University of the Aegean), Minas Metaksakis

Many Mediterranean semi-arid, hilly and mountainous areas face Land Degradation and Desertification (LDD). The intensification of crop cultivation and grazing in the last decades has been considered as a major contributor to LDD. The island of Crete has supported diverse agricultural systems and large populations of grazing animals for many centuries. Many communities around the island have relied on mixed systems of cultivation and grazing for their livelihood. The resilience of many areas on the island has been recently challenged by the simultaneous intensification of crop cultivation and grazing and the separation between animal husbandry and crop cultivation. The neighbouring areas of the Messara plain, where a variety of crops were grown for many centuries, and the mountains of Asteroussia, where sheep husbandry has been the major livelihood option for centuries, constitute linked socio-ecological systems (SES), with transhumance from the mountains to the plain. In the last 30 years, the 'complementarity' of land management between the two areas has been ruptured and a gap has grown between the shepherds on the mountains and the olive and vine growers in the plain. Each area faces its own LDD problems: salinisation, water and soil pollution in the plain, overgrazing leading to soil erosion on the mountains. This paper examines contemporary responses to LDD along with the evolution of the two socio-ecological systems based on 20 in-depth qualitative interviews with local stakeholders - shepherds, farmers, representatives of local authorities, and environmental NGOs. Informed by the complex adaptive systems (CAS) paradigm, the paper shows how the multi-level interplay between environmental, social and institutional factors in the two neighbouring areas have generated a vicious circle of loss of socio-ecological resilience. The role of culture, power relations, social and institutional capital, state policies and market mechanisms in shaping contemporary responses to LDD are particularly highlighted. The discussion of the pathways of

the gradual loss of socio-ecological resilience in these areas resolves to a great extent the 'paradox' of non-cooperation - and, in many cases, open hostility - between farmers and shepherds along with the mutual avoidance of 'obvious solutions' to socio-economic and LDD problems.

SE 22-01 - The social construction of cultural landscapes: New concepts of 'landscape' in social sciences, cultural studies and geography 1

Chair: Winfried Schenk, Johannes Renes

Playing with Gadamer: Understanding landscape through conversation

Karl Benediktsson (University of Iceland)

What does the metaphor of 'conversation' (Benediktsson and Lund, 2010) bring to landscape studies? Suggestive of a dialogic relationship, it directs attention to the mutuality that is part and parcel of the human-landscape encounter: by being in landscape and moving through it, the human is affected by that landscape, and vice versa. Hence, studying landscapes becomes not only a matter of analysing the visual responses to their scenic characteristics, nor indeed of teasing out their social construction as in much recent landscape scholarship, but of exploring the reciprocal exchanges that take place between landscape and person. In this paper, the possibilities engendered by such a dialogic approach are explored further through an examination of two central concepts of Hans-Georg Gadamer. A key proponent of philosophical hermeneutics, Gadamer was concerned with elucidating the conditions by which understanding becomes possible. For this he introduced the concepts of 'horizon' (Horizont) and 'play' (Spiel), which, I argue, may be useful for landscape studies. In particular, the concept of play highlights an 'in-between' process that involves reciprocity and active participation by the players. It can be used to highlight the embodied and affective character of landscape encounters. Experiencing and understanding landscape involves a back-and-forth movement between the person and the landscape - a playful conversation to which both sides contribute.

The social construction of landscapes: Insights from post-structuralism and historical institutionalism

Ludger Gailing (Leibniz-Institute for Regional Development and Structural Planning), Markus Leibenath (Leibniz Institute of Ecological Urban and Regional Development)

This paper highlights two specific ways of conceptualising the social construction of landscape, both of which have been developed at the interfaces of disciplines such as political science, sociology, history and philosophy: Post-structuralism and historical institutionalism. The first is closely related to thinkers such as Michel Foucault, Ernesto Laclau and - in the field of landscape studies - James Duncan. Post-structuralism emphasises discourses, the contingent nature of the social and the relations between language, society and the physical world. Historical institutionalism is linked to the works of Richard W. Scott, Douglass North and Renate Mayntz, to mention just a few. This strand of theory foregrounds the structuring effect of institutions, stability and change of institutions over time and the interplay between different types of institutions at various levels of policy-making. It has been adapted to landscape research by using the concept of path dependency. The aim is to briefly introduce both approaches and to compare them regarding their epistemological stances, the related key analytical terms, the ontologies of landscape which they imply, the question of how they conceive of the 'social construction of landscape' and finally the extent to which both approaches can be utilized to inform political processes. The comparison will be illustrated by findings from two research projects on the constitution of cultural landscapes. One project analysed the role of formal and informal institutions in local governance processes through which reified landscapes emerged as spaces for collective action. The other one focused on the production of landscape concepts in wind energy discourses at national and local levels in Germany and how these concepts were linked to political position in favour or opposed to wind power plants. Both projects were funded by the German Research foundation (DFG).

Fragmentation and re-imagination – landscape and socio-economic change in East Pokot, Kenya

Michael Bollig (University of Cologne), Clemens Greiner (University of Cologne)

During the last decade the concept of complex coupled-social systems has served as an umbrella term to understand the complexity and the dynamics of human-environment interactions. However, usually such dynamics have been

analysed in a fragmented way. Institutions, resource-based strategies and policies and their repercussions on geo-biophysical dynamics were researched. In this way these approaches usually focussed on very specific and often isolated coupling processes. Local perceptions and conceptualisations of such dynamics were usually not taken into account. We suggest that a more holistic perspective on these coupling processes can help to understand them across different temporal and spatial scales. In this presentation, we assess if the concept of landscape can contribute to this end. In order to make our point clear we refer to a concrete social-ecological system: the semi-arid savannah and its inhabitants the pastoral Pokot. Based on data from two decades of ethnographic research on the pastoral Pokot and north-western Kenya, we will demonstrate, how human-induced processes become inscribed in landscapes, and how these landscapes provide blueprints for human action. The Pokot have been pastoral nomads until recently and they managed a non-fragmented pastoral landscape. This landscape had certain geo-biophysical characteristics (vegetation, soils), a specific livelihood system (pastoralism) and pastoral identities were inscribed into particular landscape features (holy mountains, initiation sites). Since about two decades, the growing importance of agriculture, increasing sedentarization, livelihood diversification, the implementation of wildlife conservation projects and the exploitation of geo-thermal power have led to major cultural and economic changes. The landscapes in East Pokot are increasingly characterized by processes of fragmentation of formerly communally used pastures. These dynamics are manifest at different scales: individual (farm level), communal (village territory) and societal (ethnic territory) and lead to a profound and highly conflictive re-structuring of Pokot society: individuation of property rights and elite formation, territorial re-configuration of communal access rights and inter-ethnic territorial conflicts with neighbouring groups. The result is a hardening of boundaries at different scales and a re-imagination of Pokot relations to the landscape they inhabit.

Themed Places and the Doubling of Landscape – a cultural approach

Jan-Erik Steinkrüger (Universität Bonn)

This contribution would like to give an example of an interpretation of landscape from the perspective of the new cultural geography. Adapting ideas from Denis Cosgrove, James Duncan and Jeffrey Hopkins landscapes will be understood as a medium or as language. Themed places serve as an example, though some of the ideas presented might be transferable to other forms of landscape as well. Themed places, such as theme parks, themed restaurants and hotels,

zoological gardens etc., have become part of our everyday life. Even shopping malls or residential areas are becoming themed today. As Alan Bryman and Albrecht Steinecke point out, theming has become a strategy to create an atmosphere that increases the inclination to consume; it changes for example shopping into a shopping experience. Though many authors have addressed the (mostly economic) function of themed places in our society, only few such as David Kolb have taken a closer look at their mode of representation: they represent their theme as a landscape. In the case, that the theme is the representation of other times, places or spheres, we find a doubling of landscape: landscapes (as a medium) represent landscapes (as their content). This doubled character in themed places opens new questions on the relation of the presenting landscape and the represented landscape. Whereas the first can be explained through its social function, the second derives from culturally specific gazes on the world. How we represent landscapes in themed places tells us how we see the world. During my presentation I will argue, that the representations tell us what we see as different to our everyday life. This will be shown with several examples of themed places in theme parks, zoological gardens and shopping areas.

SE 22-02 - The social construction of cultural landscapes: New concepts of 'landscape' in social sciences, cultural studies and geography 2

Chair: Winfried Schenk, Johannes Renes

The public promenade as a structuring element of urban development and as an inducer of new ways of entertainment and sociability in Portuguese medium cities between 1840 and 1926

Jorge Neves (CEG - Centro de Estudos Geográficos), Maria Alexandre Lousada (CEG - Centro de Estudos Geográficos)

This communication aims to disseminate the results of an ongoing investigation into the cultural life in medium-sized cities of Portugal in the 2nd half of the nineteenth century and the 1st quarter of the twentieth century, comparing the spatial urban transformations occurring with data collected for this period on activities practices related to leisure and sociability. The strong expansion of facilities and cultural activities such as theater, musical performances, the press or the habit of leisurely family walks in public places, recorded, during the nineteenth century, in major European cities, were associated with urban models that spread, with different speeds and intensities, in smaller cities, according to dynamics resulting from various factors - in particular the views of elites with greater capacity for action and mobilization in the socio-cultural changes, the characteristics of local actors and options in morphological and functional terms, taken in the process of urban growth. The fashion of leisure in naturalized public spaces that the European bourgeois culture promoted during the first half of the nineteenth century, often associated with a charitable speech, gave birth to a movement to create boulevards, gardens and parks pooled benefits in terms of beautification, improving the urban environment and social life. The creation of lanes extended and improved by the presence of trees, was one of the recommended types, widespread, which is also widespread in many of the Portuguese under the name of "Passeio Público" (public promenade). Its realization associates the processes of urban growth with increases in the available time devoted to leisure practices and with the development of urban tourism. The present study focuses on three cities located in the center of the country, with different socio-economic dynamics, and compares the evolution and transformation of urban space, particularly the creation and revitalization of public spaces with recreational functions, especially the case of "Passeio

Público", with the results of data collection conducted to characterize cultural facilities and its location, related with the evolution of cultural life and the use of public space as a place of sociability (theater and other performances, accommodation, cafes, restaurants, a trade). The analysis of the first plans made in these cities and other documents that express the vision of the city of local decision makers, supplemented by consulting newspaper articles in local papers, show an "ideology" based on the defense of new urban forms and cultural practices being the "Passeio Público" a new kind of landscape particularly significant.

Five dimensions of the social construction of landscape

Ludger Gailing (Leibniz-Institute for Regional Development and Structural Planning)

According to a positivist understanding, a landscape is a specific portion of the earth's surface. It is an objectively existing reality. Recent work in human geography and cultural studies has widened the perspective of landscape research: while the physical 'reality' of landscapes remains a point of reference, human agency, symbolic representations, and forms of cultural practice are acquiring importance. Thus, in this paper landscapes are to be understood as social constructions: landscapes are perceived as spatial entities, constituted in cultural processes. They are emerging from ontologisations and reifications. The paper proposes a systematisation of the complex process by which landscapes are socially constructed: the analytical construction by scientists: In this context 'landscape' is a sort of analytical tool for scientific approaches. 'Landscape' legitimises scientific approaches and programmes. the subjective construction: The subjective construction of landscape is the result of landscape perception by individuals. The landscape view is the mental ability to understand a plurality of visually observable phenomena in a certain portion of the earth's surface as a defined landscape. Landscape then, is a way of seeing. the material constitution: This aspect refers to natural structures as well as historical and actual land use structures. Landscape, in this sense, is a unique result of the intended and unintended interaction of human beings with their physical surroundings. The dimension of 'materiality' is often neglected in social sciences. the collective constitution: On the one hand, interpreting a landscape as collectively constituted can imply an interpretation of a landscape resulting from long-term processes. This focuses on the emergence of landscape representations or images. Such a collectively constituted landscape can form the regional basis of collective identities, of regional utopia, or of the heritage of a

bounded space. In a short- and middle-term perspective all these ontologisations can serve as a basis for collective political action. Thus, a landscape can be interpreted as a regional political space. the construction by the constructs 1.-4.: Making the social construction of landscapes a subject of research should not disguise the institutional effects of the existence of landscapes, once they are established as ontologisations or as regional political spaces. Social constructions of landscapes act, in turn, as second natures or symbolic environments and thus affect human agency in a perpetual and ongoing process. These interdependent aspects will be exemplified by discussing selected results drawn from case studies of landscape regions in Germany. The paper concludes with consequences for further geographical landscape research as well as for the management of landscapes.

Contested public space in Chinese context with case study of 798 factory in Beijing

Fei Che (CU office)

Transformation and Rising of Chinese public space The research of the thesis is based on China's urban space revolution which has seen China's high-speed urbanization development and abundant civil class' coming into being. In the contemporary era, public spheres have been greatly disintegrated out of many causes, for example, the privatization of public space and the protective segregation of the residential community. A great deal of open and uncontrolled public space has become watched and controlled semi-privatization space. Huge suburban shopping malls have taken the place of the traditional urban pedestrian. Urban space is overwhelmed by the doctrine of consumption and the so-called Disney-land and suburbs sprawling have emerged out of it. Civil life - the activity of western cities and public space come to crisis of decline. But in rapidly-developing China, urbanization and association have been frequently changing its urban space and urban life. Along with China's economy's boost and the increasing growth of middle class in cities, will the public space of China's cities become prosperous swiftly and develop towards civil society? Will the urbanization and socialization of the Chinese cities be distinctive from the development of that in the westerns? Or has it already been distinctive? What future might it have? Case study of 798 factory in Beijing Under such a general situation, the Beijing 798 Factory has been an incredible surprise, where a variety of social communications and very real public spaces rarely seen in cities has materialised. In 2000 a great number of artists' studios and galleries appeared in the factory site. The idle factory buildings, with enormous

dimensions, cheap rents and, of course, a rather free atmosphere, attracted a lot of artists to gather there. Since then, various restaurants, coffee houses, artistic bookstores, bars, etc. have sprouted there in great quantities. 798, a once deserted area of the city, was all of a sudden bursting with youthful energy and endless charm. Its appeal lies in its maze-like vagueness and the absolutely open public space. In addition, there is also a kind of temporariness about it. And this vagueness and openness in space are even further strengthened by the previous sense of crisis concerning the possibility that it would be demolished as well as by its temporariness. 798 may have created a new type of urban space. There is no isolation. There are no forced boundaries. The vagueness in space, in its identity, in its temporariness and its completely open public space constitute the unique characteristics of 798. The essence of the contemporary crisis of public space lies in the fact that public spaces are increasingly retreating to private areas, and becoming separated from open spaces. It gives hope to those who feel exhausted in the crisis of contemporary public space.

Dialogue with localization and the production of the Hakka waterscape in South Taiwan

Shu-Chen Tsai (National Taiwan Normal University), Su-Hsin Lee (National Taiwan Normal University), Jing-Shoung Hou (Tung Hai University)

The development and transformation of Hakka village in southern Taiwan were affected by natural and social environment, especially for waterscape. The water usage caused political, economic, cultural, and engineering issues and it also have been the major reason causing conflicts between racial communities. From 18th Century Ching Dynasty occupation, a large number of Hakka immigrants constructed numerous ditches system in southern Taiwan for agricultural demand, and the Hakka hydrological engineering network links became the main reason for their social settlement. During the 19th Century Japanese occupation, political forces were involved in water usage control, which inked the country's geographical projects to hydrological and agricultural industries, and this expanded the construction of hydrological and reconstruction water territory in southern Taiwan. This study suggested the water right of Hakka settlement concealed the country authority operation, where the Hakka became the land owner due to their succession of local hydrological technique, and the waterscape became a production and interaction of society and nature. The result were analyzed base on the theory of 'the production of natural' from Neil Smith (1984), through cultural and historical data verification field survey and coding in GIS. The results showed the time-space pattern of waterscape from

18th to 20th Century, and the factor of change was influenced by combination of society, politics, and nature. Water channels also influenced the process of Hakka localization in southern Taiwan. The human geography perspective of waterscape reflect important governance issues of who has the authority of water right control and who is the actor to reproduce local waterscape.

SE 23-01 - Transition of energy systems and green industry development: The geographies of the German 'Energiewende'

Chair: Britta Klagge, Harald Rohrer

Allocating greenhouse gas emissions in Germany: Federal governance and the new geography of electricity systems

Stefan Scheiner (TU Darmstadt), Jochen Monstadt (Technische Universität Darmstadt)

Currently both, climate mitigation policies and policies to phase out nuclear energy are key drivers for the transition of power systems in Germany. By means of a multitude of measures, federal and EU energy and climate policies have provided the basis for an ongoing shift towards a 'cleaner production' of electricity. As a preliminary outcome of these 'transition policies' over the last decade the share of renewable energies in the power generation has nearly tripled to 20%, half of the nuclear power plants have been shut down, the share of coal has slightly decreased and natural gas almost doubled its share. This transition of power supply systems includes distinct (re-)distributive effects not only across different energy sectors, but also across spatial territories and the capital, investments, R&D activities and workplaces in the energy industry are spatially reallocated. Traditionally, the geography of energy industries was shaped by the spatial vicinity of centralized power plants to the key industrial sites in Germany. Here, we could distinguish between those Bundesländer with a high share of coal (NRW; BB, SL) and those with a high share of nuclear energy (BY, BW, NI, SH; HE). Taking current developments and the on-going decarbonisation and denuclearisation into account, the traditional energy powerhouses in Germany are confronted with considerable economic burden to their regional (energy) industries which are only partially and spatially unevenly compensated by the benefits of the growing low carbon industries. On the other hand, windy regions in Northern Germany, rural regions with a high share of biomass, solar regions particularly in Southern Germany and regions with production sites of green energy technologies have clearly benefited from this industrial transformation. The question of our paper is how this transition of energy industries with considerable redistributive effects across spatial territories was implemented within the cooperative German federal system. We will explain, why this consensus-oriented federalism usually relying on various formal and

informal ways of the Bundesländer to participate in federal legislation and to enforce their economic interests allowed for an effective redistributive policy. For this purpose, we analyse the redistributive effects of the transformation of the electricity industry during the last two decades focusing on the level of the Bundesländer. We will identify the economic 'winners' as well as the 'losers' of this spatial reallocation of capital, investments, R&D activities and workplaces in Germany. Arguing from an institutional perspective we will analyse the key decisions in renewable energy policy and explain how redistributive policies were effectively implemented within the system of cooperative federalism given the heterogeneous interests of the Bundesländer.

Reconfiguring regional infrastructures. Opportunities and limitations in Northeast-Germany.

Matthias Naumann (Leibniz Institute for Regional Development and Structural Planning), Timothy Moss (Leibniz Institute for Regional Development and Structural Planning)

While there is a growing body of literature on the technological and organisational dynamics of infrastructural change, especially in the energy sector, important gaps remain. First, very little research has been conducted on the different regional as well as local preconditions and outcomes of energy transitions. Different urban or rural settings are crucial for applied technological as well as institutional options. In consequence a 'patchwork-geography' of energy systems emerges, one reflecting existing regional differences. New energy infrastructures such as wind or biomass facilities can result not only in regional specialisations in the form of recently established 'energy regions', but also the shaping of new forms of urban-rural relations connecting places of energy demand with places of provision. Second, the interconnections between the transitions of energy systems and other sectors of technical infrastructure, such as water supply and wastewater disposal, transport, telecommunication, waste disposal are hardly mentioned in the literature. The paper argues that transformations in one sector of technical infrastructure have an impact on other sectors. Furthermore, sectoral transitions should be interconnected to enable more extensive reconfigurations of different regional infrastructures. The paper draws on findings from the research project 'Development of integrated land management through sustainable water and resource use in Northeast-Germany (ELaN)' funded by the German Ministry of Education and Research (BMBF). ELaN aims to develop a regionally differentiated and sectorally integrated perspective on the transition of energy systems at the interface between

decentralised energy and wastewater disposal technologies. The project investigates the use of treated wastewater in different rural areas in Northeast-Germany and its potential for biomass production in short rotation coppices for the energy supply of cities. By analysing connectivity between new decentralised forms of energy supply and wastewater disposal, it aims to support the reconfiguration of existing regional infrastructures towards sustainable systems and the reordering of urban-rural relations in the process. The paper argues that reconfigurations of regional infrastructures reach beyond technological issues to encompass new forms of infrastructural governance capable of integrating different modes and spatialities of infrastructure provision. Exploring the transition of interfaces between the social and the technical in socio-technical systems:

The German Helmholtz-Alliance ENERGY-TRANS as an example

Jens Schippl (ITAS / Karlsruher Institut für Technologie)

Triggered by different causes such as climate security, energy security or strategies for improving international competitiveness, a transition of the energy system is of utmost importance for many countries. In Germany, such a transition was recently pushed by the political decision to phase out nuclear power. So, the German energy system needs to be transformed in a relative short time. Many visions and concepts exist that outline potential future designs of such a transformed energy system. Most of these visions have in common that they assume an increasing share in renewable energy supply. Usually, they develop ideas on how fluctuating renewable energies (wind, solar) can be integrated into the energy system. But in general such future oriented studies concentrate on the technical requirements for rebuilding the system. However, energy systems are not only a mixture of technologies and infrastructures; they are socio-technical systems. A transition of the system is not at all limited to technologies but also the interfaces between technologies and society will change; the relationship between societal actors and the technologies will have to be transformed as well. Some changes along these interfaces are already emerging others are anticipated in visions on future energy systems. Examples are: Ideas linked to the concepts of 'Smart Grids' or 'Smart Homes' in general encompass an adaptation of load profiles to the energy supply. More flexibility in demand patterns of the consumers will be needed to achieve such a shift of loads (e.g. usage of washing machines in off-peak hours). New business models enable energy suppliers to control small power plants which are located in the private buildings of the users; When it comes to the urgently needed

implementation of new power lines or to the installation of new wind turbines the directly affected population often reacts with fears and protest; In the mobility sector, new propulsion technologies, such as battery electric vehicles, will change the established routines of its users; Also in the industrial and commercial sector changes might occur in terms of new business models, new regulations or decentralised supply structures. In 2011, the Helmholtz Alliance Energy-Trans was established in Germany to look at the transition of the energy system with particular focus on the demand side and on the interfaces described above. The presentation will give an overview on the interdisciplinary research in the 5 years running alliance. In doing so, the relevance of improved knowledge on potential developments along these interfaces for the understanding and the governance of energy transitions will be discussed. The presentation will further consider methodological reflections related to the conceptualisation of socio-technical system on different geographical scales.

Market formation through market integration of green electricity: Analysis of actors and institutions in the context of transformation of the German electricity market

Sandra Wassermann (ZIRN University of Stuttgart), Wolfgang Hauser (ZIRN University of Stuttgart)

The transformation of the electricity system under the condition of sustainable development and an accelerated nuclear phase-out is one of the crucial current challenges of the German economy. Due to an already successful policy support, electricity generation from renewable energies has gained a relevant share in the German energy supply system by now. For this reason enforced market integration and a more demand-oriented feed-in of electricity from renewable energies are considered as crucial next steps in the process of transformation. Hence, new regulation mechanisms are currently developed and discussed in order to ensure a smooth transition for renewable energy power plant operators from guaranteed feed-in tariffs to the liberalised electricity market. A variety of actors is involved in this development process as well as in the actual process of market integration. These actors' goals, strategies and options are examined in an interdisciplinary research project. The goal of the project was the development of an agent based simulation model as an instrument to analyse possible actions and interactions of the relevant stakeholders as well as their effects for the overall system in different regulatory frameworks. An important prerequisite for the set up of the agent based model was the thorough analysis of the relevant actors, how they were influenced by

the regulative framework, how they developed business models and routines, and how they tried to reshape formal institutions in order to meet their goals. The analysis took its analytical starting point at some theoretical assumptions of neo-institutionalism. The empirical work included literature reviews, guideline-based interviews with representatives of the important actor groups and an expert workshop which has been conducted in order to discuss and verify first results of the analysis. These results have then been translated into the formalised language of an agent based model, simulating the behaviour of producers of electricity from renewable energies and traders in Germany. We would like to present first project results with focus on the actor analysis in this process of market formation and integration. Firstly, this deals with the question how different actors have influenced the process of change. Secondly, the analysis focuses on the effect of newly developed policy frameworks for market integration of renewable energies on actors' goals, strategies, and behaviour as well as on actor networks and on the overall system.

Greening the shrinking city – new perspectives for US cities in decline

Karina Pallagst (Kaiserslautern University)

For many years, pointing at shrinking cities in the USA used to be a taboo, not fitting in the pattern of growth and progress anticipated by community leaders. Nevertheless, shrinking in terms of economic decline and population loss is an enduring phenomenon for many post-industrial US cities (Beauregard 2009). One negative effect of shrinkage is extended portions of vacant land with blighted and deteriorating buildings. To break away from a downward spiral of economic decline, some US shrinking cities (e.g. Youngstown, Cleveland, Detroit) recently started to initiate more pro-active planning, following a new paradigm of shrinking smart (Pallagst 2008). This trend includes actively dealing with vacated portions of land, seeing these spots as new assets on the way to more sustainable and livable cities. Some scholars argue that this form of shrinking smart might be breaking ground for more energy-efficient urban footprints (Mulligan, forthcoming; Audirac, forthcoming). The movement of greening, which is applied in shrinking cities, might have spillover effects for planning in general, possibly initiating a trend-reversal in US planning. While many European cities have implemented sustainable planning strategies with a wide range of efforts (Freiburg/Germany, Copenhagen/Denmark), for the US planning realm this is still a rather new trend (Benedict, McMahon 2006). The paper will present greening or green infrastructure development from the point of view of the US planning debate, emphasizing three forms of greening: right-sizing, urban agriculture, and waterfront development. Moreover, recent greening efforts will be highlighted with the examples Flint/Michigan and Detroit/Michigan, anchoring them in a debate of paradigmatic shifts and sustainable development. Living Space. A political interpretation of urban gardening.

Chiara Certoma' (Sant 'Anna School of Advanced Studies)

The growth of a global economy and new technologies has profoundly destabilised and reconfigured the idea the public space with the emergence of new political claims and actors. Non-state actors' practices are based on specific geographical places and rooted in defined social environments; by adopting new ICT they strengthen the map of transboundary claims, and produce new forms of non-cosmopolitic and non-diasporic global civic awareness. Place-based grassroots political practices it proposes can, by the means of common practices, make evident forgotten or ignored ecological relations, and explore the association of human and more-than-human aggregates in the co-constitution of inhabited space. This is the case of the emergent urban gardening. It is a spontaneous movement of citizens that reinvigorated global environmental consciousness and transformed cities into laboratories for political experiments, because it results in a form of engaged ecology by which cities' inhabitants engage in affirmative actions aimed at transforming neglected urban spaces in need of care. The gardeners contest the actual shape of the city, propose new forms of environmental planning, and prove practical feasibility of political ideologies they endorse. Throughout history, urban green spaces constituted a materialisation of political and social ideologies, and the loci where a number of political issues condensed. Critical gardening represents the most audacious use of public land scraped at the city peripheries and the marginal space of societal imagination. It may assume a number of diverse forms: allotments (namely, zones in cities claimed by the citizens and provided by local administrations for people to cultivate vegetable and flowers); community gardens (namely gardens autonomously created by people create because local governments do not, in order to reduce crime, increase social cohesion and clean environments); guerrilla gardening. Critical gardening allows a new environmental citizenship to emerge and addresses some of the most striking post-modern issues, such as the post-environmentalism, the subaltern and

antagonistic political theories, the new urban grassroots movements, the links between space and politics, the fragmentation of the individual self and the reconstruction of an innovative collective identity, the overcoming of a discourse-based political activity. In doing so, Critical Gardening brings us onto the variegated, dynamic and engaging lands where collective history takes form: the public space of gardens, allotments, flowers beds, wastelands and single spots of bare land in urban forgetfulness. It articulates urban politics in terms of inequality, division, exclusion, contestation, resistance and inclusion, and regards places as fluid space of complex power-geometries and thus, by spatialising the grand narrative of globalisation, allows plural and radical openness and a creative kind of politics.

Urban gardening and urban climate

Sascha Henninger (TU Kaiserslautern)

Actually, in shrinking cities we have to deal with a particular phenomenon: Previously it was a deficiency, now there is too much, namely landscape and open spaces. Apart from the problem that these areas could become dilapidated, it also offers the possibility to create qualitatively new purposes of urban and spatial development, using these new open spaces in a sustainable way. Alternatives to the traditional urban development can thus be tested and discussed. From a new point of view the prospects of a sustainable city can move into the scientific focus. Among other things such new open spaces lend itself as areas of renaturation, as well as for flood control, reproductive cultivation accordingly to the new trend of urban gardening and, of course to improve the urban climate. It offers an opportunity of new forms of urban green spaces, which could e. g. influence the local urban energy budget by a different type of agricultural valorisation. For this reason, currently on two fields of experimentation sweet potatoes were cultured to proof how urban gardening could affect the ambient temperatures of a rooftop as a kind of cooling equipment reducing the local urban heat island effect. Decisive for the choice of sweet potatoes was finding a horticultural product, which could be exposed to environmental stress more easily: in this specific case high ambient temperatures and intensive solar exposure. Corresponding to this, sweet potatoes can grow under stressful conditions, have relatively high abilities of latent heat loss and photosynthetic carbon fixation in comparison to plant species. First results indicated that there are obvious differences in the surface temperature of the exposed rooftop and the vegetation coverage, reaching -15 K. This offered the conclusion that the shadowing of the plants causes a slightly

smoother increase of the temperature on the rooftop. This is comparable with the effects of rooftop and façade greening. Furthermore, because of higher ambient temperatures on the rooftop and the increased exposition to the solar radiation, an increased productivity of the sweet potatoes could be mentioned. Therefore, urban gardening should not be limited acting as a kind of repair service for ailing cities. Urban gardening must come across as one module for building ecological as well as sustainable urban development. Therefore it could be a serious addition to the previously publicized rooftop and facade greenery. This requires more current pilot projects and fields of experimentation. Only through targeted experiments the urban society attains the necessary procedural knowledge and flexibility to respond to upcoming climatological as well as ecological challenges in an appropriate way. Corresponding to that urban gardening, associated with the knowledge of the applied urban climatology, can afford an important contribution in the current discussion how to handle receivables of a sustainable urban development.

Urban biodiversity management: Attitudes and behaviours

Robyn Bartel (University of New England), Don Hine (University of New England), Methuen Morgan (University of New England)

In Australia, many native ecosystems have been modified and cleared for agriculture and urban development. In concert with initiatives and regulation for multifunctional agriculture there is also increasing attention being paid to increase the area and quality of native ecosystems in urban areas. In this endeavour the attitudes and behaviours of urban dwellers in a representative regional centre were investigated. Both people participating in ecosystem recovery and the general community have been surveyed. Of those already participating, the majority of survey respondents (84%) were aware of the concept of biodiversity, and a majority (83.3%) also believe that we have a moral obligation to preserve urban biodiversity. Only 8% of those surveyed indicated that the loss of biodiversity in the community was not a problem. Almost all respondents (96%) felt that it was important the people have opportunities to experience nature in urban environments, with a similar number viewing our overall well-being and quality of life as being dependant on maintaining biodiversity. In the general community urban development is so far voted as the most extreme threat to biodiversity (44%), followed by other participant-specified threats to biodiversity (37%), the introduction of non-native animals (36%) and land clearing (35%). The results illustrate that overall awareness is high however other aspects of the study have demonstrated that few people are actively

engaged in ecosystem recovery so translating awareness into activity may be the key to successful urban management of biodiversity.

SE 23-02 - Transition of energy systems and green industry development: The geographies of renewable energy production

Chair: Britta Klagge, Harald Rohrer

Wind industry development and its geographical pattern

Pedro Campos Silva (University Osnabrück)

With the growing demand for renewable energy sources (RES), especially wind energy, worldwide, the wind industry expanded incrementally its location focus from the early centers like Denmark and Germany to attractive markets all around the world. Thus, the geography of the wind industry changed, not only in terms of new distribution channels, but also by building new production locations, research centers or establishing strategic alliances (joint ventures) with local partners. The resulting Global Production Network (GPN) of the wind industry is nowadays characterized by an increasing complexity due to changing production structures as well as transformed and interconnected flows of material, goods, capital and know-how. This Paper aims to present the changing structures of the wind industry, especially the manufacturing of wind energy turbines, through analyzing the industry's GPN as well as the underlying developments in different countries, namely Germany, Denmark, Portugal and Spain. The socio-political contexts of these countries are, as will be presented, in deed an influential variable within the industries development, because different policies to promote RES, varying industry policies, and the different (wind) energy markets directly have an effect on the wind industry's geographical pattern. In doing so, the important question of who controls the value producing and value enhancing network and who governs important processes, like R&D, will be addressed, as the resulting power asymmetries determine the wind companies' as well as the countries' position within the GPN. In addition, this paper tries to link these developments with the growing importance of (national) wind innovation systems, i.e. innovation policies and new innovation actors, to discuss the changing role of knowledge within the wind industry.

Wind power planning and landscape perception in Spain (Alpujarra and Valle de Lecrin, Andalusia)

Marina Frolova (University of Granada), Belen Perez (University of Granada)

Due to its ambitious policies Spain has achieved a very successful implementation of renewable power. Wind and solar powers have become an essential factor shaping the present-day Spanish landscape. However the Spain's landscape policies are still out of step with the development of renewable energy policies, and new infrastructures develop in Spain without any specific instrument of land use planning. The aim of this paper is to analyse some key problems of wind power planning and wind power landscape perception in Spain through the case study of Alpujarra and Valle de Lecrin (Granada province, Andalusia). As it occurs in many other Spanish rural areas characterised by depopulation and socio-economic problems, wind power is seen in these localities as a way to increase income and to raise its economic activity, although a problem of a lack of coherent planning is raising tensions and conflicts with regard to land use and to natural and cultural resources management. Our study is based on written documents analysis, field observation and in-depth qualitative interviews with the different stakeholders involved in the development of wind power projects.

Transitions in energy systems: The case of offshore wind farming

Kira Gee (Helmholtz-Zentrum Geesthacht), Andreas Kannen (Helmholtz Zentrum Geesthacht), Christian Fischer (Helmholtz-Zentrum Geesthacht)

Offshore wind farming is now well under way in Europe, driven by national renewable energy targets as well as the desire to exploit the technological advances it offers for industrial growth. As a spatially intense activity, it has precipitated a range of changes in how the sea is used. It has also given rise to a number of socio-political questions concerning renewable energy development. We seek to explore some of these against the wider context of scale and maritime governance. Unlike onshore wind farming, offshore wind farming is decidedly a game for centralized production modes. In Germany at least, community offshore wind farm projects have failed; because of the expense, only large players can afford to invest in offshore wind farming projects. As a result, offshore wind farming has grown to represent an international oligopoly with considerable power over future developments such as grids. Although it still seems carried by the confluence of public interest in renewables, political support and vested industrial interests, it also increasingly

competes with other sea uses and is in conflict with a range of other sea values at different scales. This raises two related issues: Firstly, how the costs and benefits of offshore wind farming are distributed, and secondly, who is involved in decision-making about sea space. Offshore wind farming is a case in point that decisions about sea space are increasingly the provenance of a small number of key players. Moreover, decisions about sea space (for instance energy grids) increasingly need to be taken at the international level, leading to a shift in scale in maritime decision-making. With no obvious decision-making body at the European level, what role does this leave for national and subnational decision-making bodies such as the local communities and Länder? Linked to this is a wider issue of scale, which is the question of how the costs and benefits of offshore wind farming are distributed. We argue an imbalance has sprung up between the use of maritime public goods and the distribution of the benefits derived from these goods. There is also the question of how to balance different types of value, for example how to weigh shareholder profit and the loss of other maritime goods and services against the generation of renewable energy. The presentation will look at these questions including distribution of costs and benefits linked to scales to illustrate this point at a qualitative level and discuss resulting challenges for planning and management.

Deep geothermal energy: Challenging common geographies of (renewable) energy production

Michael Stauffacher (ETH Zurich Institute for Environmental Decisions (IED) Natural and Social Science Interface (NSSI)), Matthias Gross (Helmholtz Centre for Environmental Research - UFZ)

Geothermal energy offers the benefit of a renewable energy source demanded and supported strongly in the face of the recent 'energy turnaround' in many European countries. Social scientific studies on renewable energy, however, have pivotally focused on wind, solar, and hydropower whereas geothermal power has hardly received any attention. Recent technological developments have expanded the potential of geothermal energy ranging from the continuously improving heat pump technology to providing a significant share of the electricity and heat production. This presentation will thus reflect on the geographical scope as regards these novel developments. Innovations in deep geothermal energy technologies indeed expand their geographical reach by focussing not only on hot water but as well on hot rock as potential heat source. Some technical experts even claim that deep geothermal being the only option replacing the base load still produced by nuclear power. Besides the depth of

retrieving energy from the earth, these new developments point inter alia to the political valences of local energy versus centralized production, the dependence on large corporate industries versus energy autarky of communities and the dependence on abstract expert knowledge versus local knowledge in civil society initiatives. Some further characteristics of deep geothermal energy make it worth having a second look from a social scientific perspective: the residual risk and potentially high damages of induced seismicity, the human-made nature and the low personal control of these risks, a general feeling of 'tampering with nature' and the large infrastructure at surface (high visibility). For social scientists working on the siting of large infrastructure facilities, this set of characteristics points to some potential common framing as for instance the disposal of nuclear waste, even though they both show fundamental historical differences. As can be observed in the case of CO₂ storage, such similarities can effectively be used by interest groups to delay or block respective projects. Given that many of the recently launched geothermal power plants and the drilling technologies involved inhibit many scientific uncertainties and unknowns as regards induced seismicity, CO₂ leakage, groundwater contamination, and accumulated radioactivity (among other issues) research questions along the interface between geography, sociology, and environmental management appear to be of utmost importance. The presentation thus has two overall exploratory goals: Firstly, to outline possibilities and challenges for socio-spatial research on geothermal energy in relation to other types of renewable energy, and, secondly, to deliver suggestions on how to theoretically frame the tapping of these energy reservoirs by building on current insights from the sociology of ignorance, sociology of knowledge, Science Technology Studies.

SE 23-02 - Urban landscape and nature 2

Chair: Sascha Henninger, Olaf Kühne

Urban plant migration – invasion alarm?

Götz Heinrich Loos (Ruhr University Bochum)

The flora of urban areas within central European cities is characterised by high percentages of alien plants. Only a part of the present alien plant species is invasive and the invasion behavior of the taxa concerned is different from that outside the urban areas. Habitat change has obviously led to a change in dispersal behavior and the insertion of ecological niches. Anthropogenic influences cause dispersal and habitat changes directly, whereas the effects of climate change imply no direct causing. In the course of an investigation on the occurrence, distribution and dispersal of neophytes and especially invasive plant species in the Ruhrgebiet, the largest urban agglomeration in Germany and the former most extended European old industrial region, it was studied, where the invasive species originated in rural areas, whether they also be invasive in urban-industrial biotopes or if they lose their invasiveness. Likewise, it was examined, if neophytes, which are not invasive in neighboring rural areas, receive an invasive character in the cities. It was found that only a few species are invasive, both in urban-industrial biotopes as well as in more natural sites outside the cities. The ways in which invasive plant species arrive from outside the urban-industrial areas are primarily immigration and xenophytic introduction. On the other hand, within the cities the escape of cultivated plants can directly lead to an invasive behavior of these species. With most invasive species are escaped from cultivation (ornament and crops), however, they have spread into rural areas and return from there to cities virtually. Immigration routes into the cities are traffic lines (roads and railways) and streams, whereas the importance of the respective migration path from each of the type considered dependent. Additionally, note that some species migrate, be introduced and escape from cultivation at the same time. The landuse types of especially purely urban habitats restrict the number of invasive species. Therefore it cannot be formulated in general, that invasive species are present preferably in urban habitats. On the other hand, a larger number of invaders are present in industrial land and brownfield sites, so that a general summary of urban-industrial habitats not always makes sense.

Beaches in a Metropolitan Environment: Multiple Features, Multiple Uses

Mangal Padhyegogate (Valia College of Commerce)

The city of Mumbai originally consisted of seven islands of Colaba, Old Women's Island, Mazagaon, Wadala, Mahim, Parel and Matunga-Sion. This group of islands was joined together by a series of reclamations over a period of time. Mumbai was ruled by Hindu, Muslim, Portuguese and British rulers. As the city grew, it expanded further to the north in the Salsette region. Presently it is considered to be the most densely populated city and the commercial capital of the country. As process of expansion continued, the Mumbai Metropolitan Region (MMR) was established in 1974 to address the challenges in planning and development of integrated infrastructure for the metropolitan region. MMR consists of Mumbai and its hinterland including 7 municipal corporations, 15 municipal councils and several villages. The total area is 4355 sq.km. It is linked with Mumbai through the suburban railway system and a large network of roads. MMR limits extend upto Virar in the north, Alibag in the south, Arabian sea on the west and a well demarcated boundary in the east. Its hinterland supplies raw material and labour, with the flow of goods and services maintained by fairly good transport network and communication. The impact of the region percolates to the hinterland through smaller cities. The region is rich in agriculture, fishing, dairy farming, vegetable farming and a number of small scale industries. It is endowed with several features of natural beauty that provide recreational services to the urban dweller. Being a coastal region, several beaches skirt the western front. Some are within the city proper, while some are at the periphery and beyond. Proximity and accessibility are prime factors in determining the popularity of every beach. However it is interesting to note that there are variations in the physical characteristics and level of besides popularity of the string of beaches. It was determined by a survey of 26 beaches (10 from Mumbai, 8 from Thane District and 8 from Raigad District). These beaches were classified on the basis of their physical characteristics such as length, width, texture, pH and colour as well as their efficiency for recreational purposes. The study has been conducted based on data, partly from secondary sources, but mainly from primary sources. i.e. extensive field survey. It brings out the significance of every beach in the urban landscape. In the present paper, the authors have attempted to identify the variations in the physical characteristics as well as the degree of attractiveness of beaches within the city limits and those beyond the city in the metropolitan region. **Rethinking Urban (Industrial)**

Forests – Studies about Use and Perception of a Salutogenic Resource

Thomas Claßen (University of Bielefeld), Björn Brei (University of Bielefeld), Claudia Hornberg (University of Bielefeld)

Objectives Urban nature with green and blue elements is of high value for public health (e.g. in terms of physical activity, climate adaptation strategies, reducing hazardous substances). The industrial forest Rheinelbe (a former colliery) in Gelsenkirchen (Germany) also constitutes a health-promoting resource, especially for the local population. The extent to which this resource can unfold its various potentials, depends on how it is or is not used. Decisive factors may be how the public perceives the industrial forest Rheinelbe as well as eventual obstacles to its use. In order to determine non-use, perception and possible obstacles in various population groups, in 2008/2009 two studies were carried out from a Geography of Health perspective on the use (or non-use) of the industrial forest by the (local) population. Methods In 2008 a conceptual study was conducted on procedures for developing the industrial forest (on-site observation, surveying, interviewing experts). As part of a follow-up study in 2009, a mail survey (sample size: 1000, ~6%) was taken of the population in the adjoining city district (pop. total: ~20.000). The bilingual questionnaire (German/Turkish), developed specifically for this purpose, included quantitative and (semi-)qualitative items (e.g. attendance rates). The responded questionnaires (n=240, 24%) were evaluated as descriptive statistics and compared with the results of the conceptual study. Results The industrial forest is mainly used for rest and leisure, its road also for non-motorized transport. People visiting the forest report positive - mainly mental - health effects (e.g. relaxation, good air quality) and active/passive nature experience. While those surveyed in the forest reported coming there to visit it often, residents from the adjoining area came over less often. Furthermore, individuals with an immigrant background visited the forest less often than did natives. Potential obstacles to visiting the forest were feelings of low personal safety (dependent on gender and/or nationality), no knowledge of the forest, and little or no feelings of identity with the former colliery's area. Conclusions Visitors surveyed on site and people surveyed by mail in adjoining areas perceived the industrial forest as an important and long-term health enhancing factor. This salutogenic potential is of special interest in heavily built-up areas with e.g. high levels of traffic and air pollution. From a public health perspective, the salutogenic potential of natural urban green areas needs to be optimized and communicated more broadly and

clearly, so these areas will be used by as many population groups as possible. Further research is needed to determine how the effect of targeted, long-term, target group-specific measures can be embedded already at the planning stage.

Sustainable uses of urban nature between modern and postmodern aesthetics: Reflections based on the social constructivist approach

Olaf Kühne (Universität des Saarlandes)

This lecture deals with the question of the social construction and the judgement of urban physical objects (as trees, streets, houses), which are perceived as natural. The society perceives nature ambivalent. Nature describes 'the primary and the good ['] that contrasts the society as the artificial and even destroying?. Nevertheless nature means 'the wild and the threatening, which is domesticated to protect the society' (Groß 2006: 5). In the city nature exists in a domesticated (e.g. as park) or in a less domesticated condition (e.g. as ruderal vegetation. The division of modernity and postmodernity is being discussed since more than 30 years in social sciences. Postmodernity has a constitutive aesthetic dimension. Concerning this point of view, modernity and postmodernity have different implications in the perception and assessment of urban nature. Especially the less domesticated nature contradicts the modern aesthetic scheme. It is assumed that the antagonism of legitimated and trivial culture is a substantial characteristic of modernity - which incorporates itself in a series of fundamental dichotomies like nature and culture (Fuller 1992). A typical approach of modern dichotomy is the construction of order and disorder. On the contrary postmodern aesthetics challenge and deconstruct these dichotomies (Sloterdijk 1987, 1988). Unlike the modernity postmodernity tolerates the less domesticated nature in cities which includes new possibilities of the composition of the cityscape, especially for ruined buildings and areas. Not only well-tended parks are assessed as desirable, but also untidy areas with sparse vegetation are interesting. The suggested lecture is structured in the following way: Reflections concerning the social construction of nature-culture and city-landscape Considerations about the different forms of appearance of nature in cities Characteristics: modern and postmodern aesthetics The appraisalment of urban nature against the background of modern and postmodern aesthetics Conclusion: Consequences concerning the practical planning One of the lectures aims is to open a social constructive perspective (in the tradition of Schutz 1976; Kühne 2008) and the subject-orientated perspective of the philosophic perspective of Croce (1995) for planning and design practice. Postmodern landscape planning and architecture does not mean 'anything

goes', but rather a pluralization of the population's associability (especially in the sense of the sovereigns in democratic societies). Additionally the results of empirical social scientific investigations will be presented concerning the social construction of landscape (Kühne 2006), also as results of participative observation in the practice of landscape planning (Hartz/Kühne 2010).

SE 23-03 - Transition of energy systems and green industry development: Regional and country perspectives

Chair: Britta Klagge, Harald Rohrer

Urban transitions towards sustainability

Harald Rohrer (University of Klagenfurt), Philipp Späth (University of Freiburg)

Innovation policies in the European Union are increasingly addressing 'grand challenges' such as climate change, resource depletion or aging societies. Such transformations go far beyond conventional product or process innovations and require a restructuring of broad socio-technical regimes, e.g. the built environment, systems of mobility, the energy system or the way we organize processes of production and consumption. The focus of research on socio-technical transitions has predominantly been a national or European level, while the role of place as well as the city level as part of multi-scalar governance systems has been largely neglected. However, the distributed nature and specific socio-technical dynamics of large-scale transition processes towards greater sustainability makes cities an important arena of infrastructure transformation and a crucial nexus between different levels of governance and strands of socio-political discourse. With a focus on the Cities of Graz, Freiburg and other European cities we will discuss what roles cities may play in transformation processes towards sustainable infrastructure systems, how opportunity structures for a greater urban role in such transitions look like and which limitations as well as specific advantages exist at the city level. We will be dealing with questions such as: - How can cities serve as a place of experimentation and social learning for sustainability transitions and how can they support the strengthening and growth of greener socio-technical configurations? - How are changes in the governance of infrastructures (e.g. decentralisation, market liberalisation) influencing the potential role of cities in sustainability transitions? - What is the role and dynamics of discourses and visions around urban sustainability transitions? How do such visions emerge? How do they interact with discourses and visions at different scales? - How important have external pressures (energy prices, particulate matter, new regulatory context etc.) been to destabilise the existing regime? How heterogeneous and inconsistent are urban energy or transport systems and to which extent can such frictions be used to promote change in certain parts of

the system? - How is it possible to create and keep up transition momentum? To which extent and with which strategies can urban energy transformations become irreversible, e.g. by social and material entrenchment? - Can we speak at all of 'transitions' at a city level? We are especially interested in the room for manoeuvring for cities that is left by institutional contexts and socio-technical networks beyond the city boundaries.

Energetic regionalisations as processes for the transition to renewable energies

Fabian Faller (Université du Luxembourg)

The utilisation of renewable energies (RE) can be seen as one of the most important aspects of mitigation of climate change. Implementing them in decentralised structures additionally enhances the positive effects on environment, economy, and society. By that, RE development is a major asset for sustainability in regional development contexts. To achieve it, collaboration and cooperation of various regional actors is necessary. These actors differ in their perspectives on challenges for energy development as well as on the region itself. Hence, questions of space and scale are rising: If sustainable regional development can be achieved by the decentralised utilisation of RE, which 'region' develops? Or to put it vice versa: Which processes of regionalisations are initiated through the use of RE (energetic regionalisations)? The paper focuses on bioenergy production and related processes of regionalisations in the cross-border context of Germany and Luxembourg. On the one hand, the evolution of and transition to bioenergy production is focus of the theoretical analysis. Which institutional and structural (pre)conditions are fundamental for processes of regionalisations in the biomass industry? In which ways are they connected to the socio-technical development? These questions are addressed with the conceptual approaches of evolutionary institutionalism and socio-technical transition. The first building block concentrates on institutionalisations, relevance of structures for individual actions and impacts of individual behaviours on institutions. The latter building block focuses changes in technology and their social implications, social changes and their potentials for technological changes, and 'spheres' of socio-technical changes among niches, regimes and landscapes - all aspects with respect to bioenergy development. On the other hand the day-to-day practices of individual actors in the bioenergy market are focused. In which ways do practices influence regionalisations? The research motivation shifts to processes of constitution and reproduction of bioenergy-regions. Therefore, Werlen's theory of social geography of day-to-day

regionalisations builds the theoretical fundament. 'The bioenergy-regions' are produced through embodied practices and reproduce themselves within these practices. Hence, bioenergy--regions and -spaces do not exist per se, but are socially constructed. So on the one hand, the social use of spatial categories and contexts regarding bioenergy are analytical objects. On the other hand, the relation among society, practice and spatial connotations will be addressed. The paper focuses on the conceptual framework of an ongoing research project and discusses the underlying theoretical perspectives, their operationalisation as well as the methodological research design. In empirical terms, preliminary results from an exploratory pilot study will be presented.

Transition to sustainable energy services in developing countries – the role of community socio-economic structures

*Carmen Dienst (Wuppertal Institute for Climate, Environment and Energy),
Willington Ortiz (Wuppertal Institute for Climate, Environment and Energy), Julia
Terrappon-Pfaff (Wuppertal Institute for Climate, Environment and Energy)*

Sustainable energy technologies are widely sought-after as essential elements in facing global challenges such as energy security, global warming and poverty reduction. Moreover, using renewable energy technologies offers multiple development opportunities to off-grid communities in emerging economies and developing countries. Several technical alternatives using renewable energy sources exist, which have proven adequate for responding to diverse sustainability challenges. However, although the deployment of renewable energy technologies has significantly increased in recent years, in both industrialised and developing countries, the share of renewables remains rather low in comparison to the widespread use of unsustainable and often centralized technologies. One of the most significant constraints to their adoption and broad diffusion is the socio-economic context in which sustainable energy technologies are supposed to operate. Social and economical barriers are often even more difficult to overcome than technical obstacles. Practical strategies dealing with the above mentioned socio-economic challenges are crucial elements for project design and, particularly, for the implementation of project activities. There is no one-size-fits-all solution for the successful implementation of climate friendly technologies, but each initiative, project or programme gives rise to new findings and know-how that can help accelerate the transition process in the specific geographical context. The same holds true for energy projects in developing countries supported by the WISIONS initiative. This initiative is run by the Wuppertal Institute and is supported by the Swiss-based foundation

ProEvolution. The aim is to improve the South-South and North-South knowledge transfer on good-practice implementation models for sustainable energy supply and analyse the long-term perspectives. In this study experiences from implementing community-based projects are reviewed in order to identify the practical elements that are relevant to overcome socio-economic challenges today and in the future. In order to systematise the findings an analytical framework is proposed, which combines analytical tools from the socio-technical transition framework and insights from participative approaches to development.

About the role of energy regions as part of the energy transition

Claudia Kölsche (Universität Bonn)

Modern life is unimaginable without the continuous supply of energy. However, the use of fossil and nuclear fuels contradicts the aspiration for societal environmental change and resource depletion to escape. The dependence on energy supply from politically unstable countries and the associated drain of purchasing power as well as the fear of nuclear accidents reinforce the negative side of conventional energy generation. Within the meaning of the sociological systems theory of Niklas Luhmann, politics can not steer nor intervene the processes of the economy. With the Electricity Feed Act (Stromeinspeisungsgesetz) and the Act on Granting Priority to Renewable Energy (Erneuerbare Energien Gesetz (EEG)), the German government only led a framework to the energy transition - self-referential and autopoietic. Thus, the EEG is embedded in the overall environmental debate and by this, it refers to public opinion. In the political functional system, the EEG is internationally perceived as a showcase and it ensures further political discussions. Furthermore, it contains specific payment rates, which are designed for the "language" of economy. The economy is meanwhile made up of two modes of energy supply: 1. Energy supply by central, large power plants. 2. Small, decentralized individual power plants. Regarding central, large power plants: a few technical experts monitor processes and the energy network's voltage. Traditionally, fossil/nuclear fuels are used for energy generation. Nevertheless, the renewable energy industry meanwhile also runs remarkable power plants, which are integrated in the existing network structures. The avant-garde potential of renewable energy sources, however, lies in its use of power plants, which are small, decentralized and tailored to individual needs. These type of plants are in the hands of private individuals, small and medium enterprises and municipalities. The transition of energy supply turns out to be a complex social

negotiating process. Why are some decisions space-effective and others not? Where outweighs the energy policy objective, where the economic pressure of investment need and where public acceptance? And what consequences result from this? Interesting in this context appears the consideration of energy regions. Mostly these are seen as regional associations of municipalities. Often, however, energy-economic catchment areas and infrastructure networks or similar natural space/pattern of use occurrences play also a role in the distinction. While an established energy region on the one hand significantly reduces the complexity of the topic for politics, economy but also general public, on the other hand it enables direct touchpoints for further communication and decisions. Achieving a better understanding of the underlying structures can therefore help to better understand the social negotiation process of the energy transition.

Risks & Conflicts

RC 01-01 - Anxiety, biosecurity and conflicts

Chair: Jonathan Everts, Ben Coles

The communication on invasive plants: A paradoxical attitude towards social anxiety.

Marion Ernwein (University of Geneva)

Anxiety is a physical and mental state that is linked with a feeling of rupture of the pattern of everyday life, and of uncertainty over future developments. It can be personal as well as social, and depends on the framing of a topic (Jackson & Everts, 2010). Environmental issues are factors of anxiety because of their potential for disruption and even annihilation of human life. Plant invasions are a global environmental issue, since their identification as one of the main threats to biodiversity in the 1990s. At a local scale, some invasive plants also pose considerable health problems. They thus represent a threat to biodiversity as well as human health. Their management is variable from one place to another. However, one pattern can be identified; it is their paradoxical relation to anxiety. Through the analysis of four focus groups conducted on this topic in Geneva, on the basis of a collective reading of three documents on ragweed and giant hogweed, I will show how the communication on these plants feeds social anxiety, and how anxiety shapes the relationship of the citizens to expertise and their willingness to eradicate invasive plants. Indeed, I will show that on the one hand, the information addressed to the public on this topic relies on the use of militaristic terms and dramatizing staging of science, which can be interpreted as announcing a dramatic forthcoming event. The use of metaphors and militaristic terms on this topic has received a lot of criticism from social scientists (Larson 2011, Fall & Matthey, 2011). On the other hand, the actors involved in the fight against invasive species try to turn the citizens into actors of the biological struggle. To convince them to get involved, they need to increase their accountability, especially after such controversies as BSE and GMs, which weakened the credibility of many authorities (Irwin, 2001). One way of doing so - that is also to be found in the treatment of many other biosciences issues - is through increased transparency of information and an explicitly more open, less confident treatment of science (Irwin, 2001). However, transparent information on plant invasions makes public the many uncertainties that characterize the topic: regarding the behavior of the plants that can be invasive in one place and not in another, the way they should be fought against, or their overall consequences on ecosystems. This uncertainty feeds anxiety because the

situation can be interpreted as out of control, and the role of the experts, that is to give reliable information, is challenged. The social order as well as the local environment therefore seem to be threatened. There are thus two sources of anxiety, one that is institutionalized as an agent of social change, and one that is involuntary and closely linked to uncertainty. Social practices related to biosecurity are therefore shaped through social anxieties.

Swine Flu in Mexico

Sebastian Köllner (University of Bayreuth)

Swine Flu in Mexico is the geographical point of origin of the so called 'swine flu' A/H1N1 virus. From there, the new virus spread almost all over the world, through the nodes and hubs of the globalized world. But not only the virus started to conquer one national border after the other, also a wave of global anxiety spread through national and international media, which created new imagined geographies in different societies and materialized in new behavior and thinking, especially about Mexico. In my contribution I will analyze the inner Mexican discourse concerning the 'swine flu' and will try to compare it with international news coverage. I will investigate the different imagined spatial layers which stand behind the inner Mexican discourse on the one hand and the 'international discourse' on the other hand. In a second step I will show, how thinking about Mexico as a national state and thinking about different regions in Mexico lead to novel spatial practices and behavior. To deepen the findings I will add another discursive dimension, which is not reflected in newspapers, magazines or TV-headlines: personal stories. Narratives of Mexican inhabitants will add the dimension of the personal and local geographies concerning the phenomenon to answer one important question: how did the 'swine flu' affect the everyday life and the every day practices of the people living in the so called 'epicenter' of this global event of anxiety. Sebastian Köllner, B.Sc., University of Bayreuth

Feeling blue in the landscapes of Iceland: Conflicts about the origin of species

Karl Benediktsson (University of Iceland)

Interesting and sometimes intractable social and cultural conflicts arise when biological agents that are introduced into a new ecosystem do not behave in expected ways. Such 'invasive alien species' are the subject of much anxiety in global nature conservation and discussions of bio-security, but actions to curtail

them prescribed by experts in ecological science often run counter to aesthetic or moral sensibilities of the 'lay' population. The picture can be further complicated by historical circumstances and events. Confronting a long history of unsustainable land use and land degradation, Icelanders imported during the last century a great number of plant species that were supposed to help in curtailing soil erosion and reclaiming lost vegetative cover. One of these was the Nootka lupin (*Lupinus nootkatensis*), a native of the west coast of North America. The seeds of this leguminous plant were imported to Iceland in 1945, and it was used extensively in soil conservation until very recently, not least because of its nitrogen-fixing ability. But its very vigour in these degraded landscapes has proved controversial: its conspicuous blue flowers now characterise large areas of the country in early summer, to the delight of some but alarm of others. In 2010, a programme of eradication was instigated by the Icelandic Ministry for the Environment. This involves some quite drastic measures, including the spraying of herbicides over parts of the central highland region where the plant has taken hold. Mildly put, the response to the programme has been mixed. Arguably, this is an example of politics of nature that are shaped by often strikingly unreflexive notions of naturalness and indigeneity - on both sides of the debate. This will be discussed in the paper in the light of recent critiques of concepts and categories that set the terms of the debates about bio-security.

RC 02-01 - Broadening the IPCC focus: Extreme events, vulnerability to multiple stresses and adaptation options

1

Chair: Jörn Birkmann, Susan Cutter

Climate and adaptive management: Are we doing and not learning?

Roger Pulwarty (NOAA)

Learning is of strategic importance in the decades-long process of adapting to climatic change and variability and in accumulating lessons from past and current practices. Much work and experience has shown that long-term environmental problems can seldom be dealt with by single discrete actions or policies but respond only to continuing, sustained efforts at learning, supported by steady public attention and visibility. Key gaps within the present context are that information on physical states and impacts are not optimally integrated into a coherent overall storyline, in real-time, to meaningfully characterize conditions, cumulative or intensifying impacts across climate timescales (such as during drought) are difficult to characterize. The concept of 'adaptive management' has been widely advocated as a bridge between science and policy. We discuss this idea in the context of climate adaptation but ground the discussion in the decision-making and implementation of actual adaptive management efforts. Adaptive management has three key tenets (1) Policies are experiments that should be designed to produce usable lessons; (2) AM should operate on scales compatible with natural processes, recognizing social and economic viability within functioning ecosystems; and: (3) AM is realized through effective partnerships among private, local, state, tribal and federal interests. In a watershed setting this can mean balancing equity goals, through hydropower production, conservation, and protecting cultural resources while experimenting and incorporating learning in the context of differing sources uncertainty and surprises. For this presentation we draw on the experience, both analytical and deliberative, within transboundary watersheds primarily the Columbia and Colorado River Basins in North America, which are longstanding efforts at adaptive management. Experiences, will also be drawn from other international watersheds in which the author and colleagues have been engaged, such as the Guadiana Basin between Spain and Portugal among others. One goal is to identify the strengths and weaknesses of an 'adaptive management approach' in the context of changing climatic extremes and baselines. Our approach is based on the premise that understanding how effectively common adaptation

goals are pursued, legitimized, and secured requires identification and evaluation of present systematic efforts (i.e. field-tested alternatives) to experiment, engage leadership at a variety of levels, credibly assess alternatives, and assess when initial assumptions may be failing. None of these can be designed optimally, apriori. We conclude by showing how the evolutionary or learning-based approach to 'assessment' can enter into regional and local activities in support of the goals of the IPCC and attendant assessments intended to support adaptation practice.

Social and economic tipping points in adaptive capacity – empirical lessons from small scale adaptation

Matthias Garschagen (United Nations University)

Complexity and tipping points have become popular epistemic elements within conceptual debates around climate change impact and adaptation assessment. Yet while these ideas are conceptually appealing much less work has been trying to empirically measure, assess or even forecast tipping points with respect to climate change vulnerability or adaptive capacity - in particular with respect to the interaction of gradual changes and extreme events. In addition, tipping points have been linked predominantly to large-scale bio-physical systems in the literature (e.g. the instability of large ice sheets and the break-down of ocean circulation systems). Based on empirical research on small scale adaptation processes at household and community level in Can Tho City, Vietnam, the paper aims at breaking up and broadening the above mentioned epistemic coupling. The findings suggest that many types of tipping points can be observed in small scale systems (household or community level). Shifting the perspective away from the predominant hazard focus, the analysis emphasizes in particular tipping points in social and economic spheres of adaptive capacity and explores the factors influencing them, paying special attention to the interaction of multiple stresses. Based thereon, the paper provides a first ontology of tipping elements in small scale urban systems. It is argued that examining them in detail is of key importance for understanding vulnerabilities and adaptive capacities at the respective scales. The paper concludes by discussing lessons learned for risk and adaptation governance and suggests ways in which the findings can advance the currently emerging discourse on scenario building with respect to adaptive capacity, particularly within the framework of the IPCC.

Community-Based Autonomous Adaptation and Vulnerability to Extreme Floods In Bangladesh: Processes, Assessment and Failure Effects

Md Younus (Flinders University)

The IPCC (2007) demonstrates the importance of adaptation to climate change. The IPCC warned that the Ganges Brahmaputra Meghna (GBM) will be at greatest risk due to increased flooding, and that the basin's poverty would reduce its adaptation capacity. A key issue in assessing vulnerability and adaptation (V & A) in response to extreme flood events (EFEs) in the GBM river basin is the concept of autonomous adaptation. This paper investigates autonomous adaptation using a multi-method technique which includes two participatory rapid appraisals (PRA), a questionnaire survey of 140 participant analyses over 14 mauzas in the case study area, group and in-depth discussions and a literature review. The study has three key approaches. First, it examines farmers' crop adaptation processes in a case study area at Islampur, Bangladesh, in response to different types of EFEs. Second, it assesses the V&A in response to three EFEs in 1998, 1995 and 1988. V&A are categorized on the basis of a weighted matrix index. The paper uses PRA methodology and makes an important methodological contribution for assessing V & A. Third, the paper assesses the economic consequences of failure effects of autonomous adaptation in response to EFEs. The results show that Bangladeshi farmers are highly resilient to EFEs, but the economic consequences of failure effects of autonomous crop adaptation (FEACA) on marginal farmers are large. These failure effects are defined as total crop loss against potential production, plus total agricultural cost multiplied by the number of flood events in the studied area. Total agricultural cost includes cost of seedlings, fertilizer, pesticides, land preparation, human labour, and watering. The paper estimates that the crop related loss plus plants and houses damaged due to extreme flooding in 1998 in Bangladesh was US\$14001.26 million. The paper contributes to current knowledge by filling three important research gaps as follows, 1) farmers' autonomous crop adaptation processes in response to various types of EFEs; 2) methodological contribution for assessing V & A through PRA; and 3) the economic consequences of the failure effects of autonomous crop adaptations. The findings of this study can act as a guide to policy decisions for effective allocation of adaptation funds at community level in Bangladesh. The paper concludes that urgent action is needed to improve the sustainable crop adaptation capacity at community level in the foreseeable future to cope with extreme floods under a regime of climate change.

Crystal ball or support for decision makers? Exploring opportunities towards vulnerability scenarios and trends.

Stefan Kienberger (University of Salzburg)

Within the IPCC report on extreme events (SREX) a clear correlation between future climate change and certain hazard domains has been identified. Next to that, it can be observed that the two 'major schools' within the conceptualisation of vulnerability - climate change and disaster risk reduction - are getting closer in terms of concepts. As in the past, the major challenges in vulnerability science embrace concepts and associated (spatial) methods to achieve a quantification of different vulnerability dimensions. Future scenarios and trend analysis played a more marginalised role on the sub-national scale levels. Reasons for that are the 'challenges' within conceptual manifoldness, but also in having the focus on developing suitable indicators and methods. Next to that, the availability of and access to data for indicators has to be maintained for the targeted time period. Future projections have yet been largely untouched given the uncertainty within the projection of vulnerability indicators. Within this paper, the need for future vulnerability scenarios (next to a regular monitoring) is highlighted in the context of climate change adaptation and disaster risk reduction. This is furthermore discussed through the integration of novel spatial methodologies to establish such scenarios in light of the new scenario approach currently developed through the research community and IPCC. As a case study, in the context of a climate change research project future socio-economic flood vulnerability scenarios have been developed. These followed SRES projections for time steps 2000, 2020 and 2050 and has been modelled for the Salzach river catchment in Austria and the Brahmaputra in Assam, India. The approach was built on disaggregated spatial units integrating a condensed vulnerability index. This consisted of proxy variables, which have been identified out of a complete present-state vulnerability index and its indicators were projected under a correlation with future GDP and population scenarios. Results show that impact of GDP and population growth is highest in areas where levels of vulnerability are already high. Additionally the results depict that a slow growth in population with a concurrent rapid growth in GDP is important in reducing levels of vulnerability. Based on these experiences the possibility and associated challenges to develop vulnerability scenarios will be highlighted. An outlook will be provided how critical key indicators such as land use and population dynamics could be integrated in such an approach. Critical remarks should open the discussion towards the suitability of such scenarios within decision making in disaster risk reduction and climate change adaptation.

RC 02-02 - Broadening the IPCC focus: Extreme events, vulnerability to multiple stresses and adaptation options 2

Chair: Jörn Birkmann, Susan Cutter

Contextualizing social vulnerability: Findings from case studies across Europe

Christian Kuhlicke (Helmholtz Centre for Environmental Research - UFZ), Anna Scolobig (International Institute for Applied Systems Analysis), Sue Tapsell (Middlesex University), Annett Steinführer (Johann Heinrich von Thünen Institute), Bruna De Marchi (Institute of International Sociology of Gorizia)

Vulnerability is no universal theory; it is a middle range theory attempting to integrate theory and empirical research with regard to specific social phenomena. This implies its application is only meaningful if it is contextualised both empirically as well as conceptually. This paper presents findings from social vulnerability assessments conducted in different case studies of different hazards in Europe (Germany, Italy and the UK). The case studies relied upon a common set of comparable indicators, but they also adopted a context-sensitive, qualitative approach. A shared finding across the case studies was that it was not possible to identify a common set of socio-economic-demographic indicators to explain social vulnerability of groups and/or individuals for all phases of the disastrous events. Similarly, network-related indicators as well as location- and event-specific indicators did not have the relevance we expected them to have. The results underline that vulnerability is a product of specific spatial, socio-economic-demographic, cultural and institutional contexts imposing not only specific challenges to cross-country research concerning social vulnerability but also to attempts at assessing social vulnerability in general. The study ends with some reflections upon the methodological, practical and theoretical implications of our findings.

Urban vulnerability - why and how to adapt to climate change in Santiago de Chile

Anke Schwarz (Helmholtz Centre for Environmental Research - UFZ), Kerstin Krellenberg (Helmholtz Centre for Environmental Research - UFZ), Juliane Welz (Helmholtz Centre for Environmental Research - UFZ)

The Metropolitan Region of Santiago de Chile is affected by at least two hydro-meteorological hazards: seasonal floods and very high temperatures. Both hazards will most likely be aggravated in the future by expected climate changes, going along with increased medium temperatures and changing precipitation patterns. Pronounced patterns of urban segregation as well as specific and permanently changing urbanization (land use) patterns within the city make different social groups and their housing especially vulnerable to the consequences. This contribution aims at presenting the exposure approach as well as the developed vulnerability indicators that form the basis for presenting and discussing adequate and concrete adaptation measures to flood and heat hazard in Santiago de Chile. The approach is based on an analysis of socio-economic and housing conditions and attempts to respond to the following research questions: 1) Which are the inhabitants exposed to both hazards and where and under which housing conditions do they live?, 2) What are adequate adaptive measures to respond?, and 3) Do multiple hazards call for specific or combined response capacities and activities? The results show that hazard exposure is not distributed uniformly: Whereas people with lower socio-economic status are more likely to be heat exposed, higher status groups are more exposed to flood. Accordingly, different locations within the city call for specific adaptation measures. Some recommendations that have been discussed with local stakeholders within a broad participatory process are presented, also addressing their feasibility to be implemented.

Infrastructure adaptation measures and risk management opportunities towards extreme events and climate change

Alexander Fekete (Federal Office of Civil Protection and Disaster Assistance)

The IPCC SREX report - summary for policy makers - highlights certain events that all require adaptations of infrastructures. Sea-level rise, hurricanes and flash floods impose demands to improve protection types of infrastructure such as levees, mobile barriers, and early warning systems - but also how the exposed people deal with it. Heat waves imply strains to existing cooling systems, health and rescue systems. Droughts are related to land use, consumption patterns

and irrigation infrastructure. However, in an integrative and holistic risk management approach, the vulnerability of the population to the hazard impacts but also concerning their reliance and dependency on those types of infrastructures must be considered. False perceptions of safety, social vulnerability profiles, risk government motivations all contribute to adaptation risk patterns. New approaches have to be developed for combining existing research on spatial vulnerability assessments and indices with the topic of infrastructure adaptation. One approach is broadening the perspective on infrastructure adaptation in context to climate change. Infrastructures are drivers of climate-change, are protection and adaptation measures, but at the same time, infrastructures play a major role in supplying people and are susceptible to impacts by extreme and creeping events as well. This presentation will garner fresh insights for social vulnerability and climate change adaptation research by introducing theory and methods used in risk management, business continuity management and governmental programmes in critical infrastructure protection. It uses examples from Germany, North America, UK, and Sweden and compares different usages of protection efforts, risk governance and resilience management. It includes challenges and ideas for future programmes for the integration of spatial infrastructure assessments with place-based approaches for vulnerability & resilience. A proposal for new tools and research work streams is presented which includes a risk and adaptation measures navigator. This navigator showcases a typology of measures based on lessons learned by recent extreme events including cascading effects. The successive events in Japan impacting energy infrastructure indicated some maladaptations to extreme events, which can be used to spur the development of new risk reduction and adaptation measures. No-regret measures used in emergency management will be discussed as well as terrorist prevention measures and smart grids. The expectation of sudden impacts and creeping changes is a driver for the improvement of various types of protection infrastructure, but also for supply infrastructure - water, food, energy, or traffic. Therefore, climate change and infrastructures are a major linkage between hazards, changes in the economy, risk governance and the vulnerability of the people.

Urban growth and extreme events: understanding the dynamics of risk in Ho Chi Minh City

Harry Storch (University of Technology Cottbus)

Asian cities located in deltaic settings such as Ho Chi Minh City, exhibit higher exposure levels to flood risk primarily as a result of their location, their low

elevation and if located in tropical regions, the significant annual variations of climatic and weather extremes they incur. In these often mega-urban, coastal regions, adaptation to climate change and disaster risk management have to focus on minimizing exposure and reducing vulnerability by increasing urban resilience to the future impacts of climate extremes. Scientifically predicted are the direct impacts of climate change on populations (i.e. by urban flooding) and the indirect effects through impacts on the climate-sensitive urban sectors (i.e. housing, energy system). Geographic context gives rise to the biophysical exposure, which includes factors such as topography, connectivity and urban structures which can be mediated by spatial planning or construction technologies. Further the urban fabric of a society underlies the patterns of social vulnerability, including issues such as population density, levels of income, education and risk awareness as well as institutional capacity. Here spatial planning measures to enhance the adaptive capacity should be directed towards decreasing biophysical exposures and the social vulnerability from the viewpoint of place-based risk assessments. Key urban impact and vulnerability indicators in megacities and metropolises vary considerably from settlement to settlement and even within settlements. The location, the urban structure types present, dominant building types, social-economic characteristics and existing institutional capacities are all key factors that affect the ultimate exposure, vulnerability and overall environmental performance of a settlement within a mega urban context. Exposure and vulnerability are highly dynamic factors with an important spatio-temporal dimension. Rapid urbanisation and settlement patterns driven by fast changes in socioeconomic development conditions are the key factors influencing the future levels in exposure and vulnerability to climate extremes. Traditionally only snapshots of the current urban situations have been partially integrated into risk assessments, resulting often for highly dynamic urban regions in an overestimation of climate extremes as a stressor of risk. Our impact assessment study highlights, that the influence of non-climatic stressors - like urbanisation as the spatial manifestation of socio-economic processes is still widely under acknowledged. An urgent need has arisen to readdress and improve the scientific methods and datasets to examine these non-climatic key drivers of future urban risk and to assess their relative importance for risk propagation compared to primary changes in climate. The most significant issue here is the integration of the future dynamics of urban development.

RC 03-01 - Coasts at risk by extreme events I

Chair: Andreas Vött, Helmut Brückner

Recurrence and magnitude of palaeotsunamis at the West coast of Thailand inferred from sedimentary evidence

Dominik Brill (University of Cologne), Helmut Brückner (University of Cologne), Kruawun Jankaew (Chulalongkorn University Bangkok), Nicole Klasen (University of Cologne), Dieter Kelletat (University of Duisburg-Essen), Anja Scheffers (Southern Cross University)

In December 2004 the west coast of Thailand was heavily affected by the Indian Ocean tsunami (IOT), generated by a mega-rupture of the Sunda Fault. Due to the lack of historical data, sedimentary evidence from geo-archives provides the best opportunity to improve the knowledge of recurrence and impact of potential predecessors. Crucial for the application of palaeotsunami deposits as an indicator for tsunami impact are (1) their positive identification, (2) the dating and correlation of events, and (3) the quantification of tsunami magnitudes. Ad 1) Appropriate geo-archives that provide all premises for positive identification - i.e. deposition of tsunamites, preservation over longer time scales and the possibility to discriminate them from autochthonous sediments - are rather scarce along the west coast of Thailand. In the ridge-swale successions of Ko Phra Thong and Ban Bang Sak, as well as a former lagoon at Pakarang, where evidence of potential palaeotsunamis could be detected, their discrimination from storm deposits constituted the most challenging aspect. Ad 2) At Pakarang and Ban Bang Sak the chronology of identified tsunamites was established using radiocarbon dating. On Ko Phra Thong, where AMS-14C was complicated by root contamination, optically stimulated luminescence dating (OSL) was applied. By this method, at least three prehistoric tsunamis that hit the Thai coast at 500-700, 1000-1200 and 1600-1800 cal BP have been documented. Furthermore, the chronological data allows the correlation of spatially isolated evidence, ranging from the intra and inter-swale correlation of discontinuous tsunami layers on Phra Thong island to a basin wide correlation of the 500-700 and 1000-1200 cal BP tsunamites from Thailand with contemporaneous evidence from Indonesia, India and Sri Lanka. Ad 3) To estimate the magnitude of prehistoric tsunamis, the spatial distribution of onshore deposits, as well as their depositional structure and composition have been employed, using the IOT 2004 as a reference to evaluate the approaches. Based on the spatial extend of contemporaneous tsunamites, inundation distances of several hundred metres

have been reconstructed for palaeoevents on Phra Thong; for the tsunamis of ca. 500 and 1000 cal BP an impact radius of at least the western Indian Ocean was revealed, implicating lengths of the triggering rupture similar to that of 2004. The faunal and mineralogical composition of tsunami deposits was applied to determine maximum offshore source areas, especially water depth and distance from the shoreline, as an indicator for transport distance and wave parameters. Furthermore, the application of inverse sedimentation modeling on onshore tsunami deposits allowed the estimation of onshore flow speed and flow depth.

Parameter determination of high-energy dislocated boulders for wave transport equations by terrestrial laser scanning

Dirk Hoffmeister (University of Cologne), Konstantin Ntageretis (Johannes Gutenberg-University Mainz), Helge Aasen (University of Cologne), Constanze Curdt (University of Cologne), Hanna Hadler (Johannes Gutenberg-University Mainz), Timo Willershäuser (Johannes Gutenberg-University Mainz), George Bareth (University of Cologne), Helmut Brückner (University of Cologne), Andreas Vött (Johannes Gutenberg-Universität Mainz)

In this study, terrestrial laser scanning is used to determine parameters for wave transport equations of large boulders, dislocated by high-energy wave impacts. The dislocation and transportation of such boulders, which may be tilted or even turned upside down, can be recognized, for instance, by rock pools, adhering remains of sub-recent marine fauna, algal rims and notches. In this case, dislocated boulders in coastal areas in southern and western Greece were surveyed. These coasts are directly exposed to the Hellenic trench, the major tectonic zone in the eastern Mediterranean. Thus, this region shows one of the world's highest seismo-tectonic activities and is well known for its high tsunami risk. Historical accounts and geo-scientific traces of palaeotsunami events indicate that these coasts have been repeatedly affected by tsunami landfall during the Holocene. In this study, we surveyed dislocated boulders within their topographical context using a Riegl laser scanner in combination with a DGPS. With this approach, it is possible to obtain highly accurate volumetric data of dislocated boulders by 3D reconstruction. Further parameters, such as inclination, elevation above sea level or the boulders' distance to the sea can be extracted from the 3D model of the study site. Moreover, density data of rock samples from each boulder were achieved in the laboratory for mass calculations. All parameters were incorporated into selected wave transport equations, which regard the variable "mass" as a direct input parameter for the calculation of wave heights and velocities needed for boulder dislocation. Our

results were compared to data based on manual measurement of boulder axes and roughly estimated rock density values in order to check the differences in accuracy. Our results show that terrestrial laser scanning in combination with DGPS and rock density measurements is capable to derive reliable parameters for wave transport equations resulting in an accuracy better than achieved by approximations, which are still the common method in scientific studies on boulder dislocation. Based on our data set from Greece, we found that estimated volume data together with density approximations result in a considerable overestimation of the mass of dislocated boulders. As a consequence, calculated minimum wave heights and velocities are additionally overestimated, in our case studies by up to 28 % and 83 %, respectively. Thus, we recommend that parameters for wave transport equations calculated in case studies all over the world, using "mass" data derived from measured axes and density estimations are considered with reservation until more accurate volume and mass data of dislocated boulders are available.

Morphodynamic response to episodic storm events: Forty years of surveys of an Australian coastal system, 1972-2012

Roger McLean (University of New South Wales)

Bengello (Moruya) Beach is located on the south coast of New South Wales, about 250 km south of Sydney. It is a typical crescent-shaped beach compartment with an island and tombolo to the north, and a river and headland to the south, a distance of approximately 6 km. The offshore wave climate is energetic and variable. Storm waves ($H_{sig} > 3$ m) may occur in any month. Tides are semi-diurnal with mean spring range of 1 m. The active beach is backed by a succession of dune ridges, 5 to 8 m high that have developed as a transgressive-regressive sequence during the Holocene. Since January 1972, four beach profiles have been surveyed in the south centre of the beach. Surveys were initially undertaken at fortnightly intervals until January 1976, subsequently at monthly intervals through January 1989, and since then several times a year at approximately six-week intervals to the present. The profiles are located in the most exposed central portion of the beach so as to receive waves from the greatest range of directions. Here we review the entire data set highlighting the time-series of changes in beach volume and trends in erosion and accretion over the past 40 years. The magnitude of profile change clearly illustrates the significance of the major storms (East Coast Lows, ECL) in the mid-1970s that resulted in severe erosion of the shoreline. Recovery from this erosional state took several years and it was not until the early 1980s that the

beach achieved its pre-storm antecedent condition, through incremental accretion and the development of a new foredune. Since then storms associated with ECL have impacted the beach on several occasions and the effects of these episodic events is documented here. The most notable storms since the 1970s occurred in mid-2007 and in May-June 2010. Sea conditions and beach response to these events is compared. Changes in volume and profile morphology were broadly similar though the location of the active beach profile was quite different. Similarly the recovery times (defined as the time taken for beach profile and volume to return to its antecedent condition after the erosional phase) were different. In the mid 1970s this took several years, whereas in 2007 it took a few months. Reasons for these differences are discussed. Although such events can serve as clear reminders of the potential impact of ECL storms, coastal managers should be aware that the scale of shoreline retreat during these more recent events is completely dwarfed by those of the period 1974-78, when the shoreline was some 50-60 m landward of its average 200-2012 position.

Geological and geomorphological impacts of two large typhoons from central Vietnam

Adam Switzer (Nanyang Technological University)

Typhoons Xangsane (2006) and Ketsana (2009) left behind geological and geomorphic evidence of their landfall near Lang Co and Chan May in central Vietnam. In both instances, the events caused the evacuation of several hundred thousand people, considerable deaths (at least 70 and 160, respectively) and damages to infrastructure of more than US\$600 million each time. Storm surges and waves associated with both events left sandsheet deposits and scattered cobble to boulder size clasts on the coastal landscape of this rapidly developing coast. This study details our initial investigation of multiple storm deposits from the Vietnamese coast. These deposits provide modern analogues for the study of past events regionally and globally. In each situation, the deposits show characteristics unique to their setting. In one location, Canh Duong Village, at the northern end of Chan May embayment, the Xangsane event deposited well-defined populations of cobbles (rock) and soil clasts that allows the identification of the sediment source. In a second location, several hundred meters west of Chan May Port and at the southern end of the embayment, the presence of a large tree stump with encrusting intertidal bivalve molluscs and tube worms provides a minimum transport distance for the Ketsana event. When combined with generic information on the extent, height above sea level and sedimentary

properties of the storm-deposited sandsheets, the unique qualities of the different deposits allow an accurate reconstruction of the inundation characteristics of the recent storms. Comparison of run-up data implied by the geoscientific data suggests that tide gauge analysis on this coast is not sufficient for adequate risk assessment.

Socio-economic disparities in Poland in the light of relict boundaries

Michał Dolata (University in Poznań), Robert Perdal (University in Poznań)

The contemporary territory of the Republic of Poland was defined as a result of political conclusions reached in the end of World War II. As soon as military actions came to an end and vast commuting seized, a slow-paced process of shaping new socio-economic space began. Until 1989 the Polish state was developing in the framework of so called Eastern Block, politically and economically subordinate to the USSR. A turbulent process of systemic transition began only in 1989, getting Poland closer to the Western countries and culminating in 2004 with the accession to the EU. The period of gradual social and economic integration of Polish territory did not wipe off relict boundaries - old political boundaries distinguishable in socio-cultural and economic milieus. Boundaries are often revisited considering the context of spatial differentiation of socio-economic development, transport infrastructure or voting preferences throughout the country. Differentiation of socio-economic space in Poland is analyzed mostly at regional level, i.e. voivodeships. In years 1975-1998 this set was composed of 49 fairly small units. Since 1999 the set is formed by 16 large administrative regions. In both sets the administrative borders were only partially and to a limited extent related to former political divisions in Middle-East Europe (relict boundaries). Due to this most geographic analyses did not picture the spacial differentiation, or at least did not allow to reveal the actual outline of "edges" of spaces varying in terms of social and economic development. Such divergence could only be detected at local level and also at subregional level. However, regarding the limited accessibility of statistical data these researches were undertaken merely within single voivodeships. The aim of this paper is to present the internal differentiation of socio-economic space in Poland against the background of the most significant relict boundaries. The research is carried out for the set of NUTS 4 units and focuses on the following aspects: socio-economic level of development, economy structure and labour market situation as well as political preferences of local communities. In the analysis two sets of former state boundaries are considered: in years 1815-1914 (between Empires of Germany, Austro-Hungarian and Russia) and in years 1919-1939 (between Germany and Poland)

with respect to the most relevant political, social and demographic conditions bound to their outline and undergoing changes thereof. The paper is a substantial part of the first stage in a research procedure of a project financed by the National Science Centre (N N306 791940) entitled "Socio-economic development and the pattern of growth and stagnation areas" implemented by the Regional Analysis Department in the Institute of Socio-Economic Geography and Spatial Management of the A. Mickiewicz University in Poznań.

Identity, Politics, and Persistence of Norms: Evidence from a Natural Experiment in Ukraine

Leonid Peisakhin (Center for Advanced Studies in the Social Sciences)

In this paper I make use of a natural experiment that divided a homogenous population of ethnic Ukrainians between Austrian and Russian empires in the late 18th century to demonstrate that historical legacies are not always a proxy for differences in factor endowments. I show that when otherwise identical communities are exposed to different institutions during the pivotal moment when group identity is being created, the behavior of affected communities starts to differ. Differences in behavior and attitudes between previously identical communities usually persist for a long time even when institutions that initially helped shape the change in primary identity have long disappeared. Data from a survey of 1,395 individuals in 195 settlements situated within 16 miles of the long defunct Austrian-Russian imperial border in western Ukraine demonstrate that despite numerous institutional and material perturbations the populations residing either side of the former imperial border are still very different today when it comes to political and economic behavior and attitudes. They vote for different parties, hold diverging views on both Ukraine's past and its future and do not see eye to eye when it comes to the practice of collective farming or the rule of law. I advance a theoretical explanation to account for this puzzling variation and consider plausible alternatives.

Unraveling buried borders in South-Eastern Lithuania

Dagnosław Demski (Institute of Archaeology and Ethnology)

Shifting borders make changes in political, historical, social and cultural life. Some regions had history of relatively more such transformations than other in Europe. Replacement of one state after another makes social and cultural landscape adjusted with several old traits buried less or more deeply, and what one can find reflected in various dimension of people living everyday practice.

The same is in case of South-Eastern Lithuania. People living together in the contemporary time make references to distinct periods of the past - Soviet Union, midwar period, nineteenth century, etc. The aim of the presentation based on an extensive fieldwork is to show how and why hidden borders matters today, not only as potential cause for conflict. To accomplish this survey the everyday practice was chosen as a medium through this subject of re-constructing was considered and analyzed. As everyday practice I mean not only language, schools and church, but also several other aspects of everyday life (celebrations of festivals, telling specific anecdotes, expressing peculiar verbal ways of provoking assaults on each other often reflecting taboo topics in mutual encounters, and variety of cultural incompatibility). Constructions and re-constructions cause reshuffling of spatial divisions through politics of memorials oriented in a different way to the previous political states of order. The paper also highlights the diverse historical and even mythical references of normative ideas operating behind these re-constructions, tensions between locally rooted people versus newcomers, main themes of stories published in press both official and peripheral, and the case of foreign media (television) that shapes an informational local space intensively.

The development of Slovenia and its historic borders

Matej Kralj (Universität Erfurt)

Staaten schaffen nicht nur einen einheitlichen politischen Raum, sondern synthetisieren auch eine damit korrespondierende Geschichte. Wie der Raum, gründet auch das soziale Gedächtnis auf der Grundlage der Differenz, und zwar in der Unterscheidung zwischen dem, was institutionell erinnert und was vergessen wird. Die zeitlichen und die räumlichen Komponenten lassen sich analytisch trennen, obwohl beide im dominanten Selbstbild des Nationalstaats strukturell miteinander verknüpft sind, indem sie gleichsam auf den In- und Ausschluss von kulturellen Praktiken, sozialen Gütern, geschichtlichem Wissen, Menschen, Vorschriften etc. verweisen. Die Verbindung zwischen den politisch-räumlichen und den geschichts-politischen Konstruktionen ist in einer Reihe von postsozialistischen Staaten beobachtbar. Das Beispiel Slowenien ist interessant, da die Slowenen in 1991 den eigenen Nationalstaat zum ersten Mal bildeten. Im neuen politischen Raum wurden auch die Grenzen historisch aufgeladen und objektiviert:(a) Die Grenze zwischen Slowenen und Kroaten wurde nicht nur durch die innerjugoslawischen Konflikte der 1980er relevant, sondern durch die spätere Bestrebung Sloweniens, sich von der sozialistischen Vergangenheit zu lösen. Über den genauen Grenzverlauf herrscht bis heute eine

Auseinandersetzung, bei der es weniger um einige Quadratkilometer Land und Meer geht, als vielmehr um symbolische Fragen der eigenen Zugehörigkeit und Auseinandersetzung mit der Geschichte des Eigenen. Nachdem eine zwischenstaatliche Grenze etabliert wurde, die das früher zusammengehörige trennt, wurde sie schnell als eine historische gerechtfertigt: Sie wurde zu der ältesten Grenze in Europa erklärt, einer zwischen der K&K-Monarchie und dem Osmanischen Reich, gar dem Heiligen Römischen und dem Ungarischen Königreich. (b) Im Unterschied dazu ist die Grenze zu Österreich eine, die symbolisch für die Verbundenheit mit Österreich stehen soll und welche also weniger auf Differenzsetzung als auf Einheitsbildung zurückzuführen ist. Sie markiert zum Einen die Hinwendung Sloweniens zu einem gedachten europäischen Kulturraum, zu dem man sich nun geschichtlich zugehörig fühlt; zum anderen wird auch diese Grenze historisiert, womit die Neuentdeckung der eigenen K&K-Geschichte der Slowenen einhergeht. An den empirischen Beispielen zeige ich, wie das Erinnern an historische Räume von gegenwärtigen räumlichen Strukturen bestimmt ist. Damit wird vor allem deutlich, dass historische Grenzkonflikte mehr mit dem Heute als mit dem Gestern zu tun haben; vorrangig erklärbar sind sie als Konflikte der Gegenwart, die in die Vergangenheit projiziert werden.

Internal Displacement of Communities in Manipur Hills and its Effect on Livelihood System

Periya Raikham (North Eastern Hill University Shillong)

Racism has been one of the main factors influencing force displacement as it has been witnessing in different countries around the world. The persons who have been or being forced to flee or leave their homes or places of habitual residence they are known as displaced persons. Displacements are most frequently caused by various factors like natural calamities, climatic changes and socio-economic factor, cultural and political causes. Inter-ethnic violence has become one of the common factors in almost all over the world. In North-East India, the politics generally follows the ethnic path. Ethnic-cultural mobilization and movements launched by various ethnic groups in the region has remained an ongoing process. Many ethnic groups have launched entirely new type of movements in some cases. Such ethnic movements create tremendous hardship to the people living in the area and faces force migration and thus they are displaced from their homeland. Manipur is not far from such crises and due to political aspirations and other reasons among them creates incoherent environments in the state that led to armed conflicts. In the hills four of the five districts are associated with the Naga freedom movement, thereby causing communal tension and on the other hand Kukis are demanding Kuki homeland. The feud between the two tribes Nagas and Kukis have been traditional historical and geographical, each of them try to gain political and geographical supremacy on the other from the previous century. The communal violence between Nagas and Kukis re-emerged in 1992, which was dormant after the 1919's violence. From the middle of 1992 the conflict between the two groups took an ugly turn and within a short span of time, it led to wanton killing and kidnapping, burning of houses and destruction of private and public properties as a regular practice and thus people suffer such hardships. The Naga- Kuki conflict in the hills of Manipur has led to the displacement of about 11000 Kukis and Nagas since 1992. The casualties on both sides have been severe. More than 11,000 houses belonging to both tribes have been torched in arson. More than 600 villages have been uprooted. The conditions of the displaced people are pathetic. The non-existence of formal government funded relief camps; the

displaced have faced more hardships. For this study four hill districts have been chosen i.e Senapati, Tamenglong, Chandel and Ukhrul district. It is mainly because these districts are populated with Naga and Kukis where ethnic conflicts are continuing and socio economic conditions are disturbed. The objective of study is to understand the changes of livelihood system of the internally displaced Nagas and Kukis in the four hill districts of Manipur after they returned to their original villages.

Historical reconstruction of the rural settlements of indigenous peoples of the North-East of Russia

Antonina Savvinova (North-Eastern Federal University), Viktoriya Filippova (North-Eastern Federal University)

The processes of globalization are accompanied by serious social and environmental costs, faced by indigenous peoples. Traditional areas of their settlement are usually situated in the center of economic interest, so for example in the North-East Russia natural resources associated with the mining industry and the commodity nature of development. These same areas are located in the homelands of indigenous peoples of the North, where there is traditional natural resource management: reindeer herding, hunting, fishing within the boundaries of nomadic tribal communities. Thus, there is the challenge of intensive industrial development and traditional ecological nature management in the same area. Since the beginning of the industrial development in the North and in Siberia have increased number of industrial cities, settlements of indigenous people closed as "unpromising" and the people were moved in large municipalities, which led to a reduction in their traditional areas of rural settlement. For the historical reconstruction of rural resettlement of indigenous peoples of the North-East of Russia as the main source used various maps containing information about their resettlement. Study of literary and archival material showed that the territorial organization of life of Indigenous Peoples of the North has been dictated by administrative measures, an important role in shaping the settlement system has played an administrative-territorial division. Knowledge of the dynamics of grass-roots administrative division has a special significance for the organization of spatial information, without restoring the history of the system of administrative-territorial division is impossible to conduct spatial analysis of information on the territory for a sufficiently long period. Calculation of areas of settlement of small peoples and study their interactions with the administrative-territorial boundaries allows for the reconstruction of the resettlement of Indigenous Peoples of the North-East of Russia. We made the approbation of

the spatial reconstruction of the borders and the settlements of Yakutia - one of the major subjects of the Russian Federation. For the monitoring of changes in political divisions of Yakutia we've done the work on analyses of the maps of XX century - were analyzed maps of 1914, 1927, 1941, 1953, 1962, 1989 and 2000 years. Map, scale 1:2 500 000 for the final overlay map was chosen because it allows to track changes over time and space. The calculations showed that the area of traditional settlement of indigenous peoples in Yakutia XX reduced, areas of settlement and natural resource people located within different administrative units, which affects the maintenance of cultural, economic relationships.

Across the boundary. Strategies of urban space management in the city of Sarajevo.

Elena Bassi (University of Milano - Bicocca)

This ongoing PhD research focuses on the case study of Sarajevo and its territorial partition and investigates the way in which strategies of town planning and territory management symbolically define and shape the urban spatial reality. Considering the presence of the administrative boundary that separates Sarajevo from East Sarajevo, the analysis shows that such strategies involve definitions and interpretations of reality that confirm a logic of separation and emphasize the symbolic meaning of the boundary. The Inter Entity Boundary Line (IEBL) institutionalized by the Dayton Peace Agreement signed in 1995, separates the two entities of Bosnia and Herzegovina (BiH) - Croat-Bosniak Federation (FBiH) and Republika Srpska (RS) - and at local level divides two cities that before the war were part of the same urban system: Sarajevo, including the historical neighborhoods of the city and part of FBiH, and East Sarajevo, a suburban area now included in the territory of RS. Behind its administrative importance, the boundary holds a symbolic meaning that dates back much earlier than 1995 and originates from geographical narratives that stress the connection between land and nation [Kostovicova, 2004]. Considering the presence of three constitutive peoples in BiH - Croats, Serbs and Bosniaks - such link becomes even more relevant since through time different spatial narratives have supported nationalistic claims that lead to conflicts over control of territory [Dell'Agnese, Squarcina, 2002; Kostovicova, 2004; Rumiz, 2011]. Drawing on the idea that analyzing processes and dynamics at urban scale can provide significant results also at wider level [Ashkenasi, 1988; Brown, 1993; Friedland, Hecht, 1996; Bollens, 1998a; 1998b; 2000; 2001; 2009; Calame, Charlesworth, 2009], this work investigates the role played by strategies of

urban space management in reinforcing or undermining the symbolic meaning of the boundary nowadays. Considering the characteristic of the context, Sarajevo appears a significant case study: the absence of shared infrastructures and public services between the two cities and the use of signs and symbols that constantly remark the presence of different collective identities highlight the role of town planning strategies in confirming the symbolic relevance of the territorial partition. Far from being neutral technical prescriptions, the tools through which urban policy interventions are implemented involve in their normative frame specific definitions and interpretations of reality [Lascoumes, Le Galès; 2004]. Moreover the feature of urban landscape and the way in which space is shaped and organized represent concrete manifestations of such definitions and interpretations; the analysis here presented focuses on these elements in order to shed light on the symbolic value still held by the boundary.

Geopolitics of a transborder region: Cultural regionalism in the Fergana valley. How to make geopolitics research in Central Asia.

Isabella Damiani (UMR 8586 PRODIG/CNRS)

This paper proposes a geopolitical analysis of a centrasian transborder region, the Ferghana Valley, which is today divided between the Republics of Uzbekistan, Tajikistan and Kyrgyzstan. This division and the following boundary materialisation caused many types of border conflicts : resource management, movement limitations for transborder populations and growth of nationalisms. The topic of the research is hence the analysis of power rivalries between 'territorial actors' over the 'territorial stake' of the Fergana Valley, a fertile basin of strategic location within the larger geopolitical context of Central Asia. Always a stake disputed by various territorial actors over time, the Fergana Valley now experiences power rivalries from contemporaneous territorial actors first and foremost on the border and transborder levels. By doing so, the paper introduces a new actor in the classical geopolitical pattern of analysis: the cultural regionalism. The dissertation hence offers a detailed presentation of the cultural regionalism as well as an evaluation of its past and current importance. First focusing on the centrasian context and the peculiarities which stem from its borders, the introduction presents the 'stake' Fergana and its economic and physical resources which explain its importance as a territory.

RC 05-01 - Development-induced displacement: Addressing conflict and impoverishment

Chair: Andreas Neef, Jane Singer

Hidden Losers of Development: Impacts of Displacement on Urban Locality and Settlers - a case-study of the railway project in Metro Manila

Narae Choi (University of Oxford)

This study seeks an understanding of the complex ways in which people are affected by the consequence of development-induced displacement (DID), with a particular focus on settlers remaining in the locality after displacement takes place. Displaced people have been the central concern of DID research as they bear the most obvious social cost of development in the form of forced displacement. However, few studies have addressed the fact that other people might have been adversely affected within a DID context without being physically displaced. By investigating non-displacement impacts, this research aims to identify these 'hidden' losers of development, who may be less visible than those physically displaced but who can also experience significant changes in their life. Three sets of questions are explored for the purpose of understanding non-displacement impacts on the locality and its settlers through an empirical case study of the railway upgrading project in Metro Manila, the Philippines. First, who remains in the locality after the forced displacement event? How are they able to stay on whilst others are displaced? Second, how has the locality changed since the mass- displacement? In what ways is the remaining population affected by such changes in the locality? Third, how are diverse and complex modes of living affected in different ways? Who becomes more vulnerable and who remains resilient? These questions are contextualised within the specifics of the urban area under study and also in view of broader urban changes. The complexities of both urban living and urban displacement are untangled and then reorganised into an analytical framework that was developed from analysis of the data. Data were collected through semi-structured qualitative interviews with the people living alongside the railway. Interestingly, many of the interviewees turned out to be either temporary or permanent returnees from relocation sites. Their presence was so prevalent that the field research incorporated displaced, as well as non-displaced, people, which enriched the analysis. Empirical findings confirm that physical changes in the locality, compounded by the mass-scale displacement of informal settlers, have

changed the socio-economic environment of the area significantly, which further impacts on livelihoods and the social relations of individual households. By showing that impacts of a developmental change can be more diverse and complex, this study challenges and expands the current conceptualisation of development impacts in DID research and practice, which is primarily focused on forced displacement and resettlement. This calls for a critical rethinking of the developmental change that requires human displacement, since questions remain unanswered with regard to whether such diverse and complex impacts can be addressed by policy interventions.

A political economy of displacement and resettlement in Andhra Pradesh. The case of the Polavaram dam.

Chiara Mariotti (School of Oriental and African Studies)

This paper adopts a political economy approach based on the notion of adverse incorporation in order to investigate the effectiveness of a concrete instance of resettlement in preventing the impoverishment of people displaced by development. The concrete instance investigated is the Polavaram dam in Andhra Pradesh. The dam, whose construction started in 2004 and is still in progress, will lead to the submersion of 177 villages and the displacement of 200,000 people. Of these, the greatest majority is poor and belongs to Scheduled Castes and Scheduled Tribes. The investigation dwells on the findings of a fieldwork conducted in the affected area in 2009, specifically on the results of a survey and a choice experiment, as well as on government documentation concerning the Andhra Pradesh Resettlement & Rehabilitation policy (R&R) and the Polavaram R&R package. The paper claims that resettlement of people displaced by development projects must be understood as a process of adverse incorporation, and that this approach allows the identification of the structural factors that limit the ability of resettlement to prevent the impoverishment of the displaced people. What makes resettlement a process of adverse incorporation, is that fact that it is required to dispose of people expropriated of their sources of livelihood and made redundant by the same process of development. To the extent that resettlement takes place in conditions where the agrarian sector does not guarantee sustainability and subsistence, and economic growth does not create enough employment to accommodate everyone, the displaced population is adversely incorporated into the very same process of development and thereby impoverished. The paper applies the notion of adverse incorporation to the case of the Polavaram dam. It finds that the resettlement of the Polavaram displaced population will come with

an alteration of the terms of access to the sources of livelihood, and that this in turn will produce an increase in landlessness, fragmentation of landholdings and causalisation of labour. That is, resettlement will have important dynamic consequences which ultimately will lead to the adverse incorporation of the displaced population into the local process of economic development. The paper further shows that these dynamic consequences are the results of three major shortcomings of the Polavaram R&R package: the inadequate handling of land compensation, the exclusive focus on cash compensation, and the neglect of the creation of employment opportunities outside agriculture. Finally, these shortcomings are found to depend on the interaction between the poor design of the package on the one hand, and the socio-economic characteristics of the displaced population, the features of the relocation areas and the development path undertaken by the specific context on the other hand.

Fostering participation for dam-displaced ethnic minority groups in Vietnam

Jane Singer (Kyoto University)

Construction of large hydropower dams to meet Vietnam's burgeoning electricity demand has displaced hundreds of thousands of highland residents in recent decades. Many of the displaced communities are already marginalized indigenous ethnic minorities, for whom resettlement and the loss of productive land has spelled increased, often long-term impoverishment. While that has been the prevailing narrative for the past several decades, several recent developments give promise of improved outcomes. As part of a wider grassroots democratization and economic reform process, the Vietnamese central government has enacted legislation in recent years that improves terms of land and asset compensation and allows villagers a greater voice in resettlement planning and decision-making. Intergovernmental organizations that have participated in dam projects in the region, like the Asian Development Bank and World Bank, have adopted stringent resettlement guidelines promoting greater resident participation and implementation of benefit sharing mechanisms to allocate some power authority revenues for local development activities, raising hope that dam-induced displacement can be transformed from being little more than an agency for impoverishment to being a vehicle for improved livelihoods. However, achieving positive results require transcending a host of institutional hurdles, including Vietnam's tradition of top-down, centralized rule, government distrust and condescension towards ethnic minorities and poor implementation by local government officials. In this paper the author reports on

field studies of several resettled villages in the highlands of central Vietnam and the questions they raise about the prospects for more equitable and participatory resettlement.

Involvement of the local population in large-scale land acquisition projects – insights from Mali

Kerstin Nolte (German Institute of Global and Area Studies), Lieske Voegt-Kleschin (Greifswald University)

Lately, large-scale land acquisition in developing countries (LaSLA) has received considerable conflicting media attention: Proponents conceive of LaSLA as much needed investment into the formerly neglected agricultural sector. Opponents focus on the negative social consequences of the phenomenon, pointing out that for many, especially poor and vulnerable social groups, access to land constitutes the main basis of livelihood. Thus selling or leasing land results in loss of livelihood for these people. However, LaSLA commonly targets state owned land, that is, land to which local people do not have legal property rights. Thus from an official angle no formal rights are violated. The paper presents field study data from the Office du Niger (ON) region in Mali, which has witnessed a surge of interest in the last decade. The Malian government encourages investors to undertake large-scale agricultural projects in the area in order to tackle much needed infrastructure work and development of the land. A large number of leases or bilateral agreements have been concluded recently. We look into three recent cases of investment projects in the ON, all of which are in the phase of being implemented: Two sugar investments by a Chinese-Malian investor and a public-private partnership with Malian and Western partners, as well as a huge Libyan rice project (whose future is unknown in view of the current developments in Libya). In October and November 2011 we conducted semi-structured expert interviews with government officials, civil society, and investors, and held six focus group discussions (FGDs) in three villages directly affected by the planned investments. We shed light on the process of a land acquisition in the ON and the involvement of the local population. We put a special focus on sensitization and information of the population, displacements and compensations. Moreover, we analyse the expectations of the population towards the investment. The government claims that investors bring much needed development to the area. We discuss whether this development includes the local population or benefits only few. In particular, we focus on local people who do not have legal property rights to land. We argue that in cases where land constitutes the main base of livelihood, the

leasing or selling of land can be conceived of as a violation of this human right to an adequate standard of living (UDHR, Art. 25,1) irrespective of the existence of legal property rights to this land. We acknowledge that erosion or loss of access to land can be compensated for by improving access to other capital assets and propose to employ the capability approach to evaluate what could qualify as adequate compensation.

RC 06-01 - Early warning systems for natural hazards – technical challenges and social demands

Chair.: Thomas Glade, Jürgen Pohl

Integrative landslide early warning systems

Rainer Bell (University of Vienna), Julia Mayer (University of Bonn), Benni Thiebes (Nanjing Normal University)

Landslides occur frequently throughout the world and cause numerous fatalities as well as severe economic damage each year. To reduce landslide risks and negative consequences early warning systems are a very good option. However, in the past early warning systems often failed. One important reason for this is that the early warning systems were merely technical systems, which did not take into account the needs of local actors and threatened people. Thus, integrative approaches are needed, which incorporate not only various natural sciences but also engineering, economic and social sciences. Within the research project ILEWS (Integrative Landslide Early Warning Systems) such an approach was applied. The methodological architecture of ILEWS spans from field installations of novel sensor combinations and near-real time landslide modelling to end-user optimised action advises. The monitoring of the landslide comprises continuous to periodic measurements of surface and sub-surface movements (tachymetry and inclinometers), soil moisture (2D-resistivity, TDR-probes, tensiometers) and climate data. Three different approaches are applied to model the stability of the slope and to predict slope failure. A central data analyses, visualisation and early warning platform was established using innovative geoinformation approaches and modern geodata infrastructures. Furthermore, end-user needs were explored to ensure that the early warning system meet their needs. Finally, protection goals and damage potentials were defined. The presentation will roughly summarise the main project results and then focus on 15 general principles which should be considered when new early warning systems are to be set up. These, of course, are not only valid for landslide early warning systems but also transferrable to many other hazards.

User needs and economic benefits of early recognition of droughts in Switzerland

Sylvia Kruse (Swiss Federal Institute for Forest, Snow and Landscape Research), Irmi Seidl (Swiss Federal Institute for Forest, Snow and Landscape Research)

Drought monitoring, forecasting, and early warning is only a promising investment if it provides benefits to water users. This is the starting point of the project DROUGHT-CH 'Early recognition of critical drought and low-flow conditions in Switzerland' (Funding Swiss National Science Foundation; 2010-2012). Embedded in an interdisciplinary research design the project links the hydrological and meteorological characterization and early recognition of critical drought and low-flow conditions in Switzerland with the identification of the needs of stakeholders vulnerable to droughts and decision makers from administration in order to develop an information and early recognition platform. The paper will present first results from the socio-economic work packages that focus on the specific user requirements for drought forecasting and on potential economic benefits of an early recognition information system. The main objectives of the socio-economic research are twofold: First, to assess the specific needs of Swiss water user groups with regard to an early recognition system; and second, to investigate the potential benefits regarding early recognition systems for selected economic sectors. This stakeholder based approach will ensure that the development of the information platform within the further research meets the needs of the anticipated users. Based on a survey and stakeholder workshop we have identified drought and low-flow indicators that are most important from the point of view of different user groups in Switzerland. The survey and workshop included representatives from different sectors: agriculture, forestry, energy production, water supply, shipping, nature conservation. The results show that for effective early recognition, additional information about relevant drought indicators needs to be made available (e.g. average, deviations); more importantly, information needs to be processed and interpreted according to the needs of the target group (e.g. a bulletin for low flow conditions for shipping) and transferred to the user in an adequate way (e.g. internet, sms alert). The results of the survey and stakeholder workshop therefore also show which are - from the perspective of the user groups - adequate forms and channels for information. The potential economic benefits have been assessed by using expert interviews and a semi-standardized survey focusing on three economic sectors: agriculture (fruit-growing), energy (hydropower) and forestry. First results can show what (economic, ecological, social) impacts droughts and low flow conditions can have for the different

sectors, what are currently used strategies and measures to mitigate or reduce harm/damage and what are the benefits of early recognition to prevent damages.

Cyclone Warning Systems in Coastal Districts of Andhra Pradesh With Special Reference to S.P.S.Nellore District

Nagula Nagabhushanam (S.V.University), D.Chandrasekhar Reddy (S.V.University)

Among all the coastal districts of Andhra Pradesh, the southern most is Sri Potti Sriramulu (S.P.S.) Nellore district. It is very prominent with a lengthy coastline of 165 kms lying adjacent to Bay of Bengal. The district was exposed to repeated and more number of cyclonic storms of severe intensity accompanied by storm surges, caused un measurable devastation of people, livestock, settlements, crops, soils, properties etc. This loss can be prevented by the application of timely available efficient Cyclone Warning Systems (CWS), creating proper awareness among the people about disasters and their likely impact and adopting appropriate advance measures for disaster reduction. Since, a sound early warning system is a prerequisite for effective disaster management, the state of art of forecasting and warning by Indian Meteorological Department (IMD) in mitigating the intensity of disasters in various parts of the country is briefly discussed in the present paper. The main objective of the present study is to discuss the cyclone detection and warning systems established by Indian Meteorological Department (IMD). The cyclones, storms, depressions over the Indian seas are detected and tracked with the help of conventional meteorological observations, High-power cyclone detection radars and satellites. The Geostationary Indian National Satellite (INSAT) provide continuous surveillance of the cyclones and no cyclone can go undetected in the Indian Ocean by the INSAT satellites. The cyclone warning process in coastal Andhra Pradesh, the mode of dissemination of warnings and cyclone warning centres established in the district and their functionalities are discussed in detail in the present paper. * 1. Professor, Head and Chairman BOS, Dept. of Geography, SVU, Tirupati. 2. Research Scholar, Dept. of Geography, SVU, Tirupati.

Impact of bank erosion hazard on human occupancy in the Jia Dhansiri River basin in Assam, India

Rana Sarmah (Pandu College)

Magnitude of river bank erosion in the Indian part of the Jia Dhansiri River basin is studied by comparison of differently dated satellite data. Bank line layer of the river for the years 2006 is superimposed on the layer of 2000 in GIS environment and the spatial change therein is calculated and recorded. A village layer is created using revenue circle map of the study area. This layer is superimposed on the bank line layers, and erosion areas under each village are calculated. Erosion area data of villages are classified into three classes and on this basis villages have been categorized. These categories are high erosion affected villages (loss of more than 30% area of the total village area), medium erosion affected villages (loss of 30% - 10% area of the total village area), and low erosion affected villages (loss of less than 10% area of the total village area). It is found that out of 302 villages of the study area 74 villages were affected by river bank erosion hazard during the period under study. The river has engulfed 21.43 km² (7.64%) area of the erosion affected villages during 2000-2006 which are basically intensively cropped agricultural lands and homestead areas. Socio-economic survey on the erosion affected villages reveal that over 15% families give up primary occupation for losing landed property. Majority of persons of these families compelled to took secondary and tertiary occupation after loss of their agricultural lands. As such, 69% and 2000% number of families increased in secondary and tertiary occupation during 2000-2006 after shifted their household due to bank erosion hazard. This study also reveals that over 48% families resettled acquiring government land within 2 km distance. It further reveals that loss of principal crops and other household properties has gone to the tune of '80/family/year which is quite a high amount for poor peasant whose average income is '550/family/year. Rise of bed level and development of braids, floods, coarse texture of bank materials, man made structural controls, floods, are examined to be principal causes/processes of bank erosion. Three bank erosion hazard zones of the study area viz. high, medium, and low are proposed and demarcated based on (i) location of in channel features such as large channel bar, shoal, thalweg position, etc.; (ii) structural controls such as bridge, spur, etc.; (iii) location of floodplain features adjacent to channel such as wetlands, floodplain gullies, and tributary rivers; and (iv) location of village in respect of alignment of river banks. Some measures for mitigation of bank erosion hazard and protection of local resources are made here.

RC 07-01 - Emerging risksapes and the spatial dimension of risk

Chair: Ragnar Löfstedt, Detlef Müller-Mahn

Anthropogenic Threats and Risks to the Development of Ukraine Geosystem: Analysis of the Factors and Causes

Olena Dronova (Institute of Geography of NASU), Leonid Rudenko (Institute of Geography of NASU)

Anthropogenic Threats and Risks to the Development of Ukraine Geosystem: Analysis of the Factors and Causes Olena Dronov', Leonid Rudenko 1. Human development and its economic activity has led to a significant concentration of both the population and production, which is followed by focusing of raw materials, products and wastes of various level of danger to humans and living organisms. At the same time, the ecological characteristics of the natural components of geosystems are destroyed as a result of application of imperfect technologies and engineering. Different types of emergencies combined with the dangerous geological and hydrometeorological processes appear and greatly increase the risks and threats to development. 2. We can consider Ukraine as a classic example of intensive unsustainable development during few last decades with irrational economic management of the territory and sizeable regional disproportions arisen. Despite the advantageous geographical location, flat country and temperate climate, there are many threats to human life every year due to the technical condition of the majority of industrial enterprises and social infrastructure where the main production facilities are worn by about 60 percent. In 2010, the 254 technogenic, natural and social emergencies were registered in Ukraine that had caused human casualties and financial losses. 3. The main factors causing the anthropogenic risks and threats remain: around 2.8 million cubic meters of solid radioactive waste located in various places; a huge amount of industrial waste occupying about 160 hectares; more than 1000 facilities that use or store hazardous chemicals; about 1500 explosion and fire facilities; the emergency condition of infrastructure/housing; outdated industrial processes etc. 4. The executed spatial analysis of the causes of anthropogenic risks in Ukraine geosystem allows establishing cause and consequence links of interaction/influence of various reasons as well as the reactions in human society and ecosystems in regional aspect. On the base of statistic data, correlation analysis and mapping the functional zoning of Ukraine territory has been developed identifying the types of anthropogenic pressure following from the

different contribution of various factors. 5. The root reasons of anthropogenic emergencies in Ukraine are investigated in the plane of fundamental macroeconomic and demographic problems and linked, above all things, with the specific of common man attitude to the nature and the existent social and economic situation in the country. The appropriate scientific and practical ways for the risk minimization and elimination have been substantiated by means of strategic planning instruments aiming to achieve the sustainable development of Ukraine geosystem.

Risk reduction – an integration task

Stefan Schneiderbauer (European Academy), Stefan Kienberger (University of Salzburg)

Societies all over the world face increasing risks to suffer from external shocks or stresses. Reasons for that are manifold and include environmental (climate) changes, societal changes and the combination of both. As a consequence, risk reduction is an increasingly important task in communities worldwide. Nowadays it is widely accepted that risk reduction strategies need to be embedded in a holistic risk governance approach, the basis of which is an integral, spatially explicit assessment of risk, bringing together the hazard, exposure and vulnerability components. Theoretical frameworks to do so are numerous whilst the process of transferring them into application in practice is thorny. Based on the experience of a number of applied risk assessment (and climate change vulnerability) studies, we identify integration as a major task and name four different conceptual levels of integration striving for more standardization, comparability and transferability of risk assessment methods: Concepts The dominating schools of thoughts that tackle various aspects of risk assessments differ in approaches and focus of study and/or terminology. Ideally they are at least partly merged. A minimum requirement is to be aware of the potential ambiguity of certain use of terms and to be transparent about the approach that has been applied. Methods Different spatial, non-spatial, quantitative and qualitative assessment approaches exist; certain approaches integrate statistical or expert-based weightings. For a holistic assessment most often a 'combined-methods' approach is best. In the end the choice of methods is target- (thus user-) driven and strongly relies on the study's spatial and temporal context. Policies and programs A number of risk assessment exercises depend at least partly on funds related to specific programs, initiatives or simply institutions. The development of risk assessment approaches for example in the EU is financed by the EC's SPACE, Environment and transport program. Risk

assessment with an emphasis on development paths are supported by UNISDR, UNU, the World Bank etc. Each program follows specific policy objectives and sets its focus accordingly whilst the risk assessment often could benefit from combining them. Data fusion is available in different quality originating from various acquisition methods with different spatial references (admin boundaries, pixel sizes). They often need to be aggregated and/or disaggregated to allow for integration and comparison. A holistic risk assessment integrating concepts, methods, data and policy objectives of various approaches is required in order to ensure that funds are used in the best way. The researcher's role and responsibility is to be informed and aware about the different integration needs, to apply integration activities at all required levels and to formulate such needs and relevant shortcomings as policy recommendations.

Riskscape of Pandemic Emergency Response

Jonathan Everts (University of Bayreuth)

Riskscape of Pandemic Emergency Response Jonathan Everts (University of Bayreuth) The 2009 A H1N1 pandemic (swine flu) proved right continuous warnings against emerging viruses and pandemic risk. At least since the late 1980s, the 'emerging disease worldview' became a staple of global health politics and discourse (King 2003; Lakoff 2010). National public health centres and authorities began increasingly to 'gear up' for pandemic emergency response since the 2001 Anthrax attacks, SARS in 2003, and the increasing spread of highly pathogenic avian influenza (H5N1) in 2005-2006. Looking at severe complications and the death toll due to H1N1, swine flu seems like a small pandemic event. Nevertheless, response measures were oriented at the risk of a possible H5N1 pandemic with likely mortality rates over 50 percent. In consequence, public health officials and experts worked initially under the extreme conditions of an anticipated very lethal and quickly spreading disease. Although H1N1 was acknowledged to be generally mild within a month of its first laboratory confirmation and response measures were backtracked, the riskscape initially laid out and communicated was that of a major global disease event. Analysing the construction of this specific riskscape, we would expect to find public health and scientific practices at the forefront of its creation. However, based on empirical work within the US, the riskscape produced by eminent public health agencies is neither freewheeling nor uncontested product of expert practices. Instead, we find the emerging pandemic riskscape as negotiated and overlapping with riskscape defined by international organisations, national governments, economy, the media, and the public. In

discussing processes announcing H1N1's multilayered riskscape, I seek to demonstrate more broadly the contested spatial and social dimensions of risk, risk management, and risk communication.

Uncertain topographies, landscapes of fear and geographies of violence in Sri Lanka

Benedikt Korf (University of Zurich)

This paper investigates the uncertain topographies and landscapes of fear that emerge out of the geographies of violence that shape contemporary warscapes. In his seminal work on humanistic geography, Tuan (1978) studied landscapes of fear as inscribed in mental processes of imagined geographies. In this paper, a conceptual framework is developed that goes beyond Tuan's experiential approach and territorializes landscapes of fear in the material topographies of risk and uncertainty that emerge in the interplay of war and survival economies in civil warfare. These topographies of risk are manifested in territorial orders and spatial vulnerabilities as these become confined in different time-spaces. The framework is illustrated using ethnographies from the civil war in Sri Lanka that studied the survival economies and livelihood strategies of farming and fishing families in the east of Sri Lanka in the period of 1999-2002. The empirical material will demonstrate how livelihood vulnerability and local agency are territorially confined through uncertain topographies and landscapes of fear.

RC 08-01 - Flood risks under conditions of global change: Dealing with uncertainties and dynamics of flood risk in urban areas 1

Chair: Laurens Bouwer, Volker Meyer, Christian Kuhlicke

Assessing the exposure to climate-related flood risk in the highly dynamic urban setting of Ho Chi Minh City

Nigel Downes (Brandenburg University), Harry Storch (Brandenburg University)

Delta-cities such as Ho Chi Minh City (HCMC) exhibit higher exposure levels to flood risk primary as a result of their location, their low elevation and if located in tropical regions, the significant annual variations of climatic and weather extremes they incur. Our assessment highlights that for exposure to tidal flooding, rapid urbanisation driven by socioeconomic development (including population and economic growth) is proportionately more important for emerging deltaic Asian megacities, like HCMC, than projected sea-level rise up to the year 2100, under a high-emission scenario. Furthermore the large increase in the built-up extent exposed to flood risk can also seen as an indicator to the risk associated with a corresponding increase in both terms of population and assets. These will be ultimately exposed following rapid social-economic transformations and urbanisation which are projected for the coming decades. Interestingly from the implementation of the land-use plan up to 2025/30 with an extreme sea-level rise of 1 m for 2100, two-thirds of the total estimated exposure of the built-up area results from the planned urban expansion into low-lying areas, which are widely known as flood-prone at the current max-tide. The assessment into the future impacts of urban development on the urban hydrology additionally highlights the dominant role of that rapid urbanisation processes play in future risk. With the implementation of the future development plans up to 2025/30 the impervious coverage will be seen to double for the entirety of HCMC. This act would significantly double the amount of surface-runoff - a current major cause of urban flood problems. Interestingly however, most scenarios for climate change risk, still predominantly focus only on the potential pathways of climate change, rather than integrating the socio-economic and vulnerability pathways, such as the future spatial development patterns of mega-urban agglomerations. Here focussing on improving the resolution of the climate change data is not the most critical issue, rather more important is the adoption of a more pragmatic approach to work with the

existing data at the local scale. Integrating an urban development scenario - i.e. based on the official land-use maps up to the year 2030, provides more realistic and tailored assessment results. Our study highlights, that the influence of non-climatic stressors - like urbanisation as the spatial manifestation of socio-economic processes are still widely under acknowledged. An urgent need has arisen to readdress and improve the scientific methods and datasets to examine these non-climatic key drivers of future urban risk and to assess their relative importance for risk propagation compared to primary changes in climate. The most significant issue here is the integration of the future dynamics of urban development.

Risks in mega-cities under a changing climate: Water shortage and floods in Pearl River Delta, China

Liang Yang (University of Hamburg)

Urban cluster of the Pearl River Delta (PRD) in southern China is usually portrayed as an area of water abundance. However, the view should not be static all the time. Along with the changing climate, water problems of PRD mega-cities fall into two extremes. At one extreme is the monsoon period between April to September when the area becomes flooded due to heavy rainfall within the whole river basin and some typhoon or tidal events. At the other extreme is the dry season between October to March when the cities become water stressed due to low and unsustainable water availability. Water shortage in these mega-cities is characterized by seasonal insufficient precipitation, seawater intrusion, increasing water pollution, poor water facilities as well as decreasing water amount per capita due to increasing population. While it's possible to deal with the risks when we know there would be a flood or drought, the uncertainty of climate change and its effects on water resources seems to be more frightening. This uncertainty causes a new severe risk which is that we don't know where the risk is. Besides, additional risks posed by climate change to these cities and their people will likely enlarge the disaster scale and force people to spread attention on more small troubles. Thus mitigating floods and ensuring enough water availability are the two major water resources management challenges for PRD mega-cities. This paper discusses several prior strategies to address the water issue and especially the new risks under climate change: (1) learn from and carry forward positive water engineering; (2) enhance the ability of individuals or families to respond to water risks, encourage 'own' activity based on 'their' context; (3) develop flood/draught insurance to share disasters in large scope and long period.

Finally, this paper stresses that the cities' authorities should revisit the region's development plan to develop a long-term, integrated water management strategy that recognizes the added risks from climate change and rapid development.

Invisible Dwellers, Visible Slums: Effects of Slums on the Health of Accra, Ghana

Simon Mariwah (University of Cape Coast)

In developing countries, about half of the city dwellers live in slums. However, since city authorities do not plan for or manage slums, the people lack access to municipal services such as water, roads, sanitation and sewage. This attitude to slum dwellers and approaches that disregard them, perpetuate the levels and scale of poverty, which impacts on the cities as a whole. The paper draws on existing literature and GIS data to examine how the neglect of slums increases the vulnerability of the entire city of Accra, especially during flooding. The study found that most of the perennial flooding in Accra greatly affects slums and unplanned areas, leading to the outbreak of cholera and other sanitation related diseases, which spread to other areas of the city and thereby affecting both the slum and non-slum dwellers. The study recommends that city authorities should employ a more inclusive approach to planning and land management if they are to sustain all the people who live in them.

Are areas affected by flood and stagnant water associated with poorer health outcomes in urban slums of Dhaka and adjacent rural areas?

Md. Mobarak Hossain Khan (Bielefeld University), Oliver Grübner (Humboldt-Universität zu Berlin), Alexander Krämer (Bielefeld University)

Background and objectives Globally Bangladesh is one of the worst victims of excessive rainfall and floods. Unfortunately the frequency of floods has increased substantially in recent decades due to both natural/climate-related and man-made factors. Frequent flooding in Bangladesh is a serious concern because each flood could hinder the overall economic growth, jeopardise the development activities, break down normal life, health and well-being of the affected people. Particularly megacities, coastal areas, cities and urban slums are more affected by floods and related problems such as water logging and sanitation. Higher surface runoff accumulation and lack of drainage provision and pumping facilities to remove the stagnant water cause water logging in the

cities. In Bangladesh, all the big cities are prone to regular floods. Particularly Dhaka city experiences flood almost every year during the monsoon season. Comparatively slum dwellers who constitute about one-third of the urban population are at higher risk of flooding because of low quality dwellings, lack of effective flood-proofing devices, and poor socioeconomic and environmental conditions. Considering this background, we aimed to explore whether areas affected by flood and stagnant water (FSW) have an influence on health outcomes of adults living in urban slums of Dhaka megacity and adjacent rural areas. We also assessed the differences of individual, household and area level characteristics between people living in FSW affected and non-affected areas. **Methodology** Data were collected from 3,207 adults through baseline surveys conducted in two consecutive years (2008 and 2009). Twelve big slums in Dhaka and three adjacent villages were selected for our questionnaire surveys. Face-to-face interviews using a multidimensional pre-tested questionnaire were conducted by trained university graduates. We performed various types of analyses ranging from simple frequency analysis to multivariable logistic regression modeling. **Results** Our empirical findings suggest that slums are more affected by FSW as compared to rural areas. People living in areas affected by FSW are more vulnerable in terms of individual, household and area level characteristics than non-affected people. Similarly affected people suffer more from health symptoms (namely fever, cold/cough, weakness), communicable diseases (namely diarrhoea and gastric), and poor mental well-being. However, the burden of non-communicable diseases is lower among people in FSW areas affected. **Conclusion** Well-designed and comprehensive public health interventions focusing on the individual and the community level as well as structural interventions may reduce flood-related consequences and hence improve health-related outcomes among people living in urban slums of Dhaka.

RC 08-02 - Flood risks under conditions of global change: Dealing with uncertainties and dynamics of flood risk in urban areas 2

Chair: Laurens Bouwer, Volker Meyer, Christian Kuhlicke

Solving the riddles of the flood in Central Plain, Thailand in 2011

Chaiyan Rajchagool (Payap University)

Some floods are more explainable, hence, possibly preventable than others. The flood in Central Plain, Thailand in 2011 is extremely enigmatic, not to say about its scale of disaster. Different state authorities, different civil organizations and, not to understate, different social classes and political groups have given their respective 'explanations' and, their related preventive measures. Given a few exceptions, all these pundits are categorical in their perspectives. They range from 'climate change', the mismanagement of water resources, the unregulated urban development, the power struggle among socially-grounded residents, etc, to even a far-fetched 'conspiracy theory' with ominous political motives. The proliferation of explanations as well as people's conviction themselves could well be a subject of sociological and political study. Similar to other debates of scientifically as much as politically heated issues, each position has increasingly become entrenched. The ground of communication has been eroded rather than constructively bridged. This paper, with no professional agenda and even less so political flag to carry, is an attempt to subject the significant explanations of the flooding to a critical examination. The scrutiny begins with their conceptual approaches as well as their underlying assumptions, then to read each 'findings' in relation with one another. In addition to the data of the amount of rainfall, of the reservoir capacities, of the water demand speculation, the paper will go beyond the conventional approach of supply/demand analysis. With the built-environment and human efforts from different sources and the author's own theoretical perspective, it is hoped that the paper, distancing itself from a mono causal mode, could shed some additional light on the academic and political controversies. Additionally and more importantly, it might be able to offer some preventive measures that could be relevant to future Thailand and, not least, to other developing countries in monsoon regions in general and in Southeast Asia in particular.

Adaptation to global change: Can private households contribute to flood risk reduction in German cities?

Heidi Kreibich (German Research Centre for Geosciences - GFZ), Philip Bubeck (German Research Centre for Geosciences - GFZ)

Damage due to floods have increased during the last few decades, and further increases are expected due to climate change and an increase in vulnerability. To address the projected increase in flood risk, a combination of structural and non-structural flood risk mitigation measures is considered as a promising adaptation strategy, since they take into account that flood defence systems may fail, and prepare for such unexpected crisis situations. Non-structural flood risk mitigation measures like shielding with water shutters or sand bags, building fortification or safeguarding of hazardous substances are often voluntary, and it demands self-dependent action by the population at risk to undertake such measures. It is believed that these measures are especially effective in areas with frequent flood events and low flood water levels, but some types of measures showed a significant damage mitigation effect also during the extreme flood event at the Elbe River in August 2002 in Germany. However, information is still scarce about factors that motivate people to undertake such measures, the spread of different non-structural measures in different areas and their damage reducing effects. To gain further insights into these aspects, computer aided telephone interviews have been undertaken in the cities of Dresden and Cologne in Germany. The interviews contained various questions about non-structural measures undertaken, flood experience, risk awareness, coping appraisal and suffered flood damages. The presentation will compare the situation in terms of non-structural measures in Dresden and Cologne. Questions covered are: How many households have undertaken specific measures and why? Which policies are effective to stimulate the implementation of such measures? What measures were particularly effective in reducing damage?

Challenges for the evaluation of flood risk driving forces and the development of urban adaptation strategies in the context of global climate change

Sebastian Scheuer (Humboldt-Universität zu Berlin), Dagmar Haase (Humboldt Universität zu Berlin), Martin Volk (Helmholtz Centre for Environmental Research - UFZ), Andreas Neumann (Humboldt-Universität zu Berlin), Volker Meyer (Helmholtz Centre for Environmental Research – UFZ)

If flooding and flood risk is seen in an integrative, holistic manner, it can be regarded as being steered by characteristics of elements at risk (i.e. their spatial distribution and value) and of the flood hazard (i.e. by its intensity and probability). Climate change is estimated to lead to regionally diverse changes in precipitation intensity. Whilst an increase of precipitation is expected for Northern Europe, a decrease is estimated for the South. It is further estimated that the number of extreme precipitation events will increase. These changes will feed back on hazard intensity - or hazard probability respectively - and thereby affect flood risk. Global change, i.e. land-use changes as well as population dynamics will additionally affect flood risk by altering the quantity and value of elements at risk. In this context, risk needs to be seen as a dynamic rather than a static measure. To support emergency planning, flood risk management and the development of urban adaptation strategies it is necessary to evaluate future effects of these driving forces on flood risk. We present a loose-coupling, spatially explicit modelling approach to assess flood risk driving forces in the context of global climate change. Thereby, we seek to appraise the influences of flood risk drivers and to identify future hotspots for adaptation and planning. We also aim to deduce uncertainties and shortcomings of current model approaches and projections. The case study is carried out for the Mulde catchment located in Saxony (Germany). This region has been hit by numerous large-scale flood events, e.g. in 2002 and 2006. The study focuses on the effects of climate change, population dynamics and land-use change. We couple selected hydrodynamic models (SWAT, IHACRES, TRIMR2D) with a population model (PDE) and a cellular automaton for the prediction of land-use changes (MOLAND) to create the input data for the multicriteria flood risk assessment (FLOODCALC). The case study uses projections until 2030/2050 to estimate future flood risk as a basis for the identification of regional hotspots and the development of adaptation strategies.

Knowledge and Networks – Integrated Flood Risk Management Planning in Goal-directed Networks

Gerard Hutter (Leibniz Institute of Ecological Urban and Regional Development (IOER))

Integrated Flood Risk Management Planning (IFRMP) is an ambitious task. Institutional actors ('organizations') from different governance levels and societal spheres need to work together under time pressure, resource constraints, and the possibility of misunderstanding due to limited previous working experiences and heterogeneous 'intellectual capital' (Van den Bosch et al. 2006). Consequently, research about networks and partnerships suggests that institutional actors should not work together unless it is really necessary to reach an important goal at the network level (Huxham & Vangen 2005, Provan & Kenis 2007). Against this background, the paper shows that the concept of 'goal-directed networks' is a useful concept to analyze and assess the conditions of IFRMP based on social relations between institutional actors from different levels and societal spheres. The concept of 'goal-directed networks' has been developed in a series of papers from the network literature in the social sciences (see Kilduff & Tsai 2003, Provan & Kenis 2007, Raab & Kenis 2009). Goal-directed networks are networks of organizations (at least three) that are legally autonomous (e. g., state and local authorities in Germany) and that share - to some extent - a goal at the network level (e. g., formulating and implementing a plan to reduce flood risk in a flood-prone area through structural measures, Hutter 2007). Goal-directed networks are organized through establishing a network governance form. The paper distinguishes between (1) 'self-governed network', (2) 'lead organization network', and 'network administrative organization' (Raab & Kenis 2009). The analysis refers to a goal-directed network established after the Dresden flood disaster in August 2002 ('Weisseritz-Regio') and to two other networks of different size and governance form that address specific planning challenges of IFRMP in the context of climate change adaptation in urban regions ('KLIMAFit' and 'REGKLAM'). It is the aim of the paper (1) to describe the three examples from a network and strategic planning perspective on IFRMP, (2) to assess the examples under specific criteria (such as 'Integration of different forms of knowledge') and (3) to derive conclusions that are relevant for risk governance in urban regions.

RC 09-01 - Free flow or better stay at home? Changing practices in the management of international mobility.

Chair: Martin Geiger, Harald Bauder

Migration in Control Societies: Governmentality without Territory

Joshua J. Kurz (Ohio State University)

This paper responds to the call for research on the practices motivating and promoting changes in the management of international mobility, the social consequences for migrants and societies resulting from mobility-related practices, with a view toward elaborating normative ideas of a "no borders" politics. Contemporary practices of policing migration flows no longer follow a logic of inclusion/exclusion because the border is no longer the primary site of enforcement and the goal of such practices is no longer to keep mobile populations out of a territory. Western ("receiving") states rely instead on myriad techniques that implement three broad strategies: the internalization and externalization of policing, and the excision of territory. By shifting migration enforcement away from borders, the governance of human mobility has become dislocated from territory, contributing to the rapid rise in the securitization of migration precisely because of this dislocation. This paper explores various technologies of migrant policing and their relation to, production of, and ambivalence toward various territorialities. Using Gilles Deleuze's analysis of "control societies," the author orients these technologies as mechanisms that modulate population flows in ways that produce "inclusive exclusions" and "exclusive inclusions," where migrant presence or absence is approached as a process of filtration rather than exclusion. The author argues that these control mechanisms, or modulating technologies, help to produce a generalized condition of precarity, which facilitates state and economic interventions that would not otherwise be possible. The paper concludes with a consideration of potential political subjectivities produced by and through governmentality without territory. Rather than a project of "open borders," the author explicitly locates these subjectivities as operating in a politics of "no borders," paralleling the territorially dislocated technologies of population modulation. New spaces, literally and figuratively, for politics and resistance are opened as an incitement toward articulating a stronger "no borders politics."

The IOM's Role in the Implementation of the EU-Russia Readmission Agreement

Oleg Korneev (European University Institute)

Based on the fieldwork conducted in Brussels, Moscow and Central Asia, this paper analyses the involvement of the International Organisation for Migration (IOM) in the EU-Russia bilateral cooperation on migration management. The main questions addressed in this paper relate to the formal role of the major implementing partner that the EU has assigned to IOM and to the actual 'behaviour' of IOM on the ground. This analysis is situated in the theoretical framework describing international organisations as bureaucracies and within the discussions about international migration governance and international migration management. The paper describes the context of the EU-Russia migration management cooperation and identifies major activities of IOM in Russia. Treating international organisations as bureaucracies that pursue their own interests, the paper argues that far from being a mere implementing body, IOM is an actor that, to a significant extent, has shaped the outcome of EU-Russia migration dialogue, while it is the context of this bilateral cooperation that has allowed IOM to strengthen its position vis-à-vis both Russia and the EU. Most of the existing studies on EU-Russia cooperation relating to migration issues focus on these two actors - for the purposes of research often reduced to single units, presented somewhat as 'black boxes' - without paying attention to various internal forces that underlie their policy choices and to the context in which this bilateral cooperation is forged. However, both the EU and Russia are complex objects, each representing a web of stakeholders with multiple political agendas. Moreover, this formally bilateral cooperation involves other important actors, in particular international organisations (IOs). Thus, the results of this cooperation are shaped by multiple arrangements established between these various organizational forces. The EU-Russia Readmission Agreement (2006) provides a good case for a study of such arrangements, since IOM - a global leader in so-called migration management - is involved in its implementation. This paper is divided into four parts. The first part introduces some theoretical reflections on international migration governance, international migration management and on IOs as bureaucracies. The vision of IOs as competing bureaucracies is then applied to IOM. The second part describes the context of EU-Russia cooperation on migration management focusing on the EU-Russia readmission agreement. The third part looks at IOM's activities under the projects financed by the EU in Russia. The fourth part discusses the complex

relationship between EU institutions, Russian authorities and IOM, and the multiple roles played by IOM in this setting.

"Migration as adaptation strategy": The promotion of migration management in the face of climate change

Romain Felli (University of Manchester)

Numerous recent reports by non-governmental organisations (NGOs), academics and international organisations have focussed on so-called climate refugees or migrants. This paper examines the turn from a discourse of 'climate refugees', in which organisations perceive migration as a failure of both mitigation and adaptation to climate change, to one of 'climate migration', in which organisations promote migration as a strategy of adaptation. Its focus is promotion of climate migration management, and it explores the trend of these discourses through two sections. First, it provides an empirical account of the two discourses, emphasizing the differentiation between them. It then focuses on the discourse of climate migration, its origins, extent and content and the associated practices of 'migration management'. The second part argues that the turn to the promotion of 'climate migration' should be understood as its way to manage the insecurity created by climate change. Furthermore, the promotion of migration management is justified through its supposed developmental benefits, thus turning the discourse of climate refugees into one of utilitarian international labour migration.

Transnational practices of migrant care workers in the EU – On the institutionalisation of illegalised cross-border mobilities

Anke Strüver (University of Hamburg)

Taking transnational domestic and care workers from Eastern Europe in Germany as example, this contribution focuses on the multiscalarity of economic and social relations. As a consequence of neoliberal transformations in European welfare states, demands for personal domestic services increase and are met by Eastern European female migrants. On an individual level, these migrants' activities rely on two strategies, namely rotating between places and between care and career. However, with respect to broader migration regimes and mobility politics, the labour practices of care workers rely on 'irregular' border crossings. For, despite both the (assumed) growing integration within the European Union and the intensification of cross-border labour mobility between the EU-members and their neighbouring states in the East, the free movement of

workers and full acknowledgement of their qualifications have not been established yet. Current cross-border labour politics thus result in the production of irregular migration in general and illegalised migrants in particular. Against this background, the paper specifically addresses (1) the questions of social consequences for individual migrants and involved societies (receiving societies and societies of origin) and concentrates (2) on underlying normative ideas of (the management of) human mobilities, transnational practices and cross-border migration. These points are discussed with reference to empirical research disclosing irregular cross-border mobilities of transnational care workers - as both risky and promising way of life for the migrants themselves, - as both risky and curative for the receiving societies at the same time (applying 'curative' in its literal and symbolic sense), and, finally - as a way to replace the increasingly acknowledged 'institutionalised porosity of the EU's (external) borders' with a regime that depends on the 'institutionalisation of illegalised cross-border mobilities'.

The Art of War in the Age of Digital Producibility

Oliver Belcher (University of British Columbia)

In recent years, the US military has adopted and deployed a wide-ranging array of digital technologies to visualize and store information on 'insurgents' in Afghanistan and Iraq. From geospatial intelligence and full-motion video from drones, to biometrics and digital database management, the US military has made it clear that the future of warfare will not be in analog. Instead, the certainty of a future battlespaces will be guaranteed through digital 'reality mining' and social network analysis based on digital forensics. As one New York Times reporter recently put it, '[a] citizen in Afghanistan or Iraq would almost have to spend every minute in a home village and never seek government services to avoid crossing paths with a biometric system.' However, digital imagery, as it pertains to the certainty and meaning of 'the real,' presents us with rather idiosyncratic problems. For thinkers as disparate as Heidegger, Jameson, and Benjamin, pre-digital modernity was predicated on an ontological distinction between 'reality' and 'representation,' with a representation 'here' indexing a physical reality somewhere and some point 'out there.' For Heidegger, it was between material reality and representation where certainty and the modern experience of meaning emerged -- what he famously called, "enframing." But, what happens to the status of this index when the technocultural apparatus through which (re)presentations are produced has transformed from a photographic reproducibility (Benjamin) to a digital producibility? How does the myth of certainty get woven through digital presentation? I will discuss theoretical problems associated with this 'digital event' in the context of the US counterinsurgency campaign in southern Afghanistan, where digital imagery is used to determine the extent of entire 'enemy spaces' outside of Kandahar City.

Contested Sovereignty and the Emergence of New Spaces of Violence. The Example of the Afghan-Pakistan Borderlands.

Conrad Schetter (Rheinische Friedrich-Wilhelms-Universität Bonn)

The sovereignty triangle – the connection between statehood, the monopoly of violence and territory – has undergone tremendous changes in the past decade.

The drone attacks carried out by the US-military in the Federally Administrated Tribal Areas (FATA) of Pakistan are an exemplary case for both, the legitimacy discourse and the new forms of violence; both are particular tied to space. So the paper aims to explain why the FATA are a prime example and sketches a new US-military doctrine based on the creation of such new spaces of violence. On the theoretical level this paper intends to trace the development of such new spaces of violence through the contestation of sovereignty from the debates about fragile statehood, human security, via the „war on terror“ to the idea of „ungoverned spaces/territories“. Hereby the theoretical discussion intends to reflect on the ideas of Carl Schmitt, Giorgio Agamben and Zygmunt Bauman.

Political rule in warscapes: Theoretical reflections and the empirical cases of Abkhazia and Nagorno-Karabakh

Franziska Smolnik (Stiftung Wissenschaft und Politik/Berlin)

The paper will argue that the understanding of violent conflict as warscape - introduced by ethnographers and picked up by political geographers - is well suited to also expand knowledge related to violent conflict in the discipline of political science. This will be demonstrated by exploring political rule in the South Caucasus 'de facto states' Abkhazia and Nagorno-Karabakh. In offering a more nuanced analytical lens to violent conflicts, the notion of warscape helps one to differentiate the various impacts violent conflict has had on political rule in these entities. To explore how specific configurations of political rule emerge in such setting the paper draws upon Bourdieu's analytical tools of capital and field, thus trying to present an additional perspective on warscapes that focuses on how the warscape is interrelated with complex arrangements of political rule that actors not only have to navigate but are also engaged in (re-)producing.

Exploring the labyrinth of battlefields: A gender perspective on wartime narratives and representation

Stela Arar (Durham University)

In the summer of 1982, the IDF (Israeli Defence Force) invaded Lebanon all the way to Beirut with an objective to drive out the PLO (Palestinian Liberation Organisation) leadership and destroy its guerrilla forces. Three years later, the IDF withdrew from the capital and created a buffer zone in southern Lebanon known as the security belt or, in popular parlance, 'the Strip'. Such a decision was deemed necessary, according to Israel, in order to prevent terrorist attacks from targeting its northern territories. Consequently, the security belt, a strip of

rural area with an average width of 15 km along the borders, comprising 10% of the country - fell under the Israeli occupation for more than 18 years and it was soon depopulated and virtually cut off from the rest of the country since hardly any Lebanese not from the Strip ever step foot there. For many years the status of this narrow strip of land was considered strategically critical as it remains the last military active frontier of the Arab- Israeli struggle. Moreover, hosting an array of protagonists (UN observers, IDF forces with their proxies and Hezbollah fighters), the area witnessed frequent assaults and, caught in between, Strip-dwellers were forced to make compromises necessary to survive. The paper seeks to explore not only the complex means, through which the battle space was shaped, but moreover, it examines the narratives through which a representation of the Strip was produced in the imagination of the Lebanese population.

Violence in Shangri-la: Post-conflict politics and the establishment of the new Republic of Nepal

Andrea Nightingale (University of Edinburgh)

Nepal's political transition has captured the world's attention as it attempts to write a new constitution and establish a Federal Republic. Recent ethnographic research indicates that violence and coercion along with patronage are becoming the norm, with a variety of domains of everyday life becoming increasingly politicised along political party lines. This paper explores the spaces and practices of 'post-conflict' to interrogate how violence intersects with patronage relations to build a logic of rule. Drawing on ideas of governmentality and other work on political violence, we focus on resource governance as a key context wherein various ideas of 'democracy', 'authority' and 'legitimacy' are contested and (re)produced. Through this lens we interrogate the contours of the new Republic of Nepal.

Drought, Economic Shocks and Civil War Violence: A disaggregated Study of Somalia

Niklas Harder (University of Kiel), Vincent Kahl (University of Hamburg)

Various studies have found robust correlations between economic factors and civil war onset. As this correlation suffers from severe problems of reverse causality, several authors use climate data as an instrumental variable. However, the focus on civil war onset overlooks the spatial and temporal dynamics of climate variables, economic indices and civil war violence. The proposed paper seeks to analyze whether regional factors can help to explain location and timing of civil war violence. The paper uses monthly observations from 18 different regions of Somalia (time-series cross-section) to examine the relationship between rainfall, economic stress and civil war intensity. The paper develops a theoretical model that differentiates between those patterns of violence that can be explained by strategic interaction and those patterns of violence that can be explained regional economic and climatic factors. The paper shows considerable and significant effects of regional factors on the spatial and temporal patterns of violence in civil war. The paper is largely based on theoretical literature from the field of Political Science conflict research but seeks

to use Geographical data and methods to enhance the understanding of spatial and temporal dynamics in civil war.

Climate Wars Redux? On Climate Variability and Armed Conflict in Asia.

Gerdis Wischnath (Peace Research Institute Oslo (PRIO)), Halvard Buhaug (Peace Research Institute Oslo (PRIO))

Climate change to be a driver of conflict seems undoubted in policy and media. Contrarily, the empirical literature on the topic is lacking robust findings and has not been able to support the public claims on a risk-inducing effect of climatic changes on internal armed conflict. However, most of the quantitative work in the field suffers from overly aggregated research designs and has mainly focused on linkages between climate anomalies, economic decline and armed conflict via the state level. To overcome those shortcomings, this study takes a closer look at possible linkages at the local level. Neither climatic change nor armed conflict equally affect countries as a whole. By focussing on local geographical characteristics, actor's motivations and group dynamics we argue that conflict is most likely to break out where climate extremes interact with ethno-political marginalization, population density and other local features that make some areas more prone to climate-induced shortcomings than others. We move the traditional focus away from Africa by focussing on Asia instead and we apply a disaggregated research design that captures subnational differences in climatic, social and geographical characteristics. Nonetheless, the empirical analysis finds no support for a risk-inducing effect of climate extremes on the local likelihood of conflict outbreak. Conversely, we find weak evidence for the opposite effect: conflict onset being less likely in times of climatic stress.

Space and Conflict: Religion, Politics and Violence in Ayodhya, India

Basabi Khan Banerjee (Georg-Eckert-Institute), Georg Stöber (Georg-Eckert-Institut)

Space and Conflict: Religion, Politics and Violence in Ayodhya, India According to the notions of space, the relationship between space and conflict is polysemic, comprising the area where a conflict takes place or the subject of conflict where various actors give different meaning to a locale / space and construct conflicting issues. These issues might be on the rights / control over a space, access to the space, or on its usage. Eventually the space might become a 'place of remembrance' (lieu de mémoire) for a specific conflict and ensuing

events. This presentation will look into the conflicts around the Babri-Masjid which evoked wide-spread violence extending from the locality, Ayodhya in the federal state of Uttar Pradesh (Northern Province), to the regional, national and even international scales. The Babri Masjid built in 1527 by order of Babur, the first Mughal emperor of India, and named after him, became the subject of controversy when Hindus claimed the same site as the birthplace of the Hindu deity, Lord Rama. Idols were placed in the Mosque (illegally?) on December 23, 1949 which became a judicial issue. After 1986, Hindu Nationalist groups and political parties took up this claim for their political achievements and as a means for mass mobilisation. The Masjid was destroyed in 1992 to build a new Rama temple on that site. Further development of this conflict is characterised by an outburst of communal violence in India, Pakistan and among South Asian diaspora communities abroad. In the course of time, not only the number of actors grew, but the perception of the conflict underwent changes, posing threats to : religious cohabitation the secular nature of Indian constitution and posing a challenge to the geographers, transition theorists and even economists about the cruciality of the cultural meaning of 'space'. Despite the deep involvement of the - independent - judiciary, conflict on the right to the disputed site is not yet resolved, still is a burning issue with the potential to erupt again. Additionally, Babri Masjid site has manifested into a symbol of politicised religion, communalism and fundamentalism. This presentation will try to analyse the role of conflict and impacts of violence, the interplay of various actors with their diverse positions and aims, changing and evolving through time and over space.

RC 11-01 - Indigeneity, state power and struggles over space

Melanesia's violent spaces: The case of Solomon Islands

Matthew Allen (The Australian National University)

Melanesia's violent spaces: the case of Solomon Islands This paper draws upon Michael Watts's work on governable spaces and "economies of violence" in the Niger Delta (2004a, b, c) and Colin Filer's concept of the "ideology of landownership" in Papua New Guinea (1997) to explore the interplay of resource capitalism, the state, identity, and conflict in the case of the so-called 'ethnic violence' that took place in the post-colonial Melanesian nation of Solomon Islands between 1998 and 2003. Against a backdrop of the commodification, alienation and 'mobilisation' of customary land that has been taking place in the context of globalisation and rapid socio-economic and agrarian change, this schema of the political ecology of violence is elucidated with reference to three governable spaces: customary landownership, indigeneity, and nationalism. I demonstrate the ways in which the territorialising and exclusionary logics of these governable spaces antagonised, problematised and contradicted one another, and, in doing so, gave rise to violent conflict. In sharp contrast to the resource determinism, state-centrism and ahistoricism of much of the 'resource conflict' literature, attention to governmentality and scale elucidates the highly contextual and contingent nature of the resource-related violence that took place in Solomon Islands. As has been the case elsewhere, Melanesian societies, identity groupings and nations are not blank slates upon which resource capitalism has etched linear and predictable pathways of conflict. Rather they are spaces of pre-existing forms of governance - fields of power - that have been brought into a relatively recent encounter with particular types of capitalist and statist projects. At the centre of these encounters one invariably finds struggles over access to, and control of, land and natural resources; and the Solomons case provides a salutary reminder that these struggles can only be robustly understood with reference to 'local histories and social relations' (Peluso and Watts 2001).

From Conflict to Understanding to Transformation

Marvin Drake (University of Tübingen)

Jos, a large city in central Nigeria formerly noted for its mild climate, warm hospitality and as a haven for tourism, now largely consists of completely segregated Christian and Muslim neighborhoods, each marked by a mood of anxiety, apprehension, hostility and fear toward the religious "other". The major bone of contention in what has become known as 'The Jos Crisis' is the indigene-settler syndrome, and the key question is 'Who owns Jos?'. Autocratic military regimes governed Nigeria for all but five years from 1967 until the return of democratic rule in 1999. In 1991 President Ibrahim Babangida created the Jos North Local Government Area (LGA), allowing a minority ethnic group, the predominantly Muslim Hausa, to gain political control of the central area of the city, and relegated the three majority and predominantly Christian indigenous ethnic groups to the new Jos South LGA. The indigenes interpreted the unilateral decision as a deliberate scheme to place the city under Muslim economic and political control. In the absence of an acceptable resolution a political dispute evolved into a protracted sectarian conflict, and thousands of innocent men, women and children on both sides have since been murdered just because they were Muslims or Christians. The 1999 federal constitution clearly defines the criteria for Nigerian citizenship. But it also distinguishes between indigenes and settlers in particular localities. An indigene is someone whose ethnic group has a 'homeland' in a particular politically-defined locality or state, and who was also born in the same area. Nigerians who were born and have lived their entire lives in a particular state but whose ethnic groups are native to another locality or state are always considered to be 'settlers'. No provision exists for changing someone's identity from a settler to an indigene. Settlers are at the mercy of local government officials who have the power to grant or deny citizenship rights to them, meaning they are subject to be denied: employment for certain jobs; civil service appointments; admission to secondary and tertiary educational institutions; scholarships; and opportunity to seek political offices. A research project beginning in 2012 will study the stereotyped perceptions and attitudes of individuals and groups toward the religious 'other', and how they can be dramatically changed by framing them in terms of the foundational tenets of their respective religions. The knowledge and understanding to be acquired will be applied to peacebuilding strategies beginning in 2013. The indigene - settler issue demands a political solution, but the practice of 'love of neighbor' can do much to restore peace and harmony to Jos.

Gorkhaland Movement in India: A case of indigeneity and / or a struggle over space?

Basabi Khan Banerjee (Georg-Eckert-Institute), Georg Stöber (Georg-Eckert-Institut)

Gorkhaland Movement in India: a case of indigeneity and / or a struggle over space? Multicultural concerns have been a core element in Indian constitution, in its political decisions and functions to accommodate the country's vast social and political diversity ('unity in diversity'). But these efforts of integration have been continually challenged by demands / movements for separate statehood or sovereignty since independence. New states came into existence, carved out of the initial federal states, multiplying in its numbers. Most of these struggles or movements were based on linguistic or ethnic issues. In this backdrop, Gorkhaland is another case but a special one. The Gorkhas, originally an ethnic group from eastern Nepal, were brought in the region in large numbers by the British as workers in tea and cinchona plantations. This colonial encounter is a very important historical background to understand Gorkhaland movement which is lingering for over almost three decades with the demand for a separate state, seeking independence from the federal state of West Bengal, but not from India. The demand for a statehood started as early as 1907, became stronger since 1982. The formation of Gorkha National Hill Council (GNHC) made the region somewhat calmer for a short period of time. But the attempt to include the Darjeeling Hill Council in the Sixth Schedule of the Indian Constitution could not meet the popular aspiration of the Gorkhas to create a 'diasporic public sphere' (Appudurai). Gorkha homeland question is not any more about autonomy only. Questions were raised about the representative claims of the Gorkhas over the entire Nepali population of India and on their claims of being the majority group. Since they are not the original inhabitants (Adivasis) in the claimed region, the issue has become more complex. Also the economic potential of the region concerned and political power play between the state and the other interest groups add to this complexity. This presentation aims to examine the Gorkhaland issue and tries to analyse the developments of the same to understand conflict and power struggle over space and its various forms of legitimisation in the context of a post-colonial country. The attempt will be to probe, whether the essence of the statehood demand here stems from the congruence between the federal political boundary and the ethno-linguistic boundaries of the people, or from the alleged hegemony of the West Bengal Government and its negligence. Or is it an attempt to reclaim lost territory as a consequence of partition in 1947. Or is it just the lust for power? Demands for

political autonomy in case of Gorkhaland portrays the difficulty of fitting it in a clean category of indigeneity. This struggle over the control on space is not only a multi-faceted one with many actors and interests, but is also a burning issue in India.

Antagonistic struggles over political space in Ecuador

Carolyn Schurr (Universität Bern)

'Surprisingly enough, relatively little critical reflection has been devoted to what constitutes the proper political domain, to what and where is "the political"' (Swyngedouw 2008). 'This political space I am occupying is a space from which women and especially Shuar women have always been excluded' (interview with an indigenous national deputy of the Ecuadorian Asamblea Nacional). Reading the interview quote from the Shuar deputy against Swyngedouw's reflection, we have to ask not only where the political is located but also who is in- or excluded in the spatiality of politics. In this paper, I engage with the question how spatialities of politics can be conceptualised in a way that the power relations and resulting hegemonies and marginalization that constitute these very spatialities become visible. Departing from Gregson's and Rose's performative approach to space, I suggest that their notion of performative space is inherently political as it situates power relations at the centre of their understanding of space. At the same time, I want to push Gregson's and Rose's argument further by elaborating conceptually on the antagonistic power relations that constitute the spatialities of politics. By bringing Mouffe's notion of politics as antagonism/agonism into dialogue with the concept of performative space, I intend to shed light on the way spaces of politics are brought into being, materialise hegemonic political orders and are subjects of contestation. I think through this theoretical dialogue between Mouffe and Butler - via Gregson and Rose - along my empirical research about transformations in local spaces of politics in Ecuador in three steps: First, along the (post)colonial history of Andean politics, I ask how a spatialised political order is established and maintained. Second, focusing on indigenous movement struggles in Ecuador's recent history, I highlight how Butler's notion of subversion and Mouffe's concept of disarticulation are suitable to frame counterhegemonic struggles that contest the hegemonic political order. Third, taking up Mouffe's idea of agonistic pluralism, I discuss whether the Ecuadorian political imaginaries of interculturalidad and plurinacionalidad could actually expand the categories of the political towards an agonistic democracy. Finally, I turn back to Gregson's and Rose's performative

thinking of space, summarising how their concept needs to be further developed to turn it into a vital tool for political geography.

Coping with Floods in Dhaka's Marginal Settlements: Why is Social Capital so Powerful?

Annika Salingré (Universität zu Köln), Tibor Abheuer (University of Cologne), Boris Braun (University of Cologne)

The urban poor in marginal settlements (slums) face two major problems: Everyday life is characterised by the struggle of earning enough money and thus securing food and shelter, not even talking of bigger investments like education for children or medical treatment. On top of this, natural disasters put poor people at the edge of survival many times because they have to rely on meagre livelihoods. Due to the high exposure of many Asian megacities to natural disasters large numbers of slum dwellers are threatened. However, there is an ongoing academic debate on the potential of social capital to support people to overcome crises and even to adapt to natural disasters in the long run. Literature provides substantial evidence that despite a lack of financial and physical resources and a lack of sound disaster management by the government poor people are able to cope with many things from everyday challenges to severe disasters. On the basis of an extensive standardized field survey and additional qualitative interviews in Dhaka's slums, our paper uncovers the important role of social capital in providing strong resources to the urban poor. We shall particularly elaborate on the significance of social capital to slum households in coping with severe floods. Our results show that most of the slum dwellers are able to apply various kinds of coping strategies and most of these strategies are related to components of social capital. A high prevalence of trust enables people to borrow food, clothes and money within their slum communities. Informal employment supports people to escape from the vicious circle of indebtedness. The social fabric of the households is redundant and well based on cultural and religious norms. Therefore, our empirical results support current findings in academic literature on the decisive role of social capital in enabling poor people to overcome times of crisis. This is true for severe external shocks as well as for everyday life. Thus, it must be kept in mind that these coping strategies only allow for survival. Extreme events do prevent households from accumulating economic wealth and therefore disturb long-term socio-economic development.

People's Perception on Natural Disasters and Local Survival

Strategies in Sundarban Region: A Study of Gosaba Block in South Twenty Four Parganas District In West Bengal, India

Tarun Kumar Mondal (University of Kalyani)

Sundarban is the largest active delta in the world lying at the estuaries of the Rivers Ganga and Brahmaputra. This region is rich in biodiversity and declared as World Heritage Site by UNESCO. This delta region is prone to severe natural disasters as well as man-induced catastrophic events. Gosaba Block which is identified as the study area located in Indian part of the Sundarban delta, in South Twenty Four Parganas district in West Bengal puts forward an ideal portrait for people's struggle and survival strategies against natural disasters. An attempt has been made in this paper to study the perception of the main occupational groups on the effects of major natural disasters viz. floods, tidal surges and cyclones in Gosaba Block. An endeavor has also been made to explore local survival strategies which are effective for their sustenance in this vulnerable region. 300 persons from different occupational groups i.e. people engaged in agriculture, fishing, crab collection, tiger prawn seed collection, wood collection and honey collection have been surveyed through pre-designed questionnaire. Six Focus Group Discussions have been conducted, in which each of the group comprises six members from a particular occupation. The study has revealed that all the occupational groups perceive threats differently from natural disasters and their perception varies according to their level of exposure to the environment. To cope up with the natural disasters, each occupational group has developed distinct survival strategies. For proper management of natural disasters in Sundarban delta region, the perception of people with different livelihoods and their survival strategies should be incorporated.

Role of Local Institutions in Climate-related Disaster Risk Reduction in Japan

Rajib Shaw (Kyoto University), Yukiko Takeuchi (Kyoto University)

The current study shows four examples from the small and medium sized towns and cities in Japan, which has faced climate related and geological hazards in recent past. These are: Reihoku in Kochi prefecture (early 2000 mountain disaster), Tosashimizu in Kochi prefecture (2001 flood disaster) and Saijo in Ehime prefecture (2004 typhoon disaster). All these towns and cities are characterized by higher forest and mountain cover, aged population, and lack of

economic activities. The paper shows three innovative activities of disaster risk reduction: in Reihoku by local NPO (non-profit organization), in Tosashimizu by the Voluntary Disaster Preparedness Organization (VDPO) utilizing local resources and community activities, and in Saijo by local government through school disaster education, through linking with the local business sector and revitalizing local economy. Although the nature of local institutions is different, its prominent roles in the local disaster risk reduction activities ensure its effectiveness and sustainability. Although there are limitations of these local institutions, future disaster risk reduction strategy needs to focus on the balanced approach of utilizing the local institutions, and linking these to external stimuli.

The relationship between community supports and resident behavior after the Tohoku Pacific earthquake: The case of Hitachi City, Ibaraki Prefecture

Tomoko Kubo (Meiji University), Toshiki Yamamoto (University of Tsukuba), Michihiro Mashita (University of Tsukuba), Konstantin Greger (University of Tsukuba), Misao Hashimoto (University of Tsukuba), Tom Waldichuk (Thompson Rivers University), Keisuke Matsui (University of Tsukuba)

The Tohoku Pacific earthquake caused incalculable damage in eastern Japan. The national and local governments designate evacuation sites, and residents are trained to move to these sites through evacuation drills. These evacuation sites are operated by local governments, but communities and school personnel play important roles in their practical operation, while also assisting in the reconstruction of their neighborhoods (Ishii et al., 1996). Residents' activity- fields are confirmed within walking distances during disasters, which stimulate the formation of many types of communal societies (Fujioka, 1996). Despite the fact, the relationship between community supports and the behavior of residents after an earthquake has not been sufficiently examined. Communities are expected to take account of their residential environments and attend to the needs of their weak residents. This study aims to analyze the relationship between community supports and the behavior of residents after the Tohoku Pacific earthquake in the regions surrounding the disaster. We have a special interest in Hitachi city, Ibaraki prefecture. This paper will examine above mentioned issues by way of the following process. 1) We will review Japan's natural disaster prevention regimes. 2) We will examine the result of a field survey conducted in Hitachi city detailing the city's natural disaster prevention procedures and the operation of some neighborhood evacuation

sites. 3) The behavior of residents following the earthquake is analyzed. In this part, questionnaires were sent to 2000 households, of which 492 (24.6%) were collected and used for this analysis. The earthquake and tsunami destroyed lifelines for several days in the city. According to the city, a total of 65 buildings were judged to be in dangerous condition, 251 as requiring care, and 478 were only partially damaged. The most serious damage was found mainly in the city's coastal areas, where a total of 85 houses were entirely or partly damaged, and 483 houses were flooded above the floorboards by the tsunami. On March 11th, a total of 69 evacuation sites opened, and 13,607 residents rushed into them. After the disaster, residents initially tried to go back to their homes. Depending on the damage done, they either stayed there or moved to a relative's house, or to a neighborhood evacuation site. Due to the failure of the lifelines, transportation systems, and the damage caused by the disaster, most residents had to stay within an area more limited than usual, around which they could walk or bicycle. Residents had only the human and physical resources of their neighborhoods at their disposal. Therefore, the characteristics of their local communities affected how residents behaved during and after the earthquake.

RC 12-02 - Local Responses to Natural Disasters 2

Narrative of Disaster Resilience in L'Aquila Recovery

Giuseppe Forino

In this paper the framework of responses to natural disasters is disaster resilience. Although guide lines related to disaster management suggest to strengthen grassroots capacities in post disaster recovery, often these are overwhelmed and/or marginalized by top down, centralized interventions from national governments. In this way, according to Manyena, 2006, differing paths of disaster resilience exists: one is covered by the State, aiming to reach a paternalistic and centralized outcome of assumed efficiency, and the other by grassroots, that autonomously and spontaneously try to reorganize their life. Here disaster resilience is considered in the second path, as 'a deliberate process (leading to desired outcomes) that comprises a series of events, actions or changes to augment the capacity of the affected community when confronted with singular, multiple or unique shocks and stresses, places emphasis on the human role in disasters' (Manyena, 2006, 439). The aim of the paper is to understand this process of disaster resilience in the recovery of L'Aquila, Italian city hit by the earthquake of 6th April 2009. The paper considers the necessity to analyze disaster resilience beyond a normative way, toward a new its objectification (Cannon and Muller-Mahn, 2010), and understanding power relations and different strategies from different actors (Kuhlicke, 2010; Keogh et al, 2011). In this sense, the research proposes a narrative of resilience through a qualitative methodology, based on semi- structured interviews to members of local associations and spontaneous committees born after the earthquake and taking part in the reconstruction process of the city. An highlight of the differences between two different paths of disaster resilience enacted by Italian Government and grassroots is proposed. · Cannon T, Muller-Mahn D, 2010, Vulnerability, resilience and development discourses in context of climate change, *Natural Hazards*, 55, 621-635 · Keogh D.U, Apan A, Mushtaq S, King D, Thomas M, Resilience, vulnerability and adaptive capacity of an inland rural town prone to flooding: a climate change adaptation case study of Charleville, Queensland, Australia, *Natural Hazards*, 2011, 59, 699-723 · Kuhlicke C, 2011, Resilience: a capacity and a myth: findings from an in-depth case study in disaster management research, *Natural Hazards*, online first, DOI

Communal political access and government responsiveness – evidence from India and Vietnam

Olivier Rubin (Roskilde University)

Although disaster victims are often portrayed as passive (almost apathetic) and helpless victims of nature's unpredictable wrath, recent research has brought convincing evidence to the contrary: most disaster communities are not passively waiting for the government to provide assistance in the aftermaths of natural disasters. Instead they are actively pursuing a diverse range of coping strategies to mitigate the suffering from natural disasters. Much research has focused on the communal capacities for information sharing, self-organization, and informal insurance through the conceptual prism of social capital (Aldrich, 2012; Aldrich, 2011; Adger et. al., 2005; Dynes, 2006; Nakagawa and Shaw, 2004; Adger, 1999). This paper will focus on one particular communal coping strategy: exerting a political pressure on the local government to provide emergency assistance. The aim is to address the use of political pressure as a communal coping strategy, and provide empirical examples of how the lack of such political pressure adversely affects the disaster response from the local government. In doing so, the paper will attempt to integrate findings and arguments from the literature on social capital and disasters with the political theory of government responsiveness in times of distress. In lack of a better expression, the capacity of local communities to exert a political pressure on government institutions to provide disaster assistance will here be coined political access. The political access of communes is determined by the overarching political institutions in place, as well as the specific socio-political composition of the commune in question. Drawing on two empirical cases within very different political contexts, the paper will provide evidence of how the lack of political access can have adverse effects on the government response to the disaster. The first case is Vietnam where authoritarian political institutions limit the electoral pressure that can be exerted by the local communities. The case is based on fieldwork (interviews and survey) conducted in the Vietnamese province of Quang Nam in 2011. The political institutions in place appeared to impede on communal political access resulting in a lack of devolution of power and a technocratic bias in local disaster management. The Vietnamese case will be contrasted to India where the political system at the local level is pluralistic and highly competitive. Still, however, the lack of political access among the

most vulnerable groups had strong adverse effects on the local government's response. The case will draw on fieldwork conducted in 2007 of starvations deaths in a village in West Bengal. The extensive politicization of local governance, where public policy beneficiaries are selected per political affiliation rather than need, undermined political access for marginalized groups in the village during the food crisis.

Vulnerability and Resilience to Natural Hazards: A Double Edged Sword?

Erin Joakim (University of Waterloo)

Within the context of communities affected by natural hazards, reducing vulnerability and increasing resilience has been identified as a key strategy to reduce the risk of future impacts of hazardous events. While researchers have identified that some relationship exists between vulnerability and resilience, there is some discrepancy in defining the nature of this relationship, particularly within the context of recovering communities. Some argue that vulnerability and resilience are the positive and negative aspects of a singular concept that can be represented along a continuum (see Berkes, 2007; Birkmann & Wisner, 2006; Barnett, Lambert & Frey, 2008), while others argue that the nature of the relationship is more complex (Doberstein, 2009; McGuire & Cartwright, 2008; Cutter et al., 2008). The complexity of the relationship between vulnerability and resilience can also be observed in contexts where increased resilience can lead to increased vulnerability (Gunderson, 2010; Doberstein, 2009). This research project explores the complex relationship between vulnerability and resilience through a case study of the recovery of specific villages after the 2006 Yogyakarta, Indonesia earthquake event. In-depth interviews with affected villagers, government officials, NGO practitioners, academics and other stakeholders were conducted in order to provide an understanding of the various issues and concerns related to vulnerabilities and resiliencies in the recovery process. This place-based approach provided an inherently geographic focus on discrete communities whereby local vulnerabilities, resiliencies and livelihood strategies were placed within the context of larger scale social, economic, political and institutional processes. This helped to provide an understanding of the actors impacting varying degrees of vulnerability and resilience among affected communities as well as the methods for strengthening resilience to future disaster events. The results demonstrate that the relationship between vulnerability and resilience is neither linear nor simple - in fact, the relationship was found to be more complex than originally anticipated. Various

indicators of vulnerability can have both positive and negative feedbacks on aspects of resilience. This paradoxical relationship was seen in many areas, including experience with hazardous events, strength of government institutions, faith and religious beliefs, education levels, income levels, and strength of local leaders. This indicates that the relationship between vulnerability and resilience is difficult to define and may be highly dependent on the local context.

Factors of local vulnerability – Reflections from participatory exercises in Africa and Asia

Stefan Kienberger (University of Salzburg)

Community-based disaster risk reduction programs are widely implemented in different developing countries through NGOs and donor organisations. Many of these programs focus on early warning or improve response and relief capacities at local levels. However, vulnerability reduction is also key and has been targeted through different programs. Within this paper, experiences gained on vulnerability factors identified at the local level through participatory methodologies will be discussed and methodologies integrating novel mapping approaches will be presented. The following three key questions will guide the outline of the paper/presentation: ****What are specific factors that determine the degree of vulnerability and resilience among disaster-affected communities?*** A methodology has been developed which aims to map vulnerability at the community and district level. For the identification of suitable indicators, experts but also local communities have been consulted in a participatory manner. Their inputs have been integrated through brain-storming and weighting exercises. Initially the methodology was developed in Mozambique, but has now been applied in different communities in Bangladesh, India, Malawi and Madagascar mainly in the context of floods. Results and experiences from this 'global' assessment of local communities' perceptions on key vulnerabilities will be presented and critically been discussed. Commonalities and differences will be explored and related site-specific drivers identified. ****How can external expert knowledge and local wisdom and experience be creatively combined to enhance communities' preparedness for natural disasters?*** As stated above, the identification and weighting of these factors was further integrated into maps. Community maps have been produced in the above mentioned case study areas based on participatory mapping with satellite maps. In a second attempt, the identified factors were represented as indicators and weights applied to map vulnerability on the district level. In this context the specific role of 'maps' - as expert tools - will be discussed and how they are integrated into

local level planning. Recommendations are built on the case studies in Africa and Asia, but in-depth analysis will be provided on the Búzi case study in Mozambique. **Which theories, conceptual frameworks and methodologies can inform vulnerability assessments at the community level?** As a final question the usability of frameworks arising from the academic community will be explored and how they have been applied in these local case studies. An essential conclusion here is that, the frameworks mainly guide the assessor and less the local users. However, a clear agreement on key terms is required which all involved parties need to agree on.

Chair: Andreas Neef, Rajib Shaw

Perceived Coastal Distress and Psychological/ Behavioural Resilience to Climate Change in Tsunami Affected Andaman Islands of India

Ruchi Mudaliar (BSSS College), Parul Rishi (NITTTR Bhopal)

Islands are examined due to their increased importance and their increased vulnerability to climate change related hazards. Out of the several projected impacts of climate change in India, coastal zones are apprehended to suffer the most devastating effects. India has been identified as one amongst 27 countries which are most vulnerable to the impacts of global warming related accelerated sea level rise (UNEP, 1989). Climate change in islands is associated much with stressors related to flooding, sea-level rise, land inundation, storms, cyclones etc. The high degree of vulnerability of Indian islands can be mainly attributed to frequent occurrence of cyclones and storms. Most of the people residing in islands are directly dependent on natural resource bases of coastal ecosystems. Any global warming-induced climatic change such as increase in sea surface temperature, change in frequency, intensity or tracks of cyclones, sea level rise may aggravate the potential risks to islands. New Delhi work programme (2007) to implement article 6 of the IPCC stressed six elements starting from education to training, public awareness, public access to information, public participation and international co operation. Under public awareness, a special effort to foster psychological/ behavioural change has been stressed. In view of this, a psychological assessment of Indian islanders' perceptions, stressors and resilience to climate change was conducted in Tsunami affected Andaman islands of India on a sample of 100 adult respondents selected through purposive sampling technique. Islanders' Perception to Climate Change Inventory (IPCCI) consisting of 26 items based on 5 point Likert type rating scale was used classified into different subsections like Climate Change Perceptions, Islanders' Distress, Coping/Adaptation and Psychological Resilience. Survey type research design was used and multivariate analysis of variance and correlational analysis were carried out. Results indicated respondents having reasonably good level knowledge of climate change related concepts. A moderate level of coastal distress was also being experienced by islanders, however, in spite of coastal distress, resilience was also found to be high indicating the psychological strength of the islanders of India to with stand all

odds as they were the people who experienced one of the first Tsunami of this geographic region. Results were discussed in line with human-climate interface and psychological variables in order to suggest the trade offs between individual, community and institutional responses to natural disasters so that resilience can be further promoted in islanders along with the Subjective Well Being(SWB) to overcome the anticipated distress from Tsunami like environmental events.

Social attitudes towards natural hazards in Southern Poland

Anita Bokwa (Jagiellonian University), Jaroslaw Dzialek (Jagiellonian University), Wojciech Biernacki (University School of Physical Education in Krakow)

Our paper discusses results of research on social attitudes towards natural hazards (flood, storm and landslides) conducted in 13 communities in Southern Poland. Several criteria were used to select places to be surveyed: objective degree of risk, prior experience of extreme events, size of community, strength of social bonds, social capital and quality of life. More than 2600 responses were gathered from the survey. Our main research questions were following: - does settlement size have an impact on social attitudes towards natural hazards, especially on mitigation behaviour? - are urban inhabitants less adapted to natural risks be upheld and do rural communities show more activity in the face of natural disasters? - how are attitudes differentiated according to the type of extreme phenomenon? - what are attitudes of communities recently affected by major natural disasters? - how do communities suffering frequent occurrences of extreme phenomena adapt to this situation? - are there differences between attitudes in those communities depending on how frequently they have experienced extreme phenomena? Three dimensions of social attitudes towards natural hazards were analysed: cognitive (knowledge and awareness of local hazards), emotional (feelings towards hazards, like concern and anxiety); and instrumental (actions taken in response to a potential natural disaster). A combination of these three dimensions produces various types of perception and behaviour towards the perceived hazard (Raaijmakers et al., 2008): ignorance when the local population is unaware of a threat and therefore develops no concern and takes no preventive actions; safety

Community Renovation after Natural Hazards: The Tao-Mi eco-village in Taiwan

Chien-Ping Lee (National Changhua University)

Geography by nature is about the relationship between people and land. Natural hazards happening everywhere remind us that the earth is fragile, especially so with intensifying environmental disasters in recent years. How societies perceive and respond to natural hazards continues to intrigue geographers hoping to improve the understanding and provide strategies for earth inhabitants. The second-deadliest quake recorded in Taiwan, the 921 earthquake, also known as Ji-Ji earthquake, was a 7.3 Ms or 7.6 Mw earthquake with 2,415 people killed, 11,305 injured, and US\$10 billion worth of damage. Tao-Mi, located right in the most damaged area at Pu-Li, central Taiwan, is a community successfully transformed into an eco-village in the aftermath of the disaster over the last decade. The study reviewed literature on cultural ecology, recorded memories about the 921 quake for Tao-Mi locals, explored the process of its rebirth and discussed its significance and prospects. The methods included field study, in-depth interview and discourse analysis. The Tao-Mi community has been developed into an eco-village of organic agriculture, environmental conservation, ecotourism and educational foundation through coordinated planning and reconstruction of governments, businesses, academics, and locals. Its achievements in local businesses, community living and ecological environment after natural disasters shed lights on the path of sustainable development. Key Words: natural hazards, cultural ecology, Tao-Mi Eco-village, sustainable development.

Greening the rubble and filling the gaps: Two community responses to the Christchurch earthquakes 2010-2012

Roy Montgomery (Lincoln University)

Since September 4, 2010 a series of earthquakes and aftershocks have shaken Christchurch, the third largest city in New Zealand, causing multiple fatalities and the destruction of much of the central business district. Large areas of residential housing have been condemned and it is likely that entire suburbs will become abandoned for several decades and perhaps permanently where future ground instability and liquefaction potential is judged too great. The rebuilding process is high on central and local government agendas since Christchurch and the surrounding Canterbury region are crucial to the national economy. The various programmes for recovery being developed at the present time rest principally on

funding from central government and the settlement of insurance claims. One of the principal challenges arises from uncertainties over insurance payouts and reinsurance, particularly in the private sector. To that extent it appears that Christchurch will be a city of demolition sites and vacant lots for the best part of a decade if not longer. Furthermore, although local and national Civil Defence Emergency Management systems have been activated during the most severe seismic events their response operations have not always reached those most in need as promptly as might be expected. Residents in a number of communities and neighbourhoods have thus found themselves thrown upon their own resources during the first days of major aftershock events. Because metropolitan infrastructure remains brittle and will require extensive repair and replacement over many years and despite some of the lessons learned in the civil defence and emergency response sectors local residents are now conscious that when disaster strikes they are still likely to have to fend for themselves under certain conditions. This paper documents and evaluates two specific responses to the Christchurch earthquakes. The first response is a community-based project called 'Greening the Rubble' which took root in October 2010 as the prospect of a central city of vacant lots and car parks worried a number of volunteers into action to temporarily cheer up empty public and private sites with pocket parks, native plant displays and cultural interventions. The second initiative is a different kind of 'gap filler' insofar as local communities are now drafting their own emergency response plans which seek to complement official civil defence planning arrangements. The 'Mt Pleasant Resilience and Response Plan 2012' is the first community-based plan to have been drafted to date. Both emergent responses are discussed in detail in the context of constantly changing and evolving hazardscapes and socio-economic and political conditions. It is argued that while conventional social capital theories apply these responses work also reflect a distinctly New Zealand improvisational 'can do' attitude.

Disaster Risk Reduction in Tourism – Insights from Northland, New Zealand

Susanne Becken (Lincoln University and Griffith University), Ken Hughey (Lincoln University)

Despite increased global interest in disaster risk reduction for tourism little research has occurred into how tourism can become an active participant in disaster management. The tourism sector is potentially highly vulnerable to disasters (e.g. extreme weather events), but at the same time constitutes an important resource for civil defence activities. Northland in New Zealand

provides an excellent case study of destinations that are highly dependent on tourism and at the same time exposed to natural hazards. The action research presented in this paper includes a broad stakeholder consultation process, an operator survey and a tourism workshop and culminates in the development of a bottom-up Visitor Incident Plan (VIP) for tourism in Northland. The key finding is that an integration of tourism into existing disaster risk reduction is essential for effective and efficient risk management. Further, previous experience with natural disasters, an existing network of tourism stakeholders, and strong leadership were identified as key factors in the one-year process. Details of the VIP will be presented in the paper.

Study of the 2006 Bantul, Indonesia Earthquake Damage Pattern Based on Geomorphological Characteristics

Dwi Wahyuni Nurwihastuti (Gadjah Mada University), Junun Sartohadi (Cologne University of Applied Sciences), Djati Mardiatno (Gadjah Mada University), Udo Nehren (Cologne University of Applied Sciences)

The 2006 Bantul Earthquake had created a certain damage pattern which needs to be scientifically explained. This paper is giving some scientific explanation from a geomorphological point of view. This explanation is mainly based on the current and the past landform distribution. The methods applied in the research are covering some techniques of detection of current and past landform distribution in the Bantul lowland. Remote sensing and Geographical Information Systems techniques were used for spatial analysis of both landform and earthquake damage distribution. Geophysical techniques were applied to simulate the characteristics of the unconsolidated geological subsurface of the current landforms. Moreover, some subsurface characteristics such as shallow groundwater table and soil properties were also recorded to measure their spatial correlation with the damage pattern. The current results show that the earthquake damage pattern tends to spatially follow the current landform distribution. However, in some areas the pattern is also affected by the past landforms. Of utmost importance for the interpretation of the damage pattern is the distribution and thickness of unconsolidated materials. The distribution of the relatively thin layer of unconsolidated materials can be detected through spatial arrangement of the current landform distribution. Keywords: earthquake damage pattern, geomorphology, unconsolidated materials

Post-Eruptive Lahars and Sediment-Related Disasters Following the 2010 Eruption of Merapi Volcano, Central Java

Danang Sri Hadmoko (Universitas Gadjah Mada), Muh Aris Marfai (Univ. Gadjah Mada Indonesia), Junun Sartohadi (Fachhochschule Koeln), Suratman Suratman (Universitas Gadjah Mada), Franck Lavigne (University of Paris), Rosalina Kumalawati (Lambung Mangkurat University), Gilang Arya Dipayana (MPPDAS), Afrinia Lisditya Permatasari (Universitas Gadjah Mada)

Merapi stratovolcano, Central Java (2965 m), Indonesia has erupted in 2010 and ejected about 140 million m³ of mixed nuée ardente and pyroclastic materials. The pyroclastic flows reached the distance up to 20 km from the Crater. Due to the presence of high intensity of rainfall downpouring the pyroclastic deposits at Volcanic Flanks, lahar become the major threat for the people living surrounding the volcano. Kali Putih, situated at southwestern flank of Merapi is one of the most threatened valleys in Merapi. Since 2010, more than 25 lahar flows occur at this valley. Our on-going research aims at (1) developing a comprehensive database of lahar occurrence and related disasters following the Eruption of 2010, (2) studying the lahar dynamics through multi-temporal database, (3) identifying the most important sediment sources zones, sediment transportation zones and sediment depositional zones and (4) determining the geomorphologic impacts of the lahar flows. A combination among remote sensing approach, geographic information system (GIS) techniques and field measurement has been applied in order to achieve the results of the research. Lahar database inventory showed that there were 116 lahar occurrences during the period of 13 months. Spatial distribution of lahar occurrences show that the highest frequency of lahar flow occurred in the Putih River, followed by the Pabelan River, the Gendol River, and the Boyong-Code River. The occurrence of the flows concentrates in the period from November to April with the peak events occur in January due to the highest amount of rainfall. The affected area of lahar has been mapped at the downstream area of Kali Putih. This zone is the most affected area due to the following reasons: (1) weak control of topography (flat zone and low gradient of riverbed), (2) low level of riverbanks, (3) the presence of the barrier in the valley (previous sediment and point bars), (4) low river capacity. A total of 582 houses have been affected by lahars with the damage levels vary from slight damage to total destroyed. Keywords: lahars, spatio-temporal characteristics, Merapi Volcano, Java, Indonesia

Ecological risk assessment of geo-disasters in Longnan mountainous area – a case study of Wudu of Southern Gansu

Jie Gong (Lanzhou University), Caixia Zhao, Heling Wang, Peng Sun, Yuchu Xie, Xingmin Meng

Mountainous areas are essential for sustaining the local human population and ecosystem function, but irrational human activities and geo-disasters can directly ruin the natural environment and disrupt ecosystem functioning. Ecological risk assessment (ERA) aims to estimate possible adverse effects of accidents or disasters with Uncertainty on ecosystems and their parts. Current ERA

practices, mostly focus on the likelihood of adverse effects on ecosystems of human-induced disturbance or pollution in the watershed, lake area and wetland. However, very little attention had been paid to landscape ecology and the risk estimates of geo-disaster in the mountainous area. The paper took Wudu as a case, a mountainous area with fragile ecological environment, frequent geo-disaster due to its particular terrain and rock conditions, to study the ERA caused by geo-disaster. This practice studied the effect of geological disasters in terms of landscape patterns on the environment in the mountain areas. Typical geological disasters (debris flow, earthquake, landslide) in Wudu and 6 land use types (forestland, farmland, grassland, water area, constructed and residential land, unused land) were selected as risk sources and receptors separately. Landscape index and vulnerability index were optimized as the evaluation indicator to calculate the landscape loss index, the distribution maps of main geological disasters was overlayed by GIS, then the integrated ecological loss index of every risk area was calculated. Finally, we got the spatial distribution map of risk condition of Wudu. The analysis results showed as below: firstly, the spatial difference of risk assessment was notable, the area of the first grade risk area was very small, the second, the third, the fourth, the fifth and the sixth grade risk area covered 12%, 21%, 12%, 17%, 38% of the study area respectively; secondly, the value of the ecological risk of the central and south area was greater than that in east and south part of Wudu, the high risk areas distributed mainly on the banks of Bailong river and partly in the north, the low risk areas distributed mainly in the south and east part of Wudu; Thirdly, human activities, land use types, terrain and vegetation cover on regional scale severely affected the ecological risk degree in Wudu.

Climate Change and Conflicts in Northwestern Kenya: Factors, Actors and the Way Out

Jürgen Scheffran (University Hamburg), Janpeter Schilling (University Hamburg)

Northwestern Kenya is shaped by pastoralism which is well adapted to the harsh climatic conditions. Yet, more frequent and prolonged droughts in combination with socio-economic developments and the availability of small arms have increasingly overwhelmed existing coping capabilities. Violent livestock raiding has become more deadly and destructive, particularly between the Turkana and the Pokot. I present preliminary findings from my PhD field research conducted in March and from September to December 2011 in Kenya. I interviewed all relevant conflict parties, including community members (raiders, pastoralists, elders, chiefs, and women) as well as governmental and non-

governmental representatives. Further I analyzed conflict records in conjunction with climate data to find that the conflict between the Turkana and the Pokot is driven by a complex interplay of different actors and factors. The major conflict causes are asymmetric. On the Turkana side the triple challenge of (a) reduced pasture and water availability caused by consecutive periods of droughts, (b) reduced livestock numbers caused by animal diseases and raiding, and (c) lack of adaptive capacities, has made raiding the only survival alternative other than relying on food aid. On the Pokot side where pasture and water is available, the accumulation of wealth, payment of dowry and the expansion of territory are found to be the strongest drivers for raiding. In the last part of the presentation I discuss potential approaches of conflict mitigation.

Coastal flood risk management in Jakarta, Indonesia

Muh Aris Marfai (Univ. Gadjah Mada Indonesia), Sukamdi Sukamdi (Univ. Gadjah Mada Indonesia), Danang Sri Hadmoko (Universitas Gadjah Mada)

As an archipelago country, coastal areas in Indonesia are considering as the most important area for regional and national development. Coastal areas provide many natural resources and very often as a meeting point of the economic activities such as logistic distribution, trade and industrial development. Many big cities are located on the coastal area such as Jakarta, Semarang, Surabaya, Makasar and Bali. Jakarta, one of the fast growing port cities in Indonesia, is currently inhabited by more than 9 million inhabitants. Proximately 40% of the area is low lying area and located below the sea level. Jakarta is subjected to regular flooding and coastal inundation, which was triggered due to various colliding human activities in the coastal area. This study aims at identification of the flood adaptation strategy and risk reduction program due to coastal flooding. Method of the research program is involving literature study, interview, and fieldwork observation. As an early stage of coastal flood research, this research used descriptive analysis to explore and describe the physical condition of the study area, the mitigation strategy as well as the action plan taken by government. The result revealed that the adaptation and mitigation strategy is unequally distributed among the structural and non structural. The formal institution relied heavily on the structural method, while most of the non structural methods were carried out by various NGOs and other stakeholder involved. Simple adaptation and mitigation strategy conducted by the community seems to be insufficient which leads to more impact on the environmental perspective. The current effort proposed by the national government including the structural measures and coastal defense yet being realized into practice and various obstacles should be addressed as future planning agenda, in order to reduce more losses due to the unavoidable event, entitled as flooding hazards. Keywords: adaptation strategy, coastal flooding, risk reduction, Jakarta, Indonesia

Potential impacts of surface water salt intrusion on urban water supply and irrigation in the Vu Gia Thu Bon River Basin, Vietnam

Viet Trinh Quoc (Environmental Engineering + Ecology), Lars Ribbe (Fachhochschule Köln), Harro Stolpe (Institute of Environmental Engineering and Ecology)

Salt water intrusion is a growing problem for coastal zones of Vietnam as for many other coastal areas worldwide. Climate change related sea level rise will probably pose an increasing pressure on ground and surface water salinity. This paper is assessing causes and potential impacts of salt water intrusion to surface water in the Vu Gia Thu Bon River basin in Central Vietnam. In the lower part of the basin surface freshwater resources play an important role as they supply over 1 Mio. inhabitants with drinking water and irrigate almost 30,000 ha of agricultural land. Factors determining salt water intrusion like river discharge patterns and sea level rise are analysed for current and future scenarios and time series of salinity measurements are discussed for the selected case study. Based on a comprehensive salinity hazard map developed for the lower VGTB basin, the potential impacts on drinking and agricultural water supply is analysed by applying GIS tools and analysis of intensity and frequency of salt water intrusion. The results show that the main water supply work of Da Nang city, the Cau Do Water Supply Plant, is not severely impacted by current levels of salt water intrusion. This may, however, change under future sea level scenarios. Irrigation schemes in the region are carefully investigated in order to determine water use mechanism and the potential impacts of salt water on agricultural production. Results show that around 1/3 of the total agricultural area in the region may be impacted by salt intrusion. The paper closes with discussing the limitations of the research and future research demand. Solutions regarding adequate strategies to cope with existing or future problems stemming from salt water intrusion are briefly described. Key words: salt intrusion; salt intrusion factors; irrigation, water supply quality, agricultural landuse; GIS; Vu Gia Thu Bon River Basin

Methodology of ecological risks and restrains assessment for resource-intensive industries (on example of Russian pulp and paper industry)

Maria Gunko (Institute of geography, RAS)

There are many approaches to risk and restrain assessment but few meet the objective of ensuring territories' security because of anthropogenic and natural

processes' complexity and uncertainty of emergencies. First we estimate restrains - can natural environment provide needed resources, then risk assessment - is the enterprise compatible with the healthy functioning of environment and population. Only with a satisfactory result in both cases the territory may be considered as a potential area for construction. Assessment of restrains. At the beginning one should calculate the amount of resources needed for enterprise's functioning, and then conducted an assessment of available resources of territory based on statistical data or by interpreting remote sensing data combined with cartographic modeling. However, both methods are best used together in order to verify information. Based on resulting data we may make predictions on the time period when the enterprise will be able to develop within the biological capacity of local environment. Risk assessment. From a mathematical point of view, risk is the expectation of damage for a time period: $M(D) = Q * D$, D - damage caused by disaster; Q - probability of emergency. To determine the probability of emergency situations mathematical models are used (such as representation of emergencies' flow as a Poisson stream of random events). Damage in financial terms, is assessed according to the formula for each component of geosystem: $D = V * N * K * K_s$, V - volume of pollutants emitted into the environment N - state fee for the discharge of 1 ton of pollutant K - coefficient describing the ratio of pollutant's concentration and standard maximum permissible concentration K_s - coefficient of geosystem's sustainability. The degree of sustainability to pollution was determined by the indexes that characterize: the rate of chemical reactions to convert organic and mineral substances in the atmosphere, hydrosphere, pedosphere; the intensity of material removal from geosystem with air and water currents. Based on the data compiled in series of maps, it's possible to trace the spatial differences in sustainability coefficient. The formula has been worked out during internship in Russian Research Institute of Emergency Situations and Civil Defense for the new methodic of financial assessment of environmental damage caused by emergencies at hydrotechnical structures. The above methodic allows to analyze risks and restrains, avoiding the factors that are impossible for long term prediction, as well as outdated amendments to ecological state of environment used in existing governmental methodologies. An important feature of this methodic is that it allows to estimate risks and restrains at the phase of a new industrial facility planning, so one is able to select the best site from an ecological point of view for enterprise's localization.

GIS-mapping for assessment of risks of groundwater use in Ukraine

Viktor Putrenko (Institute of Geography of NAS of Ukraine)

The main risks of groundwater use are associated with of anthropogenic pollution and natural content of toxic elements in water sources. Account of the special nature of water can prevent a negative impact on the health of local people. Therefore, mapping of geochemical anomalies of toxic elements content in water and risk assessment is an important task of complex research of territory. The main criterion for the risk of use natural waters is the maximum allowable concentration, the maximum concentration of a pollutant that does not cause adverse effects in the daily long-term effects on the environment and living organisms. The criteria for maximum permissible concentrations of the elements used by Ukrainian state standards and regulations. The basis for the study results were used for sampling of groundwater for the entire territory of Ukraine, which contain information about the content of uranium, arsenic and fluorides. The database contains an analysis of 6550 points uniformly distributed over the territory. According to the results of interpolation of data on the distribution of chemical elements were obtained by raster model, the statistical distribution of substances that have been classified according to the scales developed of legends. To map the risks have been developed rating scales based on a formal approach - comparing the data with the standards and subsequent allocation of categories of risk. The main categories are much lower than normal values, the average (about normal), elevated (above normal to 100 percent), high (multiple excess limits). Interpolation was realized by inverse distance weighting is inversely proportional to the size of the cell edge of 1 km. Further stage of research was the analysis of raster models. As a result of the analysis was to identify the main trends in the content of elements in the groundwater. The main reasons are geological factors related to the occurrence of rocks and climatic factors that determine the characteristics of migration of chemical elements. In Ukraine, were detected geochemical anomalies with elevated and high-risk groundwater use. The distribution of uranium in water due to deposits in the Ukrainian crystalline shield. Arsenic content increases from west to east of Ukraine. Individual values may exceed the standards in 3 - 4 times. Distribution of fluoride shows that they lack the west and the significant excess in the east. A combined risk assessment was to create a complex map of the methods of overlay anomalous zones of exceedance content elements. This was done in two stages. Selection based on raster models of polygons of values exceeding the standards and overlay them on a common map. Comparing this map with a map of settlements in Ukraine revealed the main territories and a population that

is in high-risk zones that are particularly increased in the zones of intersection of several geochemical anomalies.

RC 14-01 - New cartographies of risk and conflicts

Chair: Boris Michel, Georg Glasze

The emergence of counter-mapping practices in the Great East Japan Earthquake 2011

Yuichiro Nishimura (Nara Women's University), Toshikazu Seto (Ritsumeikan University)

The word of 'counter-mapping' is firstly introduced by Peluso (1995), which include the use of the modern mapping technologies including GIS for the indigenous community empowerment, and it designed to increase the power of people living in a mapped area to control the representations of themselves and to increase their control of resources (Peluso, 1995; Johnson, Louis and Pramono 2006). Though the word is mainly used for the practices in the rural community of developing countries, we would like to apply it to the critical mapping practices occurred in the huge disaster in Japan. The Great East Japan Earthquake on March 11th, 2011 has brought catastrophic damage in the huge area of Japan. In addition, the nuclear damages by Fukushima Plant of Tokyo Electric have diffused the radioactive materials on the wide range of the Tohoku and Kanto region. On this situation leads the various types of the radiation mapping activities by national government, local governments and the communities. The residents in the radioactive material diffusion area have started the counter-mapping practices. Such practices have begun because of the doubts of the radiation information by national/local government and have aimed to visualize the radiation levels of their living space. Such neogeographers made the detailed scale maps (like 1/500, 1/200, 1/100) against the small-scale map by the governments. On the other hand, these practices have faced some problems. Such mapping practices need to connect the measured radiation data to the location data and their geographical knowledge. They have to know how to use the Geiger counter; they have to know the use of GPS or location technics simultaneously. They also need the mapping and visualization methods by hand-drawn or GIS. Sometimes these methods are not fit to their geographical knowledge or imagination of the area. They also faced the problem of reliability of the information because measurement method is different and not standardized. They faced the issue of sharing and the comparing/estimation of the information. We discuss the possibility of user-made radiation maps for the daily living safety and the limitation of the sharing of the geographical knowledge in these disaster area.

'Ground truths' and 'digital echoes' – reporting into cartographies of crisis

Cate Turk (University of Erlangen-Nürnberg), Christian Bittner

Maps have long played a role as strategic instruments in times of crisis - both during armed conflict and in the management of catastrophic events. The technological innovations of the geoweb have introduced new cartographers and new types of maps to humanitarian organizations, emergency responders and political movements. In particular the possibilities of citizen sensors reporting in 'real time' from catastrophe areas and the ability to use maps to curate and broadcast information from multiple sources, both to affected areas and to interested parties around the world bring new dimensions to the social and political interactions that constitute a crisis. As part of a larger project investigating the political dimensions of these cartographies, here we call into question the nature of the information being contributed to these maps. While these new forms of mapping are lauded as successes of 'crowdsourcing' we look further into the mapped data, contrasting 'volunteered geographic information' with 'ambient' geographical information (Stephanidis et al, 2011). How much of the information in the maps are new 'ground truths'; and to what degree are these maps aggregating and re-presenting information available through other sources - resounding 'digital echoes'? Are they, by and large, mapping the views of an affected local 'crowd'? And are they being read as such? Taking a subset of maps of conflicts and natural disasters from 2011, we go on to consider how the data included (or not included) in each map works to create an imaginary of each crisis. Indeed what is and what is not mapped in these projects, shapes too our broader understanding of what constitutes a 'crisis'.

Risk mapping – the risk of mapping?

Nils Zurawski (University of Hamburg)

Security having become one of the major discourses lately, does also affect the use of cartography as well as its appearances. Such discourses open or covertly address issues of risk and conflicts. Mapping such risks, conflicts or general situations of insecurities is used to highlight the immediacy and poignancy of these - while discussing its possible political, social or legal solutions. Using cartography to these ends it should be asked whether such maps are merely illustrative or whether they produce the risks in the first place? Analysing the relation between the use of cartography and the portrayal of risk, I want to

reflect on the nature of the security discourses and how they are transported via maps, seemingly neutral, but in effect as a product of the very cartographies. I will show that the security discourses as well as the cartographies follow similar patterns of exclusion, division, threat in using such archetypical figures such as the (possibly threatening) alien/outsider/unknown or a terra incognita. Using and generating cartographies of risk and conflict has consequences on how spatial and social relations are imagined and hence spatial order is constructed. Far from being a simple tool of innocent illustration, the strategy of mapping remains highly political and hegemonic. Drawing from empirical research and theoretical work on mapping, surveillance, security and spatial perception I will highlight the interdependencies of cartographic strategies, risk and security discourses and try to develop possible counter strategies.

New approaches for mapping of natural, technological and social risks and the dangers of emergency in Ukraine

Viktor Putrenko (Institute of Geography of NASU), Leonid Rudenko (Institute of Geography of NASU)

In Ukraine, where 45.8 million people who survived the catastrophe at the Chernobyl Nuclear Power Plant (1986), the prevailing irrational economic structure and outdated technology in production, industrial and social infrastructure, the availability of chemical production with hazardous waste each year occur emergency different geographical coverage. Assessing the risks of their occurrence in different regions of the country is using different methods statistical and mathematical modelling and spatial analysis, including GIS-mapping. Modern GIS-mapping is based on the formation of map databases that are the basis for spatially distributed information presented on separate maps, atlases and geographic information systems. Combining traditional for cartography geographic modeling with database structures leads to the creation of a special type of models to identify the causes of the risks of emergencies. The main approaches, which are used in the Institute of Geography of NAS of Ukraine in the design of map databases, that are common standardization of information, the use of common classifiers, the use of uniform requirements for visualization of cartographic information. The main stages in the development of a cartographic database are: - Collection of factual information, using classifiers emergencies; - Geocoding and transformation of information for use in a spatial database; - The creation of the maps of the possible risks of emergencies; - Modeling capabilities of emergencies and their consequences by means of interactive mapping. The main advantages of map databases is multi scale and

ability to provide client spatial and attribute information. Using a single mapping object indexing system allows automated generalization of information and receive it at the national, regional or local level in the same coordinate system. This facilitates evaluation of the situation in the main managerial levels and allows the use of additional materials: satellite images, photographs and other referencing data. The database allows to realize the target selection of totality of objects in a given spatial or attribute-parameters. It is easily updated and integrated with the network resources. In this database can store the basic sets of thematic maps. The data can be promptly published in the Internet-based Web servers and free services such as Google. New approaches for mapping and modeling of various types of risks of emergency in Ukraine approved by the example of the model area of Vinnytsia region. Using the object information for each settlement of the region about various dangers (chemical, fire, radiation and other hazards) we have created a GIS model of the region, allowing to assess the risk of an emergency. Thematic layers were published on the based service Google Maps that allows any user to select data sets, get detailed information about objects and add your own information and comments.

RC 15-01 - Placemaking and guerilla strategies in contested public spaces

Chair: Martin Klamt, Martin Sondermann

The Negotiated City – An Approach to Deal with Public Protests and Resistance?

Frank Othengrafen (TU Dortmund)

The growing appropriation of public spaces by private developers and the increasingly authoritarian style of many local governments have provoked public protest and resistance among deprived groups and communities. As a result, conflicts around urban development, plans and projects arise in terms of social mobilization as recent developments, such as *Recht auf Stadt* (right to the city) in Hamburg, show. *Recht auf Stadt* is a networking initiative consisting of several smaller citizens' groups that exists since 2009. It criticizes the practices of local government in Hamburg with regard to (1) the sell-out of valuable inner-city urban real estate to the highest bidder, (2) the radical reduction of public housing, and (3) the dramatic increase of housing rents, particularly in former working-class city areas. Against this background, *Recht auf Stadt* claims that the city (a) should not be regarded as an enterprise follow exclusively an economic rationale but as a public body guaranteeing welfare services, and (b) should belong to all inhabitants, including different groups and neighborhoods, borders and spaces. Conceiving the city as a mosaic of socio-spatial configurations (Marcuse 2006), it is not only the financial powers, the real estate owners, the politicians or the media who are developing visions for the future of the city. In contrary and following Lefebvre's idea of 'the right to the city' (1967), every socio-spatial group obviously should have and, as *Recht auf Stadt* shows, wants its say on the future of the city. The idea of 'the right to the city' therefore raises the complexity of urban development and its related 'uncertainties' in form of public protests and resistance. The concept of the 'negotiated city' (Kesteloot 2002, 2005) could address these challenges, using the socio-spatial order of the city in order to unveil conflicts and institutionalize them into negotiations that potentially fulfill the right to the city. Cohesion, in this context, should be more understood as capacity to acknowledge the existence of different social and territorial groups present in the city, their diverse and sometimes contradictory interests as well as the capacity of these groups to organize themselves and for the city to create institutions in which these groups can confront each other and discuss about the city's future. It is the aim of this paper to (1) present selected

ongoing public protests in Hamburg and to summarize the consequences for (public) urban development in Hamburg, before (2) discussing the potential of the concept of the 'negotiated city' as a new approach to urban development: Is the negotiated city appropriate for Hamburg and other cities do deal with or to avoid conflicts? Which (planning) rationales and (political) institutions are necessary? Which consequences does this have for urban development in general?

From informal to formalized uses of public spaces – the integration of grass-root activities into the planning and development process of the former Tempelhof airport, Berlin

Ulrike Mackrodt (Humboldt-Universität Berlin)

In recent years, public spaces in (Western) cities have been characterized by an intensified citizens' use. These newly awakened claims for the freely accessible spaces in a city have led to a rising number of conflicts between the different urban stakeholders on how to use and design public spaces. As one consequence of this, the suitability of established participatory urban planning instruments has been challenged. The urban dwellers' wish for active participation in the placemaking process increasingly goes beyond formal opportunities of participation. It can be argued that the participatory interest of urban dwellers is more clearly implemented through their materialized and localized informal practices on-site than through taking part in public hearings or displays of planning blueprints. This mismatch between the planning authority's offers and the urban dwellers' demands for placemaking opportunities calls for the reconsideration of established planning concepts. In planning theory, though, this societal change and its theoretical implications have yet rarely been received. This paper therefore suggests a modified planning perspective on the relation between development and use of urban open spaces. Instead of imagining the citizens' use to be the end of a development process it can rather be regarded as a central element of this process itself. By including grass-root activities in the early stages of a planning process an assumably more accepted and just outcome of the placemaking process may be achieved. In a small number of cases, the need for innovative planning strategies has already been acknowledged by municipal authorities. In these cases, experimental planning approaches comprise - what until then had been - informal placemaking strategies by local citizens. In doing so, these grass-root activities are getting formalized and institutionally integrated into the planning process. The development of 'Tempelhof Park' in Berlin represents a prominent example of

this new type of planning. On the symbolic site of the former inner-city airport a park is being developed with the participation of so-called 'pioneer users': grass-root activities such as urban gardening and educational activities are carried out on designated lots inside the park. Drawing on performance theory, the paper seeks to investigate the potential of the pioneer users for obtaining a more publicly requested and accepted design for the new park than through other (predominantly discursive) participatory means. The author ultimately aims at conceptualizing a modified theoretical view on participatory planning that takes into account the new demands by urban dwellers for their public urban living environment. For this purpose, empirical data consisting of qualitative interviews with pioneer users, municipal planners and park visitors are being used as well as insights from participant observation.

Re-programming the city: alternative complex programs for public space

Christopher Rawlinson (Queensland University of Technology), Mirko Guaralda (Queensland University of Technology)

Cities have always been a vibrant nexus of people's desires, memories and activities. The coexistence of multiple functions in the public environment has been a constant in the preindustrial city. This characteristic has also been the driving element in shaping the design of public open space. Societies celebrate themselves on the public stage translating values and aspirations into the design of places as well as shaping the identity of communities through activation of space. Conflict has also been a constant in the urban life; dwellings, production, commerce and celebration have been competing for centuries in the use of space. Activities recognised as unhealthy have been relocated from the centre to the city outskirts, and with the increase in managerial concern for liability and the risk of social conflict between different social Actors; this process of expurgation has widened to include recreational activities. As a result of this segregation and isolation of key cultural generators, cities have become more controlled and sanitised environments. More recently, since 1980's, there has been a steady growth in insurgent tactics used by the public to express themselves in these sanitised environments. Guerilla Spatial Tactics and methods of Urban Hacking have dovetailed with both established counter cultures and more conservative representatives of the population, achieving their common desire for cultural generation (away from gentrified commercial culture) through alternative grass roots methods mirroring 'evolutionary' urban theories whereby small hidden changes and interventions in the socio-spatial genetic

code cause long term macro change, and eventual change in typology. Urban Hacking and Guerilla activities such as Parkour, Urbex and Guerilla Gardening demonstrate the public desire to generate culture within public space that is often non-conformist with the expurgating instruments of popular governance. In response to these instruments, urban hackers move through space identifying conflicts, circumventing adversarial exchanges, and presenting (even if only ephemerally) new realities in which culture is generated and expressed. The paper proposes, via a comparative study of guerrilla style activisms and other more structured urban social activators, alternative complex and integrated programming of public spaces allowing cultural generation instead of the expurgating policies of popular governance. The solutions proposed may not solve all pre-existing fears of spatial management, however they do reduce fear of conflict between members of the public and authorities, giving permission to urban activists, and simultaneously providing some limitations. Additionally, the proposals demonstrably create spatial activation and cultural production with resulting increases in public safety, education and health; as well as commercial, environmental and cultural sustainability.

Urban Square as a Contested Space: The Spatial Tactics of a Local Community in St. Petersburg

Elena Tykanova (St. Petersburg State University), Anisya Khokhlova (St. Petersburg State University)

In recent years St. Petersburg has rapidly developed into the arena where the competing social, economic and political interests collide. Uneven access of social groups to spatial resources and different potential of power and control over them make a reason for social tension. The dominant discourse of the elites on city development and planning often ignores the interests and values of the population. Alternative views on how contested urban spaces should be organized make the representatives of local communities consolidate and buck against the decisions of authorities. In the absence of effective legitimate means of struggle, citizens involve in protest activities, employ various tactics to contest the spatial domination of administrations and business elites and develop different modes of legitimization of their choices and actions. These spatial and discursive tactics are aimed both at the self-organization of local communities and at the presentation of their position to the authorities and the public at large. In our research designed as a set of case-studies we inquire how local communities in St. Petersburg struggle against the legal and symbolic privatization and commodification of public spaces. In this paper we focus on

the history of protection of one of the city squares - square of Courage - against the construction of a bistro and a shopping center. To analyze the modality of the community's actions, we follow A.Hirschman and distinguish between exit (attempts to change the delegate subject of decision-making); voice (declaration of discontent addressed to authorities, mass-media, NGO-s); and loyalty (passive acceptance of any top-down initiatives). Under the threat of spot construction of a commercial area just in front of the residential houses, the majority of locals chose loyalty option seeing the public space of the square as lying beyond their responsibility or opting for stowaway strategy. The exit mode was unavailable for the small action group who had no property rights to the square other than symbolic claims. Instead, activists used a wide range of actions within the protest mode: talk-ins, planting flowers in the place of future construction and even laying the foundation of a monument to the defenders of Leningrad in the WW2 after whom the square had been named. The representatives of the local community also applied numerous legitimizations of their activities that we describe through the perspective of sociology of critical capacity. Moreover, they persistently referred to history and memory of the area (events of the WW2, heroic defense of Leningrad, tragedy of the Blockade) that don't directly fall under 7 orders of worth as distinguished by L.Thévenot and L.Boltanski. They turned history and memory into effective resources of solidarity and protest and managed to symbolically re-appropriate the public space of the square and defend it from commercial build-up.

Chair: Martin Klamt, Samuel Mössner

Place-making processes and new forms of urban belonging in a central neighborhood of Madrid

Eva Youkhana (Interdisziplinäres Lateinamerikazentrum), Christian Sebalý (University of Bonn)

Madrid is undergoing an urban transformation process. Economic growth primarily backed by the real estate and service sectors has introduced the city as an international hub for business and commerce. To demonstrate the new centrality neoliberal urban governance strategies such as revaluation and progressive tertiarisation transform the historic city center to an arena for consumption, urban spectacle and tourism. At the same time demographic pressure and segregation reconfigure the dynamics of the socio-spatial urban fabric. The socially marginal working class neighborhood Lavapiés is one case in point. The construction of cultural institutions, rehabilitation projects, redesign of the public space and control of communal places foster the image of Lavapiés as a cultural destination and provoke changes in social tenancy, as well as gentrification and displacement of low endowed people. As a consequence the replacement of traditional structures and conventions provoke resistant spatial practices and make Lavapiés a highly contested space. To counteract rehabilitation programs to commercialize and control the city and thus repel heterogeneous urban livelihoods street and action art is increasingly used to symbolically re-appropriate the urban space. As such, street and action art is part of a creative guerilla strategy and has become an important resource for those who are widely excluded from hegemonic social, political, cultural and economic participation. Alternative cultural expressions are nowadays synonyms for the countervailing power of the subalterns. This was nicely documented at the example of the symbolic re-appropriation of North American cities since the late 1960s through Graffiti. While Graffiti has been used mainly by young artists to allow for the articulation of political and other forms of self-manifestations, there are nowadays different forms of street and action art used by activists and migrant groups to escape from voicelessness, to articulate exclusion and the

lack of rights and access to resources. By that means new forms of urban belonging beyond normative categorisations of social difference are produced, and citizenship is enacted by those who are not wanted to be seen by the polity. Giving the example of different initiatives and events jointly organized by activists, migrant and neighborhood groups in Lavapiés it will be shown in how public spaces are produced and places are made notwithstanding the municipal clearing and displacement strategies. It will furthermore be shown that people in search for justice produce place based belongings that are situated and dynamic rather than essentialistic.

Material and symbolic spaces of conflicts: caring for Cova do Vapor, Portugal

Margarida Queirós (University of Lisbon), Mario Vale (University of Lisbon)

With neoliberal restructuring in the 1980s and throughout the early 2000s the conditions of transforming urban places changed dramatically, strengthening urban competitiveness and weakening social support, thus making visible socio-spatial conflicts. The arena of disagreements happens in the physical level as actors claim to improve conditions of living, guarantee quality of public space, the right to the city and increase development and also, in the subjective level, as it changes urban narratives which takes neoliberal projects as given (Kohler and Wissen, 2003). The aim of this paper is to highlight the role of different actors conflicting for a specific place, in this case Cova do Vapor - a small beach neighbourhood situated at a borderland that was built simultaneously by the river Tagus and the Atlantic Ocean, located in the south bank of the Lisbon Metropolitan Area (LMA) - which has an enormous potential for urban and tourism highly profitable projects, which is until now occupied by families without significant financial resources some of them descendants from the original settlers. We emphasize the influence of local actors and power relations with other stakeholders who see that place as strategic and profitable for other land uses whereas others see it as a special reference of the Portuguese culture and organic architecture. In this paper we study the urban conflicts at Cova do Vapor, a former summer neighbourhood with a fishing community living in mobile wood houses that is today part of the LMA and became a permanent housing and a summer and weekend residence area, with about 350 popular, small, and cosy houses. This place has an allegedly illegal origin as the land ownership is private and was occupied by the residents and expanded during the 1974 Portuguese Revolution. The mounting conflict between landowner and residents association has been mediated by public authorities and ONG,

although with different strategies and approaches. Recently two architects with their students installed the 'TISA pilot project', i.e. The Informal School of Architecture in Cova do Vapor. This innovative project, which adopts the concept of organic architecture, created by the people according to their daily needs, has found its strong expression here and Cova do Vapor gained a new legitimacy through academia and research. In an unconventional way, TISA's intervention came to play and perhaps, amplify the adaptive and creative solutions of the population and offered a real opportunity to legitimate the neighbourhood, the meaning of the place and the value for Portuguese culture. In the paper we conclude that Cova do Vapor, a popular and precarious neighbourhood, a place of everyday life, shows why neoliberal urban planning is 'intrusive and blind' to the local communities and how different power relations and alliances shape everyday life of a small but proud community.

Strategies for revival toopkhaneh square in tehran as a public space

Leila Shahbazi (Bauhaus university)

In addition to rare aesthetic values, historical contexts have a value of maintaining collective memories and identifying our cities. One of the values in social topics is the discussion of maintaining a cultural memory in a historical context. A memorable urban context is indicative of the identity of that context. In fact, the identity is nothing except a collective memory of individuals, and a city without memory lacks identity. Considering that hidden values in old contexts are the main factors identifying these contexts, their recreation requires full knowledge of values and a way they identify the context. Urban space as a place of occurring social phenomena is an integral part of collective memories. While we see the space as an open and abstract range, the place is part of the space occupied by a person or thing and has a semantic and valuable load. Memories that have shaped in the past and are flowing in the collective memory of a city, give a historical identity to the urban space. An old urban space loses its efficiency gradually as a context of social interactions and collective representations and this leads to stopping a person's communication with the urban space and fading the collective memories away. Each historical district where a successful revival operation is conducted socially in is an attractive and appropriate place for staying and going: streets are full of people and wrongdoing and crime rate has also been reduced in them. By the presence and use of people, spaces are converted to a place. Urban spaces should be revived by people's presence, and for this revival, it should also be planned. As a result, an improvement in historical context requires its social revival next to physical

one. In this article, Toopkhaneh (Cannon House) Square of Tehran is taken into consideration as a case study and a live urban space since its formation until today. The square had a special credit in ancient times, and now it is also regarded as one of the busy and valid squares in Tehran. The square was established in 1281 of the lunar year; it was the place to fire cannon balls in official ceremonies and also dawns of Ramadan; hence, it was called Toopkhaneh (Cannon House), but Toopkhaneh square during its life period until today has witnessed many scenes that the most important was Sheikh Fazlollah's execution in constitutional period. The purpose of this article is to provide an appropriate solution for maintaining urban memories in this square and to utilize the space optimally with regard to its plentiful capabilities in the process of active urban life of today and also changes made in it; the solution that neither removes a memory nor eliminates its historical identity.

RC 16-01 - Power struggles – energy systems governance and conflict

Chair: Johannes Hamhaber, Günther Weiss

Leaving NIMBYs behind – Uncertainty within space-related conflicts over offshore wind farms in Scotland and Germany

David Rudolph (University of Edinburgh)

Offshore wind farms are widely considered to become a cornerstone of energy transition for securing the energy supply and tackling climate change simultaneously. But recent developments have demonstrated that offshore wind farms are far from being conflict-free, evoking confrontations with other stakeholder interests. Drawing on comparative case studies in Scotland and Germany, this paper addresses and explores various conflict lines emerging from the installation of offshore wind farms and contesting local community interests and concerns. Local resistance against wind farms opens up a vast debate about the constitutive origins of the opposition which have previously been framed by NIMBY portrayals that are now rather denounced as being too simplistic, uneducated and parochial. Such considerations may point towards the appearance of locally rooted oppositions but do not provide profound explanations due to obscuring underlying rationales. By going beyond the stigmatisation of NIMBYism, the notion of space-related conflicts is intended to turn the attention towards conflicting interests and values that are aimed at space. This does not imply that such interests can be simply located at a certain 'space', but that these interests rather involve a spatial dimension in terms of representations and appropriations of spatiality. Conflicts over the development of renewable energy facilities manifest through practices stressing socio-economic and environmental impacts that are supposed to be disruptive to people and to what is regarded as 'nature'. However, it is argued that these refer to uncertainties and claimed truths that are under negotiation during the planning and licensing processes. Hence, this notion rather points to discursive representations and assumptions of potential impacts which are supposed to be particularly informed by strategic spatial constructions in the sense of 'geography-making'. While mostly reproducing discourses that are likewise applicable to and may coincide with those stemming from controversies over onshore wind farms, local opponents to offshore wind farms draw on specific narratives in order to justify and legitimate their stances. This paper explores the story lines local actors (re-)produce to cope with and overcome various conflict

situations. In doing so, a framework reflecting on structural, subjective and spatial components of conflicts is suggested to illuminate the rationales hiding behind an alleged NIMBYism. It will be shown that oppositional story lines are, to a certain extent, related to uncertainties, risks and insecurities evolving from planning and participation structures and societal negotiation processes of spatial and economic impacts.

The tensions in sustainable energy discourses: Civil society, regionalisation and uneven development in Southeast Asia

Mattijs Smits (University of Sydney)

This paper analyses how tensions in discourses of sustainability play out in the context of the ongoing energy transitions in Southeast Asia. While discourses on climate change, renewable energy and sustainability transitions are increasingly thought of as global and homogeneous in global media and academia, their meaning and traction in different countries, scales and contexts are often quite different. There is a need to understand the tensions and complexities of these discourses to influence thinking about more equitable and sustainable energy futures. This paper analyses two tensions that exist in discourses on sustainability with reference to Thailand and Laos, two neighbouring countries in Southeast Asia. The first tension relates to the different levels of civil society involvement in shaping energy debates. In Thailand, civil society opposition to some large power projects has led to the cancellation of some controversial projects and resulted in some of these projects moving across the border into neighbouring countries such as Laos. Laos, on the other hand, has limited space for civil society expression and discourses of opposition and sustainability have mainly been institutionalised through development projects and have limited traction in government organisations and everyday life. As such, uneven development of civil society shifts the problems of sustainable energy development to different geographical locations, thereby exacerbating domestic and regional inequalities and increasing potential for conflicts. A second tension can be found between sustainability and increased regional integration. The key motivations for regional integration initiatives of regional actors such as ASEAN and the ADB are linked to infrastructural connectivity and power trading in the region. This regional dimension further complicates development of sustainable energy futures in Laos and Thailand, as these initiatives are usually geared towards facilitating private investment and often only pay lip service to the discourse of sustainable energy and potential social and environmental impacts. This paper provides a geographical insight into the tensions in the discourse of

sustainability brought about by transitions in the electricity sector, drawing on multi-site and multi-scale fieldwork on energy projects in Thailand and Laos. It challenges the implicit assumptions that global discourses, such as on climate change and sustainability, have a similar meaning at different scales or can 'trickle down' through global structures and initiatives. Instead, this paper proposes an alternative framework in which assemblages of actors engage with the challenges of energy, development and sustainability on different scales in non-linear and conflictual ways.

Local energy transition framed by international climate regimes and national energy regulation

Sybille Bauriedl (Universität Kassel)

Transition from a fossil to a renewable energy system seems to be a great solution for many problems of multiple crises. It is the solution for the peak oil crisis (by substitution of fossil resources), climate crisis (by low carbon economy), global economy crisis (by new fields for accumulation), crisis of distribution justice (by decentralized access to energy), crisis of local finances (by regional value creation) and it is the alternative of the majority after a changed risk perception for nuclear power after the Fukushima disaster. Energy transition linked with a green economy discourse might be a good strategy to stabilize the industrial-capitalist complex, but the implicit paradigm of growth seems not to be the best solution for global climate mitigation or global social justice. As long as the idea of decoupling growth and resource consumption is not reality, a sustainable energy transition must be connected with a socio-ecological transformation. The paper presents case studies on actor networks and governance formations of German renewable energy municipalities and their multiple interests to realize an energy transition by decentralized renewable energy production and supply. This transition creates a changed set of actors at the local level. New promoters of local energy policy are real estate owners, wood land owners, citizens, farmers, and regional financial service providers. Do these local actors create governance innovations within a multi level energy policy? And does more participation in political and economic processes result in a higher acceptance of energy transition? Or is the economic instrument of the national government by gratification for feed in of renewable energy the powerful framing of local governance? I will discuss these questions with the perspective of a critical political ecology, which analyses socio-economic and ecological conflicts, mechanisms of power relations and politics of scale. The framing of energy transition by energy security discourse, green economy

discourse and mitigation discourse is linked by a rescaling of the responsibility for mitigation by a low carbon energy economy to a regional level. This regionalization of energy transition is connected with many local land use conflicts like the extension of covered area for renewable energy (photovoltaic and biomass) in conflict with food production, renewable energy plants (wind power) in conflict with environmental protection (e.g. birds), health protection (e.g. noise and shadow), and electricity grid expansion in conflict with landscape protection (for tourism and recreation). These local conflicts of energy transition can be analysed as results of a politicized ecology and of socially constructed scales of mitigation strategies.

Postfordistic energy policies? Desertec and the reregulation of energy supply between Europe and North Africa

Thomas Schmitt (Max-Planck-Institute for the Study of Religious and Ethnic Diversity)

In 2009 the Desertec Industrial Initiative (DII) was founded by several, predominant German enterprises including the NGO Desertec Foundation, a kind of spin-off of the Club of Rome. The objective of DII is to organize the conditions for the realisation of the Desertec idea, which aims to supply, in a large scale manner, Europe with electricity produced in solar power plants in North Africa and the Arabic peninsula. The Desertec concept is playing with and combining different myths as the desert, the large-scale/"megatechnic" vision and the reconciliation of the North and the South. Critics of Desertec argue that the project has the intention to impede an energy transition towards decentralized energy structures in Europe and that Desertec has a neo-colonial attitude. Both the Arab spring and the disaster of Fukushima have changed the discursive landscape and the institutional conditions around the realisation of Desertec. The paper presents the ideas and current realisation of the Desertec project, and analyses central arguments of its protagonists and antagonists. It raises and responds to the question, if Desertec can be seen as a fordistic or a postfordistic project according to the categories of the French regulation school.

RC 17-01 - Resettlement and relocation as a hazard prevention strategy

Chair: Jürgen Pohl, Swen Zehetmair

Resettlement after disasters: Reducing hazard exposure – increasing susceptibility?

Jörn Birkmann (United Nations University)

The international Displacement Monitoring Centre (IDMC) and the Norwegian Refugee Council (NRC) underscore in a recent study published in 2011 that in 2010 the number of people displaced due to disasters caused by natural events, were over 42 million people with highest numbers in Asia (see IDMC and NRC 2011). The paper focuses on vulnerability dynamics due to resettlement, but with a specific focus on resettlement after disasters due to environmental change and natural hazards. In this regard resettlement is often conducted by country governments with the intention to reduce disaster risk. Resettlement in the framework of Disaster Risk Reduction (DRR) involves a complex planning process similar, but not identical to development induced displacement and resettlement (Correa 2011; Oliver-Smith 2009). While a large number of past research projects focuses on the effects of resettlement due to development projects, less research and vulnerability assessments have dealt with the various consequences of resettlement due to natural hazards. The question of dynamic changes of vulnerability of those who resettle and those who are staying in areas highly exposed to natural hazards is also less examined. Against this background the paper examines consequences and dynamic changes of vulnerability due to resettlement in disaster hit areas in Sri Lanka after the Indian Ocean Tsunami in 2004 and on flood exposed rural households in Vietnam. The comparison of resettlement strategies and processes provides insights on how different social groups are coping and adapting to the new circumstances introduced by the disaster event and the relocation processed thereafter. Conclusions on how to improve resettlement processes in the future which are likely to become an even more important topic in the light of climate change are formulated.

Community Relocation as a Flood Mitigation Measure in Germany

Thomas Kox (Freie Universität Berlin)

In times of severe flood events much needed support is often provided by authorities and private organizations. However, the aid contributes to future flood related problems, as pre-disaster situations are recreated. Relocation is seen as a measure to break this so called 'Disaster-Damage-Repair-Disaster-Cycle' (Tobin&Montz 1997). It lies within the context of preventive strategies of risk reduction and can be seen as a form of land use planning, since the final aim is to reduce the communities' exposure to flood risk. Affected communities and their residents should thus be protected against the recurrence of flood events by relocating their houses to non flood prone sites. Hence it is the most radical flood mitigation measure, and by eliminating the exposure by 100% the most effective as well. Although resettlement is well known in Germany in terms of open-pit mining (e.g. Rhineland), it is not widely used as flood mitigation measure. By following the paradigm of natural hazards research (White, Kates, Burton) and the concept of natural risk management (Hollenstein, PLANAT), the study focused on the two major relocations in Germany so far: Röderau-Süd, a town situated on the Elbe, and Moos, a village situated on the Danube. Both had been struck by serious flood events in the past. While the latter was relocated shortly thereafter, the relocation of Moos is still in progress. Even though relocations are seen as case-by-case decisions, some general requirements to the implementation and the success of a relocation effort can be set out, if specific local characteristics are taken into account: Most important requirement is the acceptance by the affected population. Without this a prevention measure on voluntary basis cannot be implemented, especially since legal foundations are lacking and no suitable precedents are available. The temporal constellation in the aftermath of an extreme event (window of opportunity), even not exclusively relevant to the implementation, favors to a large extent the feasibility of the measure since political support and financial resources are easier to acquire. The significance of a possible risk image is ambivalent. On one hand, the gained attention can lead to more of the mentioned support and money. On the other hand, the resulting fears of adverse economic consequences can lead to a negative attitude of local authorities and stakeholders towards the settlement. In addition the results pointed out, that in terms of a risk assessment the factor efficiency outweighs the mentioned extreme high effectiveness as the prior criteria. This is particularly true for small relocation areas. Here a resettlement can be more cost-efficient than, for example, the construction of a dyke, whereas the development of larger areas

are not meant to be restricted. Thus a general shift from the still existing supremacy of structural flood protection measures is not yet seen.

Vulnerability and Disaster Devastation of American Communities: Long-term Demographic Consequences

John Cross (University of Wisconsin Oshkosh)

Vulnerability of populations to disasters is a topic of growing interest among many hazards scholars and disaster planners. Cutter and colleagues (2003) developed a social vulnerability index that predicts how various geographic areas, initially counties, would respond to disaster losses. Their index has been refined and more widely recognized, and recently Esnard, Sapat, and Mitsova (2011) developed an "index of displacement vulnerability", considering long-term displacements caused by hurricanes. While the focus of these endeavors has been upon how well residents can respond to losses and how long they might be displaced, recent catastrophic destruction of several American communities by tornadoes and flooding raises questions about whether the places can recover. This paper looks at demographic changes that have resulted from devastating disasters in communities, many of which are in rural settings, throughout the United States. Communities that suffer catastrophic destruction frequently experience long-term losses of population, as their residents select relocation rather than reconstruction. Many communities suffer sharp drops in their populations immediately following major disasters, as shown by Gulf Coast settlements devastated by hurricanes and in Great Plains communities struck by tornadoes or floods. Some communities quickly rebound, while others continue losing residents. Seeking explanations of what types of communities suffer the largest proportional long-term losses of their populations, this paper looks at a sample of over seventy American communities that suffered destruction of, or major damage to, the majority of their dwellings between 1991 and 2008. Factors considered were the type of hazard event, the socio-economic and demographic characteristics of the devastated community, the pre-event size of the community, the long-term population trends before the event, and the proximity of the community to other similar sized or larger cities. Communities with younger populations typically suffered the greatest population losses, while those communities that grew in population during the decade of their destruction had pre-event median ages that exceeded the national average. Communities that were already losing populations, or were in counties losing population, before the disaster suffered far greater population declines than those that were growing. Losses also tended to be higher in communities

that lacked schools. Communities located in counties or parishes with higher social vulnerability indices were most likely to have moderate drops in population in contrast with those with the lowest social vulnerability indices.

People's perception of relocation due to natural hazards on the German North Sea coast

Daniela Siedschlag (Helmholtz-Zentrum Geesthacht)

It is a worldwide phenomenon that people settle in regions vulnerable to natural hazards. In regions of the Global South scenarios of relocation due to (natural) hazards are conceivable and often necessary. In Europe relocations in consequence of floods, avalanches, storm surges or other natural hazards are not a prevention strategy that is openly discussed by the responsible authorities and/or in civil society. Nevertheless, there are hazard prone regions in Europe and people live there. For this reason the discussion about relocation as a strategy to cope with hazards is relevant. It is not a technical or solely financial question if relocation is considered an option but also a question of perception, awareness and place identity which bind people to their homescape. Therefore, an analytical discussion of appropriate mitigation strategies to hazards has to include perceptual studies of the people affected. In other words: Are relocation strategies on the mitigation agenda of the people affected? In Germany, the North Sea coast, the North Sea islands and Halligen are such hazard prone regions. Heavy storm surges can cause dyke breaks and flooding of settlements, agricultural and industrial areas. Especially the consequences of climate change will lead to sea level rise and intensified storm activities in the North Sea region. The paper deals with the research question: - Do people - living on the North Sea coast - perceive relocation as a proper strategy to cope with sea level rise and storm surges? Furthermore, following aspects will be considered: - How do people - living on the North Sea coast - perceive the risk of sea level rise and storm surges? - Are they afraid of losing their 'Heimat'/homeland due to sea level rise and storm surges? The empirical case study is a quantitative household-based survey on the island Pellworm (500 households) and the North Friesland mainland (200 households) (Germany) and additional qualitative in-depth interviews. First results of the ongoing research will be presented and framed into the context of relocation as a voluntary hazard mitigation instrument. The results show that the people living on the North Sea coast feel connected to the sea in their everyday lives and are bound to this region. On the other hand the risk of storm surges is - particularly on the North Sea islands - omnipresent and people are aware of this risk. Insights into the

connection between people and place can lead to relevant information for the adequate management of potential relocation. One important aspect in the discussion about relocation as a strategy of risk prevention is to know about the perception of the people who would be potentially affected.

RC 18-01 - Risk governance in Southeast Asian cities

Chair: Javier Revilla Diez, Frauke Kraas

Nested response capacities to multiple risks in Vietnamese cities – Empirical lessons for advancing conceptual guidance on risk governance

Matthias Garschagen (United Nations University)

Risk landscapes in Vietnamese cities are not only highly complex due to the interaction of different types of risks but also very dynamic given the multiple socio-economic and political transformation processes as well as environmental changes. The importance of acknowledging overlapping exposures to multiple risks and their feedback relations has been emphasized in the literature (notably O'Brien et al. 2004; Leichenko and O'Brien 2008). However, it seems that this call for integrative perspectives is only insufficiently taken up by a large part of the current research on risk assessment. This is particularly true for the rapidly growing body of work on climate change impacts and the respective responses which often tends to treat climate change risk as if it emerged in isolation from other risks. In addition, when assessing the capacity of urban actors or institutions to respond to these risks, the differences but also interactions of coping vs. adaptation processes debated in the conceptual literature are often not considered as a backdrop for empirical analysis. Yet, it is argued here that considering these conceptual stimuli might provide valuable insight for enhancing knowledge on risk response capacities and eventually for improving risk governance. Against this background, the paper reflects on the usefulness of the above mentioned impulses for understanding risk complexes in Vietnamese cities and draws in particular on empirical research in Can Tho City, Vietnam, for a detailed case study analysis. Can Tho's population is heavily at risk from intensifying natural hazards but - often neglected - is also exposed to multiple other risks such as institutional insecurity with respect to land development and land titling, environmental risks related to pollution or heavy price fluctuations. Profiles and comparisons of risk cascades are therefore developed for selected socio-economic groups. This is argued to be beneficial not only for analytical but also policy communication purposes. The analysis further suggest to frame socially differentiated risk response capacity as a nested concept that combines elements previously ascribed in the conceptual literature to either coping or adaptation, i.e. combining for example short- vs. long-term response measures, spontaneous vs. planned measures, exploitive

vs. constructive measures, or measures targeting systemic conservation vs. systemic change. The empirical data allows in particular for discussing how these nested response capacities are influenced by other socio-economic conditions, and are hence socially differentiated. The paper concludes by discussing the implications of the empirical findings for improving risk governance in Vietnam's cities and beyond. In this context the need for a stronger integration of governmental and non-governmental risk response measures as well as for socially differentiated policy options are discussed. Future research needs are formulated.

Bangkok's Flood Problem: Local Vulnerabilities and the Role of Governance

Frederick Massmann (University of Kiel)

The severe flooding in Thailand during October/November 2011 impacted many northern provinces including the capital Bangkok and highlighted their vulnerabilities to external shocks. With more than 700 casualties, seriously disturbed livelihoods of millions of people and an estimated damage of US\$ 20 billion, this flood was the worst in terms of economic losses, the amount of water and people affected. In Bangkok, where the economic and population density is highest, the flood revealed political and social conditions which contributed significantly to the vulnerability of the megacity and thus to the dimension of the impacts. An understanding of the causal factors of vulnerability is crucial not only for the implementation of recovery plans, but also for building future resilience. Therefore this study analyzes the vulnerability through a holistic framework. A special emphasis is on the influence of governance, not least to contribute to a theoretical enhancement. Different governance modes are taken into account and are analyzed and classified accordingly. This paper examines two selected case-study areas in Bangkok. One area is an inner-city slum bordering the Chao Phraya River and the other area is a stream island in the northern suburbs. The underlying factors contributing to the vulnerability of the inhabitants of those areas are investigated, focusing particularly on the influence of governance processes and structures. Based on qualitative interviews the socio-economic and political conditions in the communities as well as the coping mechanisms and adaptation strategies are analyzed. Preliminary results show that the vulnerabilities are shaped by various interlinked factors which can be arranged in the above named three dimensions. The existence and effectiveness of community organizations, for instance, is closely bound to social networks within the community. Conversely a strong community organization

strengthens the social cohesion within the community by organizing common events and regular meetings. Furthermore it implements flood-adaptation measures on a local level like uplifting walkways and placing sandbags but it also negotiates for external help with the government and others. Accordingly a strong community organization is fostering resilience. The distribution of external help is criticized heavily by the local population as being unfair. Often aid packages and financial compensation are given to those in favour of the distributor. Another factor revealed during the data collection relates to serious conflicts regarding land tenure within the study areas. Many people exposed to flooding are living on governmental land without a legal status. This unsafe condition makes the occupants hesitate in applying adaptation measures to their houses or to the community respectively and hence increases their vulnerability.

Climate Risk Assessment of Urban Kathmandu

Ina Yanakieva, Udo Nehren (Cologne University of Applied Sciences), Simone Sandholz (University of Innsbruck), Jishnu Kumar Subedi (Department of Civil Engineering Pulchowk Campus, Institute of Engineering)

The presented study analyzes existing key environmental problems and regional climate trends in urban Kathmandu as a basis for assessing vulnerabilities and risks associated with CC. Over the last decades, Kathmandu, the administrative, economic and cultural center of Nepal, has been facing rapid population growth and urbanization. This development has led to severe environmental problems and inefficient urban infrastructure. Climate Change (CC) is expected to worsen existing environmental and sanitation problems in Kathmandu Valley (KV) and to increase the vulnerability of urban population to climate induced hazards. Research methods include the collection and interpretation of existing climate, hydrological and health data, survey in squatter settlements, expert interviews, field observations, and literature review. Analyzed temperature and precipitation data for a period of four decades revealed consistent and continuous increase in maximum and minimum temperatures in KV and a trend of increase in erratic and high intensity rainfall episodes. Furthermore, later onset of the monsoon and a trend of drier winters have been indicated. Potential risks associated with the observed changing climate have been identified, such as more frequent and severe flood and inundation events, frequent and extended droughts, and the introduction and outbreak of water and vector-borne diseases. Hydrological analyses have shown strong dependence of Bagmati River discharge dynamics on precipitation in KV and a correlation has been found between extreme rainfall and flood events. Chronic water shortage in urban Kathmandu is expected to

worsen with CC, posing the risk of growing water demand, decreasing groundwater recharge and groundwater depletion. Observed prevalence patterns of water-borne diseases, such as Infectious Gastroenteritis, Typhoid fever and Cholera in KV have shown clear seasonal disease dynamics with highest percentage of infections during the monsoon season. CC is expected to put extra stress on urban water quality in KV and to increase the risks of water-borne-disease outbreaks. Furthermore, it is expected to widen the range of disease vectors. Although vector-borne diseases are not yet considered a serious problem in urban Kathmandu, in the recent years the presence of Malaria, Dengue and Japanese Encephalitis in KV has been reported. A survey in squatter settlements of Bagmati and Manohara rivers in KV has revealed the high vulnerability of squatter population to present and future threats posed by CC. Living in poor housing in a hazard prone and highly polluted environment, depending on limited fresh water sources and having deficient hygiene practices, urban squatter dwellers are expected to be hardest hit by the negative impacts of CC. The study underlines the urgent need for improvements in the management of urban Kathmandu, which are essential for its resilience and adaptation to CC.

Spatio-Temporal Patterns of Crime in Association with Predominant Functional characteristic of areas - A Case Study on Urban Risks in Greater Mumbai, India

Chandrakala Joshi (K.P.B.Hinduja College of Commerce), Vinayak Phadke

The vulnerability of metro cities to crime is largely due to concentration of wealth, heavy unemployment, disparity in lifestyles, competition for sustenance, heavy population pressure on infrastructure and temptations perceived through mass media. This in turn leads to greater incidence of crime in urban metros. Crime related urban risks depend upon various socio-economic attributes including the functional characteristics of the area. The present paper offers a geographical perspective on crime by focussing upon the spatio-temporal patterns of crime in Greater Mumbai between 1996 and 2006. This exercise suggests that different functional areas are associated with specific types of crime. Upper class residential, Low class residential (with a mix of small scale industrial units), Commercial and Industrial areas were studied to find the relationship between the nature of crime and the predominant function existing in that area. Selection of study areas has remained purposive. Accordingly, four areas were selected as representatives of the types mentioned above. The secondary data was obtained from Crime Branch, Greater Mumbai. Number of cases registered

under IPC during the period 1996 - 2006 were investigated for each of the study areas. Since this information focuses primarily on the temporal pattern, intra-areal pattern was analysed by collecting data from the concerned police stations. Detailed information about the place, date and time of offence as well as information about the source area of the accused for the year 2006 was obtained by studying the crime records maintained by the respective police stations. The area wise and crime wise tabulation of data has brought together the crime of specific categories such as violence, property related, thefts, riots etc. This study has helped to appreciate the temporal pattern of crime, to locate the crime prone segments in the selected areas and examine the crime specialization in each of them. It is not surprising to find that with globalization and liberalization, the character of the city has changed and so also the ambition of criminals.

State-of-the-art and challenges of landslide susceptibility modelling at regional to continental scales

Miet Van Den Eeckhaut (Joint Research Centre, European Commission), Jean Poesen (KU Leuven, Department of Earth and Environmental Sciences), Andreas Günther (Federal Institute for Geosciences and Natural Resources), Jean-Philippe Malet (Institut de Physique du Globe de Strasbourg), Paola Reichenbach (Research Institute for Hydrogeological Protection, National Research Council), Fausto Guzzetti (Research Institute for Hydrogeological Protection, National Research Council), Javier Hervás (Joint Research Centre, European Commission)

Growing awareness of regional, national and international organizations has resulted in several initiatives fostering to identify, assess and mitigate the risks posed by landslides using scientific knowledge and innovation. Here, we present an overview of landslide susceptibility modelling at scales ranging from regions to continents, based on case-studies from Belgium and Europe. We mainly focus on the type of models, their validation and their use for regional and European policy making. Regional-scale landslide susceptibility assessments nowadays mainly comprise statistical modelling. Hilly areas of Flanders (northern Belgium) are affected by more than 330 landslides of various types. In these areas, we evaluated different statistical models among which stepwise logistic regression and discriminant analysis. Susceptibility maps produced from the logistic regression models, which can be freely consulted on the internet and which are currently used by the Flemish Government as an additional input map for land use planning and management purposes, have already proven their value. After presenting a short overview of national-scale landslide susceptibility assessments in Europe, we move to the continental scale, and present the ongoing activities of the JRC Landslide Expert Group in the context of EU's Soil Thematic Strategy for Soil Protection. This Strategy considers landslides as one of the eight main soil threats in Europe for which it is necessary to identify risk areas, i.e. areas where landslides are likely to occur in the future and where risk reduction measures have to be taken. Because of the wide variety of climate and physiographic regions in Europe, the continent was divided in seven climato-physiographic regions, and for each region a specific model was

produced. Both semi-quantitative (Spatial Multicriteria Evaluation) and quantitative (logistic regression) methods are evaluated using available Pan-European thematic maps of slope gradient, lithology and land cover as independent variables. Model calibration and evaluation are possible, because more than 110,000 landslide locations were made available by national and regional authorities from 18 European countries. Combination of the susceptibility maps obtained for each climato-physiographic region results in a European-wide landslide susceptibility map that performs significantly better than previous attempts of continental-scale landslide zoning. Finally, we conclude with some major challenges for future landslide susceptibility modelling at various spatial scales.

Landslide susceptibility maps and their importance for spatial planning strategies

Gilbert Pomaroli (Amt der NÖ Landesregierung)

Landslides are a major threat in the Provincial State of Lower Austria. They damage infrastructure, forests, agricultural land and settlements. Therefore, landslides besides floods have been of crucial importance within the spatial planning strategies of the provincial state. This is also manifested within the Spatial Planning Law of Lower Austria (1976). However, since no detailed information on spatial landslide threats were available, spatial planning could not work as effective as it should and as it does e.g. for flood hazards due to the availability of flood hazard maps. It will be shown how landslide hazards were and still are treated. However, in comparison with the flood hazard maps it became obvious that similar maps are needed for landslides. Thus, the project 'MoNOE' (Method development for landslide susceptibility modelling in Lower Austria) was initiated by the provincial government. The main aim is to prepare landslide susceptibility maps for slides and rock falls. For implementation into the spatial planning strategies, these must fulfil special requirements which encompass the optimal number of landslide susceptibility classes, the definition of meaningful thresholds for each class, the definition of recommendations for actions for each class and finally, the best colours for each class. These aspects were not only intensively discussed with the project partners carrying out the study, but also with representatives of communities and of the Austrian Service for Torrent and Avalanche Control. The project 'MoNOE' will be finished in early 2013, so that at the conference almost final results can be presented and discussed.

Landslide mapping, susceptibility modelling and infrastructure planning at regional and national scales within the UK

Hannah Evans (British Geological Survey), Claire Foster (British Geological Survey), Colm Jordan (British Geological Survey)

The combination of an increasing population density, abundance of relict landslides and a high proportion of failure-susceptible lithologies means that landslide research within the UK is paramount. New technologies are being used alongside traditional mapping techniques in a novel, multi-stage methodology for landslide mapping developed by the British Geological Survey (BGS). Variable-perspective 3-D topographic visualisation, 3-D aerial photograph interpretation and field mapping with digital data capture are all being utilised to accurately map the UK's landslides. These strategic surveys allow the BGS to better characterise and understand the country's landslides: an essential requirement for landslide susceptibility mapping, hazard assessment and infrastructure planning. Repeat monitoring of selected landslides using terrestrial LIDAR and dGPS and the formation of a proactive Landslide Response Team also help to maintain a nationally uniform, up-to-date National Landslide Database. Information derived from the BGS's strategic, repeat and responsive landslide surveys is used to inform a series of National Geohazard Assessments. These GIS-based assessments provide information on the susceptibility of the UK landmass to landslide activity, alongside a suite of 5 other geohazards. The information is used by government planners, insurance companies and utility operators as well as being made available to home buyers. This established susceptibility assessment technique has recently been further developed in order to allow asset managers to assess the susceptibility of infrastructure to landslides. In Great Britain the land owner has primary responsibility for ground instability and a duty to take measures to remove or reduce the hazards they may be aware of. With increased landsliding due to climate change forecast, management of assets with regard to landslides could become an even greater issue. The BGS landslide mapping and susceptibility modelling methodology is also suited to application in an international context and aspects of the processes have already been trialled in Madagascar and applied to Martian landslides.

Landslide Hazard Zonation Mapping of Umshing Micro Watershed using RS, GIS and GPS

Bijay Mipun (North-Eastern Hill University), Devesh Walia (North-Eastern Hill University)

Landslides constitute one of the major hazards that cause losses in lives and property. Landslides are one of the complex analyses, involving multitude of factors and need to be studied systematically in order to evaluate the hazard. Some factors are very much effective in landslide occurrence these are: slope, aspect, altitude, rainfall, landuse, geology, distance from fault, distance from roads and distance from main drainages etc. The present study is to investigate and analyze the different causative factors, which are responsible for generating landslide. The methodology used for the study of landslide zone is based on satellite data and GIS-GPS technique for Umshing micro watershed of Shillong. The location of landslide study is considered based on, lithological structure, vegetation cover, type of land use, slope angle, construction activities, river & waterways, altitude, slope aspect etc. The average annual rainfall of the state is 2599.84mm. Though the incident of cloudburst is not a common phenomena in North East India yet the areas which have higher altitude (1500m) are more prone to landslides. Especially, narrow valley, gorge, and lithology are some of the prime causes for landslide occurrence. Areas, which have low compact lithological structure are more prone to landslide. The study area is predominant of Granite, Gneiss and Ferruginous sandstone with Phyllite and Schist, therefore possibility of landslide occurrence is high. Due to the active seismotectonic phenomena in the region and creep in area of study, the Umshing micro watershed is prone to landslide. The earthquakes of moderate intensity which is a common phenomena creates new spots and gets generated that making the area more vulnerable.

RC 19-02 - Spatial landslide analysis and its implementation in spatial planning 2

Chair: Rainer Bell, Alexander Brenning

Landslide damage in hilly regions: A spatial and economic analysis from the Flemish Ardennes, Belgium

Liesbet Vranken (University of Leuven), Pieter Van Turnhout (University of Leuven), Miet Van Den Eeckhaut (Joint Research Centre, European Commission), Liesbeth Vandekerckhove (Flemish Government, Environment, Nature and Energy Department), Goele Vantilt (University of Leuven), Jean Poesen (KU Leuven)

Several regions around the globe are at risk to incur damage from landslides. These landslides cause significant structural and functional damage to public and private buildings and infrastructure. Many studies investigated how natural factors and human activities control the (re-)activation of landslides. However, few studies have concentrated on a quantitative estimate of the overall damage caused by landslides at a regional scale. Landslides lead to economic losses and both direct and indirect costs have to be considered. Societies are becoming reluctant to invest in structural measures that can reduce natural risks because of the high costs associated with these engineering and technical works. Instead, they tend towards the development of non-structural mitigation measures, such as land-use planning, regulation and building codes. If governments want to design proper policy measures to minimize societal damage due to landslides' occurrence, they need to assess the costs and benefits of different mitigation scenarios. As a first step, one needs to get a picture of the overall economic damage caused by landslides. This study therefore starts with a quantitative economic assessment of the damage caused by landslides in the Flemish Ardennes (Belgium), a low-relief region (area=700 km²) susceptible to landslides. Based on focus interviews and semi-structured interviews with homeowners, civil servants (e.g. from the technical services from the various towns), or with the owners and providers of lifelines (e.g. electricity and sewage), we have quantitatively estimated the direct and indirect damage induced by landsliding and this for a 10 to 30 year period (depending on the type of infrastructure or buildings). For example, in the last 10 year, costs of road repair augmented to 814.560 '. Costs to repair current road damage were estimated at 669.318 '. In the past 30 years, costs of measures to prevent road damage augmented to at least 14.872.380 '. To repair and prevent damage to

waterworks and sewage systems, expenditures amounted to 551.044 ' and this for the last 30 years. In the past 10 years, the cost to prevent damage to railroads augmented to at least 4.567.822 '. The value of real estate located in regions affected by landslides decreased with 15% to 35%. All these damage costs were then used to make potential damage maps. Based on the inventory of landslides frequency of landslides' re-activation and past land uses, we categorized regions that were affected by landslides in the past according to their temporal probability of landslide re-activation. This allowed us to produce a risk map for regions that were affected by landslides in the past. This paper shows that, though generally not spectacular, landsliding in low-relief regions susceptible to landslides is a slow but continuously operating process with considerable damage allowing one to identify several medium to high landslide risk zones.

Landslides hazard zonation in Jajrod river basin

Ezatollah Ghanavati

Jajrod river basin consist about 69683 hectares and located between 35° 45' N and 36° 50' N Latitude and 51° 22' and 51° 51' E Longitude. One of the most important reservoir that provide the water resources for Tehran (capital of Iran) with over 8 million population as Latian dam is situated in this basin about 10 km far from Tehran. It is more susceptible to landslide, mud flow, and other forms of mass movement. Landslide is one of the most natural hazard that causes damage to city and rural inhabit, cultural lands, roads, forest and so on. Therefore it is obvious that the landslide susceptibility mapping is very important for environmental management in this region. The objects of this study are: To study and assess the role of factors that affect landslides in Jajrod river basin. To present a quantities model to predicting potential landslides risk in Jajrod river basin. Provide the map of landslide risk mapping in Jajrod river basin. In this research 150 landslides by field study and air photographs was recognized and mapped. These landslides also pointed on 1:50000 topography map of the Jajrod river basin. Determining the effective factors on landslide in the Jajrod basin is the second stage of this research. Lithology, Slope, Slope direction, Land use, Distance to fault, Digital Elevation Model (DEM) and precipitation were the seven factors that studied and analyzed by using AHP model in GIS environment. The methodology of this research contains theses stages: 1. Reading data in Geomatic software. 2. Geometric and radiometric of images. 3. Extract NDVI of basin by ETM image. 4. Make Digital Elevation Model (DEM) by using ArcGIS. 5. Extract the slope, aspect, elevation, drainage map of basin by

using DEM. 6. Extract lithology and fault map by geology map of the basin. 7. Determination of weights of the factors by using analytical hierarchy process (AHP) methods. The result of this research represent that the AHP model is the suitable method for predicting the landslide hazard risk in this area. At the final the landslide hazard risk map of the Jajrod basin is classified in five class containing; very low, low, medium, high and very high hazard risk. In this classification about (62%) identified as high hazard risk in the Jajrod river basin. Keywords: Jajrod: Landslide susceptibility mapping: Analytical Hierarchy Process

Effects of preprocessing techniques on landslide detection based on high-resolution (HR) remote sensing data

Vincent Balthazar (Université catholique de Louvain), François Clapuyt (Université catholique de Louvain), veerle vanacker (University of Louvain)

Landsliding and accelerated erosion are common hazards in tropical mountainous regions around the world. Not only considerable financial costs are suffered, but also major ecological and environmental problems often arise in a larger geographical area. Land cover modification and conversion have clear impacts on natural disaster risks. Assessing the rate and spatial patterns of landslides is challenging given the ruggedness and the inaccessibility of mountain areas. Satellite data offer an inexpensive means of deriving complete spatial coverage of land attributes in a consistent manner that may be updated regularly. The aim of this study is to evaluate the efficiency of high spatial resolution (HR) satellite sensors to create regional landslide inventories. Detecting and mapping landslides over extensive areas is of great importance and cannot be accomplished by time consuming methods like point-based field measurements or aerial photographs analysis. HR satellite sensors with relatively high spectral and temporal resolutions might be considered for regional scale landslide inventories. However, the use of such data in steep terrain is highly constrained by topographical and shadowing effects that require appropriate and advanced pre-processing techniques. Preprocessing of remote sensing data commonly addresses atmospheric and geometric corrections, but rarely incorporates topographic corrections even though they are recognized as a major problem for quantitative analysis. To account for the effects of shadowing in steep terrain, we applied 3 levels of pre-processing techniques. The Ecuadorian Andes and Northern Vietnamese Mountains were selected as preliminary test sites, as these regions are facing rapid land use changes that are associated with an important number of mass movements. Multi-spectral

images have proven to be particularly effective for mass movement mapping, improving the 2D shape recognition of features particularly with processing techniques such as color composites, vegetation indexes, pan-sharpening, band arithmetic or principal component analysis (PCA). Landslide inventories are here created based on semi-automated detection procedures applied on 3 different levels of pre-processed satellite data. The performance of these techniques is evaluated quantitatively by comparing the semi-automated landslide inventories from high-resolution satellite data with ground-truthing data from very-high resolution (VHR) imagery and field observations. Our results indicate that the application of topographic correction techniques significantly enhances the performance of the semi-automated landslide detection in steep terrain.

Mass movement risk analysis and mapping in Pahuatlán, municipality of Puebla, México

Franny Murillo García, Irasema Alcántara Ayala (Institute of Geography, National Autonomous University of Mexico (UNAM))

Mass movement risk disaster analysis and mapping in Pahuatlán, municipality of Puebla, México. Very frequently, mass movement processes take place in the Sierra Norte de Puebla, Mexico. Different disaster events associated to such processes have occurred in 1957, 1999, 2005, 2007, 2009 and 2010 as a result of heavy rainfall or the presence of tropical storms and hurricanes. Therefore, recognition, analysis and mapping of the risk elements that determine the occurrence of mass movement disasters in this region, and particularly in Pahuatlán municipality, Puebla, Mexico, has been established as the aim of this work. Disaster research approaches have changed over nearly a century. First of all, a positive perspective was used for understanding their occurrence. Afterwards, in the seventies, the structuralism framework stressed the significance of vulnerability. As a consequence, current disaster approaches include tree basic concepts: hazard, vulnerability and risk. The estimation, assessment and treatment of risk have been identified as the most essential aspects of every single disaster. Under such framework, and following the scheme proposed by Varnes (1976), a landslide inventory, hazard and risk mapping of Pahuatlán have been carried out based on the analysis of high resolution and stereoscopic image satellite GeoEye (0.5 m resolution panchromatic) dated from December of 2009. Additionally, vulnerability was quantitatively estimated for the population exposed. The combination of these

elements was utilized to propose a landslide risk assessment for the area of interest. Results are presented here.

RC 20-01 - The fight against disenfranchisement: Emerging cultures of protest in the city

Chair: Luis Del Romero Renau, Samuel Mössner

Urban conflicts in Santiago de Chile and Buenos Aires. An international comparison of strategies and outcome of citizen participation in urban development.

Corinna Hölzl (Humboldt Universität zu Berlin)

Over a long period, civil society played a minor role in urban politics of Santiago and Buenos Aires. Due to profound processes of de-regulation, liberalization and privatization, urban development has been heavily influenced by private actors. At the same time, clientelism on the local level and, particularly in Chile, the weakening of civil society organizations forced during the military dictatorship continue to have an effect on urban democracy. In recent years, however, conflicts of interest in urban development have been on the increase. Citizens are increasingly fighting against uncontrolled development measures such as large-scale real-estate or infrastructure projects. In that context, the contribution examines the extent to which these strategies of participation in urban development contribute to a change in local governance processes and opportunities of participation. For this purpose, four urban development conflicts in the Metropolitan Area of Santiago and in the City of Buenos Aires were selected to be studied in-depth. While one conflict of each metropolis is located in an upper middle to high income neighborhood, a second pair of conflicts was selected from poor to socially heterogeneous parts of the cities. In all four cases processes of densification, displacement and increasing housing shortage are provoking strong protests. By means of different strategies, existing and newly emerging social movements and citizens' organizations are fighting against these urban transformations. The international comparative study is based on a broad range of empirical methods. Between 30 and 40 problem-centered interviews, particularly with stakeholders of urban social movements and citizen initiatives involved in the four conflicts, have been carried out. Furthermore participant observations in meetings and demonstrations as well as documents pertaining to the conflicts (plans, press materials and websites of selected initiatives) are included in the analysis. First results show that negotiation processes are varying strongly depending on factors such as resources of the urban social movements, practices and interests of the respective community as well as the governance structures of both cities. The international comparison

reveals strong differences regarding protest cultures and practices of the involved actor groups. Although the local governments partly react to the growing number of protests by incorporating additional participation instruments, rethinking of planning practices seems to be low and political will for real citizen participation is still missing.

Urban conflicts of Montreal and Valencia, 1995-2010. A comparative analysis.

Catherine Trudelle (UQAM)

Catherine Trudelle Geography Department, Université du Québec à Montréal, Quebec Luis del Romero Renau Geography Department, Université de Valencia, Spain Metropolization processes at work in contemporary societies produce social and spatial change which raise strong opposition from a variety of urban actors, leading to acts of dissent. While such urban conflict has been examined in the past, geographical analysis of urban conflicts as sociospatial processes is more recent. Systematic quantitative research on urban conflict is virtually nonexistent in terms of comparative analysis conducted with an international perspective. Systematic comparative analysis sheds light on the existing relationship between urban conflicts and socio-territorial contexts in which conflicts emerge and evolve. This article presents a comparative analysis of urban conflict that occurred in a selection of boroughs in two cities characterized by different geographical realities, Valencia (Spain) and Montreal (Canada), between 1995 and 2010. Spatial autocorrelation techniques applied on a conflict database show a significant relationship between the emergence of urban conflict and the spatial distribution of some contextual variables. Indeed, for Montreal as for Valencia, the concentration of urban conflict is the greatest in the most deprived neighbourhoods. Also, regarding management and regulation of urban conflict, results shed light on important differences between Montreal and Valencia. These differences include the outcome of urban conflicts, repertoire of action of actors involved in conflict activity, and the type of contestation faced by actors who promote the challenged urban projects. Keywords: Urban conflicts, spatial autocorrelation, local governance, urban actors, Montreal, Valencia.

Protest cultures in France and Germany about housing and “right to the city”

Elodie Vittu (Bauhaus-Universität Weimar)

The terms “right to the city” or “right of housing” are used as an action-programme by many contemporary urban social movements acting worldwide to define their actions. Henri Lefebvre’s utopian ideas and production (*Droit à la ville*, 1968) are connected to these movements. While Lefebvre criticized the post-industrial city, the contemporary organizations use the “right to the city” to face problems of the neo-liberal city. These movements protest against the gentrification of city centres, want more civil participation and public facilities or defend housing policies. All these activists use different ways to make their voices heard. I would like to compare the protest cultures in Germany and France, based on case studies. Germany has an important tradition of the protection of the tenants and supportive tenancy law. This has created powerful tenant organizations with a strong political lobby. Privatization of social housing is a central issue that they are fighting against. Also, big cities like Berlin have a tradition of squat and other alternatives movements. As a initiator of a big network of about 50 initiatives, the “Recht auf Stadt”-Network in Hamburg is a representative example of German activism. By presenting this and further networks from Berlin and Freiburg consisting of different social groups (students, tenants) claiming the “right to the city” and acting with regards to the question of housing, I will discuss characteristic projects from Germany and typical protest forms like exhibitions, art projects, walks or street parties, etc. In France, a new form of activism has recently developed. It comes from young people, connected to the media culture and does not especially follow traditional means of activism, like demonstrations or petitions. Instead, they use the social networks to catch the public’s attention. Their names are “The kids of Don Quixote” because they want to help the homeless people through camps in public space, or “Jeudi Noir” (black Thursdays) in reference to the day on which a newspaper with flat advertisements is published. I would report on their actions and also present the activities of a French association named AITEC. This group of urban experts, founded in 1983, organizes debates and produces reports to support social movements and aims at “overcoming the divide between the professionals and the activists” (full description in English <http://aitec.reseau-ipam.org/spip.php?article130>). This is a more formal way of protest but an interesting example of linking two worlds: the research and the practice. There are many French-German links about urban issues, like the fight for quality and affordable housing for all people or the production of space. But

there are also different cultures. With this comparison, I would like to highlight particular practices of urban protest.

Migrant Women and 'The Right to the City'

Gwyneth Lonergan (The University of Manchester)

In recent years, Lefebvre's (1968) concept of the 'right to the city' has been adopted by various theorists and activists as a basis for challenging the impact of neo-liberal economic restructuring on urban areas, and the exclusion of marginalised groups from economic and political decision-making in the city. However, as Atttoh (2011) points out, the concept is defined vaguely at best, and there is no consensus around who has the 'right to the city', and what this 'right' involves, or what happens if the 'rights to the city' of different individuals or groups come into conflict. To the extent that a common definition of the 'right to the city' exists among theorists, it involves the right of city inhabitants to participate in the production and use of public city space. However, as Massey (2005) points out, public space is intertwined with power relations, and is thus gendered and racialised; racial and gender power dynamics will also be present in the processes used by inhabitants to make collective decisions around the production and use of public space. As members of various marginalised groups - as women, migrants and often ethnic minorities - migrant women are in danger of being excluded by definitions of the 'right to the city' that do not incorporate critical perspectives on racial and gender oppression. Additionally, the processes that marginalise migrant women extend far beyond the city-scale to the realm of the nation-state, including, for example, increasingly restrictive immigration laws, and exclusionary discourses of national identity that are frequently both gendered and racialised. Consequently, for the concept of the 'right to the city' to be useful to migrant women, it must address the exclusion of migrant women at the nation-state scale, the scalar relationship between the nation-state and city, and the influence of this relationship on the experience of migrant women in the city. This paper will explore how the concept of the 'right to the city' can be defined in a way that is useful to migrant women activists and the wider implications of such a definition for urban protest movements. Precisely because of their location at the intersection of multiple axes of oppression, a definition of the 'right to the city' that is useful for migrant women must necessarily challenge racism, sexism and xenophobia as well as neo-liberalism, and consequently may offer greater emancipatory possibilities for all inhabitants of the city. Atttoh, Kafui A (2011) 'What kind of right is the right to the city'? *Progress In Human Geography* 35: 669- 685 Lefebvre, Henri (1968) *Le*

Income inequality and its effects on access to ecological services in a western US city

Madhusudan Katti (California State University), Andrew Rhys Jones (California State University), Kaberi Kar Gupta (California State University)

Cities now represent the primary habitat for human beings on earth, and are best studied as dynamic coupled socio-ecological systems. Modern urban development provides an excellent laboratory to examine the interplay among socio-ecological relationships. With increasing demand on limited resources, urban development often sharpens conflicts driven by socioeconomic inequalities which often result in unequal access to critical natural resources and biodiversity. Urban poverty is characterized not only by low socioeconomic status, but also by low ecological status resulting in increased vulnerability to risk factors such as food and water security. Urban land and water management decisions result from dynamic interactions between institutional, individual and ecological factors. Landscaping and irrigation at any particular residence, for example, is a product of geography, hydrology, soil, and other local environmental conditions, the homeowners' cultural preferences, socioeconomic status, neighborhood dynamics, as well as zoning laws, market conditions, city policies, and county/state/federal government regulations. Since land and water management are key determinants of habitat for other species, urban biodiversity is strongly driven by the outcome of interactions between these variables. This study addresses the significance of water as a key variable in the Fresno-Clovis Metropolitan Area (FCMA), shaping current patterns of landscape and water use, at a time when the city of Fresno is installing meters as a regulatory tool to conserve water. A recent study from the Fresno Bird Count found that bird species richness and functional group diversity are both strongly correlated with residential irrigation and neighborhood poverty. Tree species diversity shows a similar pattern. Water usage in the FCMA is also directly linked to socioeconomic status, but what exactly are the social behaviors entailed by socioeconomic status? How will water use behaviors change across the socioeconomic spectrum with changes in the cost of water due to metering? In particular, what are the implications of raising the cost of water on access to ecological services for poor residents? We examine various theoretical models

explaining outdoor water use behaviors, with the aim of assessing the resilience of such behaviors with the introduction of water metering in Fresno. We argue that socioeconomic status results from a complex interplay of cultural, economic, structural, and social-psychological factors, influencing institutional policies regarding the governance of water resources, and in turn impact biodiversity within the urban landscape through spatial and temporal variations in water usage. This study is part of a long-term research project that examines the impacts of human water usage and water use policies on biodiversity within an urban environment.

Urban Sprawl and Natural Disasters in Chilean Cities: A Geographical Overlapping of Exposure to Natural Hazards and Socioecological Vulnerabilities

Hugo Romero (Universidad de Chile)

Northern Chile cities located in and around Atacama Desert- one of the driest in the world-are increasingly growing in population, functions and size, competing for scarce and irregular water supply against mining companies, agricultural communities, indigenous people and conservation areas, and also strongly exposed to natural hazards. Cities like Arica, Iquique, Antofagasta and Copiapó, are depending much more from uncertain fossil groundwater sources, given the effects of desertification caused by climate change and extreme interannual variability of rainfall and snowfall over mountains that act like unique water towels. Growing concentration of regional population in coastal cities is not only leaching resources from inland and mountainous landscapes, forcing an almost complete outmigration of local communities, but also exposing them to severe natural hazards, like floods, landslides, droughts, earthquakes and tsunamis. Economic transformations are in turn, increasing socioecological vulnerabilities, due to socially segregated exposure and reduction of Disasters Resilience of Places (DROP; Cutter et al., 2008). Complex socioecological vulnerabilities of Chilean cities as a result of long-term 'disasters incubation' (Mulvihill and Ali, 2007), are also well exemplified by devastation caused by February 27th 2010, 8.8 earthquake and tsunami that affected mainly to the Concepcion-Talcahuano Metropolitan Area. Geographical information about floods, landslides and even areas that has been historically damaged by earthquakes and tsunamis were freely available in public organizations webpages since year 2000. However, public urban planning and housing policies did not pay any attention to these maps and reports because urban sprawl in Chile is strongly controlled by private urban development companies business and land speculation, on one side, and

social urgencies, on the other. A clear lack of environmental justice could be observed everywhere, since well-known hazardous areas have been allocated by public authorities and by the market, like the built environment of the city poorest people, who have lived for many decades, over frequently devastated areas. Urbanization-environmental differences at the NUTS 4 level in Poland: A case study

Barbara Konecka - Szydłowska (Adam Mickiewicz University), Jan Hauke (Adam Mickiewicz University)

The aim of the paper was to characterize urbanization-environmental differences among the 379 units of the NUTS 4 system in Poland, i.e. poviats-ranking towns and non-urban poviats. The research consisted of the following three stages: 1) An analysis of the internal diversity of the NUTS 4 units in terms of urbanization. As a result of their classification, three classes were obtained. The first class embraces units showing a high level of urbanisation, the second - an average level, and the third ' a low level. 2) An analysis of the internal diversity of the NUTS 4 units in environmental terms. As in the first stage, the units were divided into three classes according to a decreasing intensity of environmental care. In both stages the classification was carried out on the basis of selected indicators describing, directly or indirectly, the level of urbanization and environmental care of poviats using mathematical-statistical methods. The results are supported by graphics showing the spatial distribution of the individual classes. 3) In the final stage of the research, a two-dimensional classification of poviats was obtained: in urban and environmental terms. It allowed distinguishing poviats well-matched in both dimensions, i.e., those ranking high on both urban and environmental scores (growth areas), or ranking low (stagnation areas), as well as those with a mismatch between their levels of urbanization and environmental care (transitional areas). All results are supported by graphics illustrating the spatial distribution of the individual classes. The research sought to answer the following questions: (1) Are areas with a high level of urbanization more prone to environmental conflicts than those with a low level' and (2) Is it possible to unambiguously determine the presence of such dependencies? The paper is a substantial part of the first stage in a research procedure of the project financed

by the National Science Centre (N N306 791940) entitled 'Socio-economic development and the pattern of growth and stagnation areas', implemented by the Regional Analysis Department in the Institute of Socio-Economic Geography and Spatial Management of the Adam Mickiewicz University in Poznań.

Urban subsidence hazard: Site of experimentation in Ha Noi (Vietnam)

Christiane Weber (cnrs), Khac Dang Vu (LIVE), Frederic Masson (EOST), Cecile Doubre (EOST)

Urban subsidence hazard: Site of experimentation in Ha Noi (Vietnam) Dang Vu Khac¹, C Doubre², F Masson² and C Weber¹ ¹ LIVE ERL7230 CNRS/Uni. De Strasbourg ² EOST CNRS/Uni. De Strasbourg Context Subsidence is an unusual urban hazard which can lead to severe economic, social and structural damages. Due to geological and hydrological conditions this characteristics can be increased due to human activities like deep structures constructions (metro), water pumping (well) or hydrologic derivations. Such situations might occur more and more frequently due to urban growth and land consumption. Urban spatial extension enters in competition with other human activities like agriculture or natural preservation sites. This competition leads often to choose rather poor building sites, less productive fields, liable to flooding areas etc. In countries where urban growth is very important and intensive, several hazards might converge, flood and landslide or inversely dryness and soils contraction. Case study The case study of Ha Noi (Vietnam) is an interesting experimentation site while it combines rapid spatial extension, quick population growth, agricultural production (rice) and a particular hydrogeologic situation due to rivers, ponds, soft substratum. The rapid urban growth has induced the creation of districts on agricultural areas, the growth of population the multiplication of individual wells, the soft geologic substratum leads to lower the level of the ground in several districts. Aim The aim of this study is to map planning security plans and to alert the local authorities about the phenomenon. Mapping subsidence degree will be included in a risk management product to be introduced in the master plan of the city. Methods and data Various type of data have been collected: imagery interferometric, ERS, InSAR, ENVISAT data and also GPS points. Ground field campaigns have been set up in 2011 and 2012 to assess the methodological plan and to prepare data analyses and crosschecking. The presentation will be the occasion to precise the context and provide the first results of data processing.

Environmental services of 'El Panul' forest and urban conflict in Santiago of Chile

Cristian Henriquez (Pontificia Universidad Catolica de Chile), Marion Cereño (Pontificia Universidad Catolica de Chile), Jorge Quense (Pontificia Universidad Catolica de Chile)

Environmental services of 'El Panul' forest and urban conflict in Santiago of Chile (1) Just as most worldwide metropolis, Santiago, Chile, has expanded quickly onto rural and natural areas. During the last few years the Andean foothills have been strongly pressured by urban sprawl. One particular case real-estate project 'Fundo El Panul' located in La Florida proposes cutting down 61 hectares of sclerophilic forest and bushes for high density housing, buildings and road infrastructure. This native Mediterranean vegetation is considered a biodiversity hot spot worldwide. To evaluate the environmental services that 'El Panul' forest gives to the city, researches have been developed on the contribution it has in decreasing atmospheric contamination using the UFORE model and on local climate by registering air temperature during the 2010-2011 periods. According to the analysis, it was established that the 'El Panul' forest captures 1,063.68 tons/year of carbon, and removes 0.5 tons/year of PM10, 10.8636 tons/year of ozone, 43.2058 tons/year of nitrogen dioxide and 0.64162 annual tons of sulfur dioxide; on the other hand, the forest air temperature is 2°C lower than the air temperature of the nearby residential area, thus attenuating the urban heat island phenomenon. In 2008 the project was submitted to the Environmental Evaluation Service (SEA in Spanish) through an Environmental Impact Declaration (DIA in Spanish), nevertheless it was desisted due to questioning made by competent organisms regarding the ecological value of the forest and due to civil pressure who wants to maintain its biogeographical, geomorphological, hydrological, scenery and history particularities. At present, the project was once again submitted to the SEA through an Environmental Impact Study (EIA in Spanish), raising an urban conflict scenario between two opposed visions: conservation versus real-estate development. 'The forest 'El Panul' supplies important environmental functions for both wildlife and the community. While the percentage of carbon sequestration and air pollution control services are not as significant on a metropolitan scale, the overall effects

are positive for the environment especially in regard to reducing air temperatures. The cutting down forest and subsequent development of the sector would not only lose these attributes but also missed an opportunity for local and metropolitan government to preserve, through a partner funding mechanism, a forest remaining within the city. Beside, it will not need large maintenance for water use, would deliver significant benefits to the community and environmental education. (1) Fondecyt Project N° 1100657

Urban locational conflict resolutions: a case study of patna urban area

Priya Priyadarshini (Patna University)

Urban locational conflict can be simplified as the existing and ever-changing geography of the city and its region. It is the end-product of innumerable conflict in urban areas, and is mainly a frequent-by-product of efforts to amenities, building highways/ over bridges, alterations of traffic patterns, parks/open spaces, providing shelters for homeless. Locational conflict arises when individuals or groups express opposition to a locational or siting decisions made by others. 'Not in My Backyard' (NMBY), is a colloquial expression of locational conflict. Urban locational conflict can be seen in spatial- time context. In this context urban locational conflict remains changing even within the boundary of a city. In the developing countries like India, urban locational conflicts, mainly is a byproduct of government planning policies, expansion and rebuilding cities. The study area of this paper is Patna West (BIHAR).India has experienced a lot of changes during its urbanization processes in the last few decades from the rising vertical growth to horizontally expanding urban land-use patterns and urban amenities, besides infrastructural development which have given rise to many locational conflicts. The study area is recently in the phase of rapid population growth, which, in turn, is giving rise to numerous locational conflicts. The study is aimed at finding out genesis, level and nature of conflict, focusing on the main factors working behind the locational conflicts and examining the locational conflicts which have occurred in the last few years. The entire work is based on the primary survey through random sampling. However, a reconnaissance survey of the study area has been done before the final primary survey. The schedules were prepared on the basis of the reconnaissance survey. The data set so prepared has been statistically and cartographically treated for the explanation with regard to the findings of the problem. Patna is in that stage of urban development which has the potential to develop into locational conflicts of varied nature in the near future. Locational conflict arises

mainly due to allocation of services delivering systems. Locational conflict pits communities against corporations, local municipalities against state and other agencies and interest groups against interest groups. Most of the urban locational conflicts in the study area have risen because of the reluctance on the part of the local residents to government-sponsored development plan of infrastructure. It can be said at the outset that acquisition, demolition and construction in different localities by the government for the betterment of the quality of life of the residents of the study area have resulted in locational conflict.

Land use conflict identification in vulnerable open spaces using participatory GIS techniques

Helene Draux (London Metropolitan University)

Sea level rise due to climate change is threatening low-lying coastlines around the world. This threat is forcing those living by the sea to upgrade sea defences, therefore spending a considerable amount of money on defending cities. In the UK, residential, commercial and industrial areas are traditionally given high value; however it is more difficult to assign a value to land uses such as open spaces and areas of natural beauty. It is therefore important to understand the value of coastal open spaces. In the UK, Shoreline Management Plans (SMPs) are giving recommendations for the future of sea defences. Portsmouth, a low-lying highly densely populated city of the South of Britain has most of its coast protected by hard defences. Policies of the last SMP for the region recommended to 'hold the line', but asked for more time to consider the Farlington Marshes, the biggest open space of the city. This two hundred year old coastal marshland is a man made natural reserve defended by a sea wall, and its non-replacement would mean the end of the Marshes. Consequences on the wildlife are currently investigated, putting aside the consequences of recreational loss. This research is using three Participatory Geographic Information Systems (PGIS) techniques to explore the current uses of the Farlington Marshes, public use of open spaces in Portsmouth, perception of flood risk in Portsmouth as a whole and reactions to the proposed change in the alignment of coastal defences. The methods used consisted of a face-to-face map-based survey, activities during the Portsmouth Summer Fair and an interactive online survey based on Google Maps. Maps are used either as a way to collect information (by asking participants to indicate on the map where they walk and what they like), or to present visual information in a more quickly and easily-understandable way (when showing flood risk in Portsmouth). So far 142 participants took part in the face-to-face survey in the Farlington Marshes and Milton Common (another low-

lying open space). Between 60 and 75 people took part in each of the four activities organised during the Summer Fair. The data collected is currently being input into a GIS system to create a visual map of the value that participants give to the open space. The online survey has attracted little participation among the general public. New strategies are being implemented in order to increase the traffic on the website. So far, the preliminary results show that PGIS techniques of engagement with users of the Farlington Marshes can generate interesting data that may not be possible to collect using traditional surveys that do not involve the use of maps. It is too early to say with certainty whether the PGIS techniques used in this study may be of use in resolving conflicts. Stakeholders' interviews are currently taking place to discuss the conflicts in Portsmouth around flooding, open spaces and the Farlington Marshes.

Delhi's changing riverfront – land use conflicts surrounding the reclamation of Yamuna's floodplain for a world-class city in the making

Alexander Follmann (Universität zu Köln)

Delhi's rapid population and economic growth have resulted in high pressure on land. Additionally, the Delhi Development Authority, the city's planning authority, has an ambitious vision of transforming Delhi into a "world-class city" by the year 2021. With a total area of 97 km² the floodplain of the river Yamuna is the largest remaining natural feature within the mega-city. Degraded to a foul-smelling drain by the city's untreated sewage, the wide riverbed has been a neglected backyard of India's capital. However, being seen as underutilized or wasted land the river's floodplain has become promising for the city's make-over to become 'world-class'. Therefore, the urban poor have been evicted from the riverbed based on controversial court orders, which have held them responsible for polluting the river. Conversely, urban mega-projects like a religious theme park, the Commonwealth Games Village, an information technology office park and two metro depots (parking and maintenance facilities for Delhi's new metro rail system) have been developed on the floodplain regardless their negative environmental impacts. Though claiming to protect the floodplain, the courts have dismissed Public Interest Litigations filed by environmental NGOs in opposition to the mega-projects, which have been given the green light to be built on environmentally sensitive land despite pollution, obstruction of groundwater recharge and loss of food water retention area. The controversial developments have led to the declaration of a no-development zone along the banks in 2008; the recent plan aims to create a biodiversity zone along the river,

focusing on environmental restoration and recreational spaces. However, major challenges exist to implement the biodiversity zone: different government agencies have already violated the no-development declaration, pollution control efforts have failed due to a multiplicity of involved agencies, and corruption has stalled the implementation. Additionally, the majority of the land is not under possession of the city's planning authority and land acquisition will prove to be costly and difficult. Lastly, the essential awareness to protect and restore the river's sensitive ecosystem is missing across the public at large. Based on multi-temporal mappings and extensive interviews with relevant stakeholders among the multiplicity of government agencies, the presentation will highlight land-use conflicts with respect to river restoration and preservation of environmentally sensitive spaces within fast-growing mega-cities. The conceptual focus lies on the manifold challenges for policy making and its implementation at the interface of urban and environmental governance. Therefore, the case study analyses the interactions between different levels of government, political parties, courts, special interest groups (e.g. peasant movements), and environmental NGOs.

UDC 01-01 - (Mega)urban health in South Asia

Chair: Carsten Butsch, Mareike Kroll

Trends and challenges of non-communicable diseases in urban India

Surinder Aggarwal (Kurukshetra University)

India is experiencing demographic and epidemiological transitions concurrently. Close to one-third population now lives in urban areas with major concentration and growth happening in big cities. Massive rural migrations have contributed largely to this emerging urban trend. Fast urbanization coupled with rising incomes, sedentary life styles, faulty food habits, lack of exercise and exposure to hazardous substances is causing shift in disease pattern from communicable to non-communicable diseases (NCDs). Among the top ten causes of deaths, NCDs occupy first five positions with cardio vascular disease (CVD) at the top followed by respiratory diseases and cancers. Injuries, accidental deaths are on the rise and now considered among the top ten causes of death. Mortality patterns exhibit strong gradients with social determinants like gender, location, age, wealth, and ethnicity. Likewise emerging risk factors of smoking, obesity, alcohol consumption and hypertension are found to be strongly associated with emerging NCDs. The poor living in informal settlements are observed to suffer from double burden of communicable and NCDs. NCDs among the poor is a new phenomenon as the risk factors like smoking, drinking, lack of exercise and exposure to carcinogenic and other chemical substances is higher than middle and higher income groups. At the city level key findings reveal mega cities exhibit higher prevalence and mortality rate for CVDs and cancers, whereas for medium size cities ARIs and accidents predominate. The greatest challenge now lies for the urban healthcare systems to accommodate the higher healthcare costs (diagnostic, treatment, and medicines) associated with NCDs. Annual per capita health expenditure in India at \$ 109 is among the lowest in the world and higher allocation for urban health is a low priority for the governments at the moment. The urban health mission of the government of India is still in the formative stage. Apparently, the urban poor and other vulnerable groups are to suffer more under the current healthcare scenario. This paper examines such trends in greater depth to analyze the emerging mortality trends, especially for NCDs, with social determinants approach. Policy dimensions of interventions will be probed and suggestions made to face the new urban health challenges in India. Various mortality data sources including SRS, CRS, MCCDI, NFHS, 1 million death

study, disease registries and serial studies will be used to examine the mortality trends and inequity aspects associated with social determinants approach.

'Entitlements to health care' as perceived by stakeholders and urban poor: Why is there a preference for private facilities in the city of Chennai, South India?

Patrick Sakdapolrak (University of Bonn), Christina R. Ergler (The University of Auckland)

India - one of the focal points of the global megapolisation process - is confronted with growing urban poverty, and the urban poor bear an increasing disease burden. Results of the National Family Health Survey (2005-06) reveal that the health status of poor urban populations is not only worse in comparison to that of the urban population in general, but, to a certain extent, also to the health status of people from rural areas. One of the key determinants of the health status of the population is the performance of the health care system. In the urban context of India - especially in large agglomeration - a wide variety of health care providers are available, but not all sections of the society are benefiting from all options equally. This paper focuses on access to health care by urban poor residents in Chennai, India. It aims to reveal constraining and enabling conditions for impoverished users seeking treatment. We explore patterns of health-seeking behaviour through the reasoning of the poor residents themselves as well as stakeholders involved in providing care for these users. Particular attention will be given to the needy residents' preference for private health care providers despite the fact that costs are involved and free public facilities are available. We address this issue by combining Sen's entitlement approach with Penchansky's and Thomas' work on access to health care. Based on empirical data gathered in a qualitative research design, we argue that the mere availability of health care facilities within walking distance is a necessary but not sufficient precondition for satisfactory access to health care by urban poor. Rather, we demonstrate that access to health care facilities is shaped by 'entitlements to health care', which allow poor households that are endowed with certain resources such as income, knowledge and social networks to realise access. As the results of the interviews with users and stakeholders reveal, not only experiences of health care, but also feelings about its utilisation, are crucial in determining choice and use of health care facilities. This finding suggests that analyses of affordability and physical access to health care in less developed countries should be complemented by a focus on emotional dimensions of utilisation. We conclude that there is a greater need to consider

not only effective access to health care, but also affective dimensions of treatment for poorer citizens.

Perspectives change lives: Managing human health in Chennai slums from the inside out

Divya Rajeswari Swaminathan, Vasanthakumaran Thangavelu, Nandhini Jj, Jayanthi Swaminathan

This paper recognizes that people's perspectives change their lives, especially when management decisions are made. The study reported in the paper demonstrates how in managing human health the slum people of the megacity Chennai, India show up characteristics and perspectives necessary from the inside out. Purpose: This paper has the purpose of relating some of the urban health constructs of the people of select Chennai slums and the discussion is on discourses concerning health perceptions, including epistemologies, influences of socio-cultural norms, gendered perceptions and relations to health and exposures and vulnerabilities. For this purpose, the authors recognize the slum communities of Chennai as narrative machines, which are capable of elucidating their urban health constructs as they see them. Research Questions: How do people conceptualize health? What do the vulnerable do to continuously cope with water-related risks, to manage, maintain and protect their health? What are the constraints and the enabling factors for coping and adaptation among the vulnerable? Data and Method: Narrative analysis is a new strategy for medical geography. It works with cognitive methods, focusing on the cultural behaviour of the vulnerable in the two slums. Discourse analysis represents the voices of the vulnerable in the slums. The constructs discussed are those that have emerged from the narrative and discourse analyses and also the perspectives and insights of the slum people. Constructs and Narratives: Vulnerability and capacity to cope are the two sides of the same coin. The more one is vulnerable, the less one has the capacity to cope, and the more one tends to adopt coping mechanisms. Some of the crucial constructs of the slum communities are: For women, 'absence of disease' is a sign of good health; For men and women, 'being active and able to do regular work is a symptom of good health'; Women think of 'body resistance or stamina as good health'. In their discourses, the constructs have taken several different forms. Some of them as narratives are: We have food but disturbance of mind makes us restless, unable to eat; If we are of free mind, then we can avoid sickness and have a long life; An unclean slum man may be healthy, while a woman with clean clothes and living in more spacious house, with hygienic surroundings, could be afflicted with

major illnesses; Disease is not a result of cleanliness and hygiene, for 'having been here for more than 30 years, nobody in my family has ever been sick'. Outcomes: The paper examines and analyses the meanings and implications of the constructs and narratives for coping and adaptation and then generates strategies for overcoming vulnerabilities, real and perceived. Besides, it demonstrates how community perspectives change lives of the slum people, especially when they self-organize themselves and develop strategies for managing human health from the inside out.

What determines the level of housing satisfaction in urban slums of Dhaka? Results from the baseline survey of a cohort study in Bangladesh.

Md. Mobarak Hossain Khan (Bielefeld University), Arina Zanuzdana (Bielefeld University), Alexander Krämer (Bielefeld University)

Background Housing belongs to the main domains of life and can be defined through interrelated dimensions, such as socioeconomic, neighbourhood and cultural attributes. Quality of housing plays one of the key roles in public health, since inadequate housing may have direct or indirect negative impact on social, physical and mental health. Higher satisfaction with housing was shown to be associated with income, higher age, a smaller family, higher education, being female as well as being an owner of a dwelling. The aim of our study is to investigate the associations of individual, family and neighbourhood factors with individual housing satisfaction in Dhaka, Bangladesh. Methods The data was generated through baseline surveys (designed for one-year cohort study) conducted in 2008 and 2009. A total of 3,207 adult respondents were systematically selected. We have used a combined variable 'housing satisfaction', containing nine items related to satisfaction with different types of housing facilities (water, electricity, surrounding noise etc.). An ordinal logistic regression model was applied to predict housing satisfaction. Statistical analysis was performed using SPSS 17.0. Results Income (wealth index) had a direct effect on the level of housing satisfaction in urban slum and rural areas. Rural residents were much more satisfied with their housing than urban slum dwellers (parameter estimate 1.923, $p < 0.0001$). A strong and highly statistically significant association was detected for the 'Living area is located well to reach a doctor'. Those respondents who perceived their area as 'Very bad or bad' or 'Moderate' to reach a doctor reported much lower levels of housing satisfaction. Respondents who perceived their neighbourhood environment as not harmful for their health were much more frequently satisfied with their housing

(parameter estimate 0.953, $p < 0.0001$). Satisfaction with housing in relation to the water source displayed as well significant associations. Conclusions The major findings of our study showed complex relationship between housing satisfaction and other domains of life and confirmed the importance of including several sets of explanatory variables into analysis. The existing link between health and housing satisfaction was made obvious and is the focus of our further research. Understanding the factors which lead to satisfaction or dissatisfaction with housing and residential environment is crucial for planning successful and effective housing policies. The study brings evidence for urban planners and municipal governors about what priorities should be addressed to provide urban residents with satisfactory and safe housing, taking into account growing urbanisation and migration in the megacities like Dhaka.

Urbanisation & Demographic Change

UDC 02-01 - Conviviality and/ or confrontation? Ethnic, cultural and political diversity in public space 1

Chair: Thomas Schmitt, Lars Wieseemann

Narratives of encounter: Implications for the contact hypothesis

Gill Valentine (University of Leeds), Joanna Sadgrove (University of Leeds), Nichola Wood (University of Leeds)

This paper focuses on adults' narratives of their encounters with 'difference' to explore the processes through which attitudes (positive or negative) towards 'others' are transmitted and/or interrupted. It draws on in-depth life- history interviews structured around the construction of time-lines in which the informants identified key factors in their autobiographies from childhood to the present day when/where their attitudes developed. This data was collected as part of a larger European Research Council funded study of 'Living with Difference'. The paper examines the interviewees' narratives of encounters in terms of the evolution of attitudes over time, as well as narratives of 'fateful moments' where a sudden one-off encounter interrupts previously held perceptions of sameness or difference. In doing so, the paper identifies the importance of space and time in relation to the outcome of the informants' encounters with 'difference' and also considers how individuals resolve or reconcile contrasting positive and negative encounters to define their own understanding of their relationship to 'others'. The conclusion reflects on the implications of this research for the contact hypothesis and the geographies of encounters literature.

Encounters with a new category of the “visible poor”. On the emancipatory potential of street newspapers.

Rainer Kazig (University of Munich)

With the appearance of street newspapers in the 1990s, a new category of the 'visible poor' has arisen in many large cities: the street newspaper vendors. This development can be viewed as a subtle expression of the commercialisation of public spaces, as a consequence of which the 'visible poor' are tolerated only in the role of disciplined vendors. Many street newspapers have however emphasised the socio-political act that exists in the contact between passers-by and the vendors of street newspapers. It is presented - in contrast to the encounters with beggars who are reduced to charity - as an opportunity in

which passers-by can encounter the poor as fellow citizens ('turning beggars into salesmen'). Supplemented by biographical reports in the street newspapers, the contacts are intended to contribute towards breaking down the widespread negative image of the poor and homeless. Whether the market-like interaction with the street newspaper vendors can fulfil its emancipatory function must however be regarded as an open question. On the basis of an empirical study of mine on street newspaper projects, in my paper I would therefore like to pursue the question of the significance(s) of this new form of encounter with street newspaper vendors. As a first step, I shall focus on the visible course of the encounter. Compared with encounters with beggars, in which passers-by conduct the handing over of a donation with the greatest possible distance, the purchase of a street newspaper proceeds largely according to the pattern of buying a standard newspaper, but can also be characterised by brief conversations. To this extent, with the street newspapers, a new possibility for public interaction with visibly poor people really has come into being. They can however have different significances, to which I shall return in a second step. Besides the classic act of purchase, four different forms of purchase exist here, which are accompanied by decidedly contradictory moral motives (rewarding the deserving poor, supporting efforts towards normalisation, recognising tiring work). In fact, the encounters with street newspaper vendors also enable the image of the 'visible poor' as morally inadequate to be undermined, and to this extent they fulfil the emancipatory claim of the projects. However, in view of the ambivalent meanings of the purchase relationships, it must be clearly relativised.

Urban public parks and social sustainability

Elisabeth Buehler (University of Zurich), Heidi Kaspar (University of Zurich), Frank Ostermann (Joint Research Center, European Commission)

Urban public parks are distinguished elements of urban public spaces. As nature-oriented green and free spaces they contribute to social sustainability and to the quality of life in cities in many ways. As public spaces parks are accessible to everyone in today's democratic societies. Urban public parks possess therefore a high potential for conviviality. However, the normative logics of equal access do not mean that de facto no processes of confrontation and possible social exclusion are taking place in urban public parks. This paper discusses in which ways public parks may support social sustainability in urban settlements. Based on theories of public space it offers a transformation of the powerful, however abstract normative concept of social sustainability into concepts that are adaptable for empirical research and political debates. These

concepts focus on comfort and belonging, negotiation between equals, and social diversity. Drawing on case studies in three different neighbourhood parks in the city of Zurich in Switzerland the paper discusses people's appropriation of urban green spaces with a special focus on gender, age and activities performed. The paper also identifies elements of landscape design as well as strategies of planning and regulation that foster social sustainability in urban public green spaces. Both quantitative and qualitative methods were employed in this research project funded by the Swiss National Science Foundation. Systematic collections of representative observation data of park usage by different user groups, and its subsequent statistical analysis and visualization in a GIS mainly used quantitative methods. Qualitative methods were used in semi-structured interviews with park visitors to capture their feelings and perceptions of the park spaces, and in expert interviews. This triangulation of methods allowed combining the strengths of different approaches, analyzing the research object from different perspectives. The results of these investigations brought processes of confrontation as well as processes of conviviality to light. It also became evident that planning, design and regulation are powerful and vital instruments shaping social sustainability in urban public parks. A final report of this research project is published in German: Bühler Elisabeth, Kaspar Heidi, Ostermann Frank (2010): Sozial nachhaltige Parkanlagen. Vdf, Zürich.

Please don't cross the line: Marginal urbanity in public spaces

Felicitas Hillmann (FU Berlin)

In my paper I will concentrate on the relevance of migrant action for urban development. Starting from the concept of 'marginal urbanity', I will show that the figure of the 'stranger' has fulfilled from the outset a fundamental role for the conceptualization of urbanity, as documented in Simmels and Parks work. But this position of the stranger as the one at the margins existed mainly on a theoretical level. In reality, after world war two, with the flourishing of the welfare-states and the guestworker regimes in actu in European cities, the perception of the 'stranger' in the urban setting had been substituted by a sectoral approach that perceived migrants in the position of a consumer and receiver of help and transfer. Migrants were just not expected to contribute to urban development. In this logic especially the expression of religious identity in the public sphere, as given through the construction of mosques, was strongly debated. This deficit-oriented view on migrants has reversed only recently due to the anticipated demographic changes. Many cities became aware of their ageing populations and realized that, often, the majority of children in school age are of migrant

origin. Further, a substantial share of small businesses is set up by migrants and many contributions in cultures and sports stem from the migrant population. In multicultural cities such as Frankfurt am Main, migrant entrepreneurship makes up 54 % of all business registrations. Some cities such as London and Amsterdam succeeded in making their public places that are characterized by a strong presence of migrants, tourist attractions. Superdiversity and the involvement of highly differentiated migrant milieus are now expected to contribute to urban development. In Germany the abolition of the most important program for the social development of the cities strikes especially migrant neighborhoods, eventual difficulties are downplayed. Nevertheless migrants are expected to shape public spaces and to actively promote their migrant identity - as long as functional to the locally wanted narrative of urbanity and as long not leaving their assigned public spaces.

Social Interaction in the Iranian Residential Public Open Space

S. Neda Ghazizadeh (TU Berlin), Alireza Monam (TU Berlin)

Yard was one of the most important parts of the Iranian traditional house. Lots of activities depending on the climatic situation were accrued there. According to the limitations of modern life in the big cities of Iran opposed of the past, privet yard for every house is impossible. So the meaning of the yard has transferred to the public open space for a group of neighborhoods. Small apartments request more using of open space, even though the function of the yard has declined to necessary activities. Public space in the contemporary cities, in all its tidiness, is thought of as a secondary space, owned neither by the city nor by the individual, although it should cover a huge part of everyday activities. So designers should pay deep attention to the open space as a new yard and adapting it to the modern life. Appropriate design of public open space, will change residence's perceptions of the total space of the complex. The purpose of this research is to explore the relationship between residential public open space design and social interaction. In particular, it focuses on the role of public open space in Tehran residential complexes to fostering sense of community. The aim of this research is improving the residential building quality within the contemporary urban context by focusing on the physical properties at the residential public open spaces. The selected complexes were chosen from the medium scale and high rise blocks in the north part of Tehran. The path model analysis had architectural, socio-relational, and functional features of public open space as the exogenous variables predicting residents' evaluation of open space and the level of social interaction. The result shows people attached to the places with more social activities, and open spaces encourage the social interaction. The result implies that the meaning of neighborhood, and the quantity and quality of interaction has changed in the new life, and people expectation of social contract has reformed.

Ethnic diversity in Public Space: Syndrome Self and Other, Otherness and Spatial Exclusion, Case Study of Liberec, the Czech Republic

Jaroslav Vávra (Technical University of Liberec), Barbora Krejcová (Masaryk University of Brno)

The official figures of the Czech Statistical Office (CzSO) say the foreigners represents four per cent of the Czech population at the end of 2010. The foreigners of Liberec district, northern part of the Czech Republic, represent five per cent of the population of the district. At the end of 2011 the CzSO announced the population of the Czech Republic raised slightly thanks to the international immigration. How is it possible to read the figures? How can we interpret them? We realized the first inquiry in 2008 and 2009. The inquiry was focused on a specific group of foreigners. They taught their mother language as a foreign language of the Czechs. We inquire reasons and ways how they make a decision on host country, and key factors of their making a decision on the destination. We are interested in length of their stay in the destination and changes in their behaviour/acting during their staying in the destination, the Liberec city. Their adaptation and integration into the Czech majority was important for us too. We published the result in proceedings of IGU, Istanbul 2010. The second inquiry in Liberec was realized in 2011. We asked ourselves: How is perceived members of minority by members of majority? How do ethnic members perceive a place where they live? Is the minority spatially excluded? Is the minority becoming a part of majority? What a way? The students, would-be geography teachers, decided for small areas of the Liberec city and each student team focused on minorities in their area. They observed, enquired, talked to people and asked people to draw their mental maps. As minorities, the students have found international immigrants (the Ukrainian, the Vietnamese) as well as Roma people. We used a concept of social/spatial exclusion - in housing, labour market, education. The relevance of the results is measured by statements of members of majority as well as of students who made the inquiry in the field. One of the results of the inquiry is the members of majority in the areas do not both realize and adopt neutral attitude to minorities. The majority people evaluated minorities according to their contribution to majority (Vietnamese, Ukrainian) or danger (Ukrainian) in a local community. Be interesting the respondent of majority miss out international immigrants from developed countries (e.g. Western Europe, North America). It can be the members of Czech majority judges the members of minorities on the basis of

common adopted prejudices rather than their own experience or knowledge of Czech curriculum (schools).

Contesting Alun-alun: Power Relations, Meaning and the Production of Public Space in Yogyakarta, Indonesia

Dyah Widiyastuti (TU. Dortmund)

Yogyakarta as an old city has traditional main square, called alun-alun, which takes form as a void in front of its palace. This place has becoming a witness of changing power and political system in this old monarch as well as in the country. The initial functions of this space which were strongly related to royal purposes and display of king power upon his subjects such as processions were not intended to public purposes. Through history, alun-alun has been changing its function and becoming merely to be a public space. Going through shifting in political system along with decreasing supremacy of the king as the owner has causing dilemma in managing this space. It has been experiencing various tensions over its reproduction which is ranging from issues of privatization and commercialization, the absence of institution to the lack of its planning and regulation. Waiting for the ideal form of alun-alun through various debates among stakeholders in formulating the concept of revitalization has been creating negative impact and left this space abandoned. Taking all of these different aspects into consideration, it becomes an evident that alun-alun is part of controversy and renegotiation where various interest, meanings and values clash. My paper will show changing role and function of this public space from the initial creation in 1755 to its present where three phases of historical layer: the early, the colonial and the modern periods are distinguished. The aforementioned of historical accounts help to visualize how alun-alun has catalyzed the formation of collective urban images, which are transmitted from generation to generation. This allows the square to maintain its role as a place for the collective expression of urban life. Understanding its physical and social transformation processes will help to unveil the elements of the urban memory related to this place and the condition that have been crucial in constructing its social meaning. The values behind its transformation are considered important for formulating strategic planning in revitalizing this public space.

The Appropriation of Public Spaces by Youths

Raimund Kemper (IRAP Institute for Spatial Development)

In social geography the appropriation of public spaces by the youth is gaining growing attention since conflicts caused by bottelones, facebook parties or occupation events, as well as day to day activities like hanging out, skating or strolling, are increasingly discussed in the media. This paper reflects the findings of a nationally funded research project conducted in six cities in Switzerland (2009-2011). Within the context of a changing significance of public spaces in the adolescence, the project explains the meaning and relevance of the appropriation of 'social' public spaces for the youth and analyses the social, cultural and regulative restrictions which often lead to conflicts. The research project was designed in the context of a flagrant research deficit in the sociology of adolescence, in which space has been disregarded; as well as in urban sociology, in which adolescents generally haven't yet played a relevant role. It is theoretically rooted in the assertion that traditional object-oriented socio-ecological concepts fail to explain the meaning of public spaces for the youth; their appropriation and the conflicts enacted in them. Therefore these processes themselves remain invisible, contrary to the manifest results like vandalism or violence that are visible and perceivable in public spaces. Complementary to the object-oriented view of space and spatial processes, a subject-orientated approach has been developed that encompasses the social-spatial interaction manifested in processes of appropriation, from the perspective of adolescents. This is understood not only in a territorial sense but also as an interpretation of symbolic meanings in spaces and containing its own symbolic markings (spacing). Being in spaces is an important part of the socialization and identity building of adolescents. In a dualistic understanding of action and space (Loew, 2001) processes of appropriation and conflict do not only take place in public space. They occur through space as it becomes a category of social differentiation in the sense of Bourdieu (symbolic capital) and an expression of uneven distributed power. The adult geographies of owners, politicians or representatives of the public administration overlay those of the youth and are symbolically manifested in the built environment compliant to social regulation systems and legal regulatory measures in public spaces. This spatial marginalization and social exclusion represent a manifold disappropriation (symbolic, legal, regulatory) of the youth in public spaces, in its original sense accessible to all. Vandalism, provocations and violence as signs of disappointment, resignation and protest can be regarded as results of negative forms of appropriation. From a subject-oriented perspective new strategies for

processes for youth-oriented planning and designing public spaces are necessary and corresponding qualities must be developed.

UDC 03-01 - Do borders make regions learn?

Chair: H. Peter Dörrenbächer, Tobias Chilla

Vers l'émergence d'une région apprenante transfrontalière en Europe de l'Ouest : une nouvelle étape d'une histoire de la coopération transfrontalière dans le Rhin supérieur.

Bernard Reitel (Université d'Artois)

On peut considérer qu'un espace transfrontalier devient une région apprenante lorsque les institutions transfrontalières créées dans les domaines politiques, économiques et éducatifs deviennent des lieux où s'inventent et s'expérimentent des cadres et des dispositifs qui peuvent servir de modèles à d'autres territoires ou ensembles spatiaux. Nous chercherons à montrer que l'idée de région apprenante peut constituer une nouvelle étape de la coopération transfrontalière en nous basant sur l'exemple du Rhin supérieur. Cette dernière est souvent considérée comme un modèle de coopération du fait de son ancienneté (depuis les années 60) et parce qu'elle associe deux Etats voisins qui ont réussi à dépasser leur antagonisme, la France et l'Allemagne, auxquels s'ajoute la Suisse qui n'est pas membre de l'UE. Nous examinerons plus précisément les orientations de 3 organisations représentatives des 2 domaines évoqués : l'Euro-Institut, un centre spécialisé de formation et de conseil aux élus, Eucor, un réseau de coopération entre les Universités. Trois hypothèses sont examinées. D'une part, le caractère transfrontalier de ces organisations leur permet d'être des ressources favorisant la médiation entre territoires voisins. D'autre part, ces organisations sont des lieux d'expérimentation de l'interculturalité et d'invention de nouveaux modes d'action culturels et politiques. Enfin, ces organisations permettent aux acteurs de se confronter à différentes échelles géographiques. Si ces conditions sont remplies, on peut estimer que le Rhin supérieur peut être qualifié de région apprenante.

North Korea's Special Economic Zones at the Demilitarized Zone: In between Potemkin Villages and failed Laboratories of Inner-Korean Cooperation?

Bernhard Köppen (Univ. Koblenz-Landau)

The demilitarized zone (DMZ) between the Republic of Korea (ROK) and the Democratic People's Republic of Korea (DPRK) is judged to be the last border of the "Cold War". Even after Kim Jong Il's death, the DPRK's regime announced

that no significant changes shall be expected. The current chilled down and sometimes hostile inner-Korean diplomatic relations let sink major success' of the last decade, initiated by South Korean 'sunshine policy', into oblivion: As a tangible result, two Special Economic Zones, based on cross-border-interaction have been established nearby the DMZ. One of them dedicated to tourism and one to industrial production, the latter still operating, despite most serious diplomatic and military frictions between both nations. A close examination of that what is known about the Korean SEZ-projects reveals a relative importance of 'knowledge' and 'adaption' in the official discourse/propaganda. Nevertheless, it seems that real cross-border-cooperation can't be a real option for the DPRK's current leadership; neither before nor after South-Korea's approach of Sunshine Policy. On the other hand, as a matter of fact, the Kaesong SEZ is still working although official relations between the two Koreas reached the rock bottom. If operations were really stopped, not only a major source of urgently needed hard currency would vanish but also an estimated 40,000 North Koreans might share their knowledge about the Kaesong Industrial Complex, when being transferred to other workplaces. A scenario obviously feared by the regime. Whilst the DPRK is perceived as a totally enigmatic state by the international community and especially the 'West', the South Korean government as well as private companies haven't gained fundamental knowledge and experiences in cooperation with the North. This might become an asset for future negotiations concerning the Korean peninsula.

Civil Society Co-operation in the Russian-Finnish Borderlands: Processes of Social Learning

James Scott (University of Eastern Finland)

This paper presents results from research projects that have investigated networks of civil society organizations (CSOs) between EU member states and neighbouring countries. The focus here is on Finnish-Russian civil society co-operation in the areas of social welfare provision as well as regional and economic development. One major objective in this conjunction is to assess the contribution of this cross-border co-operation to the development of Russia's social economy as well as to discuss the various obstacles that civil society actors face in developing co-operative projects. As such, organizational, social and technical issues are important areas to be addressed. However, civil society co-operation is not a mere technical issue; understandings of the social embeddedness of civil society are also necessary in order to promote social welfare agendas. In concluding, the paper will reflect on experiences of CSO co-

operation with regard to capacity-building processes of social learning and future prospects for social enterprise.

Development factors and functional structures of border towns

Agnieszka Kwiatek-So'tys (University of Cracow), Krzysztof Wiedermann (Pedagogical University of Cracow)

Dr Agnieszka Kwiatek-So'tys Dr Krzysztof Wiedermann Institute of Geography Pedagogical University of Cracow Development factors and functional structures of border towns The changing role of a border as the result of transition in the post-socialist countries gave the new opportunities of the development of cross-border regions. On one hand these were associated with UE integration processes and on the other hand strongly influenced by the local need for changes. The transformation process in post socialist countries changed the economics conditions from central planed system to the market economy. The new role of local and regional government which gain control over the local and regional development processes is stress in the paper. The authors make an attempt to answer the question to what extend the regions and towns take advantages of cross-border location in terms of social, economic and cultural international cooperation. Results of the authors researches on cross-border regions carried out in Poland, Czech Republic and Germany proved that the best conditions for development are associated with the towns located close to the main border crossings. Communication accessibility factors are the clue elements in terms of region competitiveness in time with open borders. The lack of communication infrastructure is the significant barrier for both endogenic and egzogenic growth. It is caused by a local society isolation and results in lower social capital value. In the paper different aspects of development such as population changes, labor market, cross-border commuting, social, economic and cultural linkages are considered. Those problems are illustrated by examples of different towns (for instance Mi'dzylesie, amberk, Lubawka, aclé?, - at the Polish-Czech border and Zgorzelec, Goerlitz - the Polish-German one). The realization of these tasks was possible thanks to the detailed statistical analyze as well as field work including questionnaires conducted in mentioned towns. Authors believe that the empirical date allow for drawing universal conclusions.

UDC 04-01 - Global winners and local losers? Comparing regeneration policies in shrinking cities in America and Europe 1

Chair: Thorsten Wiechmann, Sylvie Fol

Comparing American and European Shrinking City Turnarounds: Searching for Pivotal Revival Strategies that Allow Cities to Take Charge of Their Own Destinies?

Alan Mallach (The Brookings Institution), Işıl Brachman

Shrinkage is a pervasive phenomenon among 'old industrial' European and American cities that have experienced significant economic restructuring in a post-industrial age. While significant research and writing has been done on hypothetical strategies for turning these cities around and on local innovative practices being implemented, very little is known about what elements in the aggregate ultimately create 'winners' and 'losers' among these places. Until recently, there were few, if any, success stories to draw upon; however, signs of life are emerging in several American and European cities from which it may be possible to draw preliminary conclusions. Using a comparative approach between three European and three American cities that have shown signs of recovery, this paper will begin by offering a conceptual framework for what constitutes an urban 'turnaround,' from an economic or social perspective, and then focus on characterizing and identifying 'turning points' for city revival, how these are being implemented and whether they can be replicated. Since European cities appear to have demonstrated greater progress earlier, this paper proposes to examine three European cities -- Leipzig, Manchester and Barcelona - as the touchstone for comparison with three American cities - Milwaukee, Pittsburgh and one smaller city to be selected - to identify the centrality of critical pivotal elements. The paper will also contrast these three American cities with two cities that have not yet experienced revival - Cleveland and Detroit - to differentiate their experiences and identify factors that are holding them back. No silver bullets exist for reviving older industrial cities. However, building on recent work by the German Marshall Fund and on previous research identifying 'turning point' factors (Ploger, 2012), this paper posits the existence of certain common factors that are critical for recovery - leadership; a mix of economic restructuring strategies and urban or place-based revitalization techniques; new partnerships -- whether city & regional, inter-

governmental, and/or public-private; and finally exogenous factors, such as larger political or economic shifts. This paper proposes to delve into these four pivotal elements as experienced in the six cities and to test the hypothesis that, broadly speaking, these four elements make a critical difference between 'winners' and 'losers.' This paper addresses crucial questions about what local leaders have control over, how critical exogenous factors are, and the barriers to replication. Comparing and contrasting these European and American cities will illuminate the commonalities in their recoveries and help extract critical revival elements for application elsewhere.

The comeback city and the incredibly shrinking city: Urban regeneration in Leipzig, Germany and Cleveland, USA

Matthias Wendt (Universität Bayreuth)

East German cities and US cities of the industrial mid-west have been affected by shrinkage due to deindustrialization, suburbanization and out migration. While the city of Leipzig managed to reverse this trend and shows modest growth in a contracting region the city of Cleveland continues to lose population in a persistently growing region. Considering the resurgence of Leipzig and the prolonged shrinkage of Cleveland, the paper charts perception of shrinkage, regeneration strategies as well as actors involved and asks for the conditions for innovative policies managing shrinkage to be implemented. Drawing on concepts of path dependency (Pierson 2000, Kuder 2009), urban governance (Le Galés 1998, Pierre 1999) and urban political economy (Logan/Molotch 1987) the research shows that approaches to shrinkage differ dramatically in both cities. In spite of six decades of continued population loss shrinkage is still perceived as a temporary phenomenon in Cleveland. Especially the local business community and local government do not acknowledge shrinkage and tend to perceive it as a process that can be overcome. By contrast, the depopulation of the 1990s led the local government in Leipzig to accept shrinkage as a long-term challenge. This triggered a paradigm shift in urban planning that can be conceptualized as double loop learning (Jachtenfuchs 1996) since it included both a realignment of instruments as well as general objectives. While strategies of managed decline aimed at turning the problems of shrinkage into opportunities the past 20 years also included policies to reverse the trend of out migration. In Cleveland, the persisting interpretation of out-migration as a temporary phenomenon has perpetuated optimistic re-growth policies focusing on downtown revitalization and the attraction of suburbanites and tourists. Only the foreclosure crisis enforced pragmatic decisions to deal

with the soaring vacancy rates. But as the general policies are still aimed at re-growing the city the Cleveland approach to shrinkage is framed as single loop learning. The pro-growth agenda is shaped by an elitist circle of corporate and city government personnel with weak public welfare interests. Besides the dominating growth machine a second coalition of neighborhood organizations and independent planners exhibits a high public welfare orientation and a strong commitment to the city's neighborhoods. A first conceptual approach to deal with vacant lots strategically has come out of this realm. The German reunification led to a decreasing importance of old path dependencies in Leipzig and an infusion of new personnel in city government. Grounded on a broad agreement to tackle shrinkage strategically Leipzig has embarked on new policies in urban regeneration. These approaches have been drafted and implemented in close cooperation by city government as single most important actor in urban regeneration, housing industry and a highly involved civil society.

From long-term shrinkage to re-growth? A comparative study of urban development trajectories of Liverpool and Leipzig

Dieter Rink (Helmholtz Centre for Environmental Research - UFZ), Annegret Haase, Katrin Grossmann, Chris Couch (John Moores University), Matthew Cocks

Whereas many cities in Europe experience a fairly continuous process of urban growth, a considerable number of others have experienced long periods of urban shrinkage over recent decades. Shrinkage has today become a normality in urban Europe, and is likely to continue into the future. However, in between these two poles of ongoing urban growth or shrinkage, there are cities with less pronounced trajectories. One type here is cities that underwent a phase of shrinkage but have more recently seen a recovery of population numbers. This 'turnaround' from shrinkage towards a stabilization, or even re-growth, has been increasingly reflected in the literature in recent years - a number of papers deal with the upswing of cities after a phase of decline calling it 'reurbanization', 'resurgence', 'revival of cities' or even 'urban renaissance'. Urban shrinkage and re-growth today form a part of complex changes within many European cities. Since the number of such cities has increased over recent years in a number of countries, for example in Germany and the UK, not only the question arises how re-growth can be understood, but also if and how the two processes of shrinkage and re-growth are interrelated and how the future of such cities might look like? Set against this background, the paper aims to understand and discuss the urban development trajectories of two European cities - Leipzig in

Germany and Liverpool in the UK - two cities of a similar size that underwent a phase of long-term shrinkage from the 1930s until the late 1990s (Leipzig), and even the 2000s (Liverpool). Recently, both cities have stabilized their population, and in recent years have seen a modest growth of some thousand people per year. Both shrinkage and re-growth of cities result from the interplay of macro processes (for example, economic globalization, social or demographic change) and local settings of a city (including the political and institutional settings, strategic decision-making and planning, economic performance and labour market, population characteristics and development). In our approach, we highlight the qualitative dimension of both processes, i.e. we are mainly interested in its causal relationships and underlying dynamics as well as the impact it has on different fields of urban development. The paper seeks to compare the experiences of these two cities in order to discuss how regeneration policies and planning strategies have influenced re-growth. * Helmholtz Centre for Environmental Research - UFZ, Department Urban and Environmental Sociology ** Liverpool John Moores University, School of the Built Environment

Policy responses to shrinking cities

Emmanuèle Cunningham-Sabot (University of Rennes), Sylvie Fol (Paris 1 - Panthéon-Sorbonne University)

Cités Urban shrinkage is more and more defined as a 'global phenomenon' (Pallagst et al 2009). However, the national and local modes of regulation respond differently. Planning paradigms have long focused on urban growth, and national and urban governance have been primarily oriented to reinforcing the image of cities as growth machines. Therefore the recognition and perception of shrinking cities, nationally and locally is far from being evidence for some countries. The local and national policy responses to shrinking cities will be analysed in two countries: France and the UK. Three main questions will shape the comparison: What are the differences and similarities between the policies within the two countries? What are the influences of national and regional contexts? And are these policies still influenced by the growth paradigm? References: Pallagst, K., J. Aber, I. Audirac, E. Cunningham-Sabot, S. Fol, C. Martinez-Fernandez, S. Moraes, H. Mulligan, J. UDC 04-02 - Global winners and local losers? Regeneration strategies in the absence of growth in Asia and Europe 2

Chair: Thorsten Wiechmann, Sylvie Fol

New marginal areas in metropolises in Japan – issues and policy ideas

Tetsuji Uemura (Nomura Research Institute), Daisaku Honma (Ministry of Land, Infrastructure, Transport and Tourism), Toshiyuki Kigure (Ministry of Land, Infrastructure, Transport and Tourism), Shinichi Kusano (Ministry of Land, Infrastructure, Transport and Tourism), Miki Matsuoka (Nomura Research Institute), Masahiko Natori (Nomura Research Institute), Hiromi Otsuka (Ministry of Land, Infrastructure, Transport and Tourism)

'Marginal areas' has been used in the context of rural decay. Marginal areas can be observed not only in rural areas, but also in the high street in small cities, and furthermore, recently can be potentially emerged in urban areas, even in the suburbs of metropolis in Japan. Provided the recent public finance constraints and population decline in Japan, appropriate policies should be developed before the potential problems are realized. This paper tries to develop a package of policies to cope with the problems in the marginal areas in metropolises by literature review, interviews to local governments, private railway companies, GIS data analysis and so on. Previous researches suggest that the residential complexes developed in 1960s and in the early 1970s located in the area from one-hour commutes by railway from the city centre, and in which one-person households over 85 years old are increasing are facing on their decay. These areas cannot expect the social capital as in the traditional settlements and the composition of ages is almost simple. It can be concerned that the potentiality of increase in the number of vacant houses and unused lands is, therefore, expected to be high in five or ten years. On the other hand, the areas with two of three conditions, 'more than one-hour far from city centre by public transportation', 'the 50 years history since the development', 'new towns' may survive from such a severe situation up to the policies. The Japanese ministry of land, infrastructure, transport and tourism promotes the corridor type compact cities along the railway lines. According to this policy, the private railway and government sector can make a good partnership each other in order to promote the residential shift from the elderly to the young, and the management of vacant

houses and unused lands. The history of residential complex development in Japan suggests that the marginal areas needing the management mentioned above will transition spatially by time passing. It needs the dynamic urban policy and plan to cope with the problems in metropolises in the future.

Reurbanisation as regeneration strategy of small shrinking German cities?

Sabine Beisswenger (ILS - Research Institute for Regional and Urban Development), Tim Dunkel (ILS - Research Institute for Regional and Urban Development)

In Germany urban shrinkage is a challenge that especially small and medium sized cities outside of urban agglomerations face. These cities and their regeneration strategies are in focus here. Based on numerous interviews with local stakeholders and on data on population development the paper compares the three case study cities Osterode am Harz, Pirmasens and Völklingen. During the course of the research project which provides the basis for the findings presented here it became clear that all of the cities follow some kind of reurbanisation strategy to cope with declining population numbers caused by out-migration and demographic change. For this reason the paper will give special attention to the relationship between shrinkage and the employment of reurbanisation strategies by the local urban planning authorities. Reurbanisation is here understood as an actively pursued strategy of local urban stakeholders to strengthen central parts of the city with the aim of future-oriented sustainable development of the city against the background of ongoing population decline. In this paper, firstly the medium-term developments of the three cities are presented, depicting changes in the industrial structures over the last four decades and the turning points from growing to shrinking cities. Secondly, the specific reurbanisation strategies are characterized and connected to population changes on the spatial level of single city quarters. These results are, thirdly, related to specific local developments, to urban governance constellations and urban and industrial structure and contrasted with corresponding findings on larger cities as presented in the relevant literature. Drawing conclusions from this comparison this paper finally attempts to introduce in a more abstract manner a range of reurbanisation strategies that can be found in shrinking small and medium sized cities.

Urban shrinkage in Poland in the context of the development pathways of "winners" and "losers" in the post-socialist transition

Emilia Jaroszevska (Adam Mickiewicz University Poznan), Tadeusz Strykiewicz (Adam Mickiewicz University Poznan)

The post-socialist transition that started in Poland at the beginning of the 1990s has diversified the country's level of development. The ever more readily visible polarisation that this process has produced manifests itself in the concentration of the population and economic development in metropolitan areas and depopulation and economic collapse in peripheral ones. Most metropolitan areas, which are the "winners", have been able to adjust their economies to the new market conditions fairly quickly. Even so, when analysing the biggest cities with developing metropolitan functions, from the very start of the systemic transformation one can observe a dynamic suburbanisation process there. The process of urban shrinkage - understood in terms of the appearance of problem areas suffering both, a long-term depopulation trend and a socio-economic crisis - largely affects cities and towns from the remaining group, that of "losers". They grapple with such problems as industrial decline, high unemployment rates, and an outflow of the population (especially young and educated). These are in particular old industrial towns with the predominance of the heavy, extractive and textile industries. The chief aim of the paper will be to present and compare two development paths of cities located in the same region of Poland (Lower Silesia). The first will be discussed using Wroc'aw as an example of a city belonging to the first group, of "winners". The other type of path will be illustrated by the former mining city of Wa'brzych, situated close to Wroc'aw, a mere 60 km away, but classified as a "loser". An attempt will be made to account for the differences in the development potentials of the two cities with the help of the concept of path dependence. On the basis of the identified critical junctures or windows of opportunities, factors and processes will be discussed that have crucially affected their historical growth trajectories, including the process of shrinkage. Finally, different types of regeneration strategies and their effect on the development of the two cities will be presented.

Key words:

Facing a new enemy: Reactions for shrinking-based challenges in Hungarian small towns

Gábor Pirisi (University of Pécs), Tamás Németh (University of Pécs), András Trócsányi (University of Pécs), Tímea Vercse (University of Pécs)

Shrinking is not only a phenomenon of the urban decline: it also appears in rural places, where small towns suffer from the loss of population and functions. Present demographical processes and the future perspectives together with the structural problems of dominantly rural areas shows that without the dramatic change of social and economic paradigms the depopulation and shrinking will be the most typical process for the rural areas outside the urban agglomerations for the next decades. In Hungary, where about half of the population still live in rural environment (including villages and also small towns), and where the natural loss and even more the emigration decreases significantly and rapidly the population, shrinking appears much more in these, rural level, than being an urban issue. The depopulation of villages has even started between the 1950s and 1980s and against all political intentions and public disapproval still and even faster continues today. Strategies were developed for stopping this process but no coherent plans were created to handle the shrinking. Till the last years, small towns have not suffered from the shrinking: their population became stabile, or even has been grown; most of their traditional functions were connected to the local and micro-regional public services, and were guaranteed by the state. This stability was only available due to the supply of the demographic reserves of the surrounding rural areas, and these reserves were depleted. That resulted the start of a massive decline of quantity and quality of human resources. Beside the negative trends in population, the small towns suffer a relative decline in spatial functions too. Due to the economic globalization and its macro-regional consequences, including the political, social and economic transformation of the 1990s in Eastern-Europe, the former roles of small towns in employment, supply and services has been revaluated by the markets, investors and consumers. With the forced withdrawal of state due to the finance-crises, which lead us to the reduction of welfare state - an important pillar of the Hungarian small towns' development could fall again, because these settlements based their development partly on exogenous, even on public-financed resources. Our research goal is to investigate how the small town municipalities handle the problem of shrinking. With methods of analyzing the content of development strategies and action plans, we will reveal, how conscious settlements facing the phenomenon related with shrinking and what kind of strategies and goals are developed to handle this situation. With

comparing the empiric results the statistic-based analysis of shrinking trends among the small towns we will show the most problematic fields of small towns' adaptation.

Spatial distribution of urban regeneration processes in Riga

Guntis Solks (University of Latvia)

Urban regeneration processes are considered as part of current urban development of Riga. These process are one of the key issues in order to achieve sustainable urban development in various ways and it should be important for Riga as a post-manufacturing city with significant proportion of brownfields. The purpose of this research is to characterize the spatial distribution of urban regeneration processes in Riga. The tasks of the research include: 1. Review of theoretical issues regarding urban regeneration processes; 2. Characterization of urban development trends in Riga; 3. Exploration of transformation processes of urban brownfields in Riga; 4. Determination of the spatial distribution of urban regeneration processes in Riga; 5. Evaluation of the urban regeneration processes in Riga. The research methods include review of literature, field studies, interviews with experts and GIS methods. The results are described focusing on social, economic and cultural issues, in order to evaluate their role and importance for successful urban regeneration in Riga. Various proposals and solutions for further urban development of Riga are recommended on the basis of the results of this research. Spatial distribution of urban regeneration processes in Riga is uneven what is determined by various factors - trends of the national economic growth, activities in the real estate sector, geographical location and built-up structure of particular urban areas as well as other factors. Most of the urban regeneration processes in Riga are concentrated in the central part of the city, because it is one of the most prestigious neighborhoods where historical buildings, what require redevelopment, are concentrated. Other neighborhoods, where urban regeneration activities are also common, have various different features and implications of urban regeneration processes, that determines the diverse character of urban transformation process in Riga. Urban regeneration processes in Riga are identified and evaluated based on the methodology elaborated by the author. The results are processed, appraised and interpreted in the context of local administrative subdivisions (neighborhoods) of Riga in order to represent spatial distribution of urban regeneration processes in Riga. Local urban planners and municipal authorities have declared urban brownfield redevelopment as an important tool to achieve sustainable urban development,

thus promoting formation of compact urban structure of Riga and minimizing the effects of urban sprawl. In this context urban regeneration processes have to be evaluated as an important approach for further urban development of Riga. Keywords: brownfields, Riga, urban regeneration.

Shrinking Regions in Japan: Community ownership of assets as a development potential?

Thomas Feldhoff (Goethe University Frankfurt)

In the context of a decline in the overall national population, non-metropolitan areas in Japan are most severely affected by depopulation and demographic ageing. The fast-spreading 'marginal settlement' (genkai sh'raku') phenomenon refers to communities that have reached the limits of their manageability due to dramatic depopulation and where people aged 65 years or older make up more than half the total population. This challenge requires a fundamental shift in Japan's policy response to trends of regional abandonment and collapse. Former development strategies based on the Mountain Village Promotion Act (Sanson shink' h', 1965) or the Emergency Act for the Improvement of Depopulated Areas (Kaso chiiki taisaku kinky' sochi-h', 1970) obviously failed and the government has to take into account new challenges such as globalization, social and demographic change. The paper aims to analyse current and future economic and socio-demographic challenges facing shrinking regions in Japan, and to assess the development and institutional context of related government policies. It argues that local communities should abandon the expectation of externally induced revitalisation and concentrate on asset-based community development. Giving communities the opportunity to capture the gains from public goods (e.g. natural endowments like land, wind, water) as well as private assets could improve the prospects for local livelihoods and quality of life. Community ownership of assets can be an important means to facilitate local engagement, foster local place attachment and thereby strengthen rural community resilience. Based on case studies, the paper provides some empirical evidence for this policy approach, which is a major challenge to state-society relations traditionally shaped from the top down. It requires local communities to become more independent from central government influence and to integrate

Prestige Events and Shrinking Cities: Pathway to Regeneration? The Case of Vladivostok, Russky Island and the 2012 APEC Summit

Chung-Tong Wu (University of Western Sydney), Nicolas Buchoud (Renaissance Urbaine Consultants)

Policy makers in charge of shrinking cities face many obstacles, notably a falling population and loss of economic vitality. The fear is that unless something dramatic is done these negative factors will in turn feed into each other leading the city into a downward spiral. Like their counterparts elsewhere, many policy makers look towards major events as a catalyst to catapult the city out of the vicious circle. Competing for major mass attendance events such as the Olympics, the World Cup and World Expos are notable examples. Other more political or economic oriented prestige events with restricted attendance such as the meeting of the World Bank, or the Asia Pacific Economic Cooperation (APEC) are also seen as worthy catalyst events. This paper utilizes the forthcoming APEC 2012 Summit in Vladivostok to explore the possibilities and implications of hosting a prestige event for a shrinking city. Vladivostok, a city with a population of about 578,000 is the largest Russian city in Russia's Far East region. As the capital of the Primorskiy Krai it has the distinction of being a major Russian port city located near the borders with China and North Korea. Over the last decade, Vladivostok lost 10% of its population due to a combination of factors including falling birth rate, lack of economic growth and the Eurocentric policies of the government as well as the population. In September 2012, Russia will host the APEC Heads of States Summit and several parallel meetings on Russky Island--a coastal area facing Vladivostok's main urban core. It is expected that this event of complex geogstrategic significance will kickstart the revitalization process of the city and its region and at the same time assert Russia's presence in Asia. The central government is investing several billion dollars to upgrade its airport, to build new infrastructure, expressways, bridges and new conference facilities to host the APEC meeting. The federal government has also invested in defining new flagship projects based on education, innovation and education as means to ensure a viable economic development strategy. This raises exceptional challenging and exciting conceptual and practical issues for a shrinking city in a globalized environment. APEC Summit planning has brought new investments and considerable attention to Vladivostok and Russky Island but whether these will have lasting effects will depend on a large number of factors. Experience elsewhere casts doubt on the efficacy of these strategies for a city still remote from the consciousness of its own population and the rest of the world. Utilizing

published and unpublished data, this paper compares the strategies of Vladivostok with the experience of other cities that have adopted similar strategies. It questions the conditions under which a shrinking city in a highly strategic and yet largely ignored region of Russia could be converted as the gateway for innovative urban regeneration.

Cities without Growth. Urban Development under the Conditions of Demographic and Climate Change

Babette Scurrell (Bauhaus Dessau Foundation), Heike Brückner (Bauhaus Dessau Foundation)

Saxony-Anhalt as one of the new federal states of Germany has been experiencing three essential transformations within the recent 20 years: the social-political and socio-economic transformation from a socialist into a capitalist society, a rapid demographic change and early signs of the global climate change. In 2002 the state government set up the process of the International Building Exhibition (IBA) Urban Redevelopment Saxony-Anhalt 2010 with the Bauhaus Dessau as one partner to pay special attention to the problem of demographic change. The IBA Urban Redevelopment 2010 was a 'laboratory', where innovative urban redevelopment 'tools' were tested and applied. Its objective was to build up practical redevelopment expertise and to devise pilot schemes setting standards for urban design under the conditions of demographic, economic and social change. The year 2002 was at the same time the year of the 'hundred year flood' of the river Elbe. Man-made influences like soil sealing and river regulation or unusual extreme weather events as a consequence of climate change caused a catastrophe and aroused interest in urban planning in the river basin - adapting to climate change became suddenly a very up-to-date topic. While the losses in population have not come to an end and the climate change challenging urban planning is just beginning the cities of Saxony-Anhalt can draw on experiences in change management from the recent 20 years. The authors argue that changes in urban structures, especially in urban landscapes, as well as the strong tendency to citizens' participation in urban redevelopment processes pave the way to adapt to change. Furthermore the activities towards and the debate on sustainable urban development sensitized the population to the new challenges. The paper will explore what this means for future concepts. Can the procedures and instruments designed in one transformation help to prepare the cities for the next changes? Are there opportunities in shrinking when it comes to answer the challenges of climate change? Do experiences from urban development without growth contribute to

strategies for developing a resilient city? Can prosuming, like it emerges in the energy sector, become a strategic answer to the demands of demographic and climate change? Confirming the conclusions from the processes since 1990, one outcome of the IBA Urban Redevelopment 2010 is that in cities without growth we find new actors for urban development making other sorts of investment, which result in different returns. Their manifold interests and goals, their unusual contributions to urban development and most important their experience of negotiating aims and methods of urban development with each other offer a good starting point to meet the new challenges. It might turn out, that the presumed losers of demographic change are the future winners in climate change.

UDC 05-01 - Health and sustainability in the cities of the future – the impacts of urban environments, urban green and urban blue elements

Chair: Thomas Claßen, Richard Mitchell

Using NDVI for estimating the influence and mitigation effect of urban green on heat-related excess mortality in Lisbon, Portugal

Katrin Burkart (Humboldt-Universität zu Berlin), Fred Meier (Technische Universität Berlin), Paulo Canário (Universidade Lisboa), Dieter Scherer (Technische Universität Berlin), Wilfried Endlicher (Humboldt-Universität zu Berlin)

Climate and weather exert profound effects on human health and well-being. Non-linear relationships between temperature and mortality/morbidity have been observed at high and low values. The heat-mortality and -morbidity relationship varies across time periods, regions and populations. Time-series studies have shown that different cities and population groups exhibit different responses to heat. The underlying reasons for these differences are only partially understood. The demographic composition as well as the spatial structure, the degree of urbanisation, population density or the urban design and morphology might be crucial in shaping the atmospheric effect. Due to the projected consequences of climate change, the hazardous nature of heat effects and heat-related excess mortality has been given increased attention in science as well as politics. Moreover, the superimposed urban heat island (UHI) effect is likely to aggravate health threats in urban areas. The primary objective of this study was to assess the influence and mitigation effect of urban green on heat-related excess mortality in Lisbon, Portugal. One way to mitigate the UHI intensity is by increasing the amount of vegetation in cities. The spatial distribution of the amount of urban green in Lisbon is described in terms of a common remotely sensed vegetative index, the Normalized Difference Vegetation Index (NDVI). The Moderate Resolution Imaging Spectroradiometer (MODIS) sensor aboard the Terra (EOS-AM) satellite provides data for this investigation. The MODIS Level-3 product MOD13Q1 is used to quantify the mean spatial distribution of NDVI for the period 2000-2008. The spatial resolution of NDVI is approximately 250 m. Further, the intra- and inter-annual variability of NDVI for local administrative units in Lisbon and rural areas are computed in order to clarify if the vegetative conditions during distinct hot and dry periods are significantly different from the mean annual course. In order to assess the combined effect of different

meteorological parameters, i.e. temperature, humidity, wind-speed, radiation, on the human heat balance, we applied a thermo-physiological model and calculated the Universal Thermal Climate Index (UTCI). This modelled atmospheric index is combined with daily spatially stratified all-cause mortality data using a generalized additive model (GAM) adjusting for several confounder variables, such as trend, season, day of the month and day of the year, as well as air pollution and demographic characteristics. In order to quantify heat effects above a particular threshold value we use a breakpoint model (hockey-stick model). Understanding and accounting for the role and beneficial character of urban green is of major importance for public health.

Green for All! Examples of children's therapeutic landscapes of activity from Germany and New Zealand

Silvia D. Schäffer (University of Bonn), Christina R. Ergler (The University of Auckland)

The positive impact of natural environments on adults' participation in active leisure and mental well-being is well discussed in the literature. Children's voices, however, are only a whisper in this context. With escalating indoor sedentary activities and associated limitations such as decreasing rates of physical activity and increasing prevalence of obesity, children's perspectives warrant being brought into view. Safe environments in which children can play and explore their surroundings as in past generations are limited. It is important to include children's voices more loudly in debates on nature benefits in urban areas and to foster participation in outdoor activities. We propose a theoretical framework under the umbrella of therapeutic landscapes of activity attuned to children's perspectives and needs. We embrace in this framework aspects of green environments affording children's resilience, health promotion and general well-being. In addition, we include how institutional and social settings can contribute positively to children's participation in safe outdoor activities. To embed the theoretical aspects empirically, we draw on two case studies. The German study is set within the institutionalized context of forest kindergartens, which offer children in this densely populated country regular relation to and activities in nature. Drawing on semi-structured interviews with head teachers in these settings, we present their perception on the impact of regular nature exposure on children's healthy development and well-being. In contrast, the New Zealand study draws on findings from a comparative study of apartment living and suburban housing. While New Zealand projects a "green and (c)lean" image internationally and its citizens regard themselves as outdoor people, child-led

neighbourhood walks and semi-structured interviews with parents and children revealed that apartment dwellers are divorced from knowledge of, and movement in, natural settings. Reflecting on both case studies, we conclude with a call to rethink children's present linkage with natural settings in urban environments. While restorative aspects of green environments have priority for adults, children evaluate the same environment differently; physical, mental and social benefits often arise in relation to activities carried out in natural settings. To enable children as grown ups to enjoy the restorative aspects of nature, we need to combat their recent alienation from nature and turn urban green environments into accessible places for the youngest.

Environmental and Socioeconomic Benefits of Urban and Periurban Greening: The Case of Aksu in NW-China

Martin Welp (Eberswalde University), Abdulla Abliz (Eberswalde University for Sustainable Development), Jörg Eberts (Eberswalde University), Siegmund Missall (Eberswalde University)

Urban and periurban forests in arid regions provide many ecosystem services (ESS) such as protection against dust and heat stress. China has in past decades taken great efforts to increase the forest cover in and around cities. The national afforestation program (tuigen huanlin) has been to a great extent motivated by the serious and frequent dust storms which have impacted China's megacities. But also in smaller cities major greening efforts have taken place. The Kökyar project at the fringe of the city of Aksu, Northwest China is one such prominent example, and it is frequently cited as a model for other cities in China and elsewhere. The case study is part of a project, which is focusing on river basin management in the oases around the Tarim River. Surveys and interviews in the City of Aksu revealed, that besides the concentrated and early efforts by the local government, crucial for the success have been the socioeconomic benefits which the local farmers gain from managing forests and agricultural land. In future climate change and increasing competition about scarce water resources due to agricultural expansion is likely to be a challenge for water management, and eventually for urban greening. New management ideas, such as the use of locally adapted, drought-resistant species, the use of biochar to enhance water retention of soils, as well as shift towards an ecological greening paradigm within cities are currently being discussed among scientists and stakeholders. Furthermore new economic incentives, such as payments for environmental services (PES) and improved communication and cooperation between key agencies can improve the provision of ESS of urban and periurban

vegetation in future. References: Krause, G. and Welp, M. 2012. Systems Thinking in Social Learning for Sustainability. In: Glaser, M., Krause, G., Ratter, B., Welp, M. (eds.) Blue or Green? Healthy environments in the inner city

Sebastian Völker (University of Bonn), Thomas Kistemann (University of Bonn)

Cities challenge various health problems nowadays. There is a consensus in research that urban green space contributes to human health and well-being. But having a closer look on urban green one can recognise that many spaces are in fact blue. Water has a central significance in settlement areas in history and today, i.e. as an important aesthetic landscape element or for integrated development and coordinated design. Although there is an increasing need for healthy places in cities like urban blue, those spaces are mostly disregarded as a beneficial health factor by planners. The concept of therapeutic landscapes dedicated to analyses at blue space (Völker and Kistemann, 2011) is used to analyse salutogenetic health processes at the promenades at the river Rhine in the city centres of two German cities (Cologne and Düsseldorf). The research area is analysed thoroughly using a complex of qualitative and quantitative methods from diverse disciplines to obtain a multi-dimensional image: qualitative interviews, qualitative questionnaires, participant observation, and spatial analysis. At the promenades health enhancing and health limiting aspects were recognised in each dimension of appropriation and substantiality within the basic concept. Visitors of the promenades admire the view of water and the beautiful environment. They show a clear relation to the promenade with a strong sense of place, expressed by the striking feeling of home. People experience relative social equality and conduct social relations and contacts at the promenades. They are favourite places to spend leisure time and to do recreational activities, restoring from everyday stress. Urban blue can be interpreted as a therapeutic landscape element and contributes to human health and well-being in urban contexts. The health enhancing aspects distinctly prevail health limiting aspects. The regard of urban blue as a health factor in planning issues is a large potential for enhancing health in cities.

UDC 06-01 - How European towns deal with peripheralization – different action strategies and comparable structural baselines

Chair: Sabine Beißwenger, Hanna Sommer

Peripheralisation and uneven development. Approaching spatial inequalities.

Matthias Naumann (Leibniz Institute for Regional Development and Structural Planning)

While there is a growing body of literature - initiated mostly outside Human Geography - on the 'peripheralisation' of cities and regions especially within the context of shrinkage in East Germany (Beetz et al. 2008, Bernt et al. 2010, Keim 2006), a theoretical understanding of 'peripheralisation' is still missing and there exist only few connections to other conceptual approaches to explain spatial inequalities. Especially the Anglophone Critical Geography provides an elaborated debate on 'uneven development' as the production of spatial differences within capitalist societies. Theories of 'uneven development' include more general concepts on the spatial dimension of capital accumulation (Harvey 1982, Smith 1984, Soja 2011) but also work that is embedded in certain regional or economic contexts (Hadjimichalis 1987, Massey 1995). All approaches of 'uneven development' have in common the understanding that spatial inequalities are inherent to capitalism. Despite its rich theoretical foundation, there are very few attempts to apply 'uneven development' to the analysis of regional or urban decline. Furthermore, 'uneven development' is a concept that has been neglected in research on newly emerged peripheralised regions. The paper looks on similarities and differences between the approach of 'peripheralisation' and the theoretical concepts of 'uneven development'. What are the potentials and limitations of each concept? Is it possible to combine macro theories such as 'uneven development' with micro-range concepts of 'peripheralisation'? Is 'peripheralisation' just another name for 'uneven development'? Is 'peripheralisation' applicable to cities and regions outside East Germany and what can concepts of 'uneven development' contribute to contemporary cases of urban and regional decline? The discussion of these questions addresses the fundamental problem of understanding local specifics without neglecting general and global developments as well as possibilities for theorizing research on peripheralised cities and regions.

Peripheralization and development strategies in French shrinking cities

Helene Roth (Université Blaise Pascal)

The paper will propose an analysis of development policies and strategies in cities dealing with peripheralisation in French shrinking 'regions' (départements). These cities have to cope with contradictory processes. On the one hand, the structural context (demographic, economic and infrastructural weakness), the macro-economic developments and the spatial planning strategies at national level increase the dependency of shrinking cities and strongly limit their capacity of action. On the other hand, the development of intermunicipal cooperation, the changes in multilevel governance (especially since the 1990's and 2000's laws on decentralisation, planning governance and intermunicipal cooperation) and the emergence of alternative development models contribute to open new development opportunities for local actors. How do these two processes interact in shrinking cities? Are local development theories relevant in a regional context of increasing peripheralization? Is peripheralization and increasing dependency compatible with the emergence of coherent, integrated and sustainable development strategies at urban level? In the French context, two patterns of dependency will be particularly questioned: -The role of incomes dependency as a resource for local development (Davezies, 2004) -The role of State level in urban governance, in a national context which is still shaped by a tradition of centralisation. These questions will be explored through the analysis of development strategies and actions in small and medium-sized towns situated in shrinking regions of the northern fringe of Central Massif. These studied cases present a similar structural context: emigration and demographic change; desindustrialisation and lack of innovation; internal and external stigmatisation. Nevertheless, although the structural 'background' is similar, the case studies will stress possible differentiation in strategies, actions and governance. The case studies are based on qualitative interviews of experts, completed by statistical data analysis.

Town Centre Management: The Portuguese Experience

Pedro Porfirio Guimaraes ("IGOT; CEG")

In recent decades we have witnessed a process of expansion and dispersion of the city that is unparalleled in urban history (Fernandes, 2007). Because new centralities have appeared within, or in the surroundings, of the largest cities, the once predominant centre of the city has become only the traditional centre

(Fernandes, 1994), experiencing a loss of functions to other areas. Being something that is similar across several cities and not a phenomenon unique to urban centres in Portugal, we are seeing a migration of the functions of city centres to new peripheral areas (the new centralities). This causes problems in employment and residential function (Barata-Salgueiro, 2006). The old city centre failed, in most cases, to keep pace with changes, making it more susceptible to the weakening of its position in the urban hierarchy. The old centre tends, however, to maintain a position in the city (Dear and Flusty, 1998), although one may admit as merely mentally relevant area of "the city. This superiority seems to be sometimes very faintly supported for historical reasons, assigning an importance that these spaces in concrete may not have. Some interventions in Portugal seem to be based upon these trends. Several programmes have been introduced to support the retail sector with the aim of promoting the revitalization of city centres. They have showed a certain preference for interventions located in the old central areas of cities. These programmes highlight the value that the retail sector possesses. Incorporating this sector in the revitalization of those areas highlight its importance to the city. Relations between the city and retail are dynamic and fundamental, in both directions (Barata-Salgueiro and Cachinho, 2009). Within those programmes, in 2006, 47 new mechanisms of intervention were supported in inner cities, based on public-private partnerships, formed in order to tackle the problems that have plagued these areas for decades. These new structures are based on the model of Town Centre Management schemes (TCMs). As in many other countries where this sort of measure is introduced, this intervention model admits the success of existing shopping centres in that it attempts to acquire or reproduce some of the features that they implement successfully. Adapting approaches used in private places to public space was the main focus of these schemes. The management of city centres includes topics like: promoting the city centre; putting forward common services to the retailers that individually they wouldn't be able to have; promoting an ongoing dialogue between the various stakeholders involved in the respective areas. The presentation aims to shed some light to the process of implantation of TCMs in Portugal discussing: the context in which the schemes appear; the work developed; and conclusions about the strengths and weakness of the process.

The Resilience of City Centres: The Role of Retailers

Pedro Porfirio Guimaraes (IGOT; CEG)

Cities are not static places, changes have been always a part of them. How cities respond to these changes is not the same in all of them, and the reaction is not equal in the various centres that make up a city. In fact, the various centres within cities also evolve, experiencing constant changes in their role in the urban setting. The place they occupy in the hierarchy of the city may change over time. However, there are centres that respond better to changes than others, that is, while some centres cannot adapt to change and decline, others can adapt and maintain their function in the city. This adaptation while maintaining the essential functions can be designated as resilience. Although it's a concept that arises from other sciences, the application in the context of human geography, in general, and in urban and retail studies is of high importance. In the present context, resilience, can be defined as The ability of different types of retailing at different scales, to adapt to changes, shocks or crisis, challenging the system's equilibrium, without failing to perform its functions in a sustainable way (Replacis, 2010). This presentation departs from the project REPLACIS - Retail Planning for Sustainability Cities, held in partnership with researchers from various national contexts, such as Portugal, France, Sweden and Turkey. This project recognizes that retail is a crucial element of contemporary city life and connects the sustainability of the city with the preservation of diverse retail systems, which must have the capacity to respond effectively to the needs and desires of different types of consumers (Cachinho and Barata-Salgueiro, 2010). It is intended to discuss the role of retailers in the resilience of retail areas and how their profile can influence the viability and vitality of an area. It is admitted that, generally, there are three different types of retailers, according to their attitude towards business: (1) Passive, retailers who were unable to take steps to keep the pace of change and adopt a posture of resistance to change, which can lead to decline, (2) Reactive, retailers who recognize the changes that happen and take measures in order to track changes, (3) Pro-active, retailers that realize and anticipate the changes and are at the forefront of the changes that happen in the consumption habits of the various consumers. With this presentation, we aim to understand the relationship between the type of retailers present in a particular area and the ability of that same area to be resilient and adapt to change. The analysis will be anchored empirically in several interviews that were done with retailers of distinct areas of Lisbon.

UDC 07-01 - International migration and 'glocal' spaces of vulnerability 1

Chair: Benjamin Etzold, Tabea Bork

Multi-local livelihoods. Case studies on international labour migration from Thailand.

Patrick Sakdapolrak (University of Bonn)

Castles and Miller (2003) has named the period of intensifying human mobility that is continuing to evolve since 1945 as the 'age of migration'. International migration has become one of the most important factors of global change - it has never been as widespread and its socio-economic and political significance has never been as high. The majority of people on the move are labour migrants, who embody the prototype of the migration of modern societies. One of the countries where international labour migration plays an important role is Thailand, which is a major receiving as well as sending country of migrants. Most international migrants from Thailand are originating from peripheral and marginal areas in the North and North-Eastern region. These areas have benefited less from the dynamic economic development since the 1980s and are more vulnerable against social and ecological stresses. This paper studies international labour migration on the basis of two empirical case studies from North and North-Eastern Thailand. It utilises the livelihoods approach as a frame work of analysis and as a way to embed migration in the context of social vulnerability and multi-locality. It is argued that the livelihood approach as a holistic concept, which focuses on households and daily life of people while embedding them in a broader context, is a way to enhance the understanding of migration as a multi-local livelihood strategy. The results presented are based on data gathered through quantitative, qualitative as well as participatory methods in villages in the provinces Lamphun and Khon Kean. The paper describes migration movements from the study areas as structured through changing external demands and institutionalised networks. It focuses on the causes and effects of international migration and aims to reveal constraining and enabling factors of migration. The paper shows that while social as well as ecological stresses can initiate migration, feedback processes triggered by international migration are driving forces for continuing migration flows. The paper concludes that for the explanation of migration movements there is a greater need to embed migration in multi-local networks through which resources, ideas, information and commodities flow.

The Link between Remittances, Farm Investments and Water consumption in Kerala, India

Agnes Pohle (Kassel University)

The paper answers the question how far remittances from international migrants have an impact on farm households. International Organizations as well as many experts see remittances as tool to increase income, as an engine for development, as safety net for the rural poor, and as coping strategy and/or buffer against economic shocks (Mouhoud et al., 2008; Ratha, 2007; Yang, 2007). Critics claim that remittances increase inequality of regions, do not contribute to poverty reduction, and erode social structures (Acosta et al., 2009; Åkesson, 2009). A number of surveys reveal that remittances enable households to invest into the farm sector (Taylor 2006; Cohen and Rodriguez 2005; Wouterse and Taylor 2009). Based on the New Economics of Labour Migration (NELM) and empirical evidence supplied by Möller (2002) and Wouterse and Taylor (2009) we hypothesize that households invest remittances for reducing risks by diversifying agricultural production and for overcoming credit constraints. The extent paper investigates the following questions by considering the case of Malappuram district in Kerala, India: (1) How far are remittances to rural areas used for farm investment? (2) How far do these investments influence water consumption? Malappuram district has been chosen as case study because of the high share of migrants and the high amount of remittances transferred from international migrants (Zachariah and Rajan, 2010) as well as their specific situation of water shortages during February and May (Nair and Chattopadhyay, 2005). Data encompasses 400 interviews conducted between 2010 and 2011. Results of descriptive analysis show that out of 400 farm households 32% received remittances and 21% invested remittances in the farm sector. Altogether farm households received a total of 19,176,600 Rs remittances (282,178.30 EUR) in 2010. 85 households invested 1,605,000 Rs (23,604 EUR) remittances in the farm sector in 2010. During 2006 and 2010 farmers invested a total of 5,619,158 Rs (82,582 EUR) remittances in labour wages, fertilizer and irrigation facilities and rent of farm machinery. Our analysis highlights that in the short term remittances relieve the economic situation of farm households giving room even for investments. In the long term, however, remittances increase water consumption and may contribute to water shortage. While initially mitigating socio-economic vulnerability of farmers, remittances may thus in the long run even enhance their vulnerability by deteriorating their ecological environment which has, in turn, severe repercussions on their socio-economic living conditions. Hence, this research points to the indispensable

need of including environmental impacts of remittances into the overall account. The findings help governments and national and international agencies to adequately respond to the challenges from the use of remittances by seizing their respective opportunities while preventing avoidable harm.

Lines across the desert: Mobile phone use and mobility in the context of trans-Saharan migration

Max Leonard Schaub (University of Oxford/ University of Oslo)

In West and Northern Africa, mobile phone coverage has been expanding parallelly to increased attempts by Africans to migrate overland to Europe. This paper explores possible links between the two phenomena, looking specifically into the role of mobile phones in trans-Saharan migration. It provides a first detailed description of the telecommunication processes underlying contemporary trans-Saharan migration. An analytical framework is presented that helps to explain how mobile phones facilitate migration by interacting with the social and spatial factors shaping migrants' mobility. By drawing on this framework and fieldwork conducted among Congolese migrants in Morocco, it is shown that the expansion of the communication infrastructure is, on the one hand, only one of several factors that have turned the region into a more 'transitable' space. On the other hand, the use of mobile phones is demonstrated to be central to the migration process: migrants draw on the unprecedented accessibility of contacts equipped with mobile phones to tie together novel, geographically expansive networks. Phones are also shown to be used by migrants' 'helpers' for the purpose of internal coordination.

'Under the radar': Undocumented immigrants, Christian faith communities, and the liminal spaces of belonging

Patricia Ehrkamp (University of Kentucky)

The recent proliferation of anti-immigrant legislation in the U.S. South has created new threats of detention and deportation for undocumented immigrants, and puts those at risk who provide support and services to undocumented immigrants. In this context, this paper examines how Christian faith communities seek to provide spaces of belonging and advocacy for undocumented immigrants who find themselves in increasingly precarious situations due to policing and border enforcement in the interior of the U.S. The U.S. South as a "new destination" for immigration in the U.S. serves as a case study of the rapidly changing landscapes of anti-immigrant legislation and the ways that

communities of faith have challenged such legislation (as in Alabama) and provide safe havens for immigrants at risk of detention and deportation. This paper investigates faith communities as liminal spaces of citizenship in which pastors and lay members of the congregation work through numerous tensions surrounding Christian principles of "welcoming the stranger" and the contradictory impulses provided by "law-and-order" understandings of anti-immigrant legislation and citizenship frameworks in wider society. Contrary to existing work on immigration and faith that focuses narrowly on the role of religion for civic engagement, this research is interested in the challenges and tensions that emerge within communities of faith in relation to undocumented immigrants, law enforcement, and faith interpretations. It examines the multiple strategies in which individual pastors and congregants implement their ideas of faith and social justice in ways that help undocumented migrants, but neither challenge nor affirm dominant normative and legal frameworks. Interviews with pastors show that communities of faith become important spaces of spiritual, social, and material support for vulnerable undocumented migrants. For example, some pastors provide character evaluations in order to secure undocumented migrants' path to legal residence and citizenship. Others publicly affirm the notion of "law and order" while simultaneously communicating with law enforcement officials in efforts to find strategies that reduce immigrants' risks of detention and deportation. These strategies frequently entail "laying low," that is, not disclosing support strategies to lay congregants and advising undocumented congregants to avoid public spaces where possible. Together, these findings show that communities of faith emerge as highly conflicted spaces in which pastors and lay members (among them undocumented migrants at risk of detention and deportation) have to tread carefully in efforts to open up spaces of hospitality that are always at risk of erasure by conservative and anti-immigrant forces within the community of faith and beyond.

UDC 07-02 - International migration and 'glocal' spaces of vulnerability 2

Chair: Benjamin Etzold, Tabea Bork

The everyday integration of migrants: some examples from Morocco, DR Congo and Zambia

Oliver Bakewell (University of Oxford)

Much of the analysis of international migration focuses on the interaction between the migrants and the destination state, in particular its policies on immigration, integration and the settlement of migrants. International migration is widely associated with an increase in migrants' vulnerability to economic and social exploitation, political repression and even violence. The integration of migrants into the destination society is seen as a crucial step for reducing this vulnerability. While it may be appropriate to focus on state policies in the case of highly developed states - where the administration reaches into nearly every corner of life - it must be questioned in poorer regions of the world, where the capacity of the state may be very limited, especially in remote border regions. Many countries in developing regions have very limited policies on migration and the gaps between policy and practice may be enormous. Drawing on research in Morocco, DR Congo and Zambia, this paper looks at the way different sets of migrants have integrated themselves, either in the absence of or contrary to government policies. By establishing economic, social and cultural links with local residents, different sets of immigrants have been able to establish a place in the society, even to the extent of gaining effective citizenship. It may prove politically impossible for many poorer states to adopt more liberal notions of integration. Nonetheless, it is important to analyse the processes of everyday integration that are continuing regardless. The paper argues that the complex mix of interests and negotiations which might be agreed below the level of the state - perhaps invisible to the state - may in practice, have much more significance for the lives of migrants than the best efforts of states or international organisations.

Navigating Urban Space in Eastleigh's First Avenue

Margaret Macharia (Katholieke Universiteit Leuven)

Eastleigh commercial centre in Nairobi, Kenya has undergone significant social and spatial transformations largely as a result of the redevelopment strategies

which have been initiated by the increasing Somali refugee traders in the area. Following the civil war which broke out in neighbouring Somalia in early 1990s, a huge influx of refugees migrated into Kenyan urban centres, a large number of which migrated into Eastleigh area in Nairobi. The initial perception of the refugees as a marginalised social group has however changed significantly, especially since they began to integrate economically and spatially as enterprising informal traders with access to social networks operating at both the global and local level. It examines the spatial expression of the social relations embodied in these multi-scalar networks by analysing the needs these networks are able to address. It further seeks to analyse the mechanisms that structure these commercial developments along Eastleigh's First Avenue and explores the tangible spaces being produced as a response to the social networks. Further to this, the case analyses the redistributive aspects of access to collective consumption goods such as infrastructure and public services in relation to all users of Eastleigh's First Avenue. This paper examines the concept of 'glocal' spaces of vulnerability as applied to the use of urban space in Eastleigh. Users of the urban space in Eastleigh include the local residents, the local authorities, Somali refugee businessmen operating huge shopping mall complexes and the informal street traders. The spatial reach and accessibility of the centres of distribution and consumption situated in Eastleigh's commercial area are analysed including the underlying logic guiding their organization. It also considers how the different conceptualisations of space and spatial quality of the different users in the commercial distribution centres of the shopping mall complexes on the one hand; and of the informal street, souk-like, market on the other hand; have evolved, conflicted, and been integrated in compromises on space and spatial quality. In addition it considers whose conceptualisations of space and whose spatial qualities have been or have not been integrated into these compromises and which methods have been pursued in the realisation of these compromises.

The living and working situation of African migrants in Guangzhou and Foshan, China

Birte Rafflenbeul (University of Cologne)

The living and working situation of African migrants in Guangzhou and Foshan, China. Birte Rafflenbeul, Department of Geography, University of Cologne, Germany Due to China's economic opening in the late 1970s and the following implementation of reform policies, one of the main goals set by the government was to open up the country in order to attract foreign investments and

technologies. China's rising economy attracts migrants from various countries with different social, economical and educational backgrounds. In the last three decades, and especially since China joining the WTO in 2001, the number of foreigners has constantly increased. The case of African migrants is special: Guangzhou is one of the main destinations for African traders in China due to numerous reasons (location of many factories in the PRD, the biannual occurrence of the Chinese Export Commodities Fair, proximity to Hong Kong, a well developed infrastructure, etc.). Their migration to Guangzhou started in the early 1990s but even though it got more challenging over the years, a constant increase was observed. In the preface of mega events (e.g. Olympic Games 2008 in Beijing or Asian Games 2010 in Guangzhou) the Chinese government substantially tightened its entry regulations for foreigners, making work conditions for temporary international migrants more difficult. Further, after a protest of African traders in Guangzhou in 2009, the police started to increase controls on migrants in clusters with high African densities. This was done in order to decrease the so-called "three illegalities": illegal entry, illegal housing and illegal work. These regulations made life and work of African migrants in Guangzhou and Foshan more difficult, as it got harder for them to apply or renew their visa. This paper focuses on a detailed analysis of the living and working situation and the related vulnerability of African migrants in Guangzhou and Foshan. These migrants live in different ethnical enclaves, which underlie rapid urbanization processes combined with ongoing segregation and fragmentation processes. This dynamic leads to socio-spatial clusters of African migrants that show different economical and social-cultural characteristics. The following analysis is based on a quantitative survey with 253 African migrants and a variety of different qualitative interviews that were conducted between March and May 2010. These qualitative interviews were done with different stakeholders like African traders, representatives of the migrant communities, a local resident's committee and a representative of an international organization in Guangzhou.

Roma Migrants in Germany and France: Mobility, Vulnerability and Coping Practices

Verena Sandner Le Gall (University of Kiel)

Roma migrants from South Eastern Europe figure among the poorest and most marginalized inhabitants of European cities, many of them living in precarious conditions. Like other, non-Roma migrants from the recent EU-member states Romania and Bulgaria, Roma have been seeking economic opportunities in

several EU states. With regard to migration processes and characteristics, such as the importance of circular mobility and transnational networks, they do not seem to differ much from non-Roma migrants from these countries (Legros and Vitale 2011)¹. However, in the regions of origin the situation of Roma - although these are far from being a homogenous group - often differ from non-Roma in that the previous are not only suffering to a greater extent from poverty, lack of opportunities for income generation and poor housing, but they also have to face discrimination and a marginalized position in society. Under these circumstances with often highly vulnerable living conditions and insecure livelihoods, international migration can be interpreted as one coping strategy. This contribution aims at focusing on the vulnerability of migrants in places of arrival where Romanian and Bulgarian Roma, in many cases, again face extremely poor living conditions, which include precarious habitat, often on territories at the margins of the cities, as well as difficulties concerning access to the job market and income generation, access to health services and education. At the same time, these poor living conditions as well as the high visibility Roma attain due to their specific economic survival practices call attention to the public and to policy-makers (cf. Legros and Vitale 2011)¹. Policies and administrative measures on different political levels, some of them specifically targeted at Roma, affect their daily lives (e.g. evictions and expulsion measures in France, EU migration policies and restrictions to the access to job markets etc.), and they partly also reflect actual trends of the securitization of migration policies. In this context, it is the aim of the presented research project to study the coping practices and resources that may play a role for resilience of Roma migrants who live under precarious conditions of exclusion in Germany and France. Of special interest are those ways of organising daily lives and those coping practices that are linked to political and administrative measures and requirements. The study combines a political geography perspective focusing on policies on different scalar levels with an actor-oriented approach to vulnerability. The presented contribution will explore the situation of Roma migrants from Romania in two cities in Germany and France (Hamburg and Bordeaux), presenting first results of a comparative study based on qualitative research methods. 1: Legros, O. & T. Vitale, in: Géocarrefour 86-1/2011, pp. 3 - 14 &

UDC 08-01 - Learning beyond borders: Exploring the spatialities of student mobility 1

Chair: Maggi Leung, Johanna Waters

Unsettling spatialities of student mobility and knowledge

Parvati Raghuram (The Open University), Clare Madge (University of Leicester), Pat Noxolo (University of Sheffield)

Discussions of internationalisation of higher education have been marked by a dominant 'flat' spatial imagination, in terms of fixed exchange notions of knowledge acquisition, fixed flows of travelling bodies, and the acquisitive agency of both students and institutions. We argue that, with few exceptions, the focus has been on knowledge acquisition, rather than on the circulation of knowledge produced in multiple locations. The emphasis has been on multiply-routed flows of students from particular peripheries to particular global education centres, with less attention to the complex south-south and multi-scalar interactions that characterise the shifting and uneven terrain of global student mobility. International students themselves are often hollowed out, as vessels that fill up with knowledge through mobility, rather than as potent sources of transnational knowledge circulation, producing and establishing knowledge institutions within (albeit uneven and contingently connected) transnational networks, not least through the pedagogic practices that the circulation of international students calls forth. This paper aims to unsettle the flat terrain of international student mobility. It re-examines practices of student mobility and of institutional pedagogy, to build towards an approach that is more malleable, flexible and contingent - one that thinks through the unsettling unevenness of international student mobilities.

Researching the international student experience: A methodological perspective

Laura Prazeres (University of London)

Young people are becoming increasingly mobile at a global scale. International mobility among young people is increasingly becoming the 'norm' in our globalised society. Some scholars have noted the rise of a youth mobility culture that has been socialized into a lifestyle of international mobility (Findlay et al., 2011; Fränberg, 2009; Woodfield, 2010). The growing internationalization of higher education is also contributing to the increase of internationally mobile

students. Despite this increase, international student mobility has received little attention from geographical scholars. This paper will contribute much needed attention to geographical research on international student mobility. The purpose of this paper is to provide a geographical perspective and methodological discussion on conducting research in this area. Prior work on student mobility has largely focused on the use of quantitative methods. Recent studies in the area have adopted more inductive and qualitative methodologies. This paper will discuss primarily qualitative methodological approaches to research on international student mobility, particularly visual methods and participatory approaches. The discussion will be supported by an empirical case study from my current doctoral research project on place-based and mobility-based identities among study abroad participants. My doctoral study examines the impact of place and mobility on students' sense of identity during short-term academic exchanges between Canada and the Global South. As such, the discussion will provide methodological considerations for examining the place-based and spatial dimensions of international student mobility

Negotiating heteronormative performances of gender: The experiences of international students from India in Canada

Gunjan Sondhi (University of Sussex)

This paper aims to contribute to the growing body of work on ISM experiences and extend it by introducing a gendered approach - by exploring how the living and studying abroad (re)shapes the Students' performance of gender identity. Specifically, the discussion explores the interactions between international students from India studying in the Greater Toronto Area (GTA), Canada and members of the South Asian community in GTA across multiple scales (body, family, community) and places (bars/clubs, cafes, universities, houses of friends and family, banquet halls, places of community and cultural events). In doing so, the paper serves two purposes: (a) highlights the differences between the expectations of heteronormative performances of masculinity and femininity by the members of the South Asian community, and the gender performances of the Students; and (b) shows how these differences (re)shape the gender performances of the students as they live and study in Toronto. The analysis is based on data collected between September 2010- May 2011 through in-depth interviews and participant observations with International Students from India, studying in Toronto, Canada.

Graduate migration policies and regional development in Canada & Germany

Tim Elrick (University of Erlangen-Nuremberg)

Increasingly, industrialized countries have to compete on a global scale for scarce, (highly) skilled human resources, in order to keep pace with structural changes and the growth of knowledge-centered economies. As (highly) skilled workers favor certain location factors that are generally found in urban environments, the competition is bi-scalar: the regions have to compete nationally against more attractive ones as well as internationally for 'the best brains'. While many countries have recently relaxed migration policies for certain groups of migrants, among them especially international students, many of these tend to cluster in urban agglomerations. Increasingly, non-metropolitan regions seem to take up the challenge to attract these international migrants, in order to keep up with urban regions. In this paper I will compare the political approaches of selected Canadian and German non-metropolitan regions in their challenge to attract and maintain international students to keep up in the regional development of knowledge societies.

UDC 08-02 - Learning beyond borders: Exploring the spatialities of student mobility 2

Chair: Maggi Leung, Johanna Waters

Destination Dublin: Motivations for UK students seeking international study in Dublin

Allan Findlay (University of St Andrews), Russell King (University of Sussex), Jill Ahrens (University of Sussex)

This paper seeks to theorise international student mobility in relation to the complex intertwined influences linking the globalisation of higher education to the changing global spatial differentiation of universities, and the drive by some students (and their families) to build cultural capital through acquiring the distinction of an international degree at a prestigious university. The paper arises from a major project analysing the motivations and experiences of UK students in USA, Ireland, Australia, France, Germany and the Czech Republic. The focus of this paper is a group of UK students interviewed in Dublin. As with other destination choices, Dublin attracted a specific cohort of students that was differentiated from other flows in interesting ways relating to the socio-economic and cultural contexts that shape student mobility at individual, household, school and state levels. The paper also touches on the specificities of the relations between Northern Ireland and the Republic of Ireland, as well as the rising significance of fee levels for students remaining in UK universities. The paper therefore illustrates the need to go beyond a transnational educational perspective and to recognise other spatialities and to embed international student mobility in the context of wider understandings of people's lifecourse mobility strategies.

The Transnational Migration Strategies of Chinese and Indian Students in Australia

Ghim Tan (The University of Adelaide)

Migration is increasingly transient, particularly among the highly skilled. In addition, countries engaged in a race for highly skilled labour are prepared to modify immigration regulations to attract those migrants. Australian immigration policy reflects how Australia sees international students as highly skilled migrants. Despite abundant research regarding the mobility of the highly skilled, there is a relative lack of investigation into the mobility of international students

and their subsequent migration patterns. This paper explores the nexus between immigration policy and international education by investigating the determinants of the mobility of Chinese and Indian students in Australia. While commentators are increasingly shedding more light on how international education can be a pre-cursor to permanent immigration in a host country, the emergence of transnationalism in migration literature suggests a need to examine how study locales are configured as gateways en route to an ultimate/central destination upon the student's graduation. This paper uncovers the underlying factors that motivate Chinese and Indian students in going abroad to study, as well as their future intentions when they graduate; and in the midst of this process, investigate the implications for immigration policy and the role it has in shaping their migration strategy.

International Student Decision Making: The Role of Friendship and Kinship Networks

Suzanne Beech (Queen's University, Belfast)

Over the course of the last two decades unprecedented numbers of students have chosen to leave their home countries and pursue higher education overseas. As a result, they are increasingly part of international knowledge networks, which provide them with the opportunity to study (almost) anywhere they wish, provided they have the capital to do so. My doctoral research investigates the motivations behind these mobilities and how students choose where to study. It shows that international student decision making is of a complex and multi-faceted nature. While the reputation of the university, cost of studying and job prospects all have a role to play, students are also influenced by the opinions and advice of those around them, building up complex ideas of place through these social networks. The individuals involved are diverse - friends, family and, at times, even relative strangers - share knowledge which they have gained either through their first-hand experience of studying overseas or based upon geographical imaginings they have constructed through their own networks. This paper seeks to establish how these friendship and kinship networks are embedded within the decision making of international students by drawing upon evidence from three UK universities. In short, students are influenced by a diverse range of networks when deciding to study overseas and the participants involved offer information, not only about the universities and courses at their disposal, but the cities and the regions as well.

To stay or to return? Dilemmas, decisions and justifications about cross-border educational migration

Monika Mária Váradi (Hungarian Academy of Sciences), Ágnes Er'ss (Hungarian Academy of Sciences), Patrik Tátrai (Hungarian Academy of Sciences), Doris Wastl-Walter (University of Bern)

The topic of educational migration arose in the framework of a migration research project, called Transmig (Integrating Transnational Migrants in Transition States) financed by the Swiss National Science Foundation. Transmig studies the migration processes triggered by the South Slavic wars in Vojvodina (Serbia) and Hungary by the analysis of data derived from semi-structured interviews conducted with migrants. The studied educational migration can be understood and be interpreted in the theoretical framework of both transnational and ethnic migration. Ethnic Hungarian students arriving from Vojvodina to study at universities in Hungary are transmigrants who simultaneously live in two countries and whose relations link them to two countries, albeit in different ways and with different intensities. In the frame of this specific form of transnational educational migration migrants, who are members of the transborder minority, move to a country which many of them consider their mother country, and although they are separated from this mainland by national border and the Schengen Agreement, there is no harsh cultural or language barrier. According to our research findings, educational migration is in most cases the first step towards permanently leaving behind the native country, Serbia. Nevertheless, in other cases, educational migrants, after finishing their studies, decide to return back to Vojvodina and/or try to develop and sustain a transnational, translocal life between Hungary and Serbia. In the presentation, our aim is to show what kind of reasons, underlying motives, push and pull factors (e.g. prospects of livelihood, command of the Hungarian and Serbian language, transnational networks) can be revealed behind the individual and family decisions on staying in Hungary or turning back to Vojvodina. From the interviews we have learn that next to mentioning practical reasons and motives the interviewees tend to interpret their own migratory decisions in the migrants' narratives of longing, belonging and identity; that is why we analyze data from this point of view as well. The decision about returning back can possibly be embedded either the narratives about remaining at the motherland and the moral obligation to thrive there as a minority Hungarian and/or the narratives about Vojvodinian/regional identity, described as a strong emotional linkage. Interviewees arguing about staying/returning often illustrate differences between the two countries applying the dichotomy of (developed, civilized, organized) Europe and (declining,

uncivilized, chaotic) Balkan. By this way, mentioning the 'balkanization' as main factor restraining them to return to Vojvodina, they unwittingly connect to the traditions of orientalist discourse.

UDC 09-01 - Managing changes in cultural heritage cities of South-East Asia

Chair: Mohammad Gamal Rindarjono, Thean Siew Tan

Urban heritage conservation, the case of Solo City, Indonesia

Putu Ayu P. Agustiananda (Universitas Islam Indonesia)

Urban heritage conservation, the case of Solo City, Indonesia The rapid physical development in the cities in Southeast Asia has put great pressures to the historic urban areas. It has caused deterioration, or even, loss of historic fabric. Many historic buildings had to give way to the development. The challenge that has to be resolved at present is how to promote conservation as an important principle in the progress toward sustainable development. This paper is intended to look at how Solo City, Central Java, Indonesia, has made a significant effort to conduct conservation of its urban heritage. It studies the role of the Solo Municipality in determining, planning and implementing priority programs in urban development. Reflecting its slogan 'the Solo the past is Solo the future' as well as the spirit to reaffirm the city as 'City of Culture', the city restored several historic urban space through revitalization program. This program not only consisted of physical rehabilitation, but also was related to crucial issues on social and economic improvement, like street vendor and community relocation along with traditional market revitalization. Sensitivity for local culture and cultural issues of the local authority has resulted a great success in restoring Solo's urban heritage that serves as valuable assets for tourism development. This paper concludes by addressing what has been done and what has not in the attempts of Solo to conduct 'balanced heritage management', where heritage conservation and tourism are mutually developed, that is conservation values are used as basis for sustainable tourism development. List of recommendations for the Municipality and other stakeholders will be provided at the end of the paper.

Urban Heritage Preservation and Challenges

Som Sangvasak (Battambang Municipality)

Battambang City, Cambodia Battambang is the one of the oldest cities of Cambodia, which has been transferred from a small fishing village in 19th

century. When Thai returned Battambang back to Cambodia in 1907 after more than a century of its ruling, the French took over the position and immediately started to set up a first urban development plan for the city with a very robust and functional layout. The city has inherited a rich urban heritage with a great variety of fine architecture from different historic periods of the last 150 years, representing the diverse phases of the city's development. The city center is characterized by a coherent ensemble of about 800 heritage shophouses most of them from the French protectorate period and some from the independence time (1953-1970), which was the time that Modern Khmer Architecture movement was born with its distinguished and unique style. All over the city, the outstanding Khmer architectures, French -classical style villas and beautiful Khmer traditional wooden houses and Wats (monastery), representing the city's religious heritage, can be found. Different historical urban landscapes and their respective architectures contribute to the city's unique character and beauty. Unfortunately, in the last ten years of economic boom, rapid urbanization and modernization in Cambodia are increasingly creating pressure to utilize urban land for commercial purposes and investments. Land prices have by far outstripped the value of buildings and easily encourage heritage owners to sell their properties. State land with heritage buildings in prime locations is privatised and given to developers in exchange for new public facilities in more remote areas. Furthermore, small business and shop owners from urban core areas are increasingly modernizing their properties with inappropriate renovation which contributes a lot to the irreversible loss of substance and character of heritage districts. In conjunction with weak laws and poor development control in urban planning and construction, this leads to a mix of neglect, incompetence and unawareness in dealing with cultural heritage. With this concern and seeing the significance and values of these historical buildings, urgent measures are needed to stop the continuing loss of heritage substance through inadequate new construction and modernisation. The initiative on heritage conservation was launched in 2009 by the administration. The goal of the initiative is to preserve and safeguard the unique character and authenticity of the diverse built heritage of Battambang City. The paper will demonstrate the procedures, strategies and challenges in conserving the urban heritages under the high demand of modernisation and development. Sangvasak Som, Adviser of Municipal Master Plan Team.

Cultural Heritage and Sustainable Tourism Development of Mrauk-U, Myanmar

Zin Nwe Myint (Yangon University)

Many recent studies point out the potential of tourism as an anti-poverty strategy. Over the last three decades, the growth of tourism had given opportunities for economic development of several Southeast Asian countries. Due to macro-economic significance of tourism in Southeast Asia, this industry has also played an important role. However, tourism can have negative impacts if it is not responsibly planned, managed and monitored. Endowed with many physical, historical and cultural resources, Myanmar has promoted tourism as a means for economic development especially after the introduction of market-oriented economy in 1989. Thus, 'Visit Myanmar Year 1996' was launched, and many laws and regulations have been enacted. Rich in historical and cultural heritage, Mrauk-U, an ancient capital of Rakhine, has high potentials for tourism development. To promote tourism, Mrauk-U came to be designated as a cultural heritage zone in 1996. However, arrival of tourists to Mrauk-U is still relatively few, with less than 2% of the total number of tourists visiting Myanmar. The main aim of this study is to seek the best way for Mrauk-U to be able to use tourism as an effective tool for economic development with least negative impacts. The objectives are: to find out the major problems that hinder tourism development of Mrauk-U, to examine the perceptions of the local residents, institutions and stakeholders related to tourism in Mrauk-U, and to suggest feasible means for sustainable tourism development of Mrauk-U. Rapid Appraisal method is mainly used in primary investigations. A questionnaire survey concerning the perceptions of various local residents on tourism business in Mrauk-U was conducted in June 2009. It is followed by series of interviews with all tourism related business personnel, authorities from government institutions and local handicraftsmen were undertaken. The interpretation of data is mainly qualitative and suggestions are given for community-based sustainable tourism development in Mrauk-U. Keywords: Mrauk-U, cultural heritage, tourism, poverty reduction

Urban Renewal Concepts for Yangon Downtown Living Heritage Area

Hlaing Maw Oo (DHSKD)

With change in its political system from decentralization to democratization, Myanmar has become one of the last countries recently emerging on the world arena after several decades of isolation. While Myanmar is eager to accept

foreign investment to catch up in the development with the rest of the region, foreign investors are eager to tap into Myanmar's literally untapped resources including its diversified urban heritage. Yangon, the primate city, the previous capital of Myanmar and home to around 25% of its urban population, is rich in urban heritage both tangible and intangible. Its buzzing downtown, formed of six administrative townships around the ancient Sule Pagoda and lying along Yangon River, is one of the last still surviving old downtowns in the Southeast Asia. Its liveliness and diversity makes it one of the most attractive areas for both the local users as well as the tourists. However, with vulnerability and deterioration due to its age, new demands and needs of foreign investors, as well as of modern urban quality living and social wellbeing of the city dwelling population, its survival is under increasing threat. It is therefore, urgent to develop urban renewal strategy that is based on systematic understanding of the different time, heritage and generation layers of the downtown area as well as the needs and perceptions of the users. This study analyses the evolution and the morphology of Yangon downtown area from its history and in terms of the current state of built up area, clustering of different social and economic activities, the present and the potential users as well as underlying issues in an attempt to categorize it into different zones. The study further attempts to analyse the present role of the downtown area in the overall development of Yangon City. Based on that analysis and zonation, possible guidelines for sustainable urban renewal of differentiated zones are proposed to achieve sustainable urban renewal vital for long term conservation of this unique and intricate living organism under the pressing demands of the transformation.

UDC 10-01 - Mega events, globalization and urban development 1

Chair: Eva Kassens-Noor, Jan-Erik Steinkrüger

Connection and Exclusion: Event Space and Globalization

Laura Huntton (University of Arizona)

Event space is created by cities to enhance and create connections between the host city and the global system of cities. International expositions, Olympic Games, and similar global events are useful organizing devices to assemble resources and create the political will needed to support the creation of event spaces that can serve a city over time. The city-management strategy is to use a focused period of effort to develop connections that will serve the city's development in the period after a mega-event. The mega-event with its connections and attendant infrastructure hopefully will advance a city's position in the global hierarchy, increasing regional income and prestige. The theoretical perspective of this paper is that mega-events, vehicles such as Olympic Games, International Expositions, or World Cup Games, operate in similar ways at the level of urban development, city branding, global profit, local economic development, and social change. In addition to categorizing outcomes of these events by event type this paper seeks to characterize the outcomes sought by cities by focusing on connections and infrastructure that tightens the links between a host city and the global economy. In particular, changes in a city's brand and policies directed toward place promotion and tourism promotion as well as urban redevelopment or regeneration from various types of mega-events can be argued to have similarities based on the longer-term effects of these events on urban regeneration. Urban redevelopment is somewhat enigmatic as it can be locally focused or can be globally focused. Perhaps because the Spanish regions view themselves as nations and desire to make a statement on a world stage, Spanish regional cities invest more significantly in mega-event spaces and public spaces than similar cities in other national contexts. In Spain, these event spaces represent one of the expressions of a shift to economic entrepreneurialism at sub-national scales as cities redevelop in pursuit of global competitiveness. This European form of the 'new regionalism' represents new identities using 'old' regionalist politics of culture and identity expressed through urban planning. Using case studies of two Spanish autonomous regions and their event space I explore how political regionalism and economic competitiveness create a form of regional entrepreneurship that advantages distinctive identities

promoted by events and unique practices. Planners guide this regional entrepreneurialism that responds to global and local imperatives, creating spaces that represent a symbolic and an actual landscape.

Rio de Janeiro's Mega-Event Strategy and the Re-Ordering of Urban Space

Gabriel Silvestre (UCL Bartlett School of Planning)

In October 2009, the city of Rio de Janeiro was announced the host of the XXXI Olympic Games. The news came as surprise to many commentators which have previously placed the city as the underdog amidst more high-profile bids, but for those involved with the Brazilian bid the award was the culmination of a project initiated almost fifteen years ago. During this period Rio de Janeiro's mega-event strategy evolved through failed Olympic bids, the hosting of the Pan-American Games and the engagement with hosting experiences elsewhere, most noticeably that of Barcelona. However, despite the relational nature of the project a local perspective reveals how the strategy is part and parcel of a marked change in urban governance, expected to accelerate current processes of city-making. This presentation reviews the pre-award period in order to highlight the contested development of Rio de Janeiro's Olympic project and examine the transformation of the urban space ahead of the 2016 Games.

Planning Mass Events: Management of Pilgrim Flows at the Hajj

Sven Müller (University of Hamburg)

There is a growing number of mass events throughout the world. At the same time these mass events get larger and larger. Typically examples for mass events are the FIFA world cup and the olympic games. The management - particularly in terms of security - of these events become more and more relevant: Crowd disasters as witnessed at the German Loveparade 2010 in the city of Duisburg or at the Great Pilgrimage to Makkah (aka hajj) force authorities towards a security based planning. With more than 3 million pilgrims the hajj is known as the largest pedestrian problem in the world (<http://www.trafficforum.ethz.ch/crowdturbulence/>). During hajj several rituals have to be performed by the pilgrims. One of the most dangerous ritual in terms of crowd disasters is the stoning of the jamarat at the jamarat bridge in the mena valley. In this contribution we propose a management approach based on a mathematical program in order to schedule and assign pilgrims to pre-defined routes. The schedule and the route plan yield a good balance of pilgrim

flows in space and time as shown by simulation and revealed data from several years.

Mega Events – the Promise and the Betrayal: FIFA 2010 in South Africa

Brij Maharaj (University of KwaZulu-Natal)

The 2010 FIFA World Cup (FWC) extravaganza had been widely touted as a great African mega-event which, while located in South Africa, would bring economic and social benefits across the continent. The aim of this paper is to critically assess these claims. The key arguments of the paper are that: i) the African connection was mythical; ii) the benefits for poor and disadvantaged South Africans was exaggerated and at best ephemeral; iii) the bid process for 2010 was not transparent and the ruthless profit motive and political machinations of FIFA were ignored as it was subliminally presented as a philanthropic organisation; and iv) the billions spent on preparing for the 2010 FWC would have made a huge impact in addressing South Africa's social, welfare, health and education challenges.

The Transport Legacy of the Summer Olympic Games

Eva Kassens-Noor (Michigan State University)

This paper analyzes transport legacies that remain in cities post-Olympics. Legacies in this paper are defined as infrastructural modifications catalyzed by the Olympic Games. Through in-depth interviews, document analysis, and archival reviews, the paper cross-compares the impacts the Olympics have had on transport by drawing on multiple Olympic hosts: Barcelona, Atlanta, Sydney, Athens, and London. Even though the host cities' transport systems were intrinsically different pre-Olympics, the author finds that similar features of the Olympic Transport System produced similar legacies. In explaining the creation of transport legacies through Olympically motivated drivers, the author suggests that the Olympic Games might trigger similar transport developments in future Olympic host cities.

Bad Practice? How negative role models shape the planning of mega-events – the case of London Olympics 2012.

Joachim Thiel (HafenCity Universität Hamburg), Gernot Grabher (HafenCity Universität Hamburg)

Urban planners and political strategists, in the common perception, learn primarily from good examples. 'Best Practice', in fact, seems to constitute the chief learning paradigm for planning. This paradigm not only shapes the professional ethos of planners, but also major lines of planning-oriented research. However, a closer look at actual planning practices reveals that negative experiences from 'planning disasters' (Peter Hall) influence both urban development strategies as well as specific urban projects. The proposed paper presents findings from an in-depth case study of the planning and organization of the London Olympics 2012. This research explores the impact of positive and negative past experiences on the planning strategies and actual planning practices. It particularly focuses on the role of 'bad practice' both in similar major urban development projects in London as well as in previous host cities of Olympic Games. The proposed papers aims to answer two key questions: First, it asks from which negative experiences actors and organizations involved in the

planning process learn. In this context, the paper mainly addresses bad experiences gained with attempts to re-use the Olympic venues and infrastructures after the event. Second, it asks how actors and organizations actually learn that is through which channels and practices (e.g. consultants, recruitment of staff, policy travel, desk research) experience from the past is transferred into current planning and management action.

Olympic dreams or nightmares? A comparative analysis of mega-events housing impacts.

Luis Vasconcelos (University of Barcelona)

Mega-events as a catalyst of urban transformation have been associated with driving urban change. The sporting mega-events act as a spotlight, highlighting political, economic and cultural benefits related to urban development. This paper aims to do a comparative critical analysis of the adverse social and spatial impact of mega-events on local residents and neighbourhoods. It examines the case studies of Barcelona as an Olympic city, the 2007 Pan-American Games, and the forthcoming 2014 FIFA World Cup and 2016 Olympic Games to be hosted by Rio de Janeiro in Brazil. In particular, it attempts to develop an evaluation framework to assess all potential housing impacts of the respective mega-events on the most vulnerable community segments of both Barcelona and Rio de Janeiro, and assess what they actually mean for the future of the cities and the role of mega-events in redeveloping urban space.

Is a just urban development possible? The Biennale of Landscape Urbanism in Bat Yam.

Efrat Eizenberg (The Technion)

As elsewhere, also in Israeli cities, globalized techniques of urban regeneration took over. Among these techniques is the branding of the cities under a special theme such as 'children city' (in Holon) or 'Music City' (in Kafar Saba). As part of these branding efforts there is a more recent use of art and culture events as means to enhance the city's visibility, attract visitors to it, and set processes of development in motion. The Biennale of Landscape Urbanism in Bat Yam (a medium size city adjacent to Tel Aviv) will take place in October 2012 for the third time. This specific event is particularly interesting for the examination of urban regeneration through art events. As a Biennale of Landscape Urbanism this event focuses on the locale - the actual space of the city. The different projects are located in multiple urban sites and focus on Bat Yam's public space

- its usage, design, and interactions in it. In addition, the Biennale of Landscape Urbanism in Bat Yam includes many projects that focus on nature, parks, gardens and deal with semi-urban, non-urban, or anti-urban themes and objects. The exposure of local residents to these art projects and in many cases even their direct involvement with them are practically inevitable. This paper presents the Biennale of Landscape Urbanism in Bat Yam, Israel as a technique of urban regeneration that because of its special characteristics has the potential to set in motion urban redevelopment through the betterment of the local community.

UDC 11-01 - Megacities: Informal dynamics of global change

Chair: Frauke Kraas, Peter Herrle

Informal Dynamics in Global Value Chains - The Case of the Leather Industry in Dhaka/Bangladesh

Joseph Strasser (Humboldt-Universität zu Berlin), Elmar Kulke (Humboldt-Universität zu Berlin)

The Bangladeshi leather industry outshone by the giant textile and garment industry has long been paid little attention to by policy makers. Although being highlighted as a 'thrust sector', the fifth biggest export earning industry has been losing ground contributing now only less than 3 % to both the country's export revenues and its GDP. While the higher value-added leather goods and leather footwear subsectors record soaring export growth rates, structural problems weigh on the growth and competitiveness of the still labour intensive leather processing subsector. Notwithstanding the governmental discourse on backing the inefficient tanning industry, fiscal and economic policy efforts to increase higher value-added leather exports have been insufficient. Concomitant measures to support small and medium sized tanneries upgrade their production facilities have been neglected for too long. As a response to this entry barrier, informal arrangements and strategies have been established to keep outdated factories operating and catering to the export market. Yet low enforcement of environmental regulation and comparative advantages in labour costs have given the tanneries scope in the global market. If, however, urgent investments in production technology are further delayed, foreign markets such as the EU will put into effect the threat to increase non-tariff trade barriers. In contrast, international production networks have been shaping the dynamically growing leather manufacturing subsector. Small and medium leather goods and footwear producers often strongly depend on large local lead firms and only occasionally supply foreign buyers. Tight subcontracting schemes prevailing in the domestic market in some cases even link undercapitalized local producers to international markets without providing them direct access to these. Captive relationships between both foreign and local buyers and local suppliers appear to be a dominant feature of the leather value chain. Drawing on the Global Value Chain approach, this study examines the Bangladeshi leather industry for opportunities and drawbacks that are to feed into upgrading paths. In analysing power relations at the nodes emphasis has been given on buyer-supplier

relations dissociated from the traditional concept of a large multinational lead firm governing and exerting power throughout the chain. By taking qualitative semi-structured interviews with selected stakeholders along the leather value chain this study is to shed light on as to whether and to which extent informal arrangements and strategies are beneficial for producers connecting to the global market and dealing with power asymmetry. Focusing on informal negotiation processes and practices rather than on structures has been proven useful in understanding the informal dynamics of globally intertwined economic activities.

Floating or settling down? Migrant workers and mega-urban development in the Pearl River Delta, China.

Pamela Hartmann (University of Cologne), Sabine Beißwenger (Research institute for regional and urban development), Desheng Xue (Sun Yat-Sen University)

The flexibility of China's migrant workers, i. e. their moving 'on demand' and their abundant availability as low cost labour in export-oriented manufacturing is a critical success factor of the Chinese economic growth. Despite the central importance of migrant workers in fuelling economic growth with their manpower, investors and local authorities shaped mega-urban development in the Pearl River Delta (PRD) while ignoring migrant workers as relevant actors. Until recently, the Chinese Government categorised migrant workers as rural population on a short-term working stay away from home. The case study area of Tangxia Town, a part of Dongguan, represents a typical pattern of Chinese mega-urban development. There, migrant workers' living and working conditions have been investigated in order to give an example of local development strategies under which workers take their migration decisions. By analysing own survey data of 566 migrant workers, it will be discussed which factors favour a return, what supports migrant workers' decision to stay and which migrant workers are most likely to settle down in the PRD. Building on this empirical evidence, this paper seeks to contribute to the most recent debate on the reform of the unique Chinese household registration system (hukou) and its implications for urban governance.

Mapping multi-decadal growth of the Sao Paulo urban agglomeration

Reinaldo Paul Pérez Machado (University of Sao Paulo), Christopher Small (Lamont Doherty Earth Observatory of Columbia University)

The city of Sao Paulo has evolved from small town with about 20,000 inhabitants at the very end of the XIX century to one of the biggest metropolis of the world in less than 90 years. This explosive increase of population was very noticeably during the 70's of the XX century, when the city growth with a variety of economic uses that marked, and determined, the way it expanded its urbanized surface. Evidently, among the different uses that were given to the ground, most of the territory was covered by housing facilities, to give shelter to the exponentially increasing population. The fact is that it is very difficult to differentiate from aerial photographs or satellite imagery formal-non-precarious neighborhoods from informal and precarious settlements. Spatio-temporal change mapping with remotely sensed imagery has the potential to inform a wide variety of urban research and management questions. However, conventional classification methods used at scales compatible with the sensor spatial resolution have proven to be of limited utility in urban areas, due to the spectral heterogeneity of this complex environment, which commonly combines several different materials. Spectral mixture models, on the other hand, may provide a physically based solution to the urban spectral heterogeneity issue, especially because it is possible to reduce the dimensionality of the multispectral reflectance by converting it to fractions of land cover components, thus facilitating the interpretation. The purpose of this study is to analyze the most outstanding changes occurred on the city of Sao Paulo (considering its urban agglomeration) using multi-temporal spectral mixture analysis of Landsat imagery. The analysis was based on a three component linear mixture model incorporating substrate, vegetation and dark targets, directly used for visualization on false color composites of red, green & blue respectively. Winter and summer image pairs, were selected for quality and consistency of solar illumination for two time intervals: 1986-2005 and 2000-2010. Results so far indicate an amount of change of 688.5 Km² (3.27 %) for the 1986-2005 and 708.4 Km² (3.37 %) for the 2000-2010 periods, regarding the quantity of changed surface that altered its fraction predominance from vegetation into substrate. The amount of 3.3 % calculated for both time intervals is only detectable above a given threshold. There should be certainly more changes that aren't resolvable by the satellite or they lay near the detection limit. Changes in fraction mixtures and texture also highlight high rise construction as well as vegetation abundance. A peculiarity of the increase in shadow on several parts

of the city points to the increment of the verticalization process on these areas. The phenomena appear with more intensity on the longer time span considered (1986-2005). A quantitative and visual analysis of these changes at different spatial scales is presented.

Growing Pains: Shepherding Mega Cebu through informal civil society-private sector-government arrangements

Evelyn Nacario Castro (Ramon Aboitiz Foundation Inc.), Lorna Manila (National Economic & Development Authority Region 7)

Growing Pains: Shepherding Mega Cebu through informal civil society-private sector? government arrangements. The current development turmoil in Cebu, Philippines is only symptomatic and indicative of a larger deficiency. Attendant to metropolitan Cebu's increasing population and urbanization are worsening problems related to pollution, water supply, flooding, traffic and transport, peace and order, informal settlements, health and security, and inadequacy of basic infrastructure - all affecting the productivity of public and private sectors, welfare and prosperity of people and communities, and sustainability of the environment. One of the main causes of inadequate and ineffective delivery of basic services is the absence of an institutional mechanism: policy and structure to oversee and coordinate trans-boundary inter-local planning, implementation, and monitoring of metro-wide programs and projects. In 2011, local chief executives of local government units, directors of national government agencies, and leaders of civil society and private sector organizations have recognized the importance of inter-local public and private sector collaboration - with the aim of jointly assessing and addressing common trans-boundary issues and challenges. Through a Memorandum of Agreement, they agreed to band together, cooperate and work with each other under a mutually agreed structure, the Metro Cebu Development Coordinating Board (MCDCEB) as the coordinating body for the development of area. Metropolitan Cebu covers 13 cities and municipalities located in eastern Cebu, Philippines namely: the cities of Cebu, Carcar, Lapu-Lapu, Mandaue, Naga, Talisay, Danao, and the municipalities of Compostela, Consolacion, Cordova, Minglanilla, Lilo-an, San Fernando. The MCDCEB, while only a collegial and voluntary coordinating mechanism, acknowledges the value of a comprehensive and integrated metro-wide plan for a growing metropolis and thus intends to undertake urban development planning to address problems related to land use and urban development, transport and traffic, infrastructure and utilities, public safety and security, environment and health, and, subsequently facilitate sustainable, equitable, and

inclusive social and economic development in the city-region. To facilitate its work, ensure coordination, and synchronization of LGU plans and programs - the ownership of the city-region concept, the active participation and support of all LGUs, the support from regional and national government, and the establishment of a stronger and formal institutional and policy framework are crucial. It would be worthwhile to note that, at this stage, full buy in and ownership of this Mega Cebu framework and process, particularly from local government units, is still currently being obtained - while the issues and challenges facing metropolitan Cebu has compounded with the mounting threats and increasing impacts of a changing climate.

UDC 12-01 - Megacity research for government action

Chair: Eckart Ehlers, Andrea Koch-Kraft

A comparative study of Southeast Asian and Japanese Megacities with a focus on urban areas

Masato Ikuta (Ritsumeikan University)

In consideration of future metropolitan policy across East Asia, we compared six metropolises, Jakarta, Manila, Singapore, Kuala Lumpur, Bangkok, and Ho Chi Minh City, in Southeast Asia, and two in Japan, Tokyo and Osaka. Both similarities and differences exist between current Southeast Asian and Japanese metropolitan areas. For example, the manufacturing industry has been vital for growth in both regions. Clear differences, however, can be found between Japan and Southeast Asia. In Tokyo and Osaka, the leading industries for continuing sustainable growth cannot be clearly indentified, despite the growth of research and development within the local manufacturing sector. Land use patterns also have similarities between the two regions. Western geographers have expressed a Southeast Asian metropolis as an Extended Metropolitan Region or Desa-kota model in comparison with western cities. Japanese metropolitan regions have densely populated suburban areas with wet rice cultivation, the same as in Southeast Asian metropolitan regions, and industrial plants and other urban facilities are often also located in these areas. In both regions, metropolitan development is controlled and led by the state and the central government. When assessing the urban geography of megacities, it is important to identify whether urban functions are built mainly by the public sector or by private enterprise. In Jakarta and Manila, the largest metropolises in Southeast Asia, conglomerates have played crucial roles in shaping the urban landscape, not only through industrial estates, shopping centers, and housing units, but also through various basic infrastructures. Bangkok and Ho Chi Minh City, medium scale metropolises, are the growth poles in the Greater Mekong Subregion, which is changing rapidly and includes the southern interior part of China. In Bangkok, urban planning was ineffectual until the 1990s, while Ho Chi Minh City has been changed dramatically in response to the introduction of market economies. In Kuala Lumpur and Singapore, small scale metropolises, public sectors have had a strong influence in shaping their urban areas. In particular, state and public corporations have played a crucial role. The metropolitan areas of Tokyo and Osaka were shaped mainly by private enterprises, similar to the cases of Jakarta and Manila. In contrast, public

sectors which had administratively matured tried to control expansion of the urban areas during the period of high economic growth in Japan, 1955 to 1974. Taken together, the metropolises of Southeast Asian nations are controlled more tightly by the central government than those in Japan. Regardless of the situation, we should consider creating a mechanism for systematically sharing the development experience of each metropolis.

From understanding to implementation: Meeting Ho Chi Minh City's needs for improving climate adaptation and energy efficiency

Harry Storch (Brandenburg University), Frank Schwartz (Brandenburg University)

Our urban risk assessment highlights that for exposure to climate-related impacts, rapid urbanisation driven by socioeconomic development is proportionately more crucial for emerging deltaic Asian megacities, like HCMC, than projected extreme climate changes up to the year 2100. From the implementation of the land-use plan up to 2030, the total estimated exposure to flood risk of built-up areas results chiefly from planned urban expansion into low-lying areas, which are widely known as flood-prone at the current max-tide. Traditionally only snapshots of the current urban situations have been partially integrated into impact assessments, resulting often for highly dynamic urban regions in an overestimation of climate change as a stressor of risk. Our study highlights, that the influence of non-climatic stressors - like urbanisation as the spatial manifestation of socio-economic processes - is still widely under acknowledged. As a main result, urban adaptation measures that provide benefits under current climate and a range of future climate change conditions are reliable starting points for addressing projected urban risks related to exposure, vulnerability, and climate impacts. Many of these low-regrets strategies are incorporated with other urban development goals, such as improvements in livelihoods, well-being, and environmental enhancement and so reduce the risk and scope for costly mal-adaptation. The implementation of measures in adapting the city is however still inadequate. This gap between awareness and action leads to the conclusion that HCMC faces not only a lack of reliable information but also a lack of effective planning instruments and limitations in its institutional setting. In order to mainstream climate change responses into the urban planning system and to improve response capacity, the project applies a dual strategy. The top-down oriented regulatory approach is applied firstly in response to a lack of regulation regarding environmental policy and climate change responses in the planning sector. In order to fill this

gap, 'Guidelines for Energy Efficiency and Climate Adaption' are developed. Based upon an analysis of the formal planning system, opportunities for their legal integration are identified, and their implementation pursued. The implementation of guidelines is assisting the mainstreaming of climate change responses across levels and localities. It does not ensure, however, their effective application on the local level. This top-down approach is complemented by a bottom-up strategy. Here a diverse approach including a 'Community Based Adaptation Scheme' and the elaboration of a research-based practical guide - 'Handbook for Green Housing' - that shows how energy-saving and mitigation can be integrated in the Vietnamese housing production are developed.

Adaptation to climate change in Santiago de Chile – hazard exposure and participation

*Kerstin Krellenberg (Helmholtz Centre for Environmental Research - UFZ),
Juliane Welz (Helmholtz Centre for Environmental Research - UFZ), Anke
Schwarz (Helmholtz Centre for Environmental Research - UFZ)*

In the framework of the international research project ClimateAdaptationSantiago (CAS) a climate adaptation strategy is currently being developed. This contribution shows the results that have been achieved within the science-policy approach and discusses opportunities as well as obstacles that this approach evolves focusing on social and physical exposure to flood and heat hazard in the Metropolitan Region of Santiago de Chile. It builds on scientific results regarding hazard exposure in combination with socioeconomic population data and includes irreplaceable practical knowledge from local stakeholders from different administrative levels. The results show that hazard exposure is not distributed uniformly: Whereas people with lower socioeconomic status are more likely to be heat exposed, higher status groups are more exposed to flood. Accordingly, different locations within the city call for specific adaptation measures. Some recommendations that have been discussed with local stakeholders within a broad participatory process are presented and discussed.

In the absence of statutory planning – planning on the ground

Wolfgang Scholz (TU Dortmund)

In Sub-Saharan Africa urbanization is progressing at a rate unprecedented in human history. In most countries, the state is not in a position to apply a

responsive legal framework and to mobilize adequate resources to guide urbanization. A major obstacle are the outdated legal framework and the inappropriate planning concepts inherited from colonial governments which often contradict post colonial policies and are unsuitable to respond to rapid urban growth. The chronic underperformance of the public sector vis-à-vis rapid urban growth caused a large cumulative backlog in the provision of building land and basic services. In addition, uncontrolled informal urbanization has often caused dysfunctional settlement lay-outs and urban structures. In Dar es Salaam, Tanzania, informal settlements cover now more than 70% of the city areas because the statutory system cannot provide sufficient building land and settlers have to find plots on the informal land market. It shows the need for a new approach to statutory planning in order to guide urban development effectively, to create more functional settlements, to assist the urban poor to access affordable plots with basic services, and to release financial assets for the urban economy. The paper will present results of a joint research analyzing empirically factors that determine space standards and land use in prevalent types of formally planned and informal settlements in Dar es Salaam. Goal is to identify parameters to ascertain the long-term suitability of settlements, understood as being functional and flexible to respond to future demands reflecting from socio-economic development. The research reveals that today there is not much difference between planned and unplanned settlements in regards to land use changes, land use conflicts and violation of planning regulations and procedures. More important are therefore negotiation procedures on the local level to replace the statutory system and to find solutions on the ground. The paper will present potentials but also limitation of this approach. At the centre of the research are the livelihood strategies of the residents. The overall aim is to evolve a responsive framework for statutory planning including spatial standards for settlements that reflect the current reality of urbanization under poverty while addressing future needs. Main actors will be local leaders and the community to ensure sustainable planning. Joint research project together with Prof. Dr. Sabine Baumgart, Faculty of Spatial Planning, TU Dortmund and Prof. Dr. Wilbard Kombe, Ardhi University, Dar es Salaam, Tanzania

UDC 12-02 - Middle East-North Africa (mega)urbanization processes (MENA region)

Chair: Eckart Ehlers, Andrea Koch-Kraft

Architectural Energy Efficiency for Megacities

Farshad Nasrollahi (TU Berlin)

The available technologies for saving energy in buildings as well as for active use of renewable energies have made it possible not only to have zero-energy buildings, but also to build plus-energy buildings. But for production of these materials and technologies, a great amount of resources are consumed and a high amount of CO₂ is emitted. Therefore only the amount of energy consumption of buildings is not a suitable indicator even for decision about the ecologic aspect of sustainability. From the economic point of view, the investment costs of some energy efficient buildings are sometimes so high, that the payback time of the investment is very long. Therefore constructional and technological methods of energy efficiency must not be considered as the main and the sole methods of energy efficiency. However, available technologies and building materials must also be utilized for improvement of energy performance of buildings. It must be attached more importance to cost-neutral and more ecologic methods of energy efficiency. One of these methods is architectural energy efficiency. It deals with the optimization of architectural design of buildings in order to improve the energy performance. This method of energy efficiency minimizes the resource demand as well as CO₂ production. Architectural design is a very effective method towards an integrated, cost-efficient energy concept. Factors like orientation, building form, zoning of functions, opening ratio in different orientations, sun shading etc. exceedingly affect the energy consumption of buildings. In this research, the effect of architectural design and architectural factors on energy consumption of office buildings in the climate of Hashtgerd New Town is studied. The result of this research is implemented in the architectural design of an office building, which is designed as a pilot project within the Young Cities Research Project. The energy consumption of this office building is decreased about 40% compared to available office buildings under the same conditions and with the same constructional materials. It shows that it is possible to save a high amount of energy in office buildings solely through optimization of architectural design and without needing any further material or technologies. By increasing the thermal resistance of the building envelope, the energy demand will decrease much

more. For example the sum of heating and cooling energy demand of New Generation Office Building is 57kWh/m²a, which is about 85% less than average energy demand of buildings in Iran. Based on the estimated primary energy factors in Iran the primary energy factor of this building for heating and cooling is 140kWh/m²a. The CO₂ production of this building is 196 ton per year, which is very less than other office buildings in Iran. The energy demand of this pilot project is even less than energy efficiency class "A" as the most efficient class in Iran.

Procreation of Environmental-Cultural Sustainability in the megacities of MENA cities

Somaiyeh Falahat, Mohammadreza Shirazi

Modernization and industrialization's large number of negative urban impacts on the Iranian cities becomes markedly critical and crucial in the case of the megacity of Tehran due to its current social and environmental problems. On one hand, pollution, high energy-consumption, lack of green space and water supply, and natural hazards make the city environmentally unsustainable. On the other, the lack of social cohesion and justice, unequal access to urban facilities particularly for disabled people, the social polarisation and the lack of respect to cultural and ethnical diversities make the city socially unsustainable. This matter makes achieving environmental and cultural sustainability one of the essential demands of the city, whereas achieving sustainability has not been yet integrated seriously in the urban policies of the city. Also the rupture between old and new built environment in the Middle Eastern cities, as the result of industrialization, modernization, and globalization, makes bridging the past and the future an ongoing discussion and necessitates paying attention to the cultural context in new designs. This paper assumes that the typomorphological approach can link environmental and sociocultural requirements by studying the various existent urban typologies, and can be related to a medium urban scale, between the building and the city. The goal is achieving a number of optimum urban typologies at micro-urban scale in a warm semi-arid climate by studying three-dimensional form of different compositions of voids-solids in urban textures of megacities.

New Generation Pilot Project – Finding and Realizing Transferable Technology and Materials, a Common Target of TU-Berlin and BHRC Iran

Effatolsadat Shahriari (ETH), Klaus Rückert (TU Berlin)

Iranian traditional architecture, whilst always in harmony with nature, has been using available eco-friendly local energy and low-energy-consumption constructions. Following this principle, and paying attention to the location and specific climate zone, New Generation Residential Pilot Project is trying to utilize appropriate methodology. In this way it can maximize inner space comfort without jeopardizing the environment; at the same time utilizing maximum renewable energy, providing higher flexibility and optimal use of land. Consideration of house as a residence and a place of comfort - whereas sustainability, energy efficiency and cost efficiency are the main Characteristics- is one of the most basic objectives of project, a place that can meet various cultural, social, environmental, economical and political aspects of the concept of habitation. Despite the current definition of habitation within Iranian society, - and considering cultural, social and also environmental and ecological standards - from the qualitative point of view - the main effort of project has been to achieve a relatively all-encompassing definition of residential architecture based on Iranian ideals and values. This portrays the state of nature, architecture, man, and his primary needs for habitation as an integral part of nature. Considering cultural, social, ecological and especially economical specifications of Iranian society - from the quantitative point of view we have three other crucial factors: Social - environmental potential and limitations considering target and potential groups. Topographical background of the 35 ha. Site. Technical potentials and limitation. The project has concentrated not only on the apartment but also on blocks and the sub-neighborhood as well. As mentioned before main project concept is the development of energy efficient low density buildings with a reduced building height that reflects the regulation set by master plan of 35 ha area, that is, energy efficiency, earthquake protection in the frame of maximal three stories building to keep the natural profile of area. Through the development of a energy awareness design and construction in one hand and modular system that attempts to allow flexible configuration to create multiple unique apartment buildings, the project aims to address the solutions that are contrasting widespread mass building construction, that are, large anonymous residential blocks, without paying attention to the globally important issues such as: reducing energy consumption, introducing renewable energy sources,

innovative solutions for saving energy, efficient construction techniques and affordable technology.

Evaluation of the Effect of Landscape Parameters on Outdoor Thermal Comfort in Young Cities

Alireza Monam (TU Berlin), S. Neda Ghazizadeh (TU Berlin)

According to the nature of open public space, it is involved a huge part of urban activities. One of the most important principles in designing is considering thermal comfort in order to improve the quality of space and increase user's satisfaction. Thermal comfort in outdoor settings is a topic that, until recently, has received little research attentions. Most of the researches concern thermal comfort focusing indoor spaces. This research proposes to investigate aspects of landscape architecture, which could contribute to improve outdoor human thermal comfort using landscape design elements. The present work was primarily motivated by the will to link the theoretical knowledge on Outdoor thermal comfort and the practical landscape design process in young cities. The core of the proposed research consisted of the findings relate to meteorological and geographical parameters and human comfort outdoors. This study sought to contribute towards a deeper understanding of the thermal sensation in urban open spaces. The proposed methodology can be divided into four stages: In the first stage, a review of literature relevant to urban climate and outdoor thermal comfort were applied. In addition, Area of Study and structure of the computerized model were described. At the second part of the research, outdoor thermal comfort was simulated by numerical method and measured by instruments. The model took into account the physical processes between the atmosphere, ground, buildings and vegetation, afterward simulates and measures the climate within a chosen urban open space. Then the relationship between architectural feature and outdoor thermal comfort was evaluated. At the end, the guidelines for improving outdoor thermal comfort were suggested. The focus was put on the applicability of the results. In this study, a microscale climate analysis conducted using the software ENVI-met 4 to examine the effects of various meteorological and geographical parameters on outdoor human thermal comfort. The study was focused on a part of open space in the 35 hectare of new Hashtgerd city in Iran.

UDC 13-01 - Migration trends of the baby boomer generation.

Chair: Caroline Kramer, Carmella Pfaffenbach

European Retirement Migration to Spain – Impacts, Dynamics and Characteristics

Vicente Rodriguez (CCHS-CSIC), Heiko Haas (CCHS-CSIC), Stefan Kordel (University of Erlangen-Nuremberg), Raúl Lardies (University of Zaragoza), María Casado-Díaz (University of the West of England), Michael Janoschka (Autonomous University of Madrid), Rafael Durán (University of Málaga)

When analyzing the international retirement migration in Europe, Spain stands as the prime destination for individuals, who like to relocate either permanently or temporarily there, particularly to Spanish coastal areas. In a general view, those moving Spain are shaping a relatively small group, but their influence is locally important as movers are carrying some selective features regarding their demographic situations, financial resources, life expectancy or family and social patterns of behaviour. In fact, they are searching for sun and self-realization after finishing their professional lives as it is assessed in varied research projects and papers. To a fully knowledge, a representative, large scale research project called MIRES (Migración Internacional de Retirados a España), run by the Spanish National Research Council and several other universities, started investigating the multiple facets of European retirement migration to Spain. The research was conducted in the most important regions of retirement migration in Spain by means of a standardised questionnaire and qualitative interviews, addressed to European retirees, aged above 50 years. Interdisciplinary and multi-thematic in its scope, the MIRES research project searches a set of outstanding aspects, such as mobility patterns, transnational behaviours, identity, integration, social and political participation and the use of public goods and services of retired European residents. Relying on other individual socio-demographic data, such as age, household size and composition, educational attainment, income or countries of origin, the study provides details about characteristics, impacts and dynamics of a large-scale social phenomenon. First, the existence of both, permanent and temporary residents can be regarded as a distinctive model of mobility between the countries of origin and Spain. Apart from focussing on transnational links, such as the meaning of keeping housing property in the countries of origin, we explicitly examine the link between retirement migration and tourism and impacts on social behaviour. A

further aspect we take into consideration within this context is, whether Spanish public authorities are aware of migrants' mobility and able to respond to their needs. Taking this into account, we also examine further, mainly informal strategies for individually perceived difficulties in Spain, like problems concerning legal acts or public health services. Second, we examine attachment to place in a transnational setting by analyzing satisfaction with daily life in general as well as concrete aspects like lifestyle, language skills, neighbourhood or social interactions to the Spanish population and among other residents through participation in associations and social engagement towards fellows. Another aspect, we focus on within this context encompasses socio-political involvement and European citizenship in the light of identity and belonging.

Retirement Migration of the Baby Boomers in Australia: Beach, Bush or Busted?

Nikola Sander (Wittgenstein Centre)

In the twenty-first century, Australia, like most other countries of the world, will experience an unprecedented rate of population ageing, due to declining fertility and increasing longevity. Knowledge of where the growing elderly population will live in the future is vital for the development of strategies to ensure the timely provision of adequate health, housing, welfare and aged care services. Migration of the baby boomer generation, as its members transition into retirement, will play a major role in shaping the age structure of Australia's regions.

Focussing particularly on internal retirement migration, this paper presents population projections for 23 regions of Australia to 2036, by which time most boomers will have retired. We use 2006 Census data in a multiregional cohort-component projection model to explore alternative future migration trajectories of this large generation based on a set of empirically-based scenarios. We hypothesize that three fundamental issues will shape the intensity and spatial patterns of retirement migration over the period 2006 to 2036: the distinctive behaviour of the baby boomers; the changing nature of the retirement transition; and the destination choices of retirees. The results show that changes in the intensity of retirement migration and shifts in retirement age are likely to have little impact on regional population age structures, but changes in the spatial patterns of retirement migration could significantly reshape the pace of population ageing in key destinations.

Does second home ownership trigger migration in later life?

Emma Lundholm (Centre for Population Studies), Roger Marjavaara (Department of Geography and Economic History)

While most rural and peripheral areas in western societies are suffering from depopulation due to out-migration and an unfavourable population structure, there is in many cases a positive net flow of later life migrants to rural areas. There are, however, regional differences as not all areas are equally attractive. In general, amenity rich locations tend to attract both permanent and temporary residents in older age groups. For rural and amenity rich areas, people born there or with other links to the place are more likely to move in compared to others. One important link to rural areas is second home ownership and this group is hence also potential permanent residents. The relation between temporary and permanent migration among elderly is disputed. One hypothesis is that temporary mobility substitute permanent mobility; once retired you can spend more time in a second home without having to change the permanent residence. On the other hand, it could also be hypothesised that access to a second home triggers migration; ownership of a second home nurture place attachment to that location, which might lead to migration. In Sweden, second-home ownership is frequent, especially among older age groups. Most common is second homes located in the vicinity of urban areas, close to the owner's permanent home, while other second homes are typically located in amenity rich rural areas. Second homes might also be a way to keep the links to the place of origin by keeping a property in place of birth. The generation now approaching retirement in Sweden is to a large extent an urbanisation generation, where many moved from rural areas to urban areas in the 60s and 70s, thereby constituting a potential for return migration into rural regions struck by out-migration for decades. The aim of this paper is to analyse later life migration in Sweden to explore how ownership of a second home affects migration in the age group 50+. The empirical study also explore if there is evidence of a stronger migration trigger if the location of the second home is also the place of birth. The study is based on Swedish register data and include all Swedes in the age 50+ and their mobility in the time period 2004-2008. The data also include place of birth and ownership of properties, both permanent and second homes.

Aging Baby Boomers In Germany – Migration Biographies and Residence Choices for Retirement

Natalia Zenk (RWTH Aachen), Melanie Kappler (Karlsruhe Institut for Technology)

The population development in Germany is characterized by the current demographic change and hence the German society has to face the task of dealing with its consequences. Increasing amounts of elderly persons are one facet of this change that concerns the academic discussion in the social sciences, demography and geography. In the coming years, the German baby boomer generation will reach retirement age. Due to the social change in the German post-war era, it is assumed that this generation - the future retirees - will live differently in comparison to the senior citizens of today. As a result of increasing life expectancy, retirement is becoming a self-contained stage in which later-life migration could take place. Biographical approaches in migration research describe the transition to retirement as a period of increased migration likelihood as the former fixed local workplace has lost its relevance. The current academic discussion in Germany focuses retirement migration mainly concerning the returning of this cohort to core cities, after they have left them in their family expansion phase in the 1960ies and 1970ies towards suburbia. Another aspect often mentioned is the (temporary) move to popular tourist regions in sense of an amenity migration. In contrast, recent studies point out the trend of the German future retirees towards constancy and therefore the tendency to maintain their current residences. Our talk focuses the migration biographies of the baby boomers under a life cycle perspective and links them to their desired living arrangement for retirement. Migration biographies in this case seem to be important regarding future migration acts or persistence. Long-term stability has a negative influence on mobility whereas former successful moves can encourage changes in the living arrangement of the future retirees. But the link between migration events in early and late ages is still not satisfactorily answered yet. The residence history analysis is undertaken by a combined methodological approach. In a quantitative data evaluation, migration patterns of nearly 2900 baby boomers (born 1948-1957) in selected German cities are being examined. The qualitative analysis is based on 70 qualitative interviews with persons of the same population group. The findings of the study show that only 8% of the respondents have plans to relocate their residence after retirement. Furthermore most of them would like to move only within short distances. Their preferred residential location for the future often lies in the same part of the town with the advantage of keeping the daily scope. An analysis of the migration biographies concerning social structure, lifestyles and spatial

differences will be followed by a typing of migration patterns. These in turn are related to the desired living arrangements and future residences which should target the research desideratum of the link between former and future migration.

UDC 14-01 - Multi-local living arrangements on national, inter- and transnational levels: A new old phenomenon?

Chair: Caroline Kramer, Gerald Wood

Holiday homes and multi-local living arrangements amongst urban élites: remaking an old tradition. The example of Naples

Thomas Pfirsch (University of Valenciennes)

Holiday homes and leisure-based multilocality are now widespread in European societies. But they still display marked peculiarities amongst the old urban bourgeoisie, where people often own several holiday homes and where multilocality is a long-standing tradition based on prestigious inherited family homes. This élite multilocality was initially founded on the leisurely pastimes of a life of ease, on unequal inheritance traditions, and on long out of town holidays that could last for several months. Recently, however, it has had to adapt to the rise of wage earning amongst the upper classes, a new leisure culture based on short holidays, and profound changes in family structures. Taking the example of Naples, this article analyses the evolution of holiday practices amongst the old urban bourgeoisie during the twentieth century, and the role that holiday homes play today in its living arrangements. It demonstrates that by reorganising the spatial uses and symbolic functions of their properties, traditional urban élites have been able to structure 'multilocal holiday systems' that have remained relatively stable over generations, and where the difference between 'main' and 'second' homes has never been clear. Using life stories, the residential careers and holiday practices of 50 kin groups from the Neapolitan nobility and bourgeoisie, spanning four generations from the end of the nineteenth century to the present, have been reconstructed. Individuals' residential mobilities can thus be compared to those of their relatives from a geohistorical and intergenerational perspective, within a framework of 'family residential systems'. The Neapolitan context is interesting since the nobility and the old propertied bourgeoisie are still relevant in the city élite. In fact, before Italian unification in 1861, the city was an important capital which attracted all the Mezzogiorno élite and landowners. These old families managed to structure long term multilocal systems based on four kinds of places: neapolitan palazzi, family homes located in their Italian or European regions of origin, suburban country houses, and high society seaside resorts in the Gulf of Naples? But since the 1960s, faced with the city's decay and its own declining fortunes - which instigated mass emigration to northern Italy and Europe amongst its members - and confronted by profound changes in

family practices, the Neapolitan bourgeoisie had to reshape its residential systems. The focus of its holidays was shifted from the interior Mezzogiorno to the city's neighbouring seaside resorts. Despite still relying on traditional inherited properties, the multilocal system was reorganised, within a context of property division, to suit all year round short stays, turn-taking arrangements among relatives, or international family gatherings.

Infranationale und transnationale Multilokalität: Ein empirischer Vergleich der Profile auf Basis einer französischen großen Befragung/ When age makes multilocal. Some results about the emerging multi-residentiality of young adults in Switzerland

Cédric Duchêne-Lacroix (Universität Basel)

The last months triggered uncertainty in Switzerland: Swiss voters decided to limit the construction of second homes. Some villages located in alpine resorts count today far more "cold beds" (not inhabited second homes) as principal residences. The controversy has given the image of old or foreign people who monopolize the local habitat just to live for a few weeks per year. But who know that they are more second homes in swiss urban areas? And who knows that second home dwellers are not just people between 50 and 65 years old, but also young adults. We could intuitive profile them: Students living partly in a sharing accommodation and partly by their parents. Is it really the case? Based on the swiss microcensus mobility and transport and the Panel Tree the proposed paper will show some key figures on second home in Switzerland and will focus on age effects of the multiresidentiality.

Multi-local dwellings of European Retirees in Spain – strategies of mobility and impacts on destinations

Vicente Rodriguez (CCHS-CSIC), Heiko Haas (CCHS-CSIC), Stefan Kordel (University of Erlangen-Nuremberg), Michael Janoschka (Autonomous University of Madrid), Joaquín Rodes (Catholic University of Murcia), Rafael Durán (University of Málaga), Mayte Echezarreta (Facultad de Derecho)

Against the background of a growing mobility of people, relocating from northern or central parts of Europe to Spain either permanently or temporarily can be regarded as a privileged form of leisure and lifestyle orientated mobility. Fulfilling their aspirations and expectations, Spain has evolved as the prime destination for individuals reorganizing their daily lives in retirement age by means of keeping up multi-local dwellings both in their countries of origin and in particularly Spanish

coastal areas. In 2008 the Spanish National Research Council (Consejo Superior de Investigaciones Científicas) started a representative, large scale, multi-method research project called MIRES (Migración Internacional de Retirados a España) investigating the multiple facets of European retirement migration to Spain. The research was conducted in the most important regions of retirement migration in Spain by means of a standardised questionnaire and qualitative interviews. Interdisciplinary and multi-thematic in its scope, the MIRES research project approaches both to socio-statistical data (age, income, previous working life, countries of origin etc.) and to other aspects such as mobility patterns, political participation, identity, transnational strategies and the use of public goods and services residents, to provide details about the impacts and the most recent developments of the transnational daily lives of the European retired in Spain. We explicitly focus on patterns of travelling to or receiving visits from their countries of origin as well as means of communication. Apart from transnational relationships, some individuals also maintain property in their countries of origin which may encourage the decision for returning in the light of aging. In this context, we also reveal factors of satisfaction with concrete aspects of daily life, such as language skills, neighbourhood or social interactions among European nationals (intra- and inter- relations) and with the Spanish population occurring, for instance, through joining associations or forms of social involvement. Finally, impacts on destinations, affected by leisure and lifestyle-orientated mobilities should be revealed. Considering individuals' identity and belonging, we examine strategies of registering in municipalities, as essential strategy for planning and organising public services like healthcare or infrastructure. In the light of the right of free movement within the European Union as well as the right to vote on a local scale, we finally focus on both formal and informal political involvement of EU residents in Spain. By means of the representative and large scale study, we are able to make differentiated statements due to characteristics of that privileged form of mobility as well as impacts on destinations in Spain that may even become more important with a growing amount of baby-boomers entering retirement age.

Multi-local lives of transnational retirement migrants: From voluntary to vulnerable?

Claudia Kaiser (BAGSO - Federal Association of Senior Citizens' Organisations)

International retirement migration to places with climate benefits and attractive landscapes is a growing phenomenon of the ageing populations of industrialized countries. Many retirement migrants use their new homes only seasonally and

travel between two or more homes across borders. In many cases, the decision in favour of a transnational multi-local life has been guided by experiences as tourists and by the desires and requirements of younger stages of old age. But what consequences does a mobile life-style have for the retirement migrants' experiences when becoming older? What kind of potentials and risks do they face as transnational migrants when facing age-related problems? This paper will investigate multi-local retirement migration in a transnational perspective by focussing on the individual and collective networks and social spaces encompassing both the origin and destination countries. With the example of elderly German migrants in Spain, the paper will focus on the consequences of transnational living arrangements with a closer look at the migrants' different eligibility to health care and long-term care entitlements both in Germany and in Spain and at the dynamic development of ethnic economies in the health care and long-term care sector which try to meet the specific needs of multi-local older migrants. (Cf.: Kaiser, Claudia (2011), *Transnationale Altersmigration in Europa. Sozialgeographische und gerontologische Perspektiven*. Wiesbaden: VS Verlag.)

UDC 15-01 - Naturbanisation: Urbanisation in nature and environment conflicts 1

Chair: María-José Prados, Julia Lourenço

Urbanisation in coastal nature, water management conflicts, and biodiversity impacts in Spain

Angela Hof (Ruhr Universität Bochum)

The new concept 'naturbanisation' which focuses on the challenges of residential demand in highly valued natural areas, such as national parks, shares conceptual approaches with research on environmental impacts and conflicts associated with new urban models and coastal urbanisation in the Mediterranean and Spain in particular. Here, the development of the real estate market, international capital flows, economics, institutions and policies in conjunction with tourism development and more specifically, tourist specialization, are the main drivers of urbanisation in coastal areas. Development pressure has come from changing urban lifestyles and people who seek a vacation home in rural landscapes that epitomise the aesthetical value of unspoilt coastlines, agricultural, and semi natural landscapes. The development of second homes and an increasing preference for suburban environments have resulted in the spread of more disperse land use patterns with significant impacts on land and water resources. To the extent that low density urban areas are gaining ground, a substantial increase in water consumption for outdoor uses is expected. This urban sprawl and the transformation and artificialization of the landscape is not without potentially positive effects such 'novel urban ecosystems' may have on biodiversity and which are increasingly coming into the focus of urban ecology. The presentation focuses on the environmental impacts in terms of water demand to sustain these new urban landscapes. In turn, the impact on biodiversity is discussed both in terms of habitat loss for native species and the gain of new and different habitat in gardens and other urban green spaces. The process of change in urban form, the interrelatedness of land use pattern with water consumption and biodiversity is demonstrated with results from empirical case studies in Spain. The case study areas are verging on natural areas with high ecological value and future urban expansion can only be realized by encroachment on these areas. Apart from this environmental conflict, the uncontrolled rise of water demand and the lack of anticipatory planning in the face of climate change aggravate water scarcity and the impacts of meteorological drought. A typical sign of imminent water

management conflicts is the critical level of the water demand-supply ratio and the implementation of water-use restrictions. These environmental conflicts are discussed in the wider international context, arguing that the new urban models produce social-ecological systems with specific challenges to urban biodiversity conservation, water management, and planning. This approach shares insight into spatial transformations and environmental conflicts with the new concept of 'naturbanisation', adding to the debate on displacement of land use demands and related impacts on areas with great landscape value.

The effects of naturbanization in the Catalan Pyrenees: The risk of forest fires in the wildland urban interface

Antoni F Tulla (Universitat Autònoma de Barcelona), Anna Badia (Universitat Autònoma de Barcelona), Ana Vera (Universitat Autònoma de Barcelona), Joanmanuel Soriano (Universitat Autònoma de Barcelona), Albert Pelachs (Universitat Autònoma de Barcelona)

The Catalan Pyrenees are surrounded for several urban areas which generates an intensive use of functional mountainous land: winter and summer resorts, second homes and infrastructures. Besides that, landscape quality helped to set up some natural protected areas in the region with the result of a land use conflict. Moreover, most of the land, hamlets and villages far away from main valleys are abandoned. This study addresses the issues arising from natural protected areas and the processes of disperse urbanization or 'naturbanization' based on the replacement of agricultural land with urbanized residential space, as well as territorial abandonment, which results in the loss of the area's traditional primary sector. Nowadays, the intensity of "urban" uses contrasts with territorial abandonment in mountain zones and obligates us to consider new models for territorial management. The objective of this research is to analyze how changes in the framework of territorial organization increase the risk of fires in wildland-urban interface. Our hypothesis is that changes in land use provoke changes in the natural dynamic that increase the fire risk and at the same time produce changes in social behaviors that affect the perception of risk increasing vulnerability of the surrounding area. The methodology used to analyze changes in land use between 1956 and the first decade of the 21st century and fire statistics for the period 1994-2008 added new elements to the discussion of forest fire risk in mountain zones, while making a contribution to plans for improving territorial management and designing better organization of the territory. This research is conducted within the context of the international Land Cover-Land Use Change (LCLUC) project and the debate generated by the

impact of global climate change on land cover and land use, which we study on the south slope of the Pyrenees, a mountain zone of the NE Iberian Peninsula. Keywords: Forest fires, Land Cover-Land Use Change, naturbanization, Natural Protected Areas, Pyrenees, vulnerability, wildland urban interface.

Unevenly escalating conflict between a national park and the expansion of urbanization in Warsaw (for example, municipalities Leoncin and Czosnów)

Izabella Lecka (University of Warsaw), Mirosława Czerny (University of Warsaw)

Warsaw is just a one of the few European capitals, adjacent to large protected area - Kampinos National Park. The park covers vast areas of swamps and sand dunes in the valley of the River Vistula and because of these characteristics of the environment, was not a once attractive areas for housing development. However in the 80, especially the 90. XX, was initiated a process of expansion on the outskirts of the park which threatening the natural ecosystem. At the same time the status of protected areas greatly reduced the possibility of farming and contributed to "push" of population from the relevant area of "the park on its periphery. Edges of national park became an area of intense conflict over the land. Farmers look for a new forms of economic activity. In Leoncin and Czosnow they hope to develop tourism, e.g. they want to set up stables for horses and riding clubs. Due to the small distance from Warsaw, tourists do not plan spend night here. So it is not profitable establishment of hotels or B & B. In such conditions farmers again start to sow their fields and are waiting for subsidies from EU. And besides that, due to the market in Warsaw, and greater income of the inhabitants in the capital, than in the other regions of the country, organic farming is growing. Organic farming was introduce at the border of the protected area Vistula 2000. The authors of this paper assumes that space-legal and social conflicts on the outskirts of the protected area lead to chaotic urbanization and intensification of the process of urban sprawl in the municipalities closest (to 1 hour of travel) to Warsaw. It is a process which is now very characteristic for the urban area of Warsaw. Municipalities located further away from Warsaw (1 hour travel and more) bypass the negative effects of rapid urban sprawl and benefit from its location at the crossroads of nature protected areas (national park and program Vistula 2000).

Blurring the Line between the Urban and the Rural: Transformation of Natural Spaces Into Urban Spaces in Finland

Juha Kotilainen (University of Eastern Finland)

The line between urban and rural spaces is continually being contested and transgressed in current European spaces. While the distinction to urban and rural may have been more clear in the past with urban spaces associated with certain occupations and the rural with agriculture and forestry, the decades long transformation of rural life-styles to match urban ones and movement of people to dwell in rural spaces while working in cities as well as the downturn in traditional rural livelihoods in some areas has been leading to the distinction becoming blurred. This paper explores the case of Finland and investigates its urban planning policies and practices on several scales. Finland is specific in some ways in terms of the sprawl of urban areas to rural spaces. Due to a late urbanization and sparse settlement structure within cities with many green spaces, cities in Finland are not only spreading to rural and natural areas outside the urban spaces, but also into rural spaces and natural areas inside current urban areas. This trend is moreover intensified by the aim of the governmental policy, motivated by the state environmental administration and central government alike to conform to the requirements of international climate change policy. It has been politically decided that these requirements will in part be met by urban planning efforts aiming to make the built urban spaces more dense all over the country. This goal has been set on the level of the central government, in effect obligating the planning authorities on the regional and urban scales to follow these environmental political planning goals. This environmental political planning aim raises a number of issues and challenges for the planning process. The new urban spaces being planned currently include rural areas with traditional rural activities such as animal pastures as well as protected areas including national parks. This paper sets out to analyse and compare the conflicts arising from the current planning trends. These conflicts and contestations are multi-scalar and involve a multitude of actors and policies. Planning documents and other documentary sources are used as research material.

UDC 15-02 - Naturbanisation: Urbanisation in nature and environment conflicts 2

Chair: María-José Prados, Julia Lourenço

Threats to traditional agriculture and connectivity in Peneda-Gerês National Park

*Julia Lourenço (University of Minho), Marta Fernandez (Universidad de Sevilla),
María-José Prados (Universidad de Sevilla)*

Traditional agriculture faces growing pressures as it suffers processes of intensification and abandonment. At the same time, being landscapes modeled by these activities characterized by a close interaction between man and environment, they are increasingly being valued for their contribution to biodiversity preservation. It is often claimed that certain humanized ecosystems and elements of the landscape contributing to its resilience and integrity need to be included into biodiversity preservation strategies. Traditional agricultural systems are not only biodiversity rich, but they are potential buffer and connect areas designated for biodiversity preservation. This is particularly important in a current context of increasing pressures such as expanding urban areas or climate change, throwing doubts on the ability of designated areas to effectively preserve biodiversity. Naturbanization was recently defined as a specific form of counter-urbanization that takes place in the proximity of Protected Areas. It refers to the attraction of residential and other urban activities to remote rural places, as a response to greater population mobility and the increasing share of natural values in quality of life perceptions and consequently in residential choice. As a consequence, socioeconomic and ecological impacts, often negative, take place. This paper studies land use shifts in Terras de Bouro, a municipality within Peneda-Gerês National Park, in North Portugal. The aim being to understand the extent to which intensification of land use is taking place at the expense of valuable agricultural lands, and the way these transformations could be threatening connectivity and integrity of a Protected Area. The study of Peneda-Gerês National Park is of particular interest, in the first place naturbanization processes have already been identified in this area by previous studies; in the second place, with the edition of Land Cover Map of Continental Portugal for years 1990 and 2007, this country counts on a very detailed cartography. Its minimum mapping unit being one hectare allows a better detection and understanding of some processes threatening Protected Areas, such as low intensity urbanization, which are not detected by more common

cartographic sources such as Corine Land Cover. The paper puts forward some policy suggestions for a planning for biodiversity preservation that includes not only designated areas or natural habitats, but also traditional agricultural areas. This would allow planning for social as well as environmental goals and implementing a more dynamic and sustainable management based on processes generating landscapes.

Cerros de Bogotá – objectives of the spatial expansion: Where, why and what are the consequences?

Mirosława Czerny (University of Warsaw)

Rights are earned in the city by fighting. ('). It's hard to talk about the community where people do not have common goals around which they can organize. May buy the place, but whether this act of commercial relations creates a community? (D. Harvey, 2006). The process of settlement and urbanization of new areas in the city is not devoid of tensions and conflicts. They concern how to deal with the land, its spatial organization, and finally its management. These conflicts may take the form of violence and even armed struggle. Conflicts and violence in cities are caused by various factors and it is never just one factor that leads to them. Socio-economic conditions, spatial segregation, exclusion, the weakness of the state, are only some of these factors. At the same time constant process of expansion of building area and the influx of new immigrants only worsen the situation. Bogota is Colombia's largest urban center and currently has about 8 million inhabitants. Very rapid population growth of the city and urban areas on its periphery in the past two decades has for many years been caused by the influx of settlers from rural territories. But these migrations are not ordinary wanderings on economic grounds as in other countries in the region but forced displaced people. It is now one of the most serious social problems of Colombia. The consequences of these processes for the development of Bogota are: 1. Population growth 2. Dealing with land in acts of invasion of the area or establishment of districts pirated 3. Social marginalization and growth of informal economic and spatial processes in the city. 4. Development of the city of refugees and the city of the hiding.

Naturbanization: Urban Patterns Changes in Doñana and Sierra Nevada (Spain)

María-José Prados (University of Sevilla), Alfonso Doctor (University of Huelva)

Naturbanization describes the process of urbanization in relation to the existence of protected natural spaces of great value. These processes include the search for new residential space in which the quality of the environment will be a concrete factor; the restart of traditional economic activities; the influence over the promotion of activities concerned with new activities related to the consumption of nature; the development of the construction sector; and public investment in infrastructure to improve access. All these factors have consequences for land use planning and environmental conservation in protected natural spaces. Naturbanization means the transfer and expansion of urban process to areas far from centres of urbanization, to is linked to the existence of natural resources, environmental and aesthetic landscapes. On these areas the population mobility and landscape values are strongly related. In this sense, naturbanization processes are opposed to the metropolitan de-concentration processes because the demographic size and low density of population in rural areas. This paper confirms that the population growth, residential development and the preferences of naturbanites. The paper analyses how the existence of natural protected spaces stimulates urban growth in their surroundings. The aims are to demonstrate how urban growth and urban sprawl related to naturbanization processes provoke urban pattern changes on national parks surroundings and secondly, which could be the motivations and expectations of new residents over these areas. The study is based on the information from the building endorsements approved by the Architects Associations and the aerial photographs from 1956 to 2006. Combining statistical data and photo interpretation may be possible to explore the residential development and urban patterns changes. The study areas are in the vicinity of Doñana and Sierra Nevada National Parks on south Spain, where urban areas growth and the appearance of new scattered habitat completely cut off from the traditional activities are occurring.

Changes uses of landscape in the economically influence area of Doñana National Park

Marta Barceló Villalobos

This paper presents the results of a research project about the changes uses of landscape related to naturbanisation process in the protected area of Andalusia,

Southern Spain. In particular, this project analyzes the changes landscape uses in the socioeconomically influence area of the Doñana National Park. There is statistical data about the existence of an increased resident population during the period 1975 - 2008. This factor, together with the presence of natural resources, environmental and landscape value in the territory enable the development of naturbanisation processes in the territory. The project has demonstrated empirically the increasing of land devoted to farming. It is given a quantitative description of the changes uses of landscape that occurred between 1975 and 2008. So, this proves the existence of naturbanisation processes in the field of study. In addition, it is discussed the management implications in a multidisciplinary context. It is due to the agriculture is one of the most important drivers of the economy of Huelva. To keep the importance of this activity in Huelva, a land-use plan focusing on environmental issue is essential. Otherwise, this activity is going to disappear sometime later. That is because it depends on the water resource. It is exposed the transformation rate of irrigated land uses in 1975 - 2008 period, was the largest one. The irrigation work had been multiplied two and a half times since 1975 until 2008. The extension of irrigated lands is increased by 44.518 Ha approx. These hectares came from crops under plastics and irrigation uses. The analysis of the sprawl of irrigated agriculture in the area of influence of a protected area is a clue to further assessment of the weight of the naturbanisation, and to analyze factors influencing the attraction of new residents. To do this, well-established methodologies have been developed for treatment of digital information for the development of interpretive maps of territorial processes. This methodology is articulated through the use of a geographical information system. Keywords: naturbanisation, Doñana National Park, changes uses of landscape Author: Marta Barceló Villalobos

UDC 16-01 - Neighborhood governance under conditions of globalization – An international perspective

Chair: Matthias Drilling, Olaf Schnur

Chilean and European neighbourhood regeneration policies: Comparative approach on neighbourhood concept and its delimitation

Verónica Tapia (Universidad de Barcelona)

The neighbourhood has been construed as an important focus of action for urban policy, particularly as related to regeneration tasks, as Atkinson, Dowling y McGuirk (2009:2818) state "In countries like the UK, France, and the US, the neighbourhood has become a primary scale through which service delivery, regeneration, and moral agendas around citizenship and cohesion have been approached". By observing the current panorama, we can also add Spain as well as several Latin American countries. Why this emphasis on the neighbourhood? The literature suggests a few reasons strongly related with governance issues: the neighbourhood has been considered the basic building block for maintaining social cohesion, illustrates saturation of poverty and disadvantage in parts of major cities and is perceived as the site of local community (Forrest, 2009). Also, in the current context where governments are not able to control global capitalism, the neighbourhood is the most feasible scale in which to intervene (Kearns and Parkinson, 2001). Finally, this neighbourhood approach offers an attractive alternative for tackling social exclusion through strengthening social capital (Meegan and Mitchell, 2001) and local government (Kennett and Forrest, 2006). However, the literature shows two main difficulties pertaining to the neighbourhood scale: First, there has been difficulty coming to a consensus on the explicit and commonly accepted conception of the neighbourhood scale. Second, there is the operability problem, in other words, how can we delimitate areas of intervention in order to carry out urban policy objectives (Dietz, 2002). Related to these issues several questions arise: Which neighbourhood concept is behind urban regeneration policies? How are these concepts related with governance tasks of urban regeneration policies? How do these policies define neighbourhood intervention areas? Considering the neighbourhood emphasis in regeneration policies, at least in the western world, and consequently the importance of distinguishing the different approaches, the present paper proposes to discuss these issues under a comparative perspective: Firstly, based on content analysis

methodology of official documents, this paper will identify the main trends of the most representative current neighbourhood regeneration programmes of Western Europe, delving into three points: explicit or implicit neighbourhood concepts; relations between neighbourhood concepts and governance tasks; the process of defining intervention areas. Secondly, in order to offer a geographic counterpoint, this paper will analyze these three aspects in the Chilean regeneration program "Quiero mi Barrio". This programme started in 2006 and is focused on 200 neighbourhoods throughout the country; also, this program is a relevant case because it signified the recognition of the neighbourhood scale as an explicit planning dimension in Chile.

Social Activation in a Master Planned Community: Inclusion and its Ambiguities

Nico Stefanovics (University of Edinburgh), Nico Stefanovics (University of Edinburgh)

In the context of housing, governmentality studies have largely focused on behavioural politics enforced as legal obligations upon the tenant (Flint, McGuirk and Dowling). This paper makes a point for a more direct, although not necessarily more emancipatory case of inclusive governmentality within urban redevelopment, drawing on the master planned community of HafenCity in Hamburg. Several factors have combined to create a plethora of voluntary initiatives over the first few years of HafenCity's existence, as the project misses the neighbourhood acquaintances, business clusters and shop customer loyalties found in established neighbourhoods. This indeterminacy is an asset capitalized on by ambitious individuals living in HafenCity, united in their goal to turn the area into a success, but in competition with each other. The discovery of this new build scheme by the media as a new area of innovative consumption and its growing popularity among tourists are catalysts for the successful marketing of HafenCity. Key players running initiatives in the site are alert to these circumstances, which they can reinterpret as preferable for their own self-actualisation. The Netzwerk (network) is a platform in HafenCity for residents, business people, and other institutional actors alike. My paper argues that participation in it is driven by the ambition to secure social capital, and the entrepreneurial way in which this is done may be disruptive rather than conducive to neighbourhood cohesion. The double identities of the members of the netzwerk as both neighbours and pursuers of individual interests are at unease with the supposedly collaborative spirit of the group. A missing consensus on how to calibrate diverging interest spheres in addition to the

desirability of conflict avoidance with your next door neighbours produces a 'vacuum of accountability', particularly visible when ambitious individuals exploit events hosted in the name of the *netzwerk*, as occasions to strengthen their own position. A post-occupancy evaluation in HafenCity had concluded that the bulk of needs raised by residents warranted the employment of a sociologist as a permanent 'care taker'. For the members of the *netzwerk*, he acts as advisor and conflict manager for the disparate stakeholders represented in HafenCity. The imperative of acting impartial towards all local factions alike, ingrained in his function as a mediator, however, restrain his ability to reconcile clashing interest spheres. Attempts to instruct clearly or discipline someone would make him appear as an extended limb of the planning board rather than as a partner at eye level. I will exemplify this through the case of a neighbourhood event jointly organised by the *netzwerk*. The limitations of settling tensions amongst neighbours are grounded in the lack of authority such a counsellor has, ironically because the definition of his role is to be non-authoritarian.

Neighborhood governance in metropolitan area of Paris: An erratic model

Anne-Lise Humain-Lamoure (UPEC - Lab'Urba)

This paper aims at introducing and discussing the forms of neighborhood governance in metropolitan area of Paris (France). A law on 'local democracy' adopted in February, 2002 has substantially reconfigured the political-geographic organization of urban neighborhoods. The law strongly encourages (or, sometimes, imposes) the creation of political subdivisions within the territories of communes, thereby institutionalizing new political spaces for participatory-oriented local governance. The social consensus that seems to have been created around notion of the 'political neighborhood' for Paris-area residents is less uniform than it appears, and the political status of this new kind of political neighborhood remains uncertain for municipal actors. In despite of the law, the legal regulations are very limited. Thus the variety of scope and forms as well as reasons and results of governance depends to a large extent on three factors: municipal actors' willingness, social characteristics of the neighborhoods, and conflicts related to specific interests of actors with different strategies. Especially, the methods and procedures through which this neighborhood governance take place are diverse and are tied to questions of political loyalties and socio-spatial morphology that vary in their own right from place to place. The dynamics inherent in the progressive appropriation of these neighborhoods by different local actors - dynamics tied to local political

affiliations and identities - accentuate already-visible differential effects at work in the creation of political subdivisions under the law. Neighborhood governance in the Paris area seems as erratic practices without only one theoretical or political model, at the risk of segregation effects. However these forms of neighborhood governance create new forms of connectivity between actors involved in urban administration and across different governing hierarchies and territories for public action. In this way, these forms of local governance might be perceived as a new multi-scalar perspective on regional governance in progress, from neighborhood level to metropolitan area level, without a strong municipal level. This paper is based on a long work from 2002 to 2011 about neighborhood governance in metropolitan area of Paris. This paper will be especially, but not exclusively, focused on Paris neighborhood districts.

UDC 17-01 - Neoliberal urban transformation processes in the Arab world

Chair: Ala Al-Hamarneh, Leila Vignal

The End of the Mega-Projects? Economic Crisis, « Arab Springs » and urban fabric in Egypt and Arabian Peninsula

Roman Stadnicki (CEDEJ / Ambassade de France en Égypte)

This contribution aims at questioning ourselves about the combined effects of the economic crisis and the 'Arab Spring' social protests on urbanization in Egypt and Arabian Peninsula. These concomitant events seem to have delayed or even cancelled some urban mega-projects (new towns, malls, touristic and luxury compounds, etc.) which have been negotiated, since the beginning of the 2000's, by high-ranking public authorities and powerful multinational companies. More generally, speaking from this part of the world, we notice that the neoliberal models of urban planning are slowly running out of steam, judging the recent criticisms made by more and more public and private actors or civil society's members. On the one hand, the property developers' debts, which are particularly important in the Gulf area, and the implosion risk of the real estate bubble since the 2008's financial crisis, question the current norms of urban planning. The 'Dubai model', which has been exported out of GCC, seems to have been weakened at its source: some big urban projects symbolizing the urban planning-architecture one-upmanship, either unachieved (Dubailand) or unfrequented (Global Village), constitute nowadays huge urban margins. On the other hand, the Arab spring popular uprisings appear as an additional sign of the decline of an urbanity model shaped by mega-projects and authoritarian urbanism. In Egypt, January 25th Revolution has highlighted the difficulties to have access to housing and main public services in most of cities. The 'Cairo 2050' Master Plan, which was envisaged by Mubarak as a way to improve Egypt's international competitive edge and to continue the desert's conquest, will be probably entirely reviewed. Then, the illegal occupation of vacant houses in Six of October City by squatters in October 2011, strongly repressed by the army, questions the success of the 'desert cities', in which less than 1/20th of the Greater Cairo's population live. Moreover, it shows the public authorities' incapacity to resolve the housing problem of the urban societies' lower fringes. With the advent of international circulation of urbanism models? and of what can be called the Arab Spring's 'second act', comparing Egypt and Arabian Peninsula allows to wonder if a new urban era is being outlined in the region,

both inspired by the severe economical and societal blow against the neoliberal urbanism and by the resurgence of the socio-spatial margins ('ashwa'iyat in Egypt, places of expatriate's labour forces in GCC), where inhabitants claim a right to a more equal, democratic and sustainable city. The results which are proposed in this contribution have been drawn up thanks to a mission achieved at the beginning of 2011 in GCC and also to some surveys which are conducting in Cairo since September 2011.

Neoliberal urbanism and the reassemblage of state power in Morocco and Jordan

Koenraad Bogaert (Ghent University)

Most scholars working on the Arab World typically view the state's power as something congruent with its cartographic boundaries. Power emerges from an institutional core – the regime – which exerts, via direct intervention, its hegemony over subordinated institutions, spaces and scales. As such, the regime presents itself as the privileged site of political formation, intervention and inquiry. The result is a body of scholarship that has largely neglected the dynamics of 'new state space' formation on the urban scale. Drawing on the dynamics of exemplary cases like the Bouregreg urban development project between the twin cities of Rabat and Salé, Morocco, the Abdali Urban generation project in Amman and the Aqaba Special Economic Zone, Jordan, this paper investigates the dynamics of agency formation implicated in the creation of so-called new state spaces and considers what it reveals about the whereabouts of state power and the rise of new governmental arrangements that have been elided by mainstream accounts on the Middle East and North African region. By critically engaging with the new state space literature (Brenner, 2004), we argue that neoliberal urban politics have given rise to new, wider and more open assemblages of (state-/class-)power. Foreign investors, architects, urbanists, real estate developers, etc. have become new players on the field of the state. Yet, this not necessarily means that traditional state elites are losing their power, but rather that new (capitalist) actors are drawn within reach (Panitch, 1998; Allen & Cochrane, 2010). In contrast to the neoliberal adage of economic and free market 'borderlessness' and the withering away of the national state, imagined through globalized spaces such as Bouregreg, Abdali and Aqaba, contemporary configurations of capitalist accumulation are produced by particular operations of state power. The conception of 'borderlessness' is not so much a political space outside or beyond the reach of the state, but a particular formation of power that suggests recourse to a more

complex framework of our understanding of the state. Economic borderlessness is always a produced within state borders. As such, these spaces are not really extracted from state control. Rather, their configuration involves state power and represent particular forms of an “interiorized outside” (Butler & Spivak, 2007).

Urban planning in Casablanca: An impossible convergence between neo-liberalism and spatial justice?

Pascale Philifert (Université Paris Ouest Nanterre- LAVUE)

In Morocco, the priorities established in the name of economic openness and competitiveness of the territories have become essential elements of public politics. Within the territorial policies, the new protocol resulted in a number of initiatives from the National Debate on Regional Development launched in 2000, adopted in 2004 to SNAT. The renewal of management strategies is built on new reference framework based on a triple challenge: economic efficiency, social equity, ecological balance. In their wake, a reconfiguration of scales of action (region, metropolitan area ...) and governance is encouraged. However, the implementation of these guidelines in urban strategies - or operational - highlights a number of deep reconstructions locally and also reveals the strong antagonism between environmental approach, economic performance and recognition of spatial justice. In this regard the pattern of functional organization and development (SOFA) of the central metropolitan area (2006) and the new master plan of the Grand Casablanca (2008) are emblematic of these dilemmas. Moreover those master plans and great urban projects are highly influenced by neoliberal models of growth. This paper aims to highlight the contours of the new territorial policies for the coastal region where the central social issue may seem secondary to the tangible and intangible investment that seems to require the anchoring of large Moroccan cities in the global competition claimed by power and the elites, under the influence of international agencies.

Building a new Sultanistic city: The Bouregreg Project and the Moroccan monarchy

Joomi Lee (University of Texas at Austin)

My paper studies Morocco's Bouregreg Project, a large-scale Bouregreg river valley redevelopment project. I view this project, which has been constantly emphasized as 'une initiative royale' since its official launching in 2006, as a strategic urban political enterprise of the powerful Moroccan monarchy (the Makhzan). To elaborate, rather than framing this project simply as an example of

the neo-liberal urban renewal currently sweeping the Arab world financed by Gulf petro dollars, I regard this project as the Moroccan monarchy's attempt to build a new iconographic landscape befitting their capital of a 21st century Islamic Kingdom, designed to change the image of the capital from 'Lyautey's colonial city' to 'the King's city'. It is somewhat ironic that a contemporary resurrection of the colonial urban ideologies - a realization of modernity and conservation of (indigenous) tradition over the course of the Bouregreg project - is being strongly backed by the royal palace. The Bouregreg Agency, the powerful governing body of the Bouregreg project created by a royal decree, claims that the project aims to overcome 'la parenthèse coloniale' of modern Moroccan urban history. Yet, the project's imposed royal vision of creation of a 'modern but historical' capital has a strong colonial flavour, demonstrated in both its official discourse and its rehabilitation practices. In particular, the Bouregreg Agency's persistent emphasis on 'exceptionality' of historical memory inscribed in the Bouregreg valley, heavily charged with historical monuments, and its claim to restore 'la splendeur des temps anciens' of the site, have resonance with a colonial assertion made by Lyautéy at his arrival in Rabat: 'We found here the vestiges of an admirable civilization, of a great past. You are restoring its foundations.' With the case of the Bouregreg project, this paper specifically focuses on which parts of history and what kinds of tradition have been restored in order to produce contemporary myth in the re-imaging of the country's capital as a modern Sultanistic city. By recognizing that the Bouregreg agency conceives Rabat's past identity as a 'Great Almohad city' as well as a 'Sacred city', this paper is concerned with an investigation of how the project's re-defining of the identity of Rabat and restructuring of the Bouregreg valley landscape are deeply - politically and historically - interwoven with the distinctive power of Moroccan monarchical rule, which is a phenomenon Hammoudi (1997) refers to as the 'ethnography of dispersed authoritarianism' (xiv).

UDC 18-01 - Old and new mobilities in Asia: Challenges for geographical development research

Chair: Matthias Schmidt, Basabi Khan Banerjee

New mobilities, translocal communities and livelihood networks in the Asian mountain periphery: The case of the Wakhi of Gojal, Northern Pakistan

Andreas Benz (FU Berlin)

Translocal networks have become a key issue for securing rural livelihoods in the mountain periphery of South and Central Asia. Increasing levels of migration and new forms of mobility led to the emergence of translocal communities and livelihood networks. The highly mobilized and spatially dispersed Wakhi community from the high mountain region Gojal in northern Pakistan is an illustrative case in point, which provides a better understanding of the recent processes of mobility change and the increasing importance of translocal networks for rural livelihoods. Based on results from extensive fieldwork in Pakistan in 2011, the presentation will provide an outline of the shifting mobility patterns of the Wakhi in Gojal in the context of changing livelihood systems and framework conditions. It will show how people of the Wakhi community gradually increased their mobility level and expanded their social networks to distant places to secure a living and in search for new livelihood opportunities. It will be worked out how old forms of mobility - e.g. in the context of animal husbandry and combined mountain agriculture - have been transformed, complemented, and partly replaced by new mobilities in the context of labour migration, student mobility and various forms of circular movements, leading to complex migration networks, multi-local livelihoods and the development of a translocal community. These spatial mobilization processes de-territorialized the Gojali community, where large proportions of the population have physically left their home region but maintain their identity attached to the collective representation of an imagined 'Gojal'. Translocal social networks unite this virtual community, where intensive flows of people, goods, money, information and ideas oscillate between its various sites. Gojali households today rely on translocal livelihoods, where household members are spatially dispersed and combine various income generating activities and livelihood opportunities in different contexts. In the context of this empirical example, new approaches of livelihood research, which combine 'classical' livelihood approaches with new forms of mobilities and the multi-locality of households, will be applied and tested for their potential to deal

with the analytical challenges of multiple mobilities from the perspective of geographical development research. Equally, recent concepts of translocality and translocal communities will be discussed and presented as an alternative to the predominant transnational approaches.

Across localities: Livelihood strategies and new mobilities in the Indian Himalaya

Juliane Dame (Heidelberg University)

In the context of globalization, political and socio-economic change has created new employment opportunities and changed mobility patterns in the rural South. This trend can be observed in the high mountains of South Asia, where rural households increasingly rely on diversified livelihood strategies. Against the background of field research in the Indian Himalaya (Ladakh region), this paper analyses spatial mobility as a livelihood strategy of mountain households. In Ladakh, a dissolution of the 'traditional' household - which used to rely on subsistence agriculture and to be defined as a place-based unit of production and reproduction - can be observed. Therefore, the concept of translocality is used to assess how households that are increasingly spread across localities shape their livelihoods. Empirical data from two Ladakhi villages show that mobility is associated with aspirations of enhanced well-being through better education or higher monetary income. Household members move to different destinations including the Indian lowland, the regional district capital or neighbouring villages. The findings highlight that interconnections between the (temporary) migrants and the village of origin not only encompass economic ties, but the creation of new social networks and cultural links. Movers still consider themselves as villagers (yulpa). They continue to be part of the household and social structures that they were born into. This identification of 'belonging to the village' is symbolized through participation in social events, the exchange of gifts and monetary remittances. At the same time, the dissolution of households has changed societal relations in the locality of origin (e.g. reciprocal labour arrangements in the agricultural sector). In such ways, mobility not only affects the movers, but the livelihoods of those who stay. The results highlight the complexities of new mobilities in mountain regions with a diversity of flows of people between different localities that have often been neglected until today.

Recent Internal Migration Patterns and Its Determinants in Thailand and Vietnam

Vera Junge (Leibniz Universität Hannover), Javier Revilla Diez (Leibniz University Hannover)

In fast developing countries such as Thailand and Vietnam internal migration increases rapidly. Theory on migration and development has already recognized that migrants can contribute positively to the process of convergence of living standards by distributing knowledge and income. Something neglected for a period of time is the idea of changing destination patterns and a possible polarization reversal trend with new emerging regional centers. New trends regarding destination patterns of migrants can be formed by two groups of migrants; firstly, by the possible new migrants who decide whether to move or not as well as by their destination choices. Secondly, by the existing migrants who may change their current location and often return to their home provinces. The central question is therefore, which current patterns of migration can be found for rural households in Thailand and Vietnam and whether destination patterns are shifting towards regional destinations and a polarization reversal may take place. Based on the results, we analyze how recent migrants and return migrants - who shape this process - are influenced in their migration and destination decisions. This work is embedded into the DFG-Research Unit 756 on the "Impact of shocks on the vulnerability to poverty: consequences for development of emerging Southeast Asian economies?". The data is based on household surveys conducted in 2007, 2008 and 2010 in three provinces in Northeast Thailand (Buriram, Nakhon Phanom, and Ubon Ratchathani) and three provinces in Vietnam (Ha Tinh, Thua Thien Hue, and Dak Lak). The data enables us to follow individual behavior and migration decisions over time which is crucial to understand and distinguish determinants and consequences of migration. The results show that although internal migrants still move most likely to the economic core regions of Bangkok in Thailand and Ho Chi Minh City (and Hanoi) in Vietnam, the relative importance of destinations outside of these core regions and especially within the home provinces is increasing significantly. In particular for Vietnam, a beginning polarization reversal can be therefore assumed. To analyze recent migration decisions we use multilevel logistic regression and find that regional nonfarm opportunities and migrant networks have a significant impact on the individual migration decision. Also significant differences between migrants moving to regional destinations in contrast to those moving to national economic core regions can be found. In a last step, we currently analyze the characteristics of internal return migrants and their contribution to regional

development and reduction of vulnerability of the households and home regions. These processes are accompanied by reduced communication, information and transportation costs which in turn ease migration networks and are likely to further enhance the fast change of destination patterns in the future.

The Effects of Polycentric Development on Labor Mobility in Metropolitan Areas: A Review of the Debates and an Analysis of New Perspective

Dong Lin (University of South Australia), Andrew Allan (University of South Australia), Jianqiang Cui (University of South Australia)

Sustainable labor mobility within metropolitan areas is predominantly characterized by minimising employees' job commuting distances and travel times and the application of a sustainable travel model. With urban decentralization and the evolution of mega-cities from a monocentric to polycentric spatial structure in recent decades, urban geographers and urban planners have from various perspectives highlighted their interests in polycentric models of urban development. Of particular interest is how employment decentralization in metropolitan areas that is based on polycentric spatial development affects employees' commuting trips length and their travel times has created many intense debates. There are two major reasons for the debates. One reason is whether the evolution of a polycentric spatial structure in mega cities could provide more opportunities to enhance spatial matches between the job and housing location selections of employees who live in suburban areas. Accordingly, employment decentralization would improve commuting patterns and urban congestion such as shortening individual commuting distances and travel times, thereby resulting in less reliance on private cars. Another reason is whether and how jobs-housing balance policies minimise employees' commuting trips and enhances their job accessibility. From the 1980s onwards, China's urban spatial structure changed dramatically with the 'Economic Reform and Opening-up' policy which occurred simultaneously with a new policy on housing reform, resulting in dramatic urban spatial restructuring of China's largest cities. The urban spatial structure of the majority of China's mega cities' changed from a monocentric to a polycentric model. Spatial agglomeration and dispersion were coexistent. It is generally recognized that such urban spatial evolution is accompanied by changes in people's work and residential locations, and subsequently changes in their patterns of commuting. Accordingly, China's urban spatial restructuring of its cities has created new connections and new commuting patterns between jobs and

housing locations in its metropolitan areas. To date, relatively few studies have investigated the specific characteristics of this unique Chinese situation. This article will review and discuss the debates of how polycentric spatial development in metropolitan areas impact on patterns of commuting, through a review of experiences in cities of western countries. Furthermore, the analysis will explore its implications for China's mega cities.

Chair: Iris Dzudzek, Kevin Ward

Faster, Higher, Stronger Policies: Olympic models and the making of Rio de Janeiro 2016 Games

Gabriel Silvestre (UCL Bartlett School of Planning)

Ever since the early 1990s, successive governments in Rio de Janeiro have pursued the strategy of flagship urban projects and the attraction of mega-events as part of a wider agenda to reposition the city as a consumption-oriented economy. Having the city of Barcelona as an explicit reference point, this rationale was part and parcel of the 'Plano Estratégico da Cidade do Rio de Janeiro', an urban strategic plan elaborated with the assistance of Catalan consultants which has become emblematic of the transformation of local urban governance. Among the most high-profile new policies, the bidding for the Olympic Games was as an enduring objective and a platform to engage with experiences from elsewhere. After winning the bid to host the 2016 Olympics, local organisers have pursued a dual strategy of on the one hand, forging international networks (by, for example, hiring the services of international advisers such as Tony Blair, Rudolph Giuliani and Pasqual Maragall, and establishing partnerships with the London 2012 Organising Committee) whilst on the other hand, re-defining local planning regimes to facilitate the Games. In becoming an 'Olympic city', Rio de Janeiro seems to have mobilised the necessary conditions to replicate the 'Barcelona model' and other policies drawn from previous hosts. However, an understanding of the apparent 'success' of former hosts is tied with specific historical-geographical circumstances which make the model a stylized version and a partial account of it (McCann and Ward 2010). The outcome of this policy transfer process is thus bounded by the action and selective translations of policy agents and the specific context of the new environment. This presentation draws from an ongoing doctoral research in response to the double call for continued critical research that add empirical depth to processes of policy mobilities (McCann 2011, Peck and Theodore 2010), and the need to expand contingent analyses of local embeddedness outside the North-Atlantic zone (Larner 2003, Peck 2004, Robinson 2011, Ward 2006). If former Brazilian president Luis Inácio 'Lula' da Silva was right, in affirming that mega-events will provide the 'international citizenship' of Brazil (Sanchez et al 2010), symbolising the

emergence of the country as a world leader, the making-off of this 'emancipatory' process certainly deserves great scrutiny.

New Urbanism heads South: The Case of Santiago de Chile

Michael Lukas (Universidad de Chile)

This paper presents a critical reconstruction of the introduction of new urbanism and smart growth principles in Chile in the last 15 years. Drawing on key informant interviews with real estate developers, planners and public authorities as well as the analysis of documents and media coverage, I show how in Santiago in the early nineties some of the leading business groups started to make city building one of their core businesses and in that context embarked on strategies of knowledge production on issues of urban-regional development. Cooperation agreements between neoliberally and elite-oriented Chilean and US-universities were signed and promising young architects were sent abroad in order to study disciplines as urban planning and urban design. In the late 1990s and early 2000s the returning experts made career in the public and private sector introducing new urbanism principles from different institutional sites. The result has been a profound transformation of the institutional landscape regulating urban-regional development. Modernist-style comprehensive planning has been replaced by so called 'planning through conditioning', case-by-case negotiated and contract based development agreements between the public sector and private developers, making viable a boom of Master-Planned Communities on the urban edges. While, on the one hand, the advancement of new urbanism in Chile can be understood as the result of successful entrepreneurial and neoliberal strategies aimed at legitimizing further edge urban growth through 'sustainable' large scale real estate projects, on the other hand it is important to note that it has not been a clear cut and uncontested process. The paper identifies several conflicts and contradictions between the imported principles of new urbanism and smart growth and local institutions, discourses and several opposing actor groups.

Politics of Selectivity- The process of Splitting Dhaka City Corporation

Shahadat Hossain (TU Dortmund), Md Musleh Uddin Hasan (Bangladesh University of Engineering and Technology), Afsana Haque (Bangladesh University), Shakil Bin Kashem (Bangladesh University)

Disorder in an urban quarter? Contested transformations in Hamburg-St. Pauli

Anke Strüver (University of Hamburg), Katharina Wischmann (University of Hamburg)

The contemporary restructuring of urban spaces is accompanied by changing economic and cultural practices, including a global as well as local competition of and within cities. In this context, Mark Gottdiener (2001) for example has argued that the production of signs is elementary for entrepreneurial success - because symbolic value seems more important for economic success than commodity value - and has suggested to analyze symbolic processes as part of the urban condition. In this paper we combine the economic and the symbolic, as well as discursive processes in order to disclose current urban transformations in Hamburg-St. Pauli that are characterized by globally competitive developments and marketing strategies on the one hand and local ideas of regeneration, political and social participation on the other. St. Pauli, having experienced exclusion and stigmatisation due to its images as nightclub district and as poor neighbourhood and place of alternative life-styles and politics at the same time, is currently confronted with far-reaching urban changes: As a consequence of post-fordist transformations and inner-urban modernization, restructuring processes in Hamburg-St. Pauli have impacts on socioeconomic circumstances - such as expulsion and impoverishment - but also on the quarter's built environment in terms of demolition, rehabilitation and real estate. However, these processes do not concern residential premises only: An increasing number of recent high-rise buildings can be observed in the quarter, which primarily include office-buildings and hotels. Designed by internationally renowned architects (e.g. David Chipperfield, Hadi Teherani), the outlines of these high-rises often correspond with global trends and standards and therefore represent 'globally replaceable architecture' Against theses 'local' backgrounds, the paper addresses the questions - How recent urban redevelopment strategies are negotiated and take place (both in a literal, e.g. architectural, and a symbolic sense) and make space in the quarter; - how local inhabitants express and legitimise their relations to the place and its symbols; -

how global discourses on urban restructuring are adopted locally for St. Pauli (by investors, estate agents, architects etc. but also by private firms); and - how local strategies of resistance are related to globally observable forms of public contestations.

Global models, territorial politics and the formation of homelessness policy initiatives for Australian cities

Tom Baker (University of Newcastle)

This paper builds on recent interest in the mutative geographies of policy - the necessary and ongoing changes to mobile policy knowledges as they encounter new territorial configurations. It begins by charting recent shifts in the landscape of urban homelessness policy in Australia that has led to a period of extrospective policy engagement before focusing on how a specific US-based policy model, known as 'Common Ground', was re-territorialised into a number of Australian cities. In doing so, it explores three key areas. First, the paper focuses on how the 'Common Ground' idea was re-imagined into a mobile model fit for the Australian context, which involved contested abstractions from the particularities of its policy origins. Second, the paper reflects on the way that a variety of territorially-embedded actors and political projects assembled around the development and subsequent territorialisation of the policy model. Finally, the paper concludes by reflecting on the forms of governance enacted through this mutative moment in Australian policy-making and the competing urban visions it reflects.

Consulting Firms – Travel Agents of Neoliberal Urban Policies?

Anne Vogelpohl (Goethe Universität Frankfurt a.M.)

Policy advice has become a common feature within the process of finding general principles for urban development, especially since 'knowledge' and 'learning' are seen as crucial moments of contemporary societies. The argument of this paper is that consultancies play a key role in making neoliberal urban agendas mobile for they are offering their expertise in different cities at the same time and present simple entrepreneurial solutions to complex social problems that cities face. These two aspects of the argument - the multi-local presence and neoliberal scheme - will be made evident by exemplifying consulting practices of an international operating firm in German cities: Consultants from McKinsey & Co wrote the three studies dortmund-project. Das Zukunftspaket [The package for the future], Hamburg Vision 2020 as well as Berlin 2020.

Taking these studies as examples I will first analyze the "local globalness" (McCann 2011) of consultants' advices by comparing the presented (allegedly) local specificities on the one hand and the similarity of consequent solutions on the other. And second, I will show that references to global challenges build the ground for standardized policy advices in every city. Drawing on these analyses, I will conclude with some reflections on correspondences between the consultants' global-oriented rhetoric and abstractions from concrete local problems. These correspondences lay the ground for both the policies' movability and the consultancies' promises for successful advice.

Travelling Concepts – the Role of Ideology in Transnational Urban Neoliberalization

Jenny Küinkel (Goethe University, Frankfurt)

The paper analyzes the transfer of three key urban policing concepts from the US to Germany: zero tolerance, broken windows and community policing. Based on a content analysis of the police expert discourse since 1990, a media analysis and expert interviews it shows how the reference to US policy models is shaped by and shaping local politics, often through negative transfer and (intended) transfer failure rather than successful transfer. Transfer of policies and ideas has proven to be a useful meta-concept. It can link the broad macro-analyses of the worldwide structural neoliberal change with micro-level analysis of the local diversity of real-existing urban neoliberalism. For neoliberalization is evolving through multiple local policy experiments, often including the adaptation of globally available neoliberal concepts, but also their failure. Classical policy transfer literature asks if and how fast processes of copying policies occur. The recently rising urban studies literature on urban policy mobilities foregrounds the multiscalar nature of these processes, the need to move beyond rigid classifications of transfer agents, and last but not least the way how policies change through adaptation to local contexts. The paper argues that both strands of literature can learn from a closer look at the role of ideology in processes of international and interurban learning. The German example shows that rather than aiming at transferring policies in a blue print like manner to German cities or Länder, local stakeholders strategically use references to international policing models to shape local power relations. The paper therefore concludes that the study of travelling concepts needs to distinguish more clearly between policy and ideology and to focus more strongly on politics rather than foremost policy.

The moving map of the global financial crisis: A comparative analysis of four European cities

Sara Gonzalez (University of Leeds), Ramon Ribera-Fumaz (Universitat Oberta de Catalunya), Stijn Oosterlynck (University of Antwerp), Ugo Rossi (University of Cagliari)

This paper investigates the uneven geographies of the global financial-economic crisis at the urban scale across Europe. We do so by making a comparative analysis of the uneven impact of and responses to the crisis in four different European cities: two located in North-Western Europe - Brussels (political world city) and Leeds (second-tier financial city) - and two located in the Euro-Mediterranean region - Barcelona (one of the most dynamic cities in Southern Europe) and Cagliari (the capital city of an insular 'less-favoured region'). The analysis draws on recent scholarship exploring variegated forms of neoliberalism, which focuses on how neoliberal projects 'exploit, transform and reproduce inherited geo-institutional differences' (Brenner et al 2010: 207). The added value of this approach lies in its combined focus on the (a) broader macro-economic and institutional patterns within which the uneven urbanization of the global crisis takes place, (b) local political experimentation and (c) mobility of policies across places. Although this approach allows to discover geo-institutional variation, we argue that one of its shortcomings is precisely the lack of explanation of how geo-institutional variation is produced and what the role of discourse is in all of this. Thus, to overcome this limitation, we combine with it a cultural political economy approach (Jessop, 2007), paying explicit attention to how local actors narrate the crisis and offer potential solutions to it in terms of proposed accumulation and governance strategies. By bringing together both approaches, we explore how the global crisis circulates around different locales across Europe, analyzing the diversity of impacts and responses and assessing if so far it has represented the emergence of post-neoliberal governmental rationalities. Our preliminary conclusion is that the crisis is narrated very differently in the four different cities (and is in two of the cases not even a prominent narrative feature) and that, despite the rise of promising grassroots struggles and opportunities for urban policy change in two of the four investigated cities, alternatives to urban neoliberalism have not yet emerged or are at best in their early, embryonic stages.

UDC 20-01 - Revolution or transformation? The rise of supermarkets and malls in developing countries and their urban and social impact 1

Multi-faceted modernity: Negotiating wholesale and retail infrastructure development in Central Asia's commercial centre

Henryk Alff (FU Berlin)

Almaty, the largest and most populous city of Kazakhstan, after the economic shock in the 1990s and with the rise of an emerging urban middle and upper class as well as increasing purchasing power of the population in general, has seen an unprecedented growth of trade infrastructure. However, the retail and wholesale landscape in the city is polarized between bazaars with local and (inter)national importance and western-style shopping malls and supermarkets. As a subject to urban renewal, bazaars are often negatively connoted as 'traditional' or 'unmodern' by decision-makers in the city and nation-state authorities, whose policies since the start of the economic boom actively advocate a modernisation agenda. However, the 74 city bazaars of different size and structure remain dominant in their share of trade real estate and sales of all kind of groceries and consumer goods. They play also an important role in providing (informal self-)employment to hundreds of thousands of people and the consolidation of small-scale trade entrepreneurship. 'Modern' shopping malls and supermarkets, mushrooming both within the city and the suburban area, on the other hand, largely due to deficits in management and a focus on wealthier customers find varying acceptance by the local population. The proposed paper in form of a field report is based on recent empirical data from 2011/12. It outlines the key dynamics of interrelated sides of the 'modernisation' process of wholesale and retail infrastructure in Almaty in two selected cases. It will predominantly draw on interviews with entrepreneurs, consumers and representatives of city authorities, as the main actor-groups involved, and planning documents as well as newspaper articles. In my paper I will focus on the articulation and implementation of top-down 'modernisation' goals of the local administrative bodies, how these are challenged or used by trade entrepreneurs and investors and how they are met by different groups of consumers and their specific needs. I, therefore, argue that the dichotomous notion of 'traditional'/'modern', widely applied for wholesale and retail

development, partly fails to meet the point of the local discourse. More so, the interests of the actor-groups, seemingly contradicting at first glance, unexpectedly coincide in many ways, leading to rather different short- and midrange scenarios for the development of wholesale and retail infrastructure in the transformation context of urban Kazakhstan.

Malls as nuclei of urbanization processes? A view on Chinese industrial zones

Sabine Beisswenger (ILS - Research Institute for Regional and Urban Development)

The Pearl River Delta mega urban region in Southern China has undergone industrialization processes unprecedented in other regions of the world. It therefore depicts a land use pattern which is dominated by factory space and a population majority that consists of a constantly changing mixture of inner-Chinese migrant workers. Meant for industrial production, the consumption and retail infrastructure in this region was neglected and the industrial workers' supply was mainly organized through the employing companies and small scale retail facilities. This structure is changing recently and supermarkets, hypermarkets and shopping malls are established to service the needs of the industrial workers and to free employers from the obligation to provide goods and services for their work force. Malls in focus here have little to do with high end consumption 'cathedrals' featuring luxury brands as they can be found in the centres of the main Chinese cities. The malls of the industrial zones mostly consist of a ground floor with clothes retail and an upper level with supermarket facility and do not target at the middle class as main shoppers but at the local migrant workers. The paper is based on own survey data of approx. 560 migrant workers and evaluates their usage patterns of the local retail facilities. It shows which groups are drawn to the malls, for what purpose and in which frequencies. While the survey data is used to illustrate the manifest functions (according to Merton) of the malls, additional observation and qualitative interviews are presented to analyse the latent functions those places have. It can be shown that the functions these malls fulfill for the adjacent urban area go beyond providing supply of food, clothes and basic household equipment. Instead they are foci of urban functionalities that no other institution can or is willing to provide. It is investigated which functions the malls take over, which gaps - left by employers and state institutions - they fill. Malls perform as platforms for social interaction and entertainment in various ways and are therefore interpreted as crucial nuclei of urbanization processes.

The Changing Geography of Consumption: Exploring the Rise of Super and Hypermarkets in Turkey

Nuri Yavan (Ankara University Department of Geography)

Recently, there is a growing interest on retail geography and consumption space. To understand the urban economic geographies of retailing and consumption, it is useful to look at Turkey as an example. As service sectors have experienced rapid expansion, especially the food retail industry, since 2000s, super/hypermarkets have dramatically developed in Turkey and become the winning format in fast-growing retail sector. Indeed, the rapid rise of super/hypermarkets in Turkey has changed not only traditional retailing structure and urban commercial space, but also the consumption behavior of citizens. Despite growing investment and ongoing hot debate on urban retailing and consumption sector in Turkey, however, no study has been conducted at the provincial/regional level. Therefore, this paper examines the spatial distribution and location characteristics of super/hypermarkets in Turkey. The paper uses both regression analysis and geographic information system techniques to capture socio-economic factors that determine the location of super/hypermarkets in Turkey. The paper also looks at and compares different retail formats, namely discount supermarket, classic supermarket and hypermarket, at provincial level in terms of spatial patterns and determinants. Our descriptive analysis reveals that spatial distribution of super/hypermarkets within Turkey is extremely uneven. Most of super/hypermarkets are located mainly in coastal regions and in the developed western part of the country. Some provinces/cities located in the eastern part of the country were not chosen by retail chains and thus did not receive any super/hypermarket investment so far. The hypermarkets are mostly found in the metropolitan city that are economically developed and have a relatively large population while supermarkets have spread across the regions of Turkey, mostly in intermediate cities. Our empirical results indicate that there are important differences among different retail formats regarding location determinants. Keywords: Retail, consumption, urban economic geography, supermarket, hypermarket, spatial distribution, location determinants, Turkey

Business and tourism – Engine for development for good and bad

Lotta Braunerhielm (Karlstad University), Thomas Blom (Karlstad University)

To an ever increasing extend regions, often peripheral geographical regions, puts a great faith in commerce and shopping which is regarded as a substitute

to traditional industries. Shopping is of course an essential factor for our economy and occupation, but is it enough for a stabile and long-term sustainable ground for our future challenges and international competition? The industry of business production is in some regions regarded as an important factor for building sustainable societies. At the same time it is the importance to encouraging the individual creativity. Creativity and cultural industries is looks upon as important conditions for creating local and regional development. Cultural attractive regions attract both business and individuals and culture is an important resource for marketing of places and for the experience economy. Today we can also see a wider selection of culture-related businesses. There is though a balance needed to look after the interest of a place in contrast to 'selling' a place. This problem is often discusses rather uncritical. Instead shopping and tourism as a solution on many of the structural problems of development are emphasized. These businesses are positively creators of occupations for youths but at the same time there lies a danger in regions where strategic investments again are made in an one-sided branch of business. A structure of one-sided business, apart from the position, is problematic for a regions possibility to develop successfully and on a long-term basis. This is a matter of importance irrespective from if it is a dominant paper industry, a large shopping mall or a dominant tourism industry in a region. In the same way as cites has been transformed from cities of traditional industries to cities of culture there is a development in peripheral regions on shopping and tourism. Today societies are built on shopping, business and tourism in an increased speed and places with an earlier one-sides industry are seldom investing in an non one-sides industry, an industrial community - the mill spirit. National and international stores are expected to work as an 'engine' and generate development and growth. Statistics are at the same time showing that the interests of higher education among youth in these regions are often very low. The explanation is often that the demand for higher education is non-existing or very low for the benefit of an occupation in the shopping industry. The aim of this paper is to illustrate the problems within regions which has transformed from one-sided industry to another. The level of high education, the interest of higher education among youth, high unemployment and the problem of migration within these regions are factors which are going to be the starting point in the discussions in the paper by Lotta Braunerhielm and Thomas Blom.

The Khayelitsha Business District and Mall Development: An Urban Renewal Success story in Cape Town?

Ronnie Donaldson (University of Stellenbosch), Danie Du Plessis (Stellenbosch University)

In his state of the nation address in 2001, former President Mbeki announced the launch of the Urban Renewal Programme (URP) as an area-based approach as a ten year initiative to address poverty and underdevelopment in targeted areas, with specific emphasis on improving joint government planning and implementation. Townships were spatially engineered by the architects of apartheid and excluded by design; and are today, typified by high levels of poverty and crime. It is in the undoing of these two social malaises that the URP has anchored itself on the policy agenda. The excluded by design areas have also become excluded by decline areas. The URP focused on eight urban townships in the country as pilots that would pave the way for an urban development strategy on urban renewal to be developed and implemented nationally once the ten year pilot period elapsed. The paper is a review of best lessons learnt and practices of the development of the Khayelitsha business district.

The hyperplaces and the trade districts in the Brindisi experience

Stella Pietrarossa (Bari University)

The city of Brindisi is on a natural harbor, its territory lies between the sea and the plain of 328 km and is characterized by a high agricultural vocation. Considering the morphological system, it is possible to distinguish two macro-contexts: the first consists of the old town and the modern city, the second is represented by the suburban system, where the residents suffer the consequences of the distance from the central areas also in relation to civic functions (Municipality of Brindisi, 2009). The old town of Brindisi is the epicenter of relations and exchanges, and has developed hand in hand with the business, representing the current city center. The area has a commercial vocation,

therefore, a central location and includes 200 economic activities, two-thirds of which operate in non-food sector. The problems related to the lack of parking and the general decrease in consumption lead to a loss of polarity for the exclusive benefit of the province. The "enhancement networkpath of some municipalities in the province of Brindisi" is to be worthy of attention. In fact, in 2007 and 2008 marketing strategies were launched, aimed at generating liveliness and attractiveness while shopping in town centers (AA. VV., 2009, pp. 26-36). Examining the data provided by Dr. Rotondo, the official of the "Trade in permanent employment", it emerged that in recent years the City has been restrictive in the modern type distribution, so much so that the on the territory we have a few large plants. However, it is expected the construction of a commercial integrated area that responds to the need to modernize a system in state of crisis and out of step with the times, which proved unwilling to experiment with new patterns of consumption. At the same time, considering the decline and loss of polarity of the historic center, Brindisi has followed the example of many Italian cities and in April 2010 initiated a program of actions for the creation of an urban trade district, aimed at improving the attractiveness of "a commercial container which consists of an agglomeration of spontaneous offer" (Municipality of Brindisi, 2010). Its implementation refers to a long-term goal, in order to create an environment that facilitates high-quality social relationships and activities of common life, allowing people to meet the needs related to purchases and relational aspects (Municipality of Brindisi, 2010).

Shopping Center: Between place and placeless

Flavio Bartoly (Federal Fluminense University)

In the decade of 1940 in United States and in the years 60 in Brazil, probably, the affirmative that the shopping centers were less representatives for the everyday life and that the relation the public had with this spaces were very distant would not be contested. There were not much to do in a shopping center, because the administrations didn't get the potential of being more than a center where people would just buy things and with this, attract more people. Going to the mall was then unusual, quick and only for shopping. This first insertion of the shopping in the city, characterized as a space just for shopping, homogeneous, objective and little communicative, made this urban equipment a possible example of what some authors would call 'placeless'; a standardized landscape, projected without take in consideration contexts or particular factors which could promote an identification with the people who are there. A space without peculiarities, a landscape without form, without soul, materialist (valuing

spiritual and intellectual things too little) which reduces the communication to the minimum necessarily required by objectivity. This point of view argues that shopping, by its own lack of authenticity, can't be reputed as a place. For many years, a lot of factors contributed for the considerable modification of the shopping's insertion inside the urban areas, even if the homogenized form and the main goal of the commerce are prevail. The shopping became also a space of sociability, where people meet everyday, have fun and go for a walk. Despite we can qualify the shopping's sociability as 'instrumental' (because it is a strategy of the administration in order to amplify the time to people stay and buy), the sociability is an objective itself to the users. So we took the challenge of establish a discussion about the valuation of calling the shoppings of today as placeless, especially because in nowadays, there are much more deep relationships between the shopping, the users and the city itself. Through its spatial organization, the search for a 'placed' dimension of the shopping can bring to geography, important contributions towards the comprehension of the aspects of the contemporary urban reality. With this objective, we made a bibliographic search, which provided us with the instruments to establish discussions about the conceptions of place, placeless and sociability, and also, a possibility of a better comprehension of the insertion of the shopping at urban space in nowadays. We collected also a number of data in BarraShopping and Iguatemi, well as made interviews with the administrations and users of these shoppings of Rio de Janeiro city, in Brazil.

Supermarkets Effects in India with emphasis to Kolkata

Sanjukta Ghosh (Calcutta University)

India is one of the world's fastest growing economies with a present population of 1.21billion. Due to recent economic escalation and high potential of purchasing cum spending capacity of the consumers particularly young generation are making money at a faster pace with wide employment avenues availability are moving towards the concept of supermarketisation which started in kolkata during mid 2000s registering a rapid leap of development within a span of ten years. These malls are basically acting as a means of parasites who are engulfing the small traders. The implications is particularly accelerating the wayout by which supermarkets are acting as dominant food suppliers all over India and kolkata is no exception in this regard. It has been found that the regular hectic urban lifestyle of kolkata has contributed in making daily grocery shopping from malls with a mission to get all ingredients under one roof at no extra transport costs. Percentage of shoppers are basically youngsters to high income

people who aspire for living better urges them for spending maximum. Primary drivers are the young groups who are born and brought up with television, internet and are exposed to the evergrowing transformation and cultural adoption of the urban cosmopolitan culture. Positive macro trends like mass awareness, more affluence, plastic money, promotional offers, status symbols and finally high percapita income of people involved in secondary and quinary activities are acting as prime factors for the continuous developments of supermarkets and malls in kolkata. Further analysis reveals that para-shops or corner shops of kolkata are facing difficulties due to lack of capitals which are obstructing them from providing consumer services to the customers. On the other hand concept of packaged foods are gaining importance due to their ready availability all time. Foreign food purchase is also a common phenomenon observed in malls of kolkata. Peculiarities are also observed in consumers where a large portion of able buyers consider malls as a means of "family - hangout place". The main theme of this paper is the study of the changing socio-cultural aspect of kolkata with their onsets. In nutshell supermarkets and malls are posing a great threat to the traditional retailers and unorganised sectors. Key words: Supermarketisation, Food products, Young groups, Urbanisation, Cosmopolitisation, Better Living, Transformations.

Metropolitan urban growth in Latin America. Instruments for participatory planning: Experiences with simulations models

Cristian Gabriel (Urbanismo y Diseño- Universidad Nacional de Córdoba)

Latin American cities show a urban growth process that continues the metropolization processes started in '70 and '80 of the past century, however showing different characteristics in the past two decades: changes in population structure (fall of the population growth rate, decline in growth of metropolitan central cities and related to this the growth of small and medium towns in some cases explosive in the metropolitan areas), changes in land uses (monofunctional areas following connectivity criteria), fragmented spatial organization (enclaves with limits and controlled accesses) and associated with this a social segmentation where gated neighborhoods of homogeneous high incomes groups stand in contrast to slums, agricultural fields or industrial areas. Add to this there is a lack of consideration of the territorial support with a consequent strong impact on the natural systems, only with mitigation reduces to the intervention area and in many cases with a cosmetic character and a historical resistance to investing on infrastructure. All of this in a context where planning has a weak tradition. All these factors lead to present the current urban conditions as critical and unsustainable in the short term. Moreover urban management currently has some tools such as simulations models through computer-assisted system (GIS) to visualize and to plan urban futures, incorporating citizen participation. This work records experiences in using of simulations models as planning instruments in the Latin America context, in cities with metropolitan growth and in particular discusses the experience in the construction of an urban growth simulation model for the small town of Rio Ceballos (17.000 inhab.) that integrates the metropolitan area of Córdoba (the second largest city in Argentina with 1.5 million inhab.) Finally, this paper seeks to provide some answers to the question: If it has instruments that allow understand and explain the urban growth processes and its consequences as well as different possibilities for the future, is it possible to integrate political, social, and economic actors and the general public in a virtuous planning participatory process towards sustainability horizon.

Simulating the Future Spatial Pattern of Natural Environmental Impacts of Urban Growth by Cellular Automata and Multivariate Statistics

Hsing-Fu Kuo (Department of Urban Planning), Ko-Wan Tsou (Department of Urban Planning, NCKU)

Changing land use and urban expansion are key drivers of global environmental change, and inevitably consequences of economic and social development for most cities. The change of land use in the city is unavoidable during the process for urban development. Most land utilization changes will produce negative impacts to the natural environment, especially to surface temperature, run-off and urban habitat which are easily affected by local factors. Although many case studies have already discussed about the impact to the natural environment for urban land use in the past, most have focused on single environmental index rather than the comprehensive impacts. Meanwhile, possibly owing to the lack of more detailed and identical information of land use change, most studies failed to explain spatial analysis more deeply and to master the spatial characteristics of the natural environmental impacts. This paper aims to provide a systematic assessment method to simulate and analyse the future spatial pattern of natural environmental impacts of urban growth by cellular automata, factor analyst and component analyst. We took Tainan as study area and compared impacts on future urban spatial development under two periods: (1) 1994-2005, and (2) 2005-2030. Tainan is located in the southwestern coastal plains of Taiwan, governing an area of 175.645 km². It is the oldest and now the fourth largest city in Taiwan, In terms of the impact, we describe three important environmental performance indicators to evaluate the impacts more thoroughly on heat island effects, run-off and habitat diversity, which have been used from recent studies, and then evaluated and compared the characteristics of natural environmental impacts and spatial pattern of urban land use change. The dataset of land use data for years 1994 and 2005 was collected by land use survey and year 2030 was simulated by SLEUTH-CA model. The result shows that the characteristics of natural environmental impacts can be divided into six clusters, and all three natural environmental impacts including surface temperature, run-off and urban habitat affect the city centre area seriously. With the distance farther from the city center, the surface temperature change increases and the amount of run-off decreases. Such results indicate that the urban expansion has occurred and that the habitat diversity has higher values in areas with the practice of policies or ordinances.

Sensitivity analysis to identify sensitive LULC parameter(s) when using CA Markov modeling to predict urban LULC

M. Surabuddin Mondal (Indian Institute of Technology, Roorkee), Nayan Sharma (Indian Institute of Technology, Roorkee), Martin Kappas (University of Goettingen), P. K. Garg (Indian Institute of Technology, Roorkee)

An attempt has been made to explore and evaluate the Cellular Automata (CA) Markov chain modeling to monitor and predict the future land use land cover pattern scenario in Kamrup (Guwahati) Metropolitan district, Assam state, India, using land use land cover map derived from multi-temporal satellite images. CA Markov is a combined Cellular Automata / Markov Chain / Multi-Criteria / Multi-Objective Land Allocation (MOLA) land use land cover prediction procedure that adds an element of spatial contiguity as well as knowledge of the likely spatial distribution of transitions to Markov chain analysis. In this study, evidence likelihood map were used for as knowledge of the likely spatial procedure in CA MARKOV model. This study also establishes the validity of the CA Markov process for projecting future land use and cover changes in the study area. The validation calculates various Kappa Indices of Agreement (KIA or Kstandard) which indicate how well the comparison map agrees and disagrees with the reference map. The validation shows Kstandard is 0.7928. Sensitivity analysis has been also carried out to identify the LULC parameter(s), which have the highest, lowest or intermediate influence on predicted results. The results shows that the land with or without scrub appeared to be most sensitive parameter as it has highest influences on predicted results of LULC of 2007. The second most sensitive parameter was lakes / reservoirs / ponds to predict LULC of 2007, followed by river, agricultural crop land, plantation, open land, marshy / swampy, sandy area, aquatic vegetation, built up land, dense forest, degraded forest, waterlogged area and agricultural fallow land. The least sensitive parameter is agricultural fallow land, which has minimum influence on predicted results of LULC of 2007.

Modeling regional urban dynamics with a modified version of the SLEUTH urban growth model

Roland Goetzke (University of Bonn), Andreas Rienow (University of Bonn)

SLEUTH is a well-known urban growth model based on cellular automata (CA), which simulates urban growth with four simple but effective growth rules: spontaneous growth, edge growth, new spreading center growth, and road influenced growth. A 'self-modification' functionality makes the model very

suitable for the simulation of long time spans including 'boom' and 'bust' phases of urban growth resulting in the typical S-curve expansion rate of cities. For the calibration routine at least four historic urban datasets are needed in order to calculate fit statistics between simulated and observed urbanization using different least square regression scores. Many studies that implement SLEUTH as a regional urban model are based upon remote sensing data and hence investigate a time span of maximum 40 years. Especially for larger study areas a time series of four control points (or five for an additional validation) is difficult to establish and homogeneous national or transnational land-cover datasets like CORINE or NLCD are not suitable as a data source because of their small number of individual time steps. To address this and other drawbacks of the model and to make it extendable in order to integrate new scientific findings, we re-implemented the CA-component of SLEUTH in the JAVA-based modeling platform XULU (eXtensible Unified Land Use Modeling Platform). By this procedure the original calibration routine has been replaced by the 'Multiple Resolution Comparison', a well-established method that measures the agreement between maps at different spatial resolutions. Thus, the amount of required control datasets is reduced to two. Other benefits of the re-implementation of the model are a simplified handling including the visualization of the step results, establishing the extendability of the model by object-oriented programming, and the realization of a coupling mechanism that offers the possibility to integrate human decision making to the simulation of urban growth from other static or dynamic models. Here we show exemplary different applications of the modified SLEUTH urban growth model from sample regions in Western Europe (Cologne/Germany, Dublin/Ireland, and Porto/Portugal). We use CORINE land-cover data and classified Landsat imagery as data sources, and enhance the urban growth model with external static models that deliver information on socioeconomic, biophysical, and political driving forces of the urbanization process.

Implications of climate change for livelihood conditions: A system dynamics perspective

Tabea K. Lissner (Potsdam Institute for Climate Impact Research), Dominik E. Reusser (Potsdam Institute for Climate Impact Research), Jürgen P. Kropp (Potsdam Institute for Climate Impact Research (PIK))

The causes and consequences of climate change have strong implications for development pathways: the need for a transition towards more sustainable resource use is becoming increasingly clear. On the one hand, societies have to increase their resilience to cope with increasing pressures and adapt to expected changes. On the other hand, further development should aim at mitigating climate change to prevent further pressure. Ideally, mitigation, adaptation and development should be pursued in complementary strategies with the goal of increasing and maintaining a high Quality of Life (QoL). Concepts that address the requirements for high life quality so far remain conceptual and are not applicable to model implications of management strategies for relevant domains of QoL. To address this lack of measurability, we introduce a modelling framework to quantify relevant livelihood dimensions, based on an extensive, interdisciplinary literature review. While the fulfilment of physiological needs is essential for human survival, further elements are relevant to attain adequate livelihood conditions. A quantification of these requirements can provide insights to several important issues in human-environmental systems: situations of instability or conflict may arise in those regions where the basic core needs are no longer fulfilled, whereas the potential for self-determined and stable development is possible where the fundamental needs are satisfied. Addressing the livelihood complex from a system view, strong inter-linkages between the single components become apparent. Processes deriving from global change can thus have strong direct effects, but also affect many elements indirectly. The system perspective also allows indicating where interventions (e.g. climate change adaptation) are most promising and where feedback processes or secondary impacts have to be expected. This can inform decision-makers on how to optimize decisions to improve livelihood conditions and human well-being.

The dynamics of binational urban expansion along the U.S.-Mexico border

Erick Sánchez Flores (Universidad Autónoma de Ciudad Juárez), Rolando Díaz-Caravantes (UACJ), Luis Carlos Bravo-Peña (UACJ), Marisol Rodríguez-Sosa (UACJ), Iván Ruiz-Hernandez (UACJ)

Land dynamics have been identified as a complex natural and anthropogenic multi-causal phenomenon affecting geosystems balance in several forms including, among others, urbanization, which have become a major driving force at global scale. Characterizing thus the patterns of urban expansion is critical for recognizing the magnitude of its effects and designing the policies to satisfy population growth needs according to the land resources capacities. The analysis of this dynamic is particularly complex in adjacent discontinuous areas such as border regions, where socioeconomic forces act in function of the restraints imposed by different political administrations. In this work we advance in the assessment of land change and urban growth around the main bi-national conurbations along the U.S.-Mexico border, based on remote sensing models derived from 1975 to 2010. Models show a recent period of urban sprawl, mostly in the Mexican border cities, resulting in an asymmetrical growth of the bi-national conurbations. It is plausible to link this expansion pattern to the greater southern population fluxes attracted to the border by the intense industrial activity during the 1990 decade, and the subsequent peri-urban land development seeking to offer cheap labour housing, mostly in the first half of the 2000 decade. These processes, along with insidious land speculation mechanisms, produced urban growth patterns that increased the social and environmental costs of living in border cities. The main distance to functional urban centres increased in most cities in the last 15 years, despite the emergence of the multicentre urban structures; the land use mix decreased mostly in the peri-urban fringe producing enormous dorm cities with limited access to services and urban facilities. In the same way the urban fragmentation increased, in some cases with up to 30% of the urban area left as empty space, which seems unlikely to be occupied in the short term due to the recent deceleration in population growth. This characterization of the urban expansion in bi-national conurbations of the U.S.-Mexico border allowed observing the results of different planning strategies and land control mechanisms that might help to guide a better design of effective land management policies for a more equilibrated development of the border region.

Social segregation in urban areas – an exploratory data analysis using different statistical regression models

Christian Levers (Humboldt Universität zu Berlin), Tobia Lakes (Humboldt Universität zu Berlin), Tobias Kuemmerle (Humboldt Universität zu Berlin)

Social segregation in urban areas shows distinct spatial patterns. Because this phenomenon is influenced by a variety of cultural, socio-economic and environmental factors, it is often difficult to define a set of risk factors correlated with segregation processes in urban areas. However, such a set of site-specific risk factors would be important for drafting development and planning strategies for disadvantaged areas. The aim of this study was to identify the spatial determinants of and their influence on social segregation patterns in the city of Berlin, Germany, using two statistical approaches. We use a dataset of eleven environmental, socio-economic and demographic variables to assess their relationship with a social status index, taken as an indicator for social segregation. All data was available for the entire administrative area (434 spatial units) of Berlin for the year 2009. First, we applied a selection algorithm (best subset selection) to find the 100 best linear models for each model dimension and used the BIC to select the best overall model, thus accounting for explanatory power and model complexity. Subsequently we assessed the contribution of each explanatory variable to the total explained variance via hierarchical partitioning. Second, we used a data mining technique (Boosted Regression Trees, BRT) for model selection and assessing their relative importance. Finally, we compared the results of both approaches. The linear model best predicting the patterns of social status in Berlin was able to explain 47.23% of the target's variance. We identified the following predictors with their relative contribution: Predicted Mean Vote (53.0%), population density per km² (28.6%), proportion of green and open spaces (9.3%), standard ground value (4.8%), number of 'creative' companies (2.7%) and distance to water bodies (1.6%). BRTs omitted just one variable and resulted in a better model fit (mean correlation = 0.77). The identified most influential variables were very similar to those selected by the traditional approach. Running BRTs with the predictors selected by the best subset GLM resulted in a slightly worse model fit and similar orders of importance. However, the shares of variable contributions of both BRT models differ from the linear one, which might be caused by the consideration of more variables or allowed variable interactions in the model. We show that the two different statistical approaches both highlight similar spatial determinants linked to social status in Berlin. Furthermore, BRTs enable us to show possible varying influences of the predictors along their data range. We

can conclude that environmental, social and economical factors have an influence on social segregation patterns in Berlin. These first quantitative and spatially explicit insights may allow future mapping of risk areas to allocate decision-making in an integrated environmental and socio-economic approach in urban development.

The use of urban structure types for hydro-meteorological hazard assessment

Rene Höfer (Helmholtz Centre for Environmental Research - UFZ), Annemarie Müller (Helmholtz Centre for Environmental Research (UFZ), Rüdiger Glaser (Universität Freiburg)

Currently ongoing processes of population growth and urban expansion lead to changes in land use and land cover. Besides the creation of new spaces for living and the provision of a range of opportunities, urbanization implies the disturbance of ecosystems and amplifies the generation of hazards. In addition to that urban land-use changes often take place at a high temporal speed meaning that exact data about the new physical urban body are a scarce resource. That complicates the evaluation of hazard generation in dense and heterogeneous urban areas. The potential of high and very high resolution satellite data for the monitoring and analysis of changing urban land-use patterns has frequently been shown in the past. With the application of urban structure types (UST) this research employs a more recent tool of geodata-based urban research. The objective of this research focuses on the explanatory power of UST for the analysis and assessment of hydro-meteorological hazards. The study tests if distinct USTs can be used to explain the generation of heat, flood, and water scarcity hazards in different Latin American urban settings. One municipality of Santiago de Chile was used as an in-depth study area. The analysis is based on high and very high resolution satellite (Landsat TM, Quickbird), census and GIS data. The first analysis step is the determination of hazard prone areas that are later used as a dependent variable. The second step comprises the identification and derivation of UST for the study area. The UST do thereby contain information on the proportion of vegetation, the amount and socio-economic level of the population, the elevation, the spatial location, and the distance to green spaces. Finally, the regression model is applied to proof the explanatory power of USTs in the context of hydro-meteorological hazard generation. The study shows the potential and also the limitations of UST for the estimation of hydro-meteorological hazards in a large and heterogeneous urban setting.

In principle, who benefits from SDI?

Christine Richter (University of Twente), Yola Georgiadou (University of Twente), Yola Georgiadou (University of Twente)

SDI research to date has focused on how SDI should or can be developed, how SDIs are evolving, what problems are encountered during implementation, and what the results are, often from the point of view of taken-for-granted western principles underlying the need to develop SDIs. The INSPIRE principles are a celebrated set of SDI principles in the EU. The official Indian NSDI discourse justifies the need to develop SDI by mobilizing INSPIRE-style principles. These (western) principles are being contested in India. NSDI meets opposition at the level of its underlying justifications from those who would become excluded and those who speak from the perspective of people potentially excluded. The 'losers', some of whom are able to actively oppose, are people excluded from data construction, access to land and money, and decision making if principles were fully translated into practice. We analyze qualitative, empirical data collected in Indian cities. The data captures slum mapping practices, the development of urban digital property databases, and GIS work in district mapping centers. We identify who would benefit and would lose from adherence to the western NSDI principles and how opposition to NSDI manifests itself. Who loses (opposition) and who benefits depends on situation, and does not neatly follow agency, administrative level, or socio-political categories. Therefore, we derive a typology of opponents based on who loses ability to construct data (including classifications, paper based lists, etc.), access to land and money, and/or influence on decision making. We show how NSDI shapes up in the face of such opposition. Finally, we propose a conceptualization (and explanation) of the current form and function of NSDI in India. We conclude on an optimistic note. The western principles underlying NSDI development benefit some, but not others. They are still up for debate in India, and NSDI provides a productive stage for such debate to take place.

The Politics and Knowledge Management of Megaprojects in Fast Growing Cities of the South

Loraine Kennedy (CNRS, CEIAS-EHESS)

Large-scale economic and infrastructure projects in developing countries, aimed at leveraging the potential of cities as growth engines, throw up particular challenges for urban sustainability by fuelling land speculation, exacerbating urban sprawl, reorienting employment patterns, displacing local populations and livelihoods, and increasing environmental health risks. These specialised spaces usually aim for maximum global connectivity without necessarily favouring linkages with the local economy, thereby creating risks for urban spatial fragmentation and social exclusion. As part of an international comparative study on urban resilience, two aspects of megaproject development are examined: knowledge management systems and governance patterns. We analyse the mobilisation, generation and sharing of knowledge involved with the conception of mega-projects including the models that inform urban agendas and the policy instruments used. We examine city politics to understand which local groups are driving the process, which levels of government are most directly involved, and to what extent are decisions the result of transparent and participatory decision-making processes. We are also interested in social movements contesting megaprojects, and specifically in their use of spatial knowledge. This paper presents preliminary results from case studies in Delhi and Chennai in India, with comparisons from South Africa, Brazil and Peru. This research is part of an on-going project, Chance2Sustain, financed by the European Commission (FP7).

Knowledge Construction and Exclusion in Realizing Spatial Justice

Sridharan Nomperumal (School of Planning and Architecture)

Strong juxtapositions are emerging in the context of urban development process in India (juxtaposition in terms of core and periphery, contrasting rich and the poor dominated areas in terms of service access, etc). Soja's (2010) concept of 'spatial injustice' is used along with the concepts of 'Second Capability' and 'Regulatory fractures' by Sassen (2006) to explain the phenomenon of spatial inequalities in an emerging metropolis in India (Hubli-Dharwad city in Karnataka State). The idea of 'formateurs' used by Congleton (2011) to explain the convergence of rent-seeking interest in attracting investment and spatially targeting it, is used in this paper to explain why certain areas were designed with a better infrastructure and attracted more investment than others, thereby creating 'spatial injustice'. Using the primary survey of elected representatives,

stakeholder and municipal officials interviews, this study analyses the spatial, infrastructure and budgetary inequalities in space due to lack of convergence between knowledge generated from the field and matching that knowledge through budgetary actions. In the end, the concept of 'spatial consciousness' propagated by Soja, is used to explain the importance of 74th Constitutional Amendment Act in achieving 'participatory forms of democratic politics' and social activism at the local level through 'local knowledge construction and its use in budget allocation'.

Poverty mapping in Indian cities: Improving the index of multiple deprivations

Karin Pfeffer (University of Amsterdam), Javier Martinez (University of Twente), Isa Baud (University of Amsterdam), Tara van Dijk (University of Amsterdam)

Recent discussions of urban poverty recognize its multi-dimensionality, focusing on the range of deprivations with which poor households cope (Moser, 1998; Rakodi and Lloyd-Jones, 2002). In earlier research we developed an index of multiple deprivations, theoretically based on the asset-vulnerability framework (Moser, 1998), to map multiple deprivations and their spatial variations across electoral ward levels in Indian cities (Baud et al., 2008). This city-wide approach is a spatial representation of unequal conditions in urban areas which complements smaller surveys and qualitative research frequently carried out in poverty studies. It can be used as a strategic instrument in identifying poverty hotspots, and the different combinations of deprivations loading onto the index can be made visible. However, it has several limitations. To begin with, it is confined to the information given by the Indian census and its validity is reduced over the long time period between Censuses. Second, it is an administrative area-based index, providing an average measure of the diversity of deprivations actually present, while electoral wards in India hold unequal numbers of households and are not necessarily homogenous in terms of socio-economic characteristics. Third, it ignores the relational perspective, which indicates how households differ in their access to basic services as well as social networks, even when provision of services exists. The aim of the paper is to address some of the shortcomings of the original index of multiple deprivations and to develop a more integrated spatial representation of households' multiple deprivations in urban areas. The framework for improving the index is based on different sources of spatial data in four Indian medium-sized cities in two southern states. We make use of a mixed-methods approach that includes census data from the census 2001, geographic data where available, household surveys in selected

wards covering areas with varying degree of deprivations, e-grievance (complaints) data and qualitative interviews. Therefore, the approach combines geographical information analysis, statistical analysis and qualitative analysis to come up with a fine-tuned index for measuring multiple deprivations. We conclude the paper with recommendations on measuring and mapping multiple deprivations in urban areas and possible applications to other urban areas. Values and Ethics In VGI/CO platforms: An analytical framework set on participation imperatives and governance criteri

Javier Martinez (University of Twente), Michael McCall (ITC), Gianluca Miscione (University of Twente)

This paper develops a framework for assessing how VGI/CO systems and platforms perform with respect to measures and principles of participation and other good governance criteria. The framework is applied to representative VGI/CO examples from literature and the Web, and specific cases where the authors have participated. The aim of the framework and analysis is constructivist: towards appropriate matching of VGI/CO modalities with different purposes, actor categories, governance contexts, and application fields. Firstly, the range of VGI/CO platform systems and methodologies are categorized by characteristics, histories, intentions, and practices: 1. Platform modalities and methods (sometimes participatory) for generating and managing local spatial knowledge (LSK), e.g. : VGI, HSW, crowd sourcing, PGIS, participatory mapping; 2. Broader conceptualizations of alternative knowledge formation -: UGC, Citizen Science, CO (citizen observatories), citizen journalism; and 3. Specifically GIS and GI technologies: GIS/2, web GIS, geotagging, etc. Key distinctions are between Volunteered (known & activated) information, and Opportunistic (known-but-passive, or unknown & unpermitted) involvement; and between unidirectional gathering of citizens' information, and interactive flows, as feedback or dialogue flows. Second stage is analysis of platform systems in terms of participation practice. Who are the actors? Who designs the VGI/CO frameworks? Who tests, processes, and are final users? Who supplies and owns information? What intensities of participation? The framework is used to analyse the structure, behaviour and consequences of VGI/CO systems with respect to ethical criteria and good governance principles. Do systems enhance or detract from legitimacy and accountability potential empowerment, respect for rights, validation of local knowledge equity? The framework is further developed through application to CO, VGI, and citizen science platforms, including experiences with: (i) human sensor web for monitoring urban water

delivery, Zanzibar (ii) PGIS for REDD MRV in community carbon forestry initiatives (iii) e-grievance system in India. Without current consensus on an overarching term for the set of approaches, systems, methods , we use the combined term VGI/CO (volunteered geographical information / citizen observatories).

Spatiality of urban informality: The process of (negotiated) urban transformation in Dhaka

Shahadat Hossain (TU Dortmund), Kirsten Hackenbroch (TU Dortmund)

In two recently completed research works we have investigated the negotiations of access to public space and water supply in Dhaka, Bangladesh. The research which predominantly took place in areas where access to public space and municipal services is commonly negotiated in an entanglement of statutory and informally operating actors has pointed at patterns of inclusion and exclusion and the resulting spatialities of justice on a local and city scale. Access to space and services is contested and continuously negotiated and rearranged in an environment based on patronage-like relations and hierarchies often based on charismatic local 'social' and 'political' leaders. These leaders, the local elite groups, tend to dominate decisions and negotiations. The experiences gathered in these two research works will be extended in this paper (based on continuing research work) to understand the patterns of inclusion and exclusion emerging with urban expansion and changes in the urban morphology in Dhaka. In a sphere characterised by informality as a mode of the production of space (Roy, AlSayyad 2004) the paper seeks to investigate how such spatialities of (in)justice (Soja 2010) are produced and by whom. This includes taking note of the contestations of interests in decision making on spatial expansion and distribution of public resources (e.g. land, housing, infrastructure, utilities). This paper then seeks to contribute to an understanding of how the negotiation processes leading to urban transformation can explain the persisting urban complexities and spatialities of (in)justice in Dhaka. The paper further seeks to suggest based on empirical materials which information may be used to advocate for a growing recognition and servicing of areas considered a 'socio-spatial periphery' in the eyes of urban planners and policy makers. The empirical evidence is based on qualitative and spatial data gathered from an expanding peripheral settlement of Dhaka. Different stages of development and inclusion/exclusion into the city by planning and services but also perception of inhabitants of the way they are integrated and able to access urban amenities are investigated. The relatively large and diverse settlement is investigated

following a transect axis. References Roy, Ananya; AlSayyad, Nezar (eds.) (2004): *Urban Informality - Transnational perspectives from the Middle East, Latin America, and South Asia*. Community Production of Spatial Knowledge: A comparison of the South Durban Community Environmental Alliance (SDCEA) GIS project in Durban, South Africa and the Transparent Chennai project in Chennai, India

Dianne Scott (School of Built Env. & Development Studies), Isa Baud (University of Amsterdam), Eric Denis (French Institute of Pondicherry), Karin Pfeffer (University of Amsterdam), Tuuli Ranta, Cathy Sutherland

Urban communities in fast growing cities in the developing world are increasingly creating spatial community knowledges to both challenge and contribute to planning processes of large-scale urban development projects, countering neoliberal forms of development dominating the urban landscape. These can be conceptualised as forms of 'counter-knowledge', providing alternative visions of urban futures aiming at more resilient and sustainable futures. These types of knowledge are inserted into development processes through deliberative forums ('invited spaces'), activist spaces ('claimed spaces') or 'negotiated spaces'. This paper compares two forms of community knowledge production; their contexts; the processes of knowledge production; the types of knowledge produced; the strategies used to impart this knowledge (deliberative forums/activism); the politics of community knowledge production and the outcomes of these highly politicised processes of knowledge production, transmission and exchange in the urban development process. The first form relates to a case in South Durban, South Africa, where knowledge production was initiated by the South Durban Community Environmental Alliance (SDCEA). It is a civil society organisation which engages in both state-led deliberative forums, and activist protest challenging the state. In South Durban communities live adjacent to Africa's largest port surrounded by heavy industry and refineries. Since the state and industry refuse to accept lay knowledge as valid evidence of environmental impacts, SDCEA has a strategy to produce 'civic science' - community knowledge produced scientifically - by creating their own GIS maps. These display point sources of emissions in South Durban; complaints about pollution; and qualitative narratives of residents through the GIS memo function. In this way SDCEA uses GIS to challenge urban planning processes, documenting

environmental and social injustices of increasing industrialisation and development of South Durban. The second form of community knowledge production, referred to as Transparent Chennai (TC), is an initiative of a number of young professionals, mapping social issues in Chennai, India, through a website together with a network of people providing information on situations in Chennai which can be improved. The initiative includes a GIS-based web-interface, geographic information produced by residents, and negotiations by TC professionals with local officials in order to improve existing problem areas in Chennai. It represents a middle-class community initiative within a claimed space which is being transformed into a negotiating space. Both forms of knowledge production are bottom-up initiatives with a broad network of different actors democratizing the way information is produced, used and shared.

Spatial and temporal patterns of robbery and armed robbery in Minas Gerais, Brazil

Alexandre Diniz (PUC-Minas), Gustavo Costa (PUC-Minas), Vanessa Brandão

In recent decades crime has represented a major cause of concern especially among the populations of large urban centers and underdeveloped countries. Several social, cultural, demographic, economic, and health related transformations are leveraged by the evolution of crime, calling the attention of numerous scientists. Given its undeniable importance as agent of spatial transformation, crime becomes a phenomenon inevitably attached to geography. This article seeks to understand the spatial and temporal dynamics of two criminal procedures among the municipalities of Minas Gerais State, Brazil, between 2001 and 2009 (robbery and armed robbery), identifying the mesoregions more prone to its manifestation. To this end, we use crime registration data gathered by the Military Police of Minas Gerais, Brazil. Using population data from the Brazilian 2010 census crude rates per 100,000 inhabitants were advanced for both crime offences. Seeking to smooth and adjust rates, accounting for discrepancies in population size among the 853 municipalities scrutinized, crude risk rates were submitted to a three-year moving average approach. Growth rates were produced in order to grasp the temporal evolution of the phenomenon. Standardized and growth rates were eventually mapped, and choropleth cartograms produced using municípios and meso-regions as spatial entities. Spatially, results indicate the existence of two primary focal regions for robbery and armed robbery in Minas Gerais State, namely Belo Horizonte metropolitan region and the mesoregion Triângulo Mineiro. Temporally, research data revealed that armed robbery experienced an

increase until 2004, after which the phenomenon began to decline steadily. The same behaviour was observed across robbery rates, which experienced an increase up to 2006, and a consistent decrease decrease since then. Despite the fact that the majority of municipalities were less plagued by robberies in 2009 than in 2001, one cannot deny the fact that rates are still relatively high in many cities, especially among the largest urban centers of Minas Gerais. Thus, is necessary to develop specific public policies aimed at preventing criminal activities among small and larger urban centers of the state. This research has been funded by FAPEMIG.

Strategic, integrated planning for sustainable metropolitan development: The case of Santiago de Chile

Jürgen Kopfmüller (Karlsruhe Institut für Technologie), Jonathan Barton (Pontificia Universidad de Chile)

As urbanization marks a key trend in global development, cities in general and megacities in particular play a crucial role in global change processes and thus for realizing (global) sustainability. Given the complexity and dynamics of megacities as socio-ecological and socio-technical systems as well as the complexity of the guiding vision of sustainable development, this calls for accordingly integrative research approaches, analytical tools, and governance concepts. In particular, this is the case in Latin America with its long lasting urbanization experience and several mature primate or mega-cities. In this presentation, key results of the German-Chilean 'Risk Habitat Megacity' research initiative (2007-2011) will be shown, which dealt with the Metropolitan Region of Santiago de Chile. In distinction from most previous research on megacities focusing on their global economic role or on particular sectoral issues, here an integrative research approach was applied considering both sustainability-related risks and opportunities. This approach will be outlined, consisting of analyses on several typical fields such as energy, water, transportation or land use, and an analytical framework built by the sustainability, risk and governance concepts. Selected results will be presented, related to the current and future sustainability performance based on scenarios for 2030. Against the background of key deficits and risks such as air pollution, water stress, transport gridlocks and socio-spatial polarization, institutional conditions and deficits as well as proposals for improved general and field specific governance approaches will be outlined. The presentation includes highlights of the initiative regarding the conceptual architecture, methodological considerations (for instance regarding the scenario tool), results of analyses, and governance-related recommendations. The basic objective is to show options for strategic urban planning in order to suitably implement an urban transition towards a more sustainable, equitable city. Among other tendencies, this type of transition would include a revision and reorganisation of strategies and policy

development across different levels and sectors of administration as well as a redistribution of national and local political and administrative responsibilities.

Sustainable Futures – functional use of scenario technique to identify regional system potentials

Timo von Wirth (ETH Zurich), Ulrike Wissen Hayek (ETH Zurich), Antje Kuntze (ETH Zurich), Noemi Neuenschwander (ETH Zurich), Roland W. Scholz (ETH Zurich)

Urban regions as dense nodes of material and energy consumption are not by themselves sustainable. There is widespread consensus that progress towards sustainable urban development is essential for the reduction of future resource demand. However, there is considerable debate on how planner and decision-maker can successfully contribute to more sustainable city regions. The complexity of urban and regional systems, their ongoing pace of urbanization and the inherent uncertainties of spatial and societal development exceed the abilities of traditional planning methods. In order to facilitate urban transitions, knowledge about possible and plausible future pathways is fundamental. Though it is evident that future orientation is in the core substance of planning professions, formal methodologies have only recently gained deeper attention - particularly in the academic community. Scenario analysis has evolved as a tool for systematically examining an uncertain future and enabling learning processes for strategic decision-making. Though, it remains a challenge of scenario construction for urban regions to deal with coupled human and environmental impact factors that are causally related in a dynamic system. The paper at hand presents the application of Formative Scenario Analysis (FSA) in a regional urban development context. Our findings are based on first results from an applied research project carried out in the case region Limmattal, an agglomeration close to Zurich, Switzerland. The agglomeration Limmattal is characterized by a patchwork of land uses and can be called a typical suburban region in Western Europe. The research group comprises of scientists, planners and stakeholders from the public and private sector. We make use of intense science-practice collaboration. Our transdisciplinary process led to four relevant scenarios. In essence, we identify new formal ways of a functional science-practice collaboration within the scenario building process. We further show a methodological approach on how to analyse critical system feedback loops among the relevant impact factors. This reveals regional system dynamics already during the process of scenario building and gives better understanding for a systemic identification of major development drivers. In addition, we

introduce a format for the presentation and interpretation of scenario narratives with practice agents. This format integrates spatial functions, potentials and the dimensions 'Structure', 'Gestalt' and 'Form'. FSA proves to be a suitable approach for identifying systemic sources of regional urban development while integrating all relevant dimensions for sustainability analysis from the outset on. Our findings indicate further research potentials for integrative multi-scale scenarios and for the incorporation of disruptive events towards more robust urban strategies.

Future Urban Development Patterns in Myanmar

Than Than Thwe (Human Settlement and Housing Development)

Future Urban Development Pattern in Myanmar: Geographic Setting, Economic Functions, Main Issues and Key Challenges Than Than Thwe, Myanmar This paper is organized into three parts. The first part describes 14 administrative units, 7 geographic zones and topography, demographic perspective, 24 development zones, the linkages of the largest urban centers and communication network. Then, the classification of urban centers and urbanization caused by number of different factors are clarified. By reason of the favorable geographic situation, urban extension areas, the advantages of transportation network and different modes of communication which generate more economic activities in the middle and coastal regions in addition the less development conditions of the eastern, western and northern hilly regions are explained. The vulnerable urban areas: especially the cyclone hit regions, earthquake areas and land slide areas within the urban and related regions have some constraints for the urban spatial development and limitation of road network are highlighted. The second part explains the main regional socio-economic activities which include trade with neighboring countries, establishment of industrial zones and services within the urban network which enforce for the urban area development and forms the development patterns. By integrating favorable conditions of geographic and economic activities can be seen by future urbanization patterns, trends, the large urban centers and their linkages. The third part identifies the main issues and key challenges on urban sustainable development regarding of social, economic and environment sectors. In this range, the urban developments are focused on opportunities and risks of the current activities and coming economic actions. Therefore, the required actions of balanced urban development patterns are discussed at the end. Key words: geographic setting, economic activities, urban development patterns, future trends, key challenges, balanced urban development pattern

Metropolitan sustainable development and public transportation challenges – comparing megacities In Latin America and Asia

Johannes Rehner (Pontificia Universidad Catolica de Chile), Pablo Lopez (Pontificia Universidad Catolica de Chile), Karen Martinez (Universidad Catolica de Chile)

Sustainable Development is a strategic challenge that calls for information which is comprehensive, simple, transparent and updated as well. Likewise there is a need for comparable indicators and profound understanding of specific and complex situations as well. As complex system, metropolitan areas are always individual cases and are hardly comparable to other cities. In spite of these apparent contradictions, in order to develop academic proposals for decision making there is a need for comparison at least in order to learn from others experiences. With this purpose a set of metropolitan sustainability indicators for Latin America has been applied to Latin American Metropolis by UN ECLAC (Jordan et al. 2010), an approach which we consider useful for monitoring sustainability in Metropolitan Regions. Starting from the mentioned indicator set we present selected sustainability indicators in order to contextualize the specific cases of two megacities from Latin America (Santiago de Chile and Mexico City) and two asian metropolis (Mumbai and Shanghai). The mentioned cases focus the topic of land use planning (mainly large scale urban projects) and its link to urban (mainly public) transportation. We consider this field as particularly appropriate to discuss sustainable urban planning due to its linkages and feedback to urban growth, socio-spatial patterns, environmental policies and the direct involvement of public policy makers. It is highly relevant as decisions on large scale suburban projects as well as those on urban transportation have direct, important and long-term impacts on the metropolis. The discussed cases fulfill different purposes in order to discuss the challenges of strategic urban planning in a context of extremely fast growing pressure on transportation system (especially Shanghai); the design of suburban mega-projects and related transportation challenges (Mumbai and Shanghai); the multiple social relevance of access to transportation, slum location and social vulnerability (Mumbai); the linkages and co-benefits between urban transportation policies and climate change mitigation (Mexico City) and also conflicts related to the implementation of highly integrated public transportation system (Santiago de Chile). By the discussion of these cases we show from a academic perspective the relevance of combining different methodological approaches to the issue of strategic urban planning as well as - concerning public policy - the need for combining the

logics of projects, which is often prevailing in decision making, and a comprehensive and holistic long-term vision for sustainable development.

Spatial equity in metropolitan areas: A measurement proposal based on access to public services. The case of the metropolitan area of Valencia (Spain)

Maria-Dolores Pitarch (University of Valencia)

Spatial equity in complex spaces such as metropolitan areas is a very interesting subject for research, particularly in view of its enormous potential public policy applicability. Accessibility is a frequent basis for models and explanations that attempt to throw some light on the implications of the geographic distribution of public services. Along these lines, an approach to the subject based on the population's access to essential public services (education, healthcare and social services) is proposed. Geographic Information System (GIS) tools have made a powerful contribution to the ease with which both spatial and statistical data can be handled. The study covers the Metropolitan Area of Valencia, in Spain. It is based on the location of public facilities and the population's ability to move around by public transport (city buses and underground/tram network). The objective is to give an overview of the situation in this area and point to problem zones in the context of the metropolitan area with the aim of suggesting solutions to their problems that may help to improve their social and spatial sustainability and equity. This requires a complex modelling of urban mobility on the networks that carry it, an exercise for which TRANSCAD 6.0 transportation GIS software was employed. In order to achieve the nearest possible fit to reality, three types of networks were studied: the pedestrian network, the Valencia city bus network (EMT) and the Metrovalencia underground/tram network in the different municipalities it passes through. In all cases, the transport service frequencies and their operating speeds were considered for all the different lines. The journey time matrices obtained in this way were used to construct an accessibility index, the Spatial Separation Index. The main conclusion, from a strictly territorial point of view, is that the VMA is a space that presents considerable inequalities, some municipalities lack basic public transport and in some in the west and south of the area, access to all types of service is very poor. These zones include particularly troublesome neighbourhoods from a social point of view, some physically isolated, with many low-income families and little provision of public transport. The proposed model

makes it possible to detect black spots in which the inhabitants' quality of life is clearly affected. Additionally, access to the different types of public service is also very unequal. Given this context there is an evident risk of urban fragmentation and segmentation, which is reflected in social matters (and viceversa). The relationship between mobility and social exclusion in an advanced society is not caused by a lack of social opportunities but by the lack of access to them.

Contrasting demographic and land-use dynamics: The dichotomy of urban and suburban development in the Metropolitan Area of Santiago

Ellen Banzhaf (UFZ – Helmholtz Centre for Environmental Research), Annegret Kindler (UFZ-Helmholtz Centre for Environmental Research)

The rapid population growth and urban expansion in Santiago puts enormous pressure on the environment: agricultural land is now gradually being transformed into built-up areas, while the share of green space dwindles. Suburban construction, e.g., in the Andean piedmont, and the clearing of avalanche forests in mountain regions produces long-term environmental impacts such as heightened imperviousness of land surfaces and their respective consequences. Demographic and land-use change are major drivers of urban growth and produce multi-faceted patterns. In this study the simultaneous spatial processes of increase in the suburbs and decline of population in the urban area, and the expansion of built-up land use into suburbia are investigated for the 34 municipalities of the Metropolitan Area of Santiago de Chile (MAS). The contrasting development is studied for the 22 central urban and the 12 suburban municipalities of the MAS. Identifying the principal features of land-use change is an important task and findings should in particular provide information on time, space and quantity. Land-use changes were calculated based on remotely sensed data for the time 1993 to 2009, and indicate urban growth through the transformation from agricultural use and other open spaces. It shows the amount of land changed into built-up areas and demonstrates the direction and pace of urban growth. The changes in the demographic dynamics of MAS will be analysed as the major drivers of environmental quality and therefore of quality of life. The environmental quality can be described by the complex multi-dimensional set of abiotic, biotic and human characteristics that are localised in place and time. Human beings highly influence the urban environment through constructions of various kinds modified and perceived as components of their daily surroundings which have impact on

their social and economic circumstances and their health and well-being. Demographic change leads to land-use change and urban growth. In order to investigate population change as a driving force for urban growth, use was made of urban and regional statistics taken from census data. Investigations of population dynamics made on two spatial levels comprise the MAS in total and the subdivision of the urban and suburban municipalities. A detailed analysis of population dynamics was made for the time period 1992-2009 to establish the spatial distribution of the population in the different municipalities and the changes over time, and to identify municipalities with a growing, declining or stagnating population in the MAS with respect to the spatial indicators of environmental quality. Selected source and performance indicators are analysed to assess the impact of human settlements on the ambient local and regional environmental conditions in relation to environmental health and well-being. They form the baseline for a status quo analysis and are the prerequisites for explorative scenarios.

Support of Strategic Urban Planning by Participatory Application of Spatial Information Technology

*Silke Boos (Institute for Spatial Information and Surveying Technology (i3mainz)),
Hartmut Müller (Institute for Spatial Information and Surveying Technology (i3mainz))*

Access to spatial information has become indispensable for numerous aspects of urban development, planning and management. The increasing importance of spatial information is reflected in recent strides in spatial information capture (especially satellite remote sensing and Global Navigation Satellite Systems), management (utilising Geographic Information Systems (GIS), database tools) and access (witness the growth in distributed web mapping services), as well as in the development of analytical techniques such as high resolution mapping of urban environments. For encompassing a more efficient management, access and use of spatial information many countries around the world have adopted spatial data infrastructures (SDI). The implementation of this concept for megacity management is also evolving and is reflected in a majority of the worlds existing mega cities using at least some elements of an SDI. Besides better urban planning capabilities the creation of megacity SDI and spatially enabled web services are providing new opportunities to more closely involve citizens in consultations and land administration functions. In the field of data capturing urban sensing techniques provide a promising mean to fill the current gaps in urban information needed to monitor growth and change across the megacity

and to forecast areas of risk. The new generation of urban sensors, including cellular phones, RFID tagged items, GIS related technologies, Web 2.0 and crowdsourcing have significant potential in providing the managers of megacities - and their citizens - with unparalleled access to a comprehensive range of current spatial and environmental information about the evolving workings of their megacities. Peoples' movements can be monitored; their use and modes of transport determined and people can voluntarily provide information about changes to their environment. This information is potentially much more up-to-date than equivalent information from official channels and can certainly provide change intelligence in a highly dynamic environment and in that way support more effective cross-jurisdictional and inter-agency decision-making in priority areas such as emergency management, disaster relief, natural resource management and water rights. This article presents the results of a study conducted by the FIG (International Federation of Surveyors) about the impact of collection, integration, management and sharing of reliable spatial information on megacity management. It highlights the current state of spatial information management in the world's megacities and recommends strategies for improving urban planning in large urban areas through the use of participatory data spatial data capturing techniques, spatial data infrastructures and a sustainable spatial information management.

Towards Sustainability and Resilience of Cities and Regions: Integrated Geodata as One Step along the Way

Julia Neuschmid (CEIT Alanova), Manfred Schrenk (CEIT Alanova)

By 2050 two-thirds of the world's population will live in urban areas (UN Habitat 2006) and the urbanisation process is depleting the world's resources and the chief culprit behind climate change. Spatial planning aims at making cities and regions more sustainable and resilient, so that they can handle changes, grand challenges and can balance ecosystem and human functions on long-term. The practice is challenging because cities and regions are dynamic structures and spatial planning processes are very diverse across Europe and the world. However, in a context where environmental threats, vulnerability of cities and regions, biodiversity loss, excessive land use, energy supply, and climate change become more and more global, there is a need for integration of various sources of data and information at different scales. This is why planning has great hopes in the past year's development of Spatial Data Infrastructures (SDI). SDI gives access to geographic data that is stored and maintained by different data providers in different sources on international, national, regional and local level,

harmonised according to common standards, and shared across administrative and thematic borders. The past decade has been influenced by a change of paradigm regarding accessibility of geodata. Traditionally geographic data and information management has been characterised by semantic and structural heterogeneity, multiple storage, and lack of coordination which results in incompatible datasets. Today there are numerous European, national, regional and local initiatives that support the development from "information islands" to "information systems". INSPIRE - the European Directive for a Spatial Data Infrastructure - provides a robust framework. The EU-project HLANDATA contributes to the harmonisation process focusing on land use and land cover data across Europe and addressing several application areas such as the management of waste, and land monitoring. The HLANDATA geoportal provides one central access to decentralised data using web service technology so that users can visualise data from different sources together in one map with one common legend. Geographers, planners, GIS analysts, public administration, decision makers, researchers, the public, all these stakeholders and more require access to adequate and comprehensive data to achieve interdisciplinary and holistic approaches, transparency and participation in decision-making, efficient integrated data management, comparison of data, and monitoring of changes for a sustainable development. SDI can be a supportive element for spatial planning processes as it provides more harmonised data input than ever and helps to better understand and steer urban and regional dynamics.

Sustainable transport planning in Metropolitan Regions: The experiences of Catch_MR

Janez Nared (Scientific Research Centre of the Slovenian Academy of Sciences and Arts)

Transport is a key factor in economic development, as economic growth requires ready access to resources and market. This applies in particular for Metropolitan Regions as engines of economic growth and as regions with very diverse functions. However, this need for mobility and economic growth has as side effect rising volumes of traffic and levels of congestions with significant impact on the environment. The ultimate goal is to have metropolitan regions where transport, and therefore economic growth has minimum impact on the environment (environment-friendly modes of transportation), thus achieving a sustainable transport system, and considering its environmental, technical and socio-economic dimensions. These aspects could not be assessed separately as they are strongly interdependent and consequently require an integrated approach. The above mentioned problems are comprehensively tackled within Catch-MR project, where cooperation between Metropolises and their surrounding functional regions is put to the fore in case of Berlin-Brandenburg, Budapest-Central Hungary, Gothenburg Region, Ljubljana Urban Region, Oslo-Akershus, Province of Rome, and Vienna-Lower Austria. In the paper the situation in the afore mentioned European Metropolitan Regions is described basing on the results of regular workshops attended by regional experts and organized to discuss urgent issues and to exchange experiences.

Transportation, Land Use Change and the Sustainability in the Metropolitan Area of Santiago de Chile: Scenarios and the Policy Challenges until 2030

Dirk Heinrichs (Institute of Transport Research), Andreas Justen (Institute of Transport Research)

Transport defines accessibility of locations for residential and commercial use and is a powerful driver of land use change in cities and urban regions. Since transport development involves large investment in physical infrastructure, the

decisions on transport development are quite difficult to reverse and their implications particularly of long term character. However, long-term knowledge about a city's future development is hard to generate given short-term priorities of planning units and the uncertainties associated to demography, economy and political constellations. Nonetheless, long-term considerations of the transport system as well as their implications on land use change are a crucial prerequisite for urban planning and policy. The Metropolitan Area of Santiago de Chile (AMS) has experienced a dual development in terms of transport in the recent decades with significant and mixed implications on both mobility and land use change. On the one hand, the development of a tolled highway network and its expansion into the urban periphery has promoted private car use and enabled the development of new monofunctional residential and commercial areas well beyond the boundary of the consolidated city. In parallel, the implementation of the integrated public transport system Transantiago together with improvements in the accessibility of depopulated inner city areas has increased the potential demand for public transport modes and, as some observers claim, positively contributed to a return of residents to the central areas or the city. Departing from these recent developments in Santiago's urban public and private transport system and using forecasting modeling techniques, this contribution describes plausible transportation scenarios and their interrelation with land use change until the year 2030. We firstly project some of the main transportation trends for key indicators like motorization rate, current and expected congestion levels, modal split and accessibility levels. Assumptions regarding economic and demographic growth for the AMS, as well as infrastructural projects and operational improvements are considered. Secondly, we assess the likely associated changes in land use, in particular the location of households in the Metropolitan Region. Thirdly, we discuss the sustainability implications of the scenarios, which for example predict increasing travel demand and share in motorized individual travel, rising travel times in combination with further spatial expansion. Based on the differences between the scenarios, we conclude with a discussion on the future challenges and suggest strategic policy options for an integrated transport and land use policy in Santiago.

Implications of an Underground Pedestrian System Strategy in Shanghai: Is It a Sustainable Development In Central Areas of Mega Cities?

Jianqiang Cui (University of South Australia), Andrew Allan (University of South Australia), Dong Lin (University of South Australia)

China is experiencing profound social reform. Decision-makers, developers and planners have had to confront problems arising from rapid population growth and urbanization associated with this period of rapid social reform, such as land shortages and environmental deterioration. Against this backdrop of tumultuous urban change, Shanghai has had an Underground Pedestrian Systems (UPS) strategy in place over the past three decades that integrates subway construction, combining commercial functions, employing underground spaces for denser, more compact cities and reshaping the city's image into an ultra-modern metropolis befitting the 21st century. During this period, the Strategy has led to a process of continuous development and incremental improvements, which has altered people's transport and shopping patterns, thus significantly affecting urban life. The advantages of UPS are their general convenience and public popularity but on the other hand, there has been criticism of their physical and functional short comings. This paper explored Shanghai's UPS strategy from two aspects: (1) as a pedestrianisation strategy reclaiming the pedestrian realm; and (2) as an underground space utilization strategy accommodating pedestrian, public and commercial usage. Data were collected from a review of government sourced documents and a field survey in Shanghai through observation, face to face questionnaires and interviews. Document analysis and a UPS usage survey in Shanghai revealed findings related to the planning, design and management of Shanghai's UPS, which provides wider policy, design and management implications for emerging UPS in China's other major metropolises.

Urban Growth sustainability assessment based on spatial analysis of urbanization pressure in the landscape

Carolina Rojas (University of Concepción), Joan Pino (Autonomous University)

Sustainable urban growth in metropolitan areas of Latin America is a recent phenomenon, characterized by a rapid process of aggregation and occupancy of land for housing, industry and roads. This has completely transformed the natural landscape spaces previously occupied by pastures, agricultural areas and in some cases, sites with large areas of ecological value. In this study the

main goal is to analyse urbanization as a pressure upon the landscape coverage using spatial distribution model of this force and its relationship with five geographical spatial variables (distance to urban areas, distance to coastline, distance to the central bussiness district, height and slope) in the metropolitan area of Concepción, Chile (MAC). This pressure is considered a global forces and transformer of the landscape and is identifiable in very dynamic zones. The period of analysis is from 2000 to 2010 and also incorporates the future urbanization with the vision of urban planning for the next decade. The main results indicates that the built-up area grew from 10,861 ha (2000) to 17, 087 ha (2010), which represents almost 6% (> 17 000 ha) of the metropolitan territory, increasing a coverage by more than 6,000 hectares. Considering the future scenario, provided by the planning, the urbanized area will increase by more than 10 thousand hectares, i.e. 27,000 urbanized hectares, increasing the built-up area by more than 10%. From 2000 to 2010 the urbanized area increased by 57% with the cost of losses of bare soil (3569ha), prairies (1082 ha) and agricultural land (526 ha). In the future the increment in built-up area more than 10 000 hectares will be manifested mainly in terms of further losses to the scrubs (2,736 ha), bare soil (2714 ha) and forest plantations (2,680 ha). All coverages will be altered, including the most ecologically valuable zones such as native forest (200 ha) and wetlands (80 ha). Urbanization happens dynamically in the coastal lowlands in heights less than 300 meters and slopes less than 20%, near to urban zones (<10 km) scattered on the edges of zones that in the year 2000 were peripheral. In relation to the vulnerable spaces the urbanization in the first ten kilometers from the coastline grew with the cost of losses bare soil (55,2%), prairies (17,7%) and agricultural land (7,6%). These growing areas are affecting the naturality of wetlands, especially where they have a disturbed matrix within the urban zones. To sum up, urban sprawl is characterized by a complex agglomerated form, and also by a horizontal and peripheral increase, while one of the consequences of urbanization is the morphological fragmentation of the neighboring coverage, affecting in particular the connectivity of wetlands and their biodiversity.

Climate change and resource governance in Santiago de Chile: Integrating scale considerations for more sustainable development

Jonathan Barton (Pontificia Universidad de Chile), Jürgen Kopfmüller (Karlsruhe Institut für Technologie), Helmut Lehn (Karlsruhe Institute of Technology), Volker Stelzer (Karlsruhe Institute of Technology)

Increasingly there is pressure for a localization of decision-making in order to promote more sustainable development options in local and regional contexts. This is one of the key messages that emerge from the Brundtland report of 1987 and Agenda 21 of 1992. With Rio +20 on the horizon in 2012, the question emerges about how effective shifts to local and regional resource management have been over the last twenty years. This article takes the case of the Santiago Metropolitan Region and how the resources of energy and water are being planned and managed in order to establish whether the localization of decision-making regarding resource use has taken place in accordance with the goals of sustainable development. This is particularly important in view of the challenges of climate change forecast for the coming century. For this reason, the resources of energy and water provide the focal points for this research. Since the Santiago Metropolitan Region, centred on the Santiago Metropolitan Area of 34 municipalities, imposes a considerable burden on national resource supply given its concentration of over 40% of the national population, it provides a strong example of the challenges of resource management and how governance systems are able to match resource demands and resource supply in dynamic, panarchic systems. Climate change offers an interesting set of external constraints with which to explore the limitations of existing governance regimes and reveals the need for new governance regimes that are able to 'draw down' decision-making about resource management to local and regional levels where major decisions have to be taken regarding innovation, efficiency, pricing and other factors. With expected reductions in water availability of 40% based on current levels (CAS, 2011) in an A2 climate change scenario by 2070, and rising per capita energy needs according to current demand trajectories, significant changes are required in the current resource management model. Not only will supply need to increase but demand will have to be controlled more effectively. Current national resource management structures would appear to be

inadequate for generating more sustainable local and regional development since they are relatively rigid and the market mechanism provides a weak response to changing resource availability, as expected in climate change projections. The article argues that decision-making for resource management must be shared across panarchic socio-ecological systems, from national to regional and local levels in order for appropriate decisions to be taken at appropriate levels. This follows the logic of subsidiarity and 'acting locally, thinking globally' on resource management.

Land use change and sustainable local settlement development. Target values for spatial planning in municipalities.

Alexander Mayr (ILS - Institut für Landes- und Stadtentwicklungsforschung)

Countering land use change is a target all over the world. It is attended by the reduction of urban sprawl and soil sealing. The kinds of reactions and concepts are very different. In some countries there is just a scientific or political discussion, other countries have concrete maximum target values of land consumption. Germany's target is to reduce the daily land use change for human settlement and transport from more than 100 hectares in 2002 to 30 hectares in 2020. In the years 2008 to 2010 the land consumption was between 75 and 95 hectares per day. To achieve these objectives, in Germany many instruments were developed and initiatives were established. Land use became a widely discussed topic. Recent model calculations, however, predict that the target set for 2020 will be missed. A major obstacle is seen in the fact that this target was formulated at federal level. In contrast to this, the settlement development is decisively decided at the local and regional level. But what does the 30-hectare target mean for the individual municipality? How many hectares can still be developed without endangering the achievement of the objective? The questions remain completely open. There is a lack of concrete target values at the local level. However, these target values will be required during the decision-making and planning processes if land use change is an important factor in the weighing of interests, in order to support sustainability in urban development. A new approach is the certification system 'Meilenstein 2012' (engl.: milestone) for soil-saving municipalities, funded by the Ministry for Climate Protection, Environment, Agriculture, Nature Conservation and Consumer Protection of the German State of North Rhine-Westphalia. The certificate, which will be reviewed regularly, should be used initially for city marketing. It is intended by the federal state to stimulate the reduction of land use change in municipalities. Thereby it was necessary to define the indicators of a soil-saving

municipality, also with reference to the 30 hectare target. For an appropriate acceptance among the concerned local actors, the consideration of the specific local conditions as well as the transparency of the scoring system are of great importance. At the same time, these were the main challenges in developing the evaluation process. The various used qualitative and quantitative criteria address both policy and planning. At the conference the developed instrument, especially the used criteria, shall be presented and discussed. In principle, it can be applied to other spatial levels and other states. The presentation focuses on the quantitative criteria and the used valuation standard. For instance the specific target values for the criteria 'land use change' were set by using a multiple regression analysis. First application experiences and reactions of local spatial planning actors can be shown.

Regional Effects of Urban Planning – an informal instrument to support sustainable strategic planning

Anja Brauckmann (Research Institute for Regional and Urban Development)

Sustainability needs long range strategies. Consequent sustainable planning can't just focus on a few years. But in practice diverse and near-term interests dominate planning. A common example in Germany is that municipalities continue to develop new residential areas or business parks in spite of the fact that they are suffering from population decline. The focus lies in the objective target of gaining positive effects, for instance from the fiscal point of view. But regional competition, high operation costs for future generations, irreversible environmental damage or social exclusion are possible consequences which decision makers often can't evaluate because of their complex interdependencies like the municipal fiscal equalisation scheme or ecological mechanisms of action. In recent years, some innovative instruments had been developed in geo and space science in order to illustrate long-term, especially fiscal effects of settlement development. Policymakers can see the consequences of their decisions. These instruments were tested successfully, but some potentials for further development were collected. A new instrument called RegioProjectCheck resulting from these experiences is currently in development. The instrument deals with residential and business areas on the regional level and presents their long-term effects. It does not only look at fiscal effects, it also integrates ecological and social effects resulting from settlement development such as CO₂-Emissions, land use and ecological value that are modeled as well as accessibility and social exclusion. The diverse dimensions of sustainability are reminded to policymakers and planners on the local and

regional level. It should be used in an early stage of planning to offer the possibility to discuss alternative locations for projects. The instrument is currently in the test and development phase in cooperation with German regions. One trial deals with a regional development plan and prospective housing areas. At the conference fiscal effects will be compared with ecological effects for this case study as an example for possible results. Location comparisons and regional development strategies are part of this example. The question of how different effects are evaluated will be discussed with the focus on negotiation processes. Summing up, this input discusses the surplus of these kinds of instruments and if they are able to raise awareness for all dimensions of sustainability and encourage these actors to decide from a (more) comprehensive sustainable point of view.

Green spaces in the city- Vital elements for urban sustainable development. Case of study Cluj Napoca city.

Florina Cozea (Babes Bolyai University)

The urban sustainable development involves the execution of urban equipment, planning the land and spaces, taking social measures that will lead to people's physical and psychological and to rule a rational development and planning of the urban agglomerations. For each urban settlement the needs are characteristic and the measures taken by the authorities for the sustainable development need to suite to local necessities. However there are 6 measures for an urban sustainable development applicable in general for all urban areas such as: urban sprawl, redeveloping industrial sites, regenerating brownfield sites, sustainable constructions, green spaces and regenerating distressed neighborhoods. The green spaces have numerous functions when situated in the city: landscape and aesthetics, sanitary, utilitarian, economical, protection, educational and scientific and last but not least: social. It is required a special attention in order to increase the allocate space, to planning and exploitation in a more efficient way. It has been established an average value of green space per citizen in the cities: 24 m² (European cities). In case of Cluj Napoca, this value is 18 m²/ citizen, calculated for a population of 319000, without taking into account the students who are enrolled here and whose number is over 100000, in this case the value lowers to 16 m² / inhabitant. This indicator evidence a lot of negative issues in Cluj Napoca such as: increased pollution, chaotic urban planning, people don't have places to go out and socialize, to play sports or to relax their body and mind. The most important function of green space in the city is sanitary through which the microclimate is improved by tempering the

temperature, the moisture and the air currents, the atmosphere is purified by reducing the pollutants; the green space also warns and heals the psychological pollution. Some of the measures that can be taken for the improvement of this aspect of the green spaces in Cluj Napoca are: transformation of the degraded urban spaces in green areas by planting vegetation and shrubs hence, the economical value of this spaces will increase, every new building is to respect the law in terms of green space and playground for children, in many cases this green space is being replaced by a parking for cars, to implement the green belts around the city and to stop the constructions in the forests outside the city area that are also declared natural sites, making spaces for outdoor sports surrounded by green areas, educate the citizens and especially the children so they understand the importance to protect the green area from the city. Key words: green space, planning, urbanism, sustainable development, settlement

UDC 24-01 - Sustainable urban environments for the future 1: Modeling of sustainable urban environment

Chair: Martin Sauerwein, Juergen Breuste

Transit Oriented Development: An Alternative to Suburban Development in Post-Socialist Metropolis?

Josef Mares (Charles University Prague)

Despite North American and Western European long-term experiences with negative impacts of suburbanization and numerous efforts to regulate suburbanization, post-socialist suburban development appears to enjoy many problems associated with rapid unregulated suburban growth. One of the most prominent strategies aimed at reduction of negative impacts of suburbanization is Transit Oriented Development (TOD), employed throughout both North America and Western Europe. Since there is historically dense rail network in the Czech metropolitan areas recently enjoying significant improvements and there is abundance of rail brownfields, TOD might be a good solution for suburban development issues as well as for ensuring efficiency of public money spent on rail transit infrastructure and operation. The paper assesses the potential of TOD to reduce negative impacts of suburbanization by comparing suburban development at four rapidly developing model areas in the Prague metropolitan area representing: 1. traditional suburban centre with rail connection (Ricany), 2. suburban village with rail connection (Zelenec), 3. emerging suburban centre with no rail connection (Jesenice), 4. villages with no rail connection. The model areas are compared by: 1. land use analysis, 2. accessibility of services analysis, 3. transportation analysis. The first two model areas (Ricany, Zelenec) represent possible results of minimalist TOD implementation (since it developed around rail stations), while the other two represent typical sprawl-like suburbs emerging with low linkage to public infrastructure. The research question is whether rail suburbs show more sustainable and citizen-friendly characteristics than sprawl-like suburbs. The paper will conclude by discussion of development needs of studied areas and possible tools for encouraging TOD and in general more sustainable forms of suburban development in post-socialist metropolis.

How sustainable are the Private Cities of Chennai and its Environs? A Case of Gated Cities of the OMR and the IT Corridors

Divya Rajeswari Swaminathan, Jayanthi Swaminathan, Vasanthakumaran Thangavelu

Introduction: Since early 1980s, the developmental goals of global South have become increasingly tied to the neoliberal agenda of private investment in urban spaces. The governments are progressively leaving the task of 'conceptualization and execution' of urban development to private players. In neoliberal policy framework, segregated and gated private cities are being developed for private consumption and production and are being located near the major urban centres and in pristine natural environments. These private cities are being built in public-private partnership, where public sector provides high speed mobility corridors, electricity and water, the private groups govern the cities and decide who will live in these cities, what will be their occupations, what will they consume and produce, and how much one would pay for living in these cities. **Study Area:** Chennai is one of the megaurban centres of India with a population of around 5 million (Census 2011). The East Coast Road and the Old Mahabalipuram Road, which is the IT Corridor of the megacity Chennai, were the pioneers in providing gated communities to the residents of Chennai. **Research Questions** Do private cities celebrate equality of opportunities for all segments of society wishing to live in private cities? How deeply inclusive are the private cities? How do relationships between public authorities and gated communities affect segregation patterns? **Objectives** To assess the environmental sustainability and economic viability of people living in the private cities. To examine, focus and assess the role of local governments in the context of Public-Private Partnership in gated communities and how effective are they in making the private cities 'inclusive'. **Methodology** A participatory appraisal and a questionnaire survey are the methods of study. The two approaches would help to ascertain the sustainability of the urban environments created by the private cities. A direct observation method is also employed to assess the conditions of the people living in the private cities. A community mapping exercise has been used in this regard as well and in respect of citizenship and sense of belonging. **Conclusion:** This presentation looks critically at the 'city making' and 'eco-city planning' processes and reflects upon the claims of ecological sustainability, economic viability, and amicable relationships with peripheries, in regard to Chennai's OMR and IT Corridors. It reflects also upon the displacement of farmers/village communities and their encounters with hypermodernity of the

private cities and issues of citizenship and belonging, and democratic accountability of these cities.

MGUS Design of a Sustainable Urban Management Model

Vergara Adrián (Universidad del Norte)

The proportion of urban population is increasing day by day worldwide. The same phenomenon occurs in Colombia, where it now represents 72% of the total population and continuous increase has been predicted. This overcrowding increases the possibility of environment deterioration, especially when urban growth takes place in a chaotic way and is mainly formed by marginal population and the receptor territory lacks the tools to manage these growths or the arguments to stop or reorient settlements. All this generates a diminished authority lacking the strength to enforce the Territorial Ordinance and a vicious cycle is conformed to a corresponding decrease in the quality of life of the population and a negative message for the opening of development opportunities. The main environmental damages accompanying urban concentrations are on natural resources especially on the people whose environment stops being healthy and their socio-economical conditions force them to overcrowding. This research results from the above mentioned situation and it aims at designing tools which take into account the variables susceptible to be intervened to attain benefits for the population, which have an incidence in sustainable urban development (social, economical, environmental) and that could anticipate the effects of any measure. They will also assure the quantification of not only the economical resources in order to implement them, but also their availability for public examination and additionally that the intervention measures be transparent, concerted, public, accepted, respected, enforced and executed. The main tool is an analysis model for sustainable urban management, measured based on quality of life and human development indicators. This model will be validated in Barranquilla and its metropolitan area. It will be located in the 60's of last century and the following decades up to the present time. Once validated, it will be used to simulate future.

A Geographical Analysis of Solid Waste Management in Delhi, India

Subhash Anand (University of Delhi)

Delhi, being the most urbanized, polluted and having highest density of population, is facing numerous civic in infrastructural problems. The problems of waste disposal are compounding everyday as amount of garbage is increasing and area available for dumping is shrinking. Management of municipal solid

waste is a hot and crucial problem in Delhi and lacking in sustainable and scientific collection, transportation and disposal. Municipal waste of study area is highly bio-degradable in nature which has higher moisture content and low calorific value that is why it is more suitable for composting purposes than incineration. It was found that there was no clearcut standard for the placement of waste receptacles. People of Delhi were not using different coloured bins as per their purpose. The spatial analysis of the number of dustbins, garbage carrying trucks and sanitary workers reveals that their availability gradually declines from core to periphery Municipal Corporation of Delhi (MCD) zones. Karol Bagh, Sadar Paharganj and Shahdara (S) zones are identified as highly served zones (HSZ) whereas Nazafgarh and Narela are characterized as least served zones (LSZ). About 95 per cent waste is dumping at three landfills and about 5 per cent is going for composting. 46 per cent people were not satisfied by providing MCD services and suggest for fixing the accountability of MCD staff. Around 0.1 million rag pickers including children and women are working in extremely unhygienic, unsafe and vulnerable environment. They are contributing immense role in Solid Waste Management (SWM) sector but their services go unthankful and unaddressed.

UDC 24-02 - Sustainable urban environments for the future 2: Urban ecosystem services: Processes, pattern and planning

Chair: Martin Sauerwein, Jürgen Breuste

Urban Ecosystem services on the local level – Urban green spaces as providers of urban ecosystem service

Juergen Breuste (Salzburg University)

Ecosystem services are provided on different scales. The local level is the basic unit for ecosystem services. These are landscape elements or basic ecosystems differing from their neighborhood by structure and functions. In urban areas the concept of urban (ecological) structural units (USU) has been approved to differentiate micro-climatic, biotic, soil and hydrological. These USU can be used as basic concept of providers of urban ecosystem service. The USU dominated by biotic elements, the urban green spaces are investigated in their ability to provide these services in different qualities and quantities. The different urban green structure types like lawns, bushes, different tree covered areas etc. are effective to use for a semi-quantitative evaluation of its services instead of extreme resource consuming measurements. The study is based on general available knowledge on urban green functions and on example studies especially in Central Europe, but also in Latin America and China. This allows qualifying different urban green space types by its internal structure of vegetation, size, shape and location in relation to at least a semi-quantitative scaling of its urban ecosystem services under different cultural circumstances. The evaluated urban green spaces are street trees, neighborhood parks, district parks, city parks, urban forests and allotment gardens. The assessed urban ecosystem services are provisioning, regulating, supporting and cultural services. The URGE-manual, a tool developed by an inter-, transdisciplinary and international team to which the author belonged, is tested for its adaptability to the task of evaluation of urban ecosystem services on the local level for urban green spaces. The actual urban challenges, land use change, adaptation to climate change, demographic change and cultural diversity demand a systematic evaluation of urban ecosystem services with constant monitoring. A new planning paradigm related to urban ecosystem services is urgently needed to develop and to implement.

Impact of Urbanization on Agricultural System: A Study of Regional Imbalances around Big Cities

Suman Singh (Banaras Hindu University)

India faces the most acute pressure on agricultural land. Today every million hectares of land supports 7.27 million people. Forty three percent of the land is under cultivation, one of the highest in the world, with these few evidences and its relation with rapidly growing urbanization. Over the past fifty years, while India's total population increased by about 3 times, the total area of land under cultivation increased by only 20.27 percent from 118.75 million hectares in 1951 to 142.82 million hectares in 2001 while land for non-agricultural uses as housing, industry and others, were increased from 9.36 million hectares to 22.97 million hectares in 1951 to 2001. The impacts of the urbanization especially around the few big cities are undesirable both from point of view of balanced regional development and from the viewpoint on the serious negative impact on agricultural system and neighboring rural economies. The present paper analyses the phenomenon of transformation of agricultural land into urban uses and its adverse impact on agricultural system in and around big cities of Eastern Uttar Pradesh.

The Value of Bicycle and Pedestrian Paths: Measuring Social and Environmental Benefits of Investments along the River Neckar

Jost Wilker (ILS- Institute for Regional and Urban Development), Karsten Rusche (ILS - Research Institute for Regional and Urban Development), Christine Rymas-Fitschen (ILS - Research Institute for Regional and Urban Development)

High quality environments play an important role in building competitive cities and regions. They are contributing strongly to quality of life for communities and employees. Therefore, Green Infrastructure, defined as a network of multifunctional open spaces, parks, trees and woodlands, is a valuable part of the urban economy. It is a certain type of regional amenity delivering various benefits for inhabitants such as recreation, ambient air quality and biodiversity. Within Green Infrastructure networks, cycle and pedestrian paths link green and open spaces with each other, improve their accessibility and help users to experience nature. Accordingly, they can be seen as the essential connecting element of regional Green Infrastructure. This makes paths crucial multipliers of green benefits. But due to shortages in public finances and the competition with other land uses, investments in green infrastructure need to be justified by economic evidence. In the field of ecological economics a huge body of

literature analyses the use and non-use values of certain functions of ecosystems. Herein a broad range of ecosystem types - from urban wetlands to rainforests - have been analysed and valued with the help of different methods like replacement costs, contingent valuation or hedonic pricing. Conversely, research so far only deals with the value of cycle and pedestrian paths in very few cases. Consequently, the approach presented closes this research gap by focusing on the economic value of cycle and pedestrian paths as a relevant part of Green Infrastructure. This issue is explored by applying the contingent valuation method for a newly designed bicycle and pedestrian path along the river Neckar in the city of Esslingen in Germany. Before its redesign, featuring a new layout along the renaturalized riverbanks of the Neckar providing sojourn areas and a better track surface, the path was directed on a major road. Against this background, a user survey has been conducted to identify the importance of the track for its visitors and local citizens. A representative sample (N=972) reveals the respondents' use preferences, opinions and possible willingness to pay for several improvements within the regional cycle network 'Neckartalradweg'. We found that approximately 40% of the respondents are willing to pay in general and that average willingness to pay among all respondents is 19.91 Euro per year. Several determinants that affect these figures are investigated further in statistical and econometric approaches. Here, detailed information on the factors that enforce general and absolute willingness to pay is highlighted. Finally, based on a user count, the total annual value to support improvements in Green Infrastructure in the Neckar region on the part of users is estimated. By this means, economic values of green infrastructure that help strategic planning and decision-making in the long run, are measured.

Urban greenery as a key to sustainable cities: Assessing an urban tree program in a Latin American megacity

Sonia Reyes-Paecke (Pontificia Universidad Católica de Chile), Ulrike Weiland (University of Leipzig)

Urban trees enhance the cityscape and add to balancing urban air temperature thus contributing to improving urban environmental and living conditions and to building sustainable cities. These regulating and cultural ecosystem services are relevant especially for heavily transformed megacity environments. For this reason several cities have implemented urban tree programs. However, patterns of urban tree cover are determined by complex interactions between human decisions and ecological processes, which also take on various distinctive forms in differing geographical and political contexts. In Santiago (Chile) an urban tree

program has been implemented with the target mark of seven million trees in four years. Although the number of trees has increased, and the program includes funding for the coming years, it should incorporate ecological and social goals to ensure long term sustainability. In order to contribute to optimizing the further program implementation, in this research we are interested in the impact of the urban tree planting program on (i) the species composition and (ii) the share of native trees. The objective of this research is to analyze and assess the decision making process while implementing the urban tree program in Santiago (Chile) by interviewing stakeholders involved in this process on various scales. The decision-making process involved in the selection of urban vegetation represents a key factor for explaining its structure and composition. The main criteria for the selection of urban trees were low water needs, mix of evergreen and deciduous trees, available space, low susceptibility to parasites or pests, and root characteristics of the adult tree. The implementation of the urban tree program in Santiago faces some difficulties due to several interacting factors: the need to increase the number of nurseries to reach the program goals; the fact that to increase native tree production requires seeds to be collected in the wild instead of the city, which implies a change in current practices; funding for planting and maintenance requires multiple sources, which involves coordination and cooperation between public and private institutions; more efficient use of water for irrigation is essential to ensure long-term maintenance; and the need to involve communities in planting and maintaining urban trees implies new procedures for local administrations. The research highlights some common structural issues that will likely face other megacities in developing their own programs.

UDC 24-03 - Sustainable urban environments for the future 3: Sustainable urban environment in different urban cultures

Chair: Martin Sauerwein, Jürgen Breuste

Slum upgrading 2.0: Effects of relocating Nairobi slum dwellers into a new settlement in its semi-rural hinterland

Tara Boekhout (Radboud University Nijmegen)

Slum upgrading 2.0: Effects of relocating Nairobi slum dwellers into a new settlement in its semi-rural hinterland Urbanisation, i.e., the process of absolute and relative growth of the urban population mainly takes place in developing countries. In this part of the world urbanisation is foremost uncontrolled and generates serious problems. For example, most of the immigrant urban population is absorbed in the slums and informal settlements. Living conditions are challenging. Nairobi, the capital city of Kenya, is one of the fastest growing cities in Africa. The city is confronted with an enormous housing problem. There are not enough suitable houses available for the poor population. Besides the local authorities other players have recently entered the field of addressing housing problems. For example, Jamii Bora, the largest microfinance institute in Kenya, has been focusing on helping the poor and marginalised in the country since 1999. After years of experience assisting slum dwellers Jamii Bora concluded that they needed to start a housing project for their members. The project included the building of a new town outside of Nairobi. Some 60 kilometers to the south-east of Nairobi in semi-arid land which is mainly inhabited by Maasai pastoralists, Jamii Bora found land to build their town. The project was presented as a model for socially and ecologically sound low-income housing development. However, the building of this new town in the outskirts of Nairobi creates pressures on the fragile environment and the natural resources like water and land. As a result, original inhabitants felt threatened and aired resistance towards the project. The local community argues that the project puts pressure on natural resources especially water. They also fear the rise of insecurity and political marginalisation as the influx of outsiders with different ethnicities and slum background increases. They fear the negative influence of the project on their pastoralists culture. In addition, the wildlife conservation community states that the project threatens the wildlife in the area and will block the wildlife migration corridor from Nairobi National Park. The resistance towards

the project developed itself into a legal struggle which was won by Jamii Bora. Hence, at the end of January 2008 the construction of 2,000 houses was embarked upon. So far two neighbourhoods of 250 units each have been completed and another is under construction. The fears of the opponents are still alive, as the issues raised have not been solved. Moreover, Jamii Bora has hardly fulfilled the memorandum of understanding they composed with the local Maasai community. This paper aims to provide insights and discusses the effects of this unique process of nuclear urbanisation and slum upgrading project. The conducted research is part of the CoCooN project which is a research program on Conflict and Cooperation over Natural Resources in Developing Countries.

The place of small towns in the balanced rural development

Reihaneh Soltani Moqadas (Pyram Noor University)

The place of small towns in the balanced rural development In macro planning, the creation and expansion of small towns is one of the strategies to develop rural areas. Considering the theory of rural-urban joints that can foster development, the hierarchy of rural settlements in various spatial and temporal dimensions influence the type and the direction of urban-rural relationship. An increase in the economic self-sufficiency of rural settlements can lead to a more balanced and moderated relationship with the city. In this regard, small towns will have a mediating role that can reduce the polar effects of metropolis. It is due to the fact that these towns are based on the regional socioeconomic features, possessing all structures and functions compatible with the rural areas and can provide optimal and efficient services. The functions of these towns will encourage the rural economics and reduce the visits of the rural settlers to the city. These towns can also play a preventive role in rural-urban migrations if they undertake their role efficiently and be able to influence their regional management and planning. However, the lack of attention to the knowledge and required skills at managing levels will hinder the effective performance of these towns and metropolis will continue to have their special role due to their concentration of various functions and production management.

Meeting the urban challenge? Urban agriculture and food security in post-conflict Freetown, Sierra Leone.

Tony Binns (Otago University), Kenneth Lynch (University of Gloucestershire), Roy Maconachie (University of Bath), Paul Tengbe (Fourah Bay College)

Sierra Leone is emerging from a long period of political instability and is ranked among the world's poorest countries. During the civil war of the 1990s, widespread forced outmigration left much of the countryside abandoned, as residents fled to the safety of the capital city, Freetown. Consequently, food production became severely dislocated and the agricultural sector is a major concern to governmental and non-governmental development agencies. This paper examines urban and peri-urban agriculture (UPA), at a crucial point in Sierra Leone's post-conflict reconstruction. Drawing on recent field-based data, the paper contributes to the growing debate about how urban planning and development can promote an 'enabling environment' for UPA. The paper argues that a detailed evaluation of UPA is needed to determine how agricultural activities can fit in with urban structure, urban problems and the livelihoods of a wide range of actors in and around the city. The paper concludes that UPA is a vital element of household food security. It could potentially play a fundamental role in safeguarding the urban food continuum and promoting sustainable urbanization in the post-conflict period and beyond.

Sustainable development of urbanized territories of Ukraine

Artem Mozgovyi (Institute of Geography of the National Academy of Sciences of Ukraine)

Based on human geographical analysis of possible sustainable development of urbanized territories of Ukraine was established the necessity of inculcate of policy on new base to keep resources and urgency of measures concerning preserving, resumption and protection of all kinds of resources and improvement of city environment and surrounding. The investigation has been carried out within the concepts of human geography. On the basis of the factual material of the national and foreign scientists the author determines the way of achieving the sustainable development of urbanized territories as the model of the future destiny of mankind. Scientific-methodical bases of the urban geographical decision of city environmental problems, the regional ecology specifications regulating quality of environment and stability of development of urbanized territories are elaborated. These territories are considered as a basis and as an element of the settlements systems. Action of the mechanism of self-control in

development of the urbanized territories is analyzed, ecological essence of process of urbanization and sustainable development is opened. Principles of a policy on new base to keep resources and urgency of measures concerning preserving, resumption and protection of all kinds of resources and improvement of city environment and surrounding are determined. The new type of object of urban geography - urbanized territories within the limits of which maintenance of conditions of ecological balance

UDC 25-01 - The 'migration & development-hype' and its implications for geographical research

Chair: Martin Geiger, Yvonne Riaño

Migration, development, and no hype in sight

Stephan Duennwald (ISCTE-IUL)

The ambitious debate about a migration and development nexus is quite high up in the sky, seen from the perspective of a remote African town. Explorations in two Malian regions with high outmigration rates reveal that a migration and development nexus is more than ambivalent on the ground. Examples show that both fields of (external) intervention do not seem to be connected too closely. Traditional development aid is reluctant to enter the field of migration, and new organisations explicitly addressing migration and development often lack experience. Donors, agents and target groups differ, and only the project ideas, given a limited choice within smaller scale rural development, seem to be the same. It can be further questioned in how far mutual effects (migration triggering or hampering development / development slowing down or accelerating migration) can be predicted. These rough causal relations seem to be less adequate in a context where development is defined differently among local and external actors, and migration is a process designed by a multitude of factors. Different migration traditions, based on regional and ethnic divides, inform needs and views of migrants and their families back home. Out of an anthropological perspective, the findings are used to develop a model of place/flow dynamics, taking development assistance and migration / migrants' remittances as two bundles of flows interacting with each other, and rather creating turbulences than synergies.

Globalized realities of Sri Lankans in Muscat (Oman). Towards a relational geographical development research in the context of migration studies.

Veronika Deffner (RWTH Aachen)

In hardly any other region in the world are labour migration and modernisation processes so closely linked together than in the Gulf. Since the 1970ies this area has needed a large cheap work force - and a comparatively lesser number of highly skilled expatriates - to make the modernisation boom possible. The geographic proximity and cultural similarity as well as the dependence on each

other to continue developing have paved the way for an 'economy of migration'. Thus oil-producing Gulf States and South Asia are connected through complex and asymmetrical interdependences. Development as such has several meanings if seen from different angles such as the social or individual point of view or even within discursive terms. On the one side it e.g. ranges from ensuring ones livelihood in the short to medium run, reducing ones individual vulnerability, but also signifies the growing dependence of nation states on remittances from abroad. On the other hand it can imply the strategic and long term development of infrastructure or the building of global superlatives. The social and economic transformations taking place on both sides have to be observed through reciprocal connections and outcomes. Therefore, a critical approach with a relational perspective is recommended. Subsequently, the complex migration system of Asian nationals to the Gulf States has to be analysed using a variety of perspectives. Different interests, dependences, relations and strategies of power as well as resources, constraints and different significances of capital should be considered. While researching the situation of Sri Lankans in Oman, the following perspectives have to be an essential part of the empirical analysis: The recruitment policies as well as cultural and political hegemonial claims of the Omani society; the recruitment policies and governmental dependencies of Sri Lanka; the local, yet global (everyday life) realities of the Sri Lankan migrants in Oman and the subjectivities of the migrants and their family members back in Sri Lanka. Bourdieu's Theory of Practice enables such a relational perspective. Individual social practice has to be studied while keeping their mutually influential and structural social settings (of power) in mind. To understand the trans-local significance for and the mechanisms of the construction of different realities from migrants in the native as well as in the country of destination, it is fruitful to integrate concepts of remigration and Diaspora research into such a perspective. Hence if the geographical development research leans towards a praxeological focus it would contribute hugely to the postulation for a relational approach as Bourdieu's theory entails the critical self-reflection of the researcher's own normative settings and ideas (e.g. development).

Rethinking the migration and development nexus from a translocal perspective. The case of the Wakhi of Gojal, Northern Pakistan.

Andreas Benz (FU Berlin)

Most approaches directed towards the migration-development nexus are concerned with the question, how migration can contribute to the development

in a certain sending region. Implicitly, these approaches are based on the assumption that a certain community is attached to a certain area. They are based on a container-like conception of space and tend to presuppose a congruence of a group of people and the area where they live. This kind of container-like and essentialist thinking leads to raising the wrong questions on the migration-development nexus. Communities and regions hardly ever formed homogeneous and persistent 'natural' units, and in times of increased mobility and migration in a globalizing world they do less than ever. Continued migration and mobility have led to the spatial dispersion of people belonging to one basic social unit, e.g. households and families. Between the different places in these migration networks, a translocal social space has emerged, which connects the people in various distant geographical sites, and enables the households to pursue translocal livelihood strategies. People circulate between the different geographical sites in these translocal livelihood networks and are often not clearly localizable in one place. The congruence between community and region is no longer given in times of globalization, and therefore the question for the migration-development nexus has to be asked in completely new way: It is no longer the question for effects of migration on development in a defined sending region, but rather the question for the effects on the translocal community to which the migrants belong. Correspondingly, the notion of development has to be freed from its spatial container: to talk of 'regional' development doesn't make much sense from a translocal perspective. Applying a human-centered notion of development, as e.g. the capabilities approach suggests, development is not attached to a certain spatial segment, but rather to people. Since the basic social units of these people have become translocalized, development no longer takes place in a certain region or spatial container, but in translocal networks. Based on results from extensive fieldwork in Pakistan in 2011, the presentation will exemplify the above outlined theoretical considerations with regard to the case of the Wakhi community in Gojal, Gilgit-Baltistan. After decades of far-reaching mobility and migration processes, the Wakhi community has turned into a translocal community, spread over many places within and outside Pakistan, but well-connected by intensive exchange networks and united by a joint identity. Through mobility and migration, the Wakhi community underwent a parallel process of rapid socio-economic development and increasing translocalization. Development in the Wakhi community therefore cannot be grasped in terms of regional development, but rather by relational development in translocal networks.

Migration, development and the 'Rising Powers' – theoretical challenges

Parvati Raghuram (The Open University)

The relative resilience of countries like China and India to the global economic downturn has led to renewed speculation about what the global economic map will look like in decades to come. In a world of binary terminologies - North-South, West-East, developed-developing - each predicated on locating growth in particular parts of the world, what would we call these countries now? Academics and policy makers are beginning to engage with these issues but the fundamental challenge that spatial shifts in the sites of economic and demographic growth pose to theories of migration and development are yet to be fully assessed. The burgeoning literature on migrants as agents of development too often takes a familiar North-South optic with regard to the direction of migration and the places that need developing. The continued, even expanding, economic growth in countries like India and China has been accompanied by shifts in migration patterns. These countries have seen the termination of some old patterns of migration, intensification of others, and emergence of new migration streams. The constituents of such migration include return migrants (due to recession in the global North), those returning due to increased job opportunities in these countries, entering through waged work or as entrepreneurs, family migrants and students. This paper offers a reading of the existing conceptual map for analysing migration and development and some possible ways forward. It also outlines some conceptual and methodological challenges involved in reformatting our thinking on migration and development globally.

UDC 26-01 - The Mobility of Human Capital and Knowledge

Chair: Harald Bauder; Stefanie Föbker

“If my family integrates, I may stay a few more years” – the role of the family for the migration of highly skilled professionals

Daniela Temme (Universität Bonn), Stefanie Föbker (Universität Bonn)

International mobility is often seen as a precondition and key element for the career of highly qualified professionals. Highly skilled migrants are perceived as flexible labour following attractive job offers. However, it is often disregarded that these international professionals also have a family. The family is affected by the migration decision and influences it at the same time. Our paper explores the role of the family for the decision to migrate, the settling-in process and future migration plans. Our paper is based on an empirical study in three German university cities, focussing on the migration of foreign researchers. It is intended to supplement these results with additional findings from a new research project concentrating on other groups of highly qualified professionals (managers, journalists). Our results emphasize the significant role of families in terms of settling in a new locale. Foreign researchers living with their partners or children in Germany have more diverse access to social networks. At the same time, the family situation can result in rapid emigration from Germany or in abandoning the intention to migrate right from the start.

What moves? An Inquiry into the moveability of capital and knowledge along Chinese-German academic mobility trajectories.

Maggi W.H. Leung (Utrecht University)

International movements of scientists and researchers have become more common in the increasingly inter-connected global knowledge economy. Geographic mobility is often perceived as a key to academic excellence and career advancement by scholars especially in advanced economies. In China where international geographical mobility is a newly-gained privilege after the advent Open Door Policy in 1978, academics belong to one of the most mobile subsets of the population. These 'mobile brains' are considered as embodiments of knowledge, skills and other forms of human capital. Their movements across space are hence perceived as a (direct and mostly unquestioned) indicator of these embodied resources. Beyond celebrating the

numerical growth of academic mobility (in terms of the number of scholars on exchange, programmes and partner universities etc.), the experiential impact on the scholars is little understood. Drawing upon recent findings from 64 in-depth interviews with Chinese scholars of postdoctoral or above level who have had exchange/work experiences in Germany and six key informants, together with a postal survey (123 Chinese scholars with mobility biography to Germany), this paper unbundles 'academic mobility' and examines the moveability of human capital and knowledge along Chinese-German academic mobility trajectories. Key questions asked include: (i) Whose and what capital and knowledge (and hence who) is considered worthwhile to be (made) mobile? (ii) How do the transfers work (also in terms of spatiality and temporality)? (iii) What is the impact of these transfers in creating/reinforcing/challenging knowledge structures and hierarchies across different spatialities? Interview materials illustrate the differentiated transferability of knowledge, academic credential/recognition and capital (after Pierre Bourdieu) across space, which can be accounted for by an array of factors ranging from discipline, gender, age, academic position and the (perceived) global hierarchy of knowledge and expertise. The paper will also demonstrate how Chinese and German scholars and administrators manage (define/defend/demolish) uneven knowledge interfaces in the transnational/translocal academic fields.

Reconceptualizing the German academic diaspora: From homeland to home culture

Heike Jöns (Loughborough University), Elizabeth Mavroudi (Loughborough University), Mike Heffernan (University of Nottingham)

Geographers have recently become interested in the economic, social, and cultural benefits of diasporic networks that have shaped the emergence of a global knowledge economy and are increasingly mobilized by governments across the world as an important transnational resource (e.g., Mohan 2006; Blunt 2007; Larner 2007). Little research, however, has been done on how these transnational assets have impacted on knowledge production in science and higher education, and on the role that biographical relations have played for academic mobility and the formation of transnational knowledge networks (Fahey and Kenway 2010; Robertson 2010). In this paper, we are using the concept of academic diaspora to examine how researchers, who worked at U.S. universities when taking at least one period of research leave in Germany from 1954 to 2000, participated in networks of cultural and academic exchange between the United States and Germany. Our prime interest lies in the extent

and nature of biographical ties to Germany among this transnationally mobile group of U.S. researchers in order to compare how those with and those without such linkages engaged in further interactions after their research leave in this country. Our findings reveal a wide range of biographical ties to the host country that go far beyond those established through birth and ancestry but also motivated researchers with such linkages to be more likely involved in the construction of lasting US-German knowledge networks than colleagues without such connections. In particular, US-German academic relations were significantly shaped by biographical ties based on cultural knowledge, language skills, educational and work experience, relatives, partners and friendships. Therefore, we suggest to expand the notion of diaspora towards an elective concept that substitutes the defining criterion of ethno-territorial linkages to a homeland with emotional ties to a culture in which one feels at home. Germany can thus capitalize not only on skilled emigrants and their descendants but on all those abroad who share a sense of belonging to German language and culture or to family and friends living there.

Transnational Mobility of Academic Labour in Canada and Germany *Harald Bauder (Ryerson University)*

International migrants often segment into the low-skill sector of the labour market of a receiving country. When academics migrate, however, this devaluation of skills does not always occur. In fact, transnational mobility is often associated with the accumulation of cultural, social, and other forms of capital that can propel academic careers. In this presentation I explore the circumstances under which transnational mobility raises the value of academic labour. In particular, I am presenting the preliminary results of a qualitative analysis of data obtained from interviews with internationally mobile early- and mid-career academics in Canada and Germany. These results are interpreted in light of the forms of capital academics accumulate through mobility, the rationale for moving to a different country, and the structural contexts in which mobility occurs and is strategized.

UDC 27-01 - The socio-spatial reconfiguration in Gulf Arab cities

Chair: Belgacem Mokhtar, Montasser Abdelghani

Neoliberal Urban Planning in GCC Cities – The Issue of Governance

Jonas Margraff (Johannes Gutenberg-University Mainz)

Neoliberal Urban Planning in GCC Cities - The Issue of Governance In the last 10 years the cities in the GCC have been undergoing huge re-structuring and re-planning processes based mainly on a new alliance between a 'New Economic Policy (NEP)' and 'New Urban Policy (NUP)' that is reflected in a new type of urban planning based on 'Large-Scale Urban Development Projects (LSUDP)'. The main aim of such urban planning is to generate rent from real estate developments and to decouple the urban planning from social urban development. Especially, but not exclusively, the cities in the UAE (Dubai 2015 and Abu Dhabi 2030) have been showing new alliances between local political decision makers, investors, urban planners and international consultants. Other cities in the region were for all practical purposes copying the pioneer experience of Dubai; Doha, Jedda, Muscat, Riyadh, Kuwait and Manama have all adopted - either new comprehensive or partially modified - the already existing urban development plans. The economic crisis in the real estate market has affected the implementation schemes of these plans in scale, shape and time. Nevertheless, the already implemented parts of plans have by all means changed the urban spaces. This paper is part of a long-term study on neoliberal urbanization processes in the GCC region. The aims of this paper are: First, on the governance level we map out how the process of decision making in urban planning in the GCC countries functions. Second, by exemplifying some of the modifications done in the urban development plans in the region, we give a primary reading of the influxes of the economic crisis on the governance processes in urban planning and in the LSUDP in the region.

Qatar off and running – construction and competition challenging Qatar for the FIFA World Cup 2022

Nadine Scharfenort (Johannes Gutenberg-Universität Mainz)

Globalisation and Urban Development of a Container Port City: The Case of Salalah (Oman)

Steffen Wippel (Zentrum Moderner Orient (ZMO))

Salalah, for a long time an unspectacular town in today's southern Oman, appeared on the economic world map when its container port was built over a decade ago. As a central transshipment hub near the world's main East-West trade route, the port is now among the world's top transshipment terminals and has been complemented by additional infrastructural and urban projects. This paper examines the current urban reconfiguration of Salalah under the impact of boosted globalisation in a theoretically informed manner, referring to characteristics of contemporary port cities. The current wave of globalisation has seriously affected trade logistics and port development, with container terminals becoming pronounced nodal points in the network of global flows. The development of port cities is often described using a sequential model of several historical phases of port/city interaction. Thus, in the past, inner-city harbours were integral parts of the city's economy and society, but technological changes have resulted in the increasing functional and spatial separation of the port and the city. Yet, authors point to the high diversity of trajectories. Particularly in eastern parts of Asia, containerisation contributed to a specific model of port-cum-city evolution, where ports and cities still keep developing more contiguously. In this context, integration into the global economy has important consequences for the physical landscape. Characteristically, the port area is only one example of the newly established sites in Salalah that are fenced and gated, thus contributing to the fragmentation of the wider agglomeration. Consequently, the paper tries to trace common and specific features of Salalah's development into a port city compared with models worldwide as well as with other Gulf cities.

Reconfiguration of Retail Trade in Gulf Arab Cities – case study Muscat, Sultanate of Oman

Montasser Abdelghani (Sultan Qaboos University)

In recent decades, the cities in the Gulf Arab countries have been experiencing substantial social and economic changes, which are caused by internal and

external factors: An important factor is the strong boom in the region as a result of high oil prices. The availability of capital and business, in these cities, made them a popular destination for global investors, internal migration and for a large number of immigrants from other regions of the world, especially the surrounding areas. Another factor that led to changes in the cities of this region is the will of the states to diversify their economic bases to reduce their dependence on oil. Here, the factor of economic globalization should be mentioned, which has opened new opportunities for the region with free movement of goods, ideas and people. One of the most affected sectors, with above mentioned factors, is the retail trade, which is experiencing considerable changes. The forms, structures, functions and importance of retail trade, in cities of Gulf region, have clearly changed during the past two decades. Retail trade has come to play a more important role in the economies of states and the economies of the cities. The changing and restructuring of retail trade is, in quality and quantity, an international phenomenon found in all the world's cities. The extent of restricting retail trade depends closely on the city's size, demography, its political and administrative status, and its local, regional and international importance. The Arab Gulf cities have witnessed a change in the function of retail trade and seen new components added to it, e.g. the emergence of giant hypermarkets and the online electronic trade. In addition to improvements in goods and commodities and styles of supply and demand, the changing of the retail trade, in these cities, has produced significant changes in redistributing land use because some retail trade areas have assumed great importance, unlike their situation in the past. In fact, the commercial value of what used to be the central city locations has begun to decrease and has seen a reduction in patrons, while some suburban areas have attracted new customers. These changes pose many questions such as whether the city center area will still attract internal and external tourism. Many studies have been conducted on this topic and applied to the conditions of American and European cities. Although the Arab cities are witnessing the same phenomenon, (reconfiguration of retail trade), it has not received enough scholarly attention and examination from Arab geographers till now. Consequently, a scientific study is needed to direct the theories, already applied to foreign cities, to Arab ones. Muscat, in this regard is a suitable choice as a typical Arab city in the region. The results of the proposed study will help Arab geographers to obtain a better understanding of this urban phenomenon and will be of great significance both theoretically and practically

UDC 28-01 - Towards a new centrality of world society: Future faces and functions of urban centres in the 21st Century

Chair: Ilse Helbrecht, Peter Dirksmeier

Global city formation, new urban centres and the transnationalization of urban policies

Christof Parnreiter (Inst. f. Geographie)

Departing from the commonsensical idea that global cities are amongst the most characteristic features of the new spatial formation of world society, the presentation takes the notion of 'centre-building' literally and argues that global city formation is frequently accompanied by a deep restructuring of the built environment. This restructuring is caused by quantitative and qualitative changes in the office market, because the growing presence of producer service firms has spurred not only the demand for office spaces in general, but for prime office spaces in particular. Because this demand is neither quantitatively nor qualitatively met by vacancies in the traditional CBDs, global city formation is, as Sassen (2001, 334) argues, usually characterized by '(t)he rapid building of one high-rise office complex after another'. The presentation backs this claim with a detailed analysis of the making of a new CBD in Mexico City since the 1990s. I maintain that with Santa Fe, built at a former dump in Western parts of the city, a clearly delimitably global city space has emerged: It is there where most of the construction of prime offices spaces has taken place, and it is there where to most of the foreign and FIRE-sector firms operating in Mexico have relocated their regional headquarters. Yet, the restructuring of the built environment goes beyond the construction of New Downtowns and / or the expansion of traditional CBDs. Rather, the governance of the production of urban spaces has shifted to entrepreneurial planning. Cities around the world have replaced Master through Strategic Planning, which is far from pure planning methodology. It is often linked to specific contents, namely the implementation of urban mega-projects, which are often related to global city formation, and to public-private partnerships, which have become primary vehicles with which to promote, organize, and finance urban development. Understanding the channels, institutions, and the 'industry' involved in the spread of strategic plans helps to understand that Strategic Planning has emerged as a transnational standard of urban policies, which is oriented toward the project of creating hospitability for

global firms (Parnreiter 2011). To exemplify this conceptual argument, the presentation analysis shifts in urban planning in Mexico City which have been instrumental in governing the production of global city spaces.

Contesting centrality in Jakarta Metropolitan Area: Have new towns promoted deconcentration?

Delik Hudalah (University of Groningen), Johan Woltjer (University of Groningen), Tommy Firman (Institute of Technology Bandung), Haryo Winarso (Institute of Technology Bandung/ Ministry of Foreign Affairs of Republic of Indonesia)

Following Soeharto's market-oriented development policies, new town development has been rapidly applied as an urban deconcentration strategy in Indonesia. As the result, since the late 1980s, new towns and industrial estates, which were mostly initiated by private developers, have dominated land development projects in Jakarta Metropolitan Area (JMA). The paper investigates the extent to which these new towns have effectively reduced suburban functional dependence on the main city of Jakarta. First, the paper indicates that major town builders in the suburb have shifted their activities from property development towards town management. In the early stage of suburbanisation, their core business was focused on selling houses and building local facilities. However, due to tighter competition, many of them have changed their paradigms to attract industrial investment and regional facilities such as high-class shopping malls, star hotels, universities, and theme parks. The new towns have promoted not just population deconcentration but also decentralisation of jobs and wider urban lifestyles. They have played a key role in changing the spatial structure of JMA towards a polycentric form whereby specialised regional centres begin to flourish in the suburb. Consequently, the centrality of Jakarta as the long-standing regional growth centre is now being contested. It is found that the emerging private-driven spatial structure has reinforced social division, caused spatial fragmentation, and encouraged inconsistent planning policies. Making urban deconcentration strategy more sustainable, we suggest an integrated approach in new town development planning. First, there is a need to carefully include the private parties on the current government-centred regional governance structure. Under Indonesia's decentralisation policy, it is also important to build the institutional capacity of the suburban governments in order to meet the challenge of rapidly restructuring region. key words: deconcentration; new town; urban structure; suburbanisation; Jakarta

Everyday activities of residents in New Downtowns. A case study of Hamburg HafenCity.

Flemming Giesel (German Aerospace Center (DLR)), Julia Jarass (German Aerospace Center (DLR))

Urban planning has to face new challenges at the beginning of the 21st century. Depending on economic, demographic and social factors different processes of urban transition can be observed. While some cities or districts are shrinking, other urban areas are experiencing the phenomenon of re-urbanization. From the perspective of urban planning this "renaissance" of the city bears great potential and challenges at the same time. The rising demand for housing in inner city areas strengthens the city's position and its functions. Therefore, one attempt to promote the development of the inner city is the construction of new urban centers, so called New Downtowns. In contrast to the historically developed Central Business Districts these areas represent a new and different centrality. Equipped with modern architecture, cultural mega-projects and leisure facilities these urban spaces express a new representativeness of cities. In this context the question arises how those people choosing to live in New Downtowns can be characterized. To what extent do they make use of their residential environment in terms of leisure activities, place of work and local amenities? What kind of travel behavior do households in New Downtowns have and how do they assess their residential neighborhood? What are the demands of residents living in New Downtowns regarding neighborhood characteristics and are they satisfied with the existing urban structures? It is possible to analyze the issues set forth above using existing data. In 2009, the research project "DC Noise" (Demographic Change: New Opportunities in Shrinking Europe, INTERREG IVB, 2008-2010) assessed Hamburg HafenCity among four other areas in Hamburg with regard to everyday life activities, travel behavior and the living environment. For this session of IGC 2012 we intend to apply an empirical approach to the issue of New Downtowns. Analyzing the socio-demographic structure of the research areas, it was found that people living in Hamburg HafenCity are substantially different from the respondents in the other four research areas: They earn almost twice as much as the residents of the other four survey areas in Hamburg and live mainly in one or two-person-households. This specific and homogeneous household structure demonstrates that people self-select themselves to some extent by choosing Hamburg HafenCity as a residence. Regarding their living environment, the results show that "proximity to the city-center", "cultural facilities" and "evening activities" are the most important factors for the residents of Hamburg HafenCity. In this session we

want to provide a closer look on how the residents of Hamburg HafenCity conduct their everyday life. Based on the analysis of action spaces our focus will be on demonstrating where working and leisure activities take place and how the residents there evaluate their residential environment.

Beyond the global city concept

Richard Smith (Swansea University)

This paper prepares the ground to move the theoretical and empirical agenda of global urban studies beyond its dominant neo-Marxist tradition towards a broadly conceived poststructuralist approach to include research in actor-network theory, cultural-economy, social studies of finance, and post-continental philosophy. First, a previously unacknowledged account of the neo-Marxist back-story to the global city concept is explicated to foreground how Sassen's concept presides over a common epistemological tradition in urban studies that envisions capitalism as a totalizing structure to assume it is commanded and controlled through strategic urban loci. Second, Taylor's interlocking network model is interrogated to reveal how it not only contradicts Sassen, but is a structuralism bedevilled by a sorites paradox problem where cities are indistinguishable from, and therefore totally reducible to, structures. Finally, the paper moves beyond the global city through recourse to a broadly poststructuralist literature that is construed to foreground an attentiveness to the limits of capitalist control - viz., the global city - and the necessity for a conceptualization of cities as multiple, eventful, socio-material assemblages, that are never quite in control because as multiplicities they are alive with that which is not yet fully actual.

UDC 29-01 - Towards a process-based understanding of spatiality: New perspectives on dissolving the rural-urban divide 1

From 'Carpet' to Patchwork': City-regions, 'corridor of connectivity' and the production of marginalities ?

Tassilo Herrschel (University of Westminster)

The challenges of peripherality have been a recurring theme in discussions and policies aimed at regional (economic) development and inequalities. Peripherality is generally geographically defined as "edges" of a territory, based on distance from a centrally positioned "core". and "periphery". Yet, this paper argues, such "edginess" is not the only form of peripherality and need not be merely a passive condition. Indeed, it may be actively produced. Peripherality may take on different, rather fuzzy forms, and embrace different scales. This makes conventional simplistic divisions into (urban) "core" and (rural) periphery rather more difficult and conceptually less convincing. Much of the recent discussions about governance and territoriality have argued for "new" forms of territoriality and associated forms and practices of governance vis-à-vis growing economic change: open, flexible, non-territorially defined, network based, and informal. Fixed territories with associated qualities are increasingly being replaced by more selective, linear spaces based on actual or perceived connectivities. The result is an effective dissection of 'conventional', contiguous territoriality into linear spaces of preferred connectivity between which new de facto peripherality are produced as "in between-ness" rather than conventional "edginess". Conventionally, such peripherality includes a close association with rurality, sparseness of population and remoteness. Yet this need not be so. Marginalisations through absence of connectivity may also exist within 'core regions', including city regions, and embrace different forms - suburban, ex-urban, Zwischenstadt, rural. Territoriality, and the belonging to it, is thus becoming less important than connectivity between actors with shared interests and purpose; being part of a network matters, rather than mere embeddedness in a region as fixed territory. Geography matters, but linkages, interrelations, connectivities and accessibility matter even more so, especially as they project perceived distances as either "beyond reach" or relative proximity. Policies aimed at peripherality need to keep this in mind. Belonging to a city region has

become a key political agenda for projecting positive development prospects and thus appeal to other core areas. And this serves the attempt to become part of a 'network of success'. Not belonging to any such network is thus rapidly becoming an increasingly urgent policy challenge. Changes to actual and perceived peripherality need to be achieved through targeted, imaginative policies addressing emerging fragmented spatialities, and overcoming the "territorial trap". The Oresund region offers an interesting example.

Urban-rural partnerships in Europe and Germany

Rupert Kawka (Bundesinstitut für Bau-, Stadt- und Raumforschung)

Although there is still a clear-cut distinction between an urban and a rural policy in the EU and the individual member states, the Territorial Agenda 2020 stresses - again - the goal of territorial cohesion also on the meso level, i.e. between urban and rural regions. Also the new regulations for the structural funds focus more on this aspect, thus showing both a new and a continuous interest in these functional regions. Why 'new and continuous'? On the one hand, the topic came into the European discussion in the middle of the 1990s with the ESDP, on the other hand, the idea was somehow dormant and hardly brought into action. But the debate on metropolitan regions and the question about the position of rural counties within these regions demand a discussion about territorial cohesion and about urban-rural partnerships. Another aspect has to be discussed in this respect: Is there a need for a new compromise between a balancing and growth policy - against the background of the ongoing financial crisis, overwhelming public debts, increasingly difficult public borrowing and a perhaps future shrinking economic output in those regions generating money for balancing policy? Can large-scale co-operations between urban and rural as well as economically strong and weak regions contribute to this compromise? There are only few examples of really integrated (i.e. not sectoral) joint urban-rural development approaches within Europe. The German demonstration project (MORO) 'Supraregional partnerships' is a very extensive approach in Europe - in terms of the variety of projects, the spatial size and the analysis. The project has provided many hints about relevant topics in dependence of the distance between urban and rural regions, the management of initiatives to strengthen the relations between the different types of regions, the overall governance and the question about the spatial extent of such a partnership. This touches the aspect about the stakeholders, their regional and sectoral backgrounds, their varying understanding of time horizons, goals and approaches - and about individual and shared regional visions. This

demonstration projects also showed central success factors to build urban-rural partnerships and to overcome the urban-rural divide for mutual benefit. 'Supraregional partnerships' has strongly contributed to the European debate about urban-rural partnerships, because it stressed neither merely urban nor only rural areas, but the connections between the two types (rather three, because the suburban areas should not be neglected) and the management of the relations to improve the regional situation. The project has shown that co-operation leads to a surplus value for all - or at least many - places within such a partnership and that the traditional understanding of rural or urban can be overcome with good initiatives.

Urban-Rural Relationships – analysing and reflecting linkages and flows

Annegret Repp (Leibniz Centre for Agricultural Landscape Research), Thomas Weith (Leibniz Centre for Agricultural Landscape Research)

Industrialisation and globalisation have caused massive changes in land use and in interrelations between different types of space. New forms of labour, increasing mobility and new information technology modified complex flows of goods and people. The dichotomy between rural and urban started dissolving and transitions amongst the two categories increased, including the creation of new types like peri-urban areas. Unlike this in analytical as well as political concepts the defined dichotomy between urban and rural persists up to now. One reason is the indifferent and simplified use of indicators like land use, settlement structures or economic productivity for creating types and classifications. One other reason is the missing reflection and integration of flows and interrelations between subspaces according to concept of space of flows defining space as a product of interrelations (Massey 2005). In consequence the relationships and flows in between have rarely been analysed and discussed. A review of scientific literature indicated lack of comparative data on flows between urban and rural areas until today (SPESP 2000). Best known are some physical flows like water and migration of people, analysis about flows of information and knowledge are mainly missing. Politics of interrelations like between programmes for rural areas and programmes for the urban areas are still exceptional. The full paper and the presentation will focus this analytical gap and connected governance deficits, based on an overview on concepts and models reflecting urban-rural relationships, including analytical concepts such as urban metabolism or regional governance. The aim is to provide a basis for the discussion in relation to the following questions: In which way reflect the existing

analytical and governance concepts spatial flows? What are conceptional consequences reflecting spatial interrelations? Which gaps between the current regional and political challenges and these concepts can be identified? And what are consequences for regional governance? Answers to these questions will give also indications for redefining spatial categories. The presented discussions and results are part of a project funded by the German Federal Ministry of Education and Research (BMBF) within the funding measure Sustainable Land Management. The funding measure has been designed to generate basic knowledge and to provide relevant strategies for action which are needed for sustainable land management decisions (BMBF 2008). References: BMBF Federal Ministry of Education and Research (2008): Announcement of regulations for the Sustainable land management funding measure, 24th of October 2008 Massey, D. (2005): For Space. "Rurality" as Experience. Reconstruction-centered methodologies as a way to investigate spatial categories within everyday life experiences.

Henrik Gasmus (Technische Universität Chemnitz), Sabine Scharfe (Leibniz Institut für ökologische Raumentwicklung)

When talking about the "urban" and the "rural", discussion should start with open concepts. In this perspective investigating and dissolving the urban-rural divide deals not necessarily above all with theoretical problems, but also with empirical findings and methods of conducting and analysing data. One opportunity to approach the distinction respectively its involved dualities is to ask for leib-based and experience-driven phenomena of "what it is" to inhabit and--- moreover---to live in a place. That's why the paper will focus on people who consciously decided to leave metropolitan surroundings and to live auf dem Land. They are regarded as sensitive persons concerning social and cultural aspects of possible (and then as existing presupposed) differences between urban living and everyday life within non-"urban" circumstances. So these people, sociologically investigated due to their assumed "pioneer"-role in peripheralised "rural" contexts, can also be understood to be experts of insignificant everyday details that mark---if this is the case---a unique, hybrid or contradictory otherness with regard to the places where they lived before. With a focus on "experiences" in a strict empirical sense we want to stress different traditional reconstruction-oriented methods of qualitative sociological research,

as phenomenological and hermeneutical ones: for instance example-based hermeneutic procedures (Hahn, 1994) and objective hermeneutic (Oevermann, 2000). They represent a wide set of approaches to get involved with experiences in a deeper, today often called "constructivist" way in order to investigate a person's latent Deutungsmuster and Lebenspraxis. Arguing this, we will introduce firstly the basic methodological concepts of the mentioned reconstruction-centered methods. In a second part, we would like to portray and analyse cases of persons who moved from somewhere else in half timbered houses (Umgebindehäuser) in the German part of Upper Lusatia, where the population is declining since almost 1990. Nevertheless we can find there a range of biographical patterns connected with reconstructing old houses and forming a "rural" landscape aiming at a good life and keeping individual habitation experiences in mind. Making sense of these examples and the life-world category auf dem Land will guide directly to our conclusion suggesting qualitative approaches to handle the urban-rural divide methodologically.

Fuzzy vs. fixed boundaries: The governance of migration and translocality in transit cities

Eva Dick (Technical University of Dortmund), Thorsten Heitkamp (Technical University of Dortmund)

During decades urban and rural development were considered separately. Predominant explanatory models provided a rather static view on rural-urban mobility according to which rural areas were seen as starting points and urban areas as destination areas of migration. Individuals and households seeking a better life by migrating to the urban labour markets were assumed to be leaving their hometowns and villages for good. This generic view is also nurtured by global statistics indicating the progressive urbanization process. And in cities delimited by fixed administrative boundaries weak urban governments often seek to mould public regulation into static and predictable forms, thereby neglecting the specific needs of their mobile populations. Contrary to conventional views on rural-urban migration, in many developing countries temporary circular or seasonal migration between rural and urban areas has proved to be the dominant type of mobility. In the context of translocal householding and networking, many temporary migrants retain strong links with their rural home areas; other rural-urban migrants use cities as a mere stepping stone before moving further onwards, sometimes internationally. Therefore we argue that urban areas in developing countries increasingly convert into places of transit as opposed to places of destination. This calls for alternative forms of governance which accommodate increasingly complex and fluid patterns of mobility, not least fostered by neoliberal globalisation. As yet urban policies and planning only unsatisfactorily respond to non-permanent migration processes and their role in sustaining people's livelihoods. This is in part due to a lack of mobility-related data, but - in our view - even more to a lack of intimate experience with the situation on the ground and therefore specific expertise being distilled into adequate planning practice. National and local governments and administrations are often ill-informed about e.g. housing, (informal) employment, infrastructure and service requirements of their mobile and often

transitory populations. Development analyses and strategies in these fields tend to be delimited by deterministic thinking thereby neglecting people's translocal livelihoods, engagement and networks that cut across fuzzy urban-rural boundaries, forming new soft spaces with their very own development requirements. Based on commencing case studies in Ghana and South Africa, the presentation will place emphasis on the need for incorporating new and more flexible forms of formal and informal urban governance into the spatial regulation of transit cities, thereby addressing the complexity of current migration processes and translocal livelihoods.

Between Village and City: Rural-Urban Linkages in the Broader Region of Hyderabad

Angela Jain (nexus Institut for Cooperation Management and Interdisciplinary Research), Alva Bonaker (nexus Institut for Cooperation Management and Interdisciplinary Research)

The enormous growth of the South Indian metropolis of Hyderabad is a result of constant rural-urban migration. In fact, around 30 per cent of the population are migrants. Regarding the huge scale of the phenomenon some questions subsequently arise: (how) can these people be integrated into the city? Do they actually become an integral part of the city or do they rather keep their lives centred around their places of origin? How do they influence the living in the city? Such questions emphasise the crucial importance of the social aspects of rural-urban migration and linkages for sustainable mega city development. The study on rural-urban linkages in the region of Hyderabad is part of research within the Indo-German project 'Sustainable Hyderabad'. The interdisciplinary research, including literature review as well as empirical research (interviews with migrants of different groups and local experts in Hyderabad), was conducted as part of two dissertations and an ongoing social study. Considering that phenomena such as circular migration and community networks exist disconnected from spatial boundaries, as Steinbrink (2009) suggests in his concept of translocal livelihood strategies, we focus on translocality rather than merely on migration. Going beyond conventional migration studies that analyse the moving of people from one place to another, we also take into account that many people are part of the city and the place of origin at the same time. Analysing the motivations for migration, patterns of migration and the livelihood strategies of the people/communities involved we are presenting a typology for the region of Greater Hyderabad. With the help of these types it is possible to identify societal structures such as close personal linkages and vivid exchange

systems between rural and urban areas. As a result, social developments and potential changes in this context are mainly observable in form of social mobility (within the caste hierarchy) and differences between the generations regarding the emotional bonds to the place of origin. In the case of Hyderabad these linkages are very intense, but varying in form according to the socio-economic position of the people involved. Though they constitute a big share, not only poor agricultural labours or small farmers migrate in search for securing their survival, but different kind of people move to the city searching for education, work, marriage or driven by other motivations. The different backgrounds they come from shape their lifestyles and social networks which ultimately form a part of the city society. The central finding of the study is that migration is not a single action beginning at a certain point of time and ending at a certain point of time. The rural-urban linkages rather influence the lives of many citizens constantly. This has an impact on life in the villages as well as on cohabitation in the city where life is partly influenced by rural lifestyles.

Overcoming the rural-urban divide – livelihoods and food security along the rural-urban continuum

Axel Drescher (Freiburg University), Johannes Schlesinger (University of Freiburg), David Iaquina (Nebraska Wesleyan University)

Urbanisation is a complex process of social transformation. It is arguably the most significant demographic trend to emerge over the twentieth and twenty-first centuries, and it has deeply affected the entire landscape of human endeavour. However, it is not sufficient to characterise urbanisation and its effects as the simple distinction between two categories, 'rural' and 'urban'. Rather it is dialectic in geographic space which creates a complex patchwork of transformed and transforming 'in between' areas. This patchwork includes diverse combinations of urban functions embedded in spaces traditionally dominated by agricultural production. Commonly referred to as the periurban, this interface is highly dynamic and often overlooked by scientists, town planners and policy makers. Much of this oversight is due to two factors: the inherent complexity and 'messiness' of the areas and the oversimplification of the periurban itself in the form of a single entity. Building on previous work which identified a more articulated vision of the periurban, called the periurban typology, this paper presents the results of an innovative transect approach, clarifying the varied patterns of spatial and temporal changes along the rural-urban continuum. The results are based on research in six medium-sized towns in five African countries. In each town a standard questionnaire and GIS

approach was used to assess various facets of agricultural production along a continuum from the town centre through the periurban zones outwards into the surrounding rural areas. Using various indicators of food security, the focus of this research is on natural resource use and its importance for the livelihoods at different locations along the continuum. Typically, both subsistence and market agriculture play a significant role in the local livelihoods of rural people in sub-Saharan Africa. Increasing evidence also points to their importance in many urban and periurban households. Yet there is limited understanding of how the relative contribution of agriculture to local livelihoods changes along dynamic urbanising gradients. The results demonstrate the insufficiencies of simple rural-urban distinctions and provide support for the continuous yet irregular nature of dynamic urbanising gradients which we have elsewhere termed a 'lumpy continuum'. Further, these results move the periurban typology out of the conceptual arena and into the practical. Together, this work has important implications for town planning and land-use zoning, and both local and large-scale programmes and policies aimed at reducing livelihood vulnerability, enhancing access to land and alleviating food insecurity.

“Urban” or “rural”? “urban” and “rural”: Perceptions of quality of life in French and Polish small towns

Helene Mainet (Université Blaise Pascal- CERAMAC), Agnieszka Kwiatek-Soltys (Pedagogical University of Cracow)

In the paper authors focus on the perceptions of quality of life in small towns in France and Poland and the use of urban and rural references in the urban marketing and inhabitant's appreciations. Small towns are a good way to question the construction of territorial models and modes of spatiality as they make over 75% of all cities and are inhabited by over 21% of all urban population in Poland and similarly in France (89% of urban units and 22,4% of the urban population). 'Small' towns are small in size (from 2000 to 20 000 inhabitants according to official and academic references in France and below 20 000 inhabitants in Poland), but they are playing a key role in the attractiveness of urban spaces and their surrounding areas. Depending on their spatial location, they can be in the direct influence of bigger towns or situated in more isolate context (peripheral small towns). The issue of mobility is also important, due to more extended commuting distances. People can live in a small town, in a 'rural' environment, and work in bigger cities. The identification of the motives of settlement in small towns in both countries became the important element of the paper. Very often, local stakeholders are using urban

and rural references to promote their territory, leading to commonplace pictures ('city where life is good', 'human sized towns'). Representations of rurality and urbanity, and their clichés, are widely used. Positive aspects of both are mobilised (equipments and services, urban dynamism on the one side; friendliness, solidarities and inter-acquaintance on the other) and negative sides are often minimized. Is this mixing of urban and rural promotion a pertinent one or does it tend to blur references and identifications? Furthermore, in a context of social demand for a better quality of life, linked with increasing impacts of sustainable development criteria, what are the perceptions of small towns' inhabitants? Do they identify themselves as living in 'urban', 'rural' or 'in-between' places? Is this urban-rural spatiality important for their choice of residence and everyday practices? Does the rural or urban lifestyle can still and to what extent be treated as the element of space identification? Those elements will be illustrated by empirical fieldworks conducted in French and Polish small towns, in a Polonium Research Program, in 2011 and 2012. Issues of comparison will be exposed but also elements of more general and systemic analysis on the urban-rural divide through small towns perspectives.

UDC 30-01 - Un pont sur le fossé ? Le rôle des villes moyennes comme intermédiaire entre déprise rurale et mégapoles

Chair: Andreas Obersteg, Christophe Demazière

Le rôle des villes moyennes dans les systèmes spatiaux : Nommer et évaluer l'intermédiaire

Helene Mainet (Université Blaise Pascal- CERAMAC), Jean-Charles Edouard (Université Blaise Pascal)

La question des relations entretenues entre les villes secondaires et les territoires est récurrente dans les travaux portant sur l'organisation des systèmes spatiaux et des réseaux urbains, tant aux échelles nationales que régionales. Les fonctions territoriales qu'elles assurent sont variées et complémentaires comme en témoigne la diversité des appellations. Si certains auteurs insistent sur la taille et donc principalement sur leur positionnement dans la hiérarchie urbaine (ville "moyenne", "secondaire", "d'équilibre"), nombreux sont ceux qui valorisent la logique fonctionnelle ("Market towns", "District towns", "pôles de croissance", "Secondary Growth Poles"). Tous mettent l'accent sur les interactions et articulations jouées par ces villes "charnières", "intermédiaires", "médiannes" ou "de transition" à travers les fonctions d'appui, de distribution et de réseautage, d'intermédiation, variables selon les échelles d'analyse et les contextes territoriaux. Face à des campagnes en évolution, parfois dépeuplées, parfois plus dynamiques, faut-il toujours considérer les villes secondaires comme des "centres", comme des "relais" ou comme des "pôles" - Que reste-t-il de dynamiques relationnelles parfois héritées à l'heure de l'augmentation des mobilités et des communications, dans des contextes démographiques parfois fragiles, au moment où on ferme le tribunal, l'hôpital local, en attendant la gendarmerie et le collège - Dans d'autres cas, les mobilités favorisent le recours direct aux niveaux supérieurs de la hiérarchie urbaine et les effets de court-circuitage des niveaux intermédiaires sont visibles. Sans prétendre à l'exhaustivité, nous souhaitons apporter, à travers une analyse comparative de l'abondante littérature scientifique anglophone et francophone portant sur les relations urbain-rural et sur les réseaux urbains, des éléments de compréhension et de comparaison à la dimension intermédiaire des villes moyennes, variable selon les contextes territoriaux (européens, africains, etc.) et remise en question par les évolutions sociopolitiques récentes. L'analyse comparative nous

permettra également d'interroger le sens même des termes "intermédiaires", "secondaires", "moyens", dans des contextes socioculturels et économiques parfois très différents, et selon les échelles qu'ils mobilisent (locale, régionale, nationale, internationale).

Spatial evolution of one of the oldest Transylvanian settlements, Turda, Cluj county

Puscasu Adina Maria (Babes-Bolyai University), Bruckner Leonard (Babes-Bolyai University), Vasile Surd (Babes-Bolyai University)

As one of the oldest settlements in Transylvania, Turda is an important element in this region. The town lies on the foundations of an ancient Geto-Dacian site, Turidava. From the second to the fifth century AD, Turda was also preceded by an important Roman citadel, Potaissa, a name which in time changed to its present form, Turda. Whereas in the Middle Ages it would become the summer residence of Transylvania's princes, as well as one of the main political centres of Transylvania, and a vital hub for commerce in the surrounding area. Due considerably to its geographical location, it became possible for this community to develop strong economic functions up to this time in history. The exploitation of all its resources, be it salt and stone for the chemical and construction industry, the fertile agricultural land or the rich forests, the strategic position of the site, all this led to the emergence and continuous growth of this town. The modernization process that swept the Habsburg Empire, including Transylvania, around the middle of the 19th century had the consequence of bringing urban life to the forefront. The years 1850-1851 mark the first steps in urbanization, the beginning of a shift of the center of gravity of economic life from the village towards the city. The nationalization process that started in 1948 not only erased the previous establishment, but defined the economic development of the area. The policies of the ruling communist party, which aim to increase the national industrial capacity, lead to the development of Turda, in two complementary directions: the establishment of large scale, brand new industrial sites and the enlargement of existing production facilities. Turda gradually became the most important location of the building materials industry on a national scale. The expansion of urban areas, the nationwide migration of a large part of the population towards towns and cities and the rapid urbanization of the second half of the twentieth century were the results of the Five-Year Plan to turn Romania into an industrial powerhouse. Starting from 1944, Turda expanded especially towards the south and east, where the bordering village of Poiana is incorporated in the city limits and a new district of blocks of flats is

built. After 1970, as the population keeps leaving for the urban areas where employment is easily attained, rural population numbers start to decline and Romanian village life alters significantly. The impact of industrial development would ultimately be catastrophic to all rural settlements within the isochronous limit of 45', especially for those located within the 30' isochronous limit. Starting with 1990, we see not only the economic transition from state owned to private economy, with the consequent rise in the unemployment rate, but also the emergence of a unique phenomenon in Europe: the migration of city dwellers towards rural areas and a slight increase in the share of rural population.

Les problèmes socio-économiques choisis des villes transfrontalières sur la frontière polonaise

Roman Matykowski (Adam Mickiewicz University), Elzbieta Bilaska-Wodecka (Jagiellonian University), Katarzyna Kulczynska (Adam Mickiewicz University), Katarzyna Kulczynska (Adam Mickiewicz University)

Avec la fin de la Première Guerre mondiale, plusieurs pays européens ont trouvé leur renaissance, entre autres la Pologne. Le tracé de certaines frontières y compris une partie de la frontière entre la Pologne et la Tchécoslovaquie a été fixé à la suite des décisions internationales, celles-ci prises par le Conseil des Ambassadeurs de certains pays de l'Entente (1920). C'est ainsi que la ville de Cieszyn homogène jusqu'à cette époque a été divisée en deux organismes urbains séparés. C'était pareil après la Deuxième Guerre mondiale; à la suite de la Conférence de Potsdam (1945) la nouvelle frontière polono-allemande reposait sur les fleuves de l'Odra et de la Nysa (Oder et Neisse) et les villes telles que Görlitz, Guben, Frankfurt-Oder et Küstrin ont été divisées. De telles villes fonctionnent dans la littérature spécialisée en tant que villes partagées ou villes-doublons. De sept villes partagées (dont six sur la frontière polono-allemande et une sur la frontière polono-tchèque) quatorze entités urbaines ont été créées où le critère d'une ville moyenne (nombre de population dépassant 20 mille habitants) est rempli par sept villes: 'eský T'in, Cieszyn, Görlitz, Zgorzelec, Frankfurt-Oder, Guben, Forst/Lausitz et aucun ensemble de deux villes ne dépasse au total 100 000 habitants. Le présent article a pour but de démontrer les ressemblances et les différences dans le développement des villes partagées après la fin de la Deuxième Guerre mondiale, ainsi que les causes de cet état. Une remarque particulière sera portée sur les changements subis dans la structure démographique, dans l'économie et le secteur des services. La localisation transfrontalière et les limitations résultant des directives étatiques en ce qui concernait entre autres le déplacement de la population dans la zone

frontalière ont troublé le développement des centres municipaux nouvellement créés. Zgorzelec, S'ubice, Guben et 'eský T'in privés de leur centre historique avec les infrastructures: commerciale, des services et bien souvent celle du transport en commun ont été forcés de planifier et de créer non seulement un nouveau centre-ville dans le tissu urbain déjà existant mais également des composants séparés de la structure spatiale (par ex.: les centres commerciaux).

Housing policy paradigm shifts and actors' relations: Multilevel governance in the Global South, The case of Nairobi, Kenya

*Joseph Kedogo Masilwa (ITT-Cologne University of Applied Sciences),
Johannes Hamhaber (Cologne University of Applied Sciences)*

Currently the world is rapidly urbanising with the urban areas of the Global South accounting for over 90% of the world urban population growth. This rapid urbanisation in the Global South coupled with insufficient or missing urban policies and governance structures, economic growth and other socio-economic processes is giving rise to serious urban problems, such as the proliferation of slums and social fragmentation. Moreover, the urban arena in the South has become very complex and fragmented, involving heterogeneous actors at various scales, with disparities in their powers, roles, interests and perspectives - a continuous source for conflict potential. Furthermore, these actors possibly have different paradigmatic stands which prevents the attainment of common ground and effective cooperation, thereby severely undermining attempts toward 'good urban governance'. The current dominant paradigm of 'good urban governance' calls for an appropriate and well functioning multi-level and multi-actor urban governance system that integrates all actors, permitting effective negotiations and bargaining amongst the actors from the local to global levels, thus creating a more socially sustainable arena. As such, understanding and enhancing the actors' relationships becomes *condicio sine qua non* for attaining sustainable and inclusive urbanisation. This paper, based on an ongoing PhD project, therefore deals with the question of how the changing paradigms of housing and urban policies have evolved and - instead of being subsequently replaced - are still concurrently prevailing and competing with each other. Based on a multilevel stakeholder analysis of the urban arena in Nairobi's informal settlements, it examines the actors at different scales (international, national, city wide and the local grassroots levels), and from the different sectors (state, market and civil society, also including informal to illegal actors). In this way, the actors may be mapped according to the paradigmatic views they subscribe to. Based on the fundamental incompatibility of their paradigmatic stands and interests, the paper postulates that the profound lack of common ground and mutual understanding not only undermines effective

cooperation, but also jeopardizes the potential success of the latest paradigm of good governance in dealing with the increasing urban challenges in the Global South

Politics of (im)mobility-the case of rickshaw ban in Bangladesh

Musleh Uddin Hasan (University College London), Julio D Davila (University College London)

In a mobile world cities are increasingly being planned for mobility. Cities in developing countries are no longer interested to lag behind the race and are vigorously pushing for motorization friendly infrastructure and policies including regulating non-motorized vehicles. However, as these cities are featured by differential access of their population to income, opportunities, differences in age, ability, (perceived and practised) gender role and interest distribution of new or increased mobility is a highly political or politicized decision which increases the mobility of one group only at the cost of reduced, if close not nil, mobility of the other. In the name of increasing mobility in the urban roads in Bangladesh popular and extensively used non-motorized vehicle rickshaw (a tri-cycle) is gradually being shifted out and banned from different roads in large cities. Taking the case of rickshaw ban in Dhaka, Capital of Bangladesh, this study would seek to identify the primary losers and beneficiaries in different daily and occasional activities involving mobility. It will also try to identify the hidden or indirect stakeholders of the decision as the decision is said to affect either negatively or positively the livelihood of the rickshaw-wallas (rickshaw-peddlers), business of several other interest groups including car and real estate enterprises. Finally it will also through light on the decision making process and investigate how, if at all, the voice of the less vocal and powerful are heard or not.

How Sports Change the Geography of Power in Urban Environments

Christina West (Universität Mannheim)

Analysing uneven geography of power in urban environments means not only localizing unevenness in cities and describing different practices and processes of the production of spaces, but rather understanding how collectives as well as individuals produce and reproduce unevenness. This process-related view allows one to address the matters of practice and positioning in social, spatial, normative, and communicative contexts - the basics for social and cultural affiliation, whereby individual and collective identity is constructed. The basics for

the identity-construction, which is fixed in the collective memory, are common implicit and explicit knowledge, recollection and memory. The development of the we-identity coincides with the emergence of distance, or distinction, from the 'other'. After defining a theoretical framework for the complex relation between identity and 'othering' and the connection of collective memory and (re)-production of unevenness, the paper shows how streetfootball changes identity construction of socially insufficient integrated young people in South America, Europe, Africa, and Middle East. Mostly, their former identity and memory construction is affected by experience of direct and structural violence. Social positions and roles in their every day life which is inseparably linked to the uneven geography of power are passed to and fixed in the communicative memory since generations. By playing streetfootball, according to the 'Medelliner Ansatz' of the international social-profit-organisation streetfootballworld, identity changes through the basic principles fair play, tolerance, and communication. The players are able to integrate the perspective of the 'others' so that their collective memory will be broadened, a reconstruction of their former identity will be possible, they are able to create innovative solutions for social, spatial and individual challenges, and the perception of different urban spaces (mostly public) will be redefined. First time in their life they are able to produce space and to influence the urban geography of their cities. Capoeira, as a traditional Brazilian martial art, today has a similar function, re-creating 'dominant spaces'. By 'playing' Capoeira, space is claimed against the power holders, herewith strengthening self-consciousness and creating a we-identity. In contrary to streetfootball, Capoeira has a low organisation level. Instead, fair-play is guaranteed by a strong power hierarchy. Thus, meaningful group-specific realities with their spatial relation and the connected communication are constituted in the collective memory, as there the subjective-mental, the social-cultural and the physical-material reality are associated. Therefore streetfootball as well as Capoeira are media to cope with dominant spaces and to change them into ephemeral dominated spaces (counter-spaces).

Islamisation and Urban Growth in Java, Indonesia : A Geopolitical Economic Perspective

Hafid Setiadi (University of Indonesia)

Discussion of Islamisation is not only associated with the spread of religious values, but also related to the activity of trade and the opening of the new lands. In Java, all three of these themes had occurred simultaneously and then experienced a rapid development since the 15th century. In the period of 15th

century until the 16th, many Islamic kingdoms raised and fell by turns with any ideology and their economic and political motives. As a result, Java experienced an complex of territorialisation. By a spatial-historical approach, this paper shows how that territorialization have an effect on the fashion of emergence and collapse of the cities in Java. Spatial dynamics of urban growth reflected changes of mode production of political space which run by each the Islamic regime. The city played an important as a symbol as well as an identity of political power of dominant regime. Key words: islamisation, urban growth, territorialisation, Islamic regime, political space

Defining Urban Space – The Changing Governance in Dhaka's Transport Sector

Elvira Graner (South Asia Institute), Mahboob Elahi Akhter (Institute of Governance Studies, BRAC University Dhaka)

For defining urban space, the transport sector needs to be attributed a quintessential role, and even more so in (mega)cities. While in many urban agglomerations in Asia there has been a dramatic increase in motorised urban transport there has often also remained a bizarre mosaic of different modes of transport. These seem to cater to different strata of the urban population and from this vantage point, the transport sector can also be seen as a crucial proxy for social change. At the same time, we conceptualise cities as a site (or 'arena') of contested space, where the elite and middle class aim at re-defining the allocations of space according to their

What lies behind the Sea and Sun? Analyzing the geographies of power in the tourist city

Ismael Yrigoy (University of the Balearic Islands), Sònia Vives (University of the Balearic Islands)

What lies behind the Sea and Sun? : analyzing the geographies of power in the tourist city Ismael Yrigoy Cadena and Sònia Vives Miró Since the 50s, the European Union project has created mechanisms to guarantee the process of capital accumulation. These mechanisms have been led by public institutions (ranging from global actors to nation-states administrations), but also by private actors. Both agents have assured a particular role for these spaces in the global circuits of capital and have also taken an active role in setting a particular pro-growth elite specialized in touristic and building sectors. This paper attempts to analyze the power relations that have shaped the coastal 'pleasure peripheries' as one of the solutions to the overaccumulation process of the main European's economies. In these sense, the first aim of the paper is to identify the different players that have been related to the production of space in Palma (Mallorca, Spain) since the Franco dictatorship until nowadays, focusing on the current

crisis. The second goal is to analyze the different spatial strategies developed by those actors, ranging from the global policies to the local strategies.

Rural area as a product of contemporary economic-geographic development in Bosnia and Herzegovina

Rahman Nurkovic (Faculty of Natural Sciences)

The paper deals with an issue of the image that contemporary economic-geographic development of Bosnia and Herzegovina shows. In Bosnia and Herzegovina, as in other ex real-socialist countries in Europe, rural area has had a quite different development in last fifty years. However, part of 'image' is close to image in economically most developed capitalist countries: number of agricultural population reduces on their level, and different interests considerably affect, here and there, the creation of new perceptions of rural development in Bosnia and Herzegovina. Simultaneously, it is an attempt of response to increasing need for empirical researches on the new meanings that are attached to rural areas and their 'new' identities. In contemporary period of economic-geographic development in rural areas in Bosnia and Herzegovina there is around 30 % of agricultural population, and majority of this area today has characteristics of distinct lagging behind in development, which indicates to clear negativity of all demographic, socio-cultural and spatial-planned indicators. Only 12 % of these areas are within the balanced development or expansion. With a change of socio-economic system into market economy, rural areas of Bosnia and Herzegovina are facing new challenges. One of them is, certainly, a development of contemporary economic activities. Therefore, from a broader context of rural change and for the needs of this article, we are going to focus on agrarian production as elements that have been deemed compatible functions of rural areas for a long time. At the same time, it should be emphasized that agricultural products should be observed as a result and a factor of other changes in rural area of Bosnia and Herzegovina.

UDC 32-01 - Urban informality as post-socialist routine?

Chair: Daniel Göler, Bernhard Köppen

Communities rooted in place: A reality in post-soviet cities? The case of Riga.

Maija Uša (University of Latvia)

The development of the 'compact' city in the Socialism period created a large concentration of residents (by restriction of the size of one's house and its diversity), disregarding the needs of families or lifestyle. The values of Soviet urban space were based on satisfaction of basic needs. There were specific features characterizing Soviet urban planning: standardization of individual apartments, lack of private property and semi-private space, lack of individuals' responsibility about common space. Neighbours' help-out and support were more a necessity than a desire. After the collapse of Soviet Union the political, economic and social structures in formerly centrally planned societies significantly changed. Therefore the formation of communities rooted in place, that are mostly based on informal contacts, initiatives and communication, in Post-soviet space is both actual, but insufficiently explored question. E.g., in the case of Riga, the idea about communities rooted in place and neighborhoods has become popular only in the last few years. During this period a few significant researches regarding historical urban structure and economical geographic questions as well as tendencies of real estate have been done. At the same time there are not many researches regarding neighbouring, informal communication and formation processes of territorial communities in Post-soviet neighborhoods not only in Riga, but also in other Post-soviet cities. Therefore in this research the author is probing into three different neighbourhoods in Riga. The research is based on residents' point of view about their neighborhood and their explanations and expectations about territorial community development in it. The data is gathered by using semi structured in-depth interviews with residents of the specific neighborhoods and representatives of formal/informal neighbourhood initiatives (e.g. NGOs) as well as unstructured observations done by the author of the research. The data is analysed by using principles of grounded theory and analytical induction. The results show and allow to make judgements about factors that influence the formation processes of communities rooted in place in a post soviet city. Key-words: community rooted in place, neighbourhood, Post - soviet city.

Urban informality in post-socialist Albania: The case of the peri-urban area of Shkoder city

Dritan Rustja (University of Shkodra)

This paper analyzes the development of urban informality in post-socialist Albania, based on a concrete case-study. Firstly, it makes a general consideration on this issue in a national level, discovering its causes, evolution and consequences. After that, the paper turns its attention to the spatial transformations that occurred in the peri-urban area of Shkodra city after 1990, positively in "Rrethinat" commune, which has experienced the most dramatic social, economic and land use transformations in Shkodra region during this period, along with Shkodra city itself. This is the first study undertaken for this area and it aims to examine the causes, the dynamics and the impact of these transformations over the community and land use. Using a diverse range of geographical research methods, the study finds out that the most immediate problems that need to be addressed are: the lack of an administrative identity for this area, the high degree of economic, demographic and settlement informality and the lack of an adequate public infrastructure. It concludes on emphasizing the necessity to develop and carry out a general regulatory plan for this territory as the final solution to all the above mentioned problems and as a way to achieve sustainable development. Key words: spatial transformation, peri-urban area, Shkodra city, informality, regulatory plan

Informal Housing in Post-Socialist Croatia – Trends and Perspectives

Dubravka Spevec (University of Zagreb), Sanja Klempic Bogadi (Institute for Migration and Ethnic Studies)

This paper analyses urban development and housing policy in post-socialist Croatia, with the emphases on informal housing. During socialist period a serious housing shortage in Croatian cities was caused by the inflow of migrants from rural areas, induced by intensive industrialisation. Former Yugoslavia implemented a housing policy based on the dominance and control of the state, which organised, built and allocated large housing estates in the cities, and at the same time did not restrict individual housing construction. Significant part of this individual housing construction was informal, especially on the outskirts of large cities, without proper planning permit and without essential infrastructure services. This have become a serious problem since the state wasn't able to fulfill all housing demands; informal housing was seen as one of the ways to deal with housing shortage for low-income households. This trend continued during

post-socialist period; it intensified especially during 1990s, as a result of lack of public investment in housing, and large inflow of refugees and internally displaced persons. Due to the fact that Croatia has no housing policy, and the rental sector is unorganised (the public rental sector barely exists and rents in the private rental sector are very high), and that the state did not sanctioned illegal housing construction, the legalisation of the informal housing has been seen as a solution. Informal housing first appeared and today is mostly present in larger Croatian cities. With tourism development and building of second houses in settlements on the Croatian coast, informal housing has become a big problem for planning and sustainable development in this part of Croatia.

Re-Organizing the urban system in Mongolia: Impacts of political, economic and demographic trends

Eva Maria Gardemann (Albert Ludwigs Universität Freiburg)

Throughout the last hundred years, and in particular since the 1950s, Mongolia has experienced a process of urbanization on an unparalleled scale and speed: from a very low percentage of the population living in cities in the 1920s to 70% in 2010. In post-socialist Mongolia, new migration processes promoted economic and demographic concentration in the primate city Ulaanbaatar, while other urban agglomerations witnessed severe population losses and decline in their urban functions. It is assumed that these dynamics will continue in the coming decades as future trends are more likely to be driven by demographic and global economic trends than by national development policies. Against this background the presentation analyzes the major changes which contribute to the continued transformation of the Mongolian urban system: the clustering of growth in a few large urban centers on one hand and the decline of many smaller urban areas on the other. The guiding question is: How will modifications that affect Mongolia's policy, economy and demography reshape the urban system over the next decades? Research is based on both qualitative and quantitative methodological approaches by combining statistical information with the results from interviews with leading players and stakeholders in the ongoing processes of urban development. Mongolia's urban system goes back to two major phases of urban settlement: the 'pre-revolutionary' phase, extending from the 17th century to 1921, accounts for settlement-patterns that are consistent with a nomadic society. The second, the 'socialist' phase shaped a nationwide hierarchical urban system with a rapidly growing industrialized core and vast regions where development remained far slower and more dispersed. Since 1990, transformation and internal migration have led to even higher socio-

economic rural-urban disparities. Today, plans to exploit the enormous mineral resources in the peripheral south-east Gobi accompanied by the global demand for commodities point to a possible shift of the north-south disparities; which means that the resource-rich South would grow faster than the industrialized core with its outdated production facilities. However, increasing service-sector orientation could also foster the concentration of growth in the existing large urban centers. Furthermore demographic trends are expected to be a major contribution to Mongolia's city development by causing enormous migration flows. A process that takes place beyond official urban development patterns is the emergence of various informal settlements especially in the context of small-scale artisanal mining. Even though it is hard to predict which development scenario will prevail, it is likely that changes affecting economy, policy and demography will result in a highly polarized urban system with a few large urban of high growth rates and numerous smaller centers, trapped in a vicious circle of decline.

UDC 33-01 - Urban poverty – Conceptions of everyday life under persistent conditions of inequality

Chair: Ulrike Gerhard, Eberhard Rothfuss

Self organization in the context of urban Food Security using the example of Street Food Vendors.

Lea Jenkner (University Bonn), Divya Rajeswari Swaminathan

In rapidly growing megacities like Chennai the issue of assuring food security for all inhabitants, especially the urban poor is a key factor for sustainable urban development. Street food vendors play an important role for the lower- and middleclass to meet their daily dietary needs. They provide cheap and ready-to-eat meals around the city at convenient places for their customers. The aspect of self-organisation is especially important in the 'urban age'. Not only are (mega)cities growing faster than ever, they are also beginning to exist in the whole world. Urban problems are thus increasingly global challenges. The number of people who are employed in the informal sector is especially growing in megacities. This leads to the question how these self organised workers can be included in city planning rather than excluded.

Socio-spatial Impact of affordable housing for urban poverty in China: The case of Nanjing

Dongqi Sun (Nanjing University)

Along with the housing marketisation reform, affordable housing for urban poverty program has been implemented for more than ten years in China. It remedies the emergent weaknesses in the housing sector marketisation process, but critically it also brings new social and spatial inequalities to the household living in the affordable housing area. This research uses a longitudinal data set of commuting behavior of household in poverty that are forced to live in the affordable housing to test the nature and strength of the association between residential change and employment location. Do households in poverty expend commuting distances when they live in affordable housing area and what are the differences for pre- and post relocation for them? The analysis utilizes descriptive measures of distance and time to work for pre- and post-residential relocations. The results show that household in poverty resettled in the affordable housing area have poorer access to employment than before and they suffer spatial mismatch.

Towards the Social Sustainability of Low Cost Housing in South Africa: The Role of Social Capital and Sense of Place in Zanemvula, Port Elizabeth

Leizel Williams-Bruinders (Nelson Mandela Metropolitan University), Anton de Wit (Nelson Mandela Metropolitan University)

The idea of sustainable development has attracted considerable debate since its introduction. However, of the basic elements of sustainability, the economic and environmental dimensions have traditionally attracted the bulk of academic and other attention. Consideration of the much-overlooked area of social sustainability and its general concern for the maintenance and/or improvement of human well-being is a more recent phenomenon in sustainable development discourse (Maloutas, 2003). Wide-spread awareness of the sustainability of development has brought with it an increased concern amongst communities, governments and others over the means to assess progress (sustainability) towards sustainable development. The conceptualisation of social sustainability has however narrowed its operational focus down to the useful implication of the concept of social capital (Bhuiyan, 2011; Goodland, 2001; Dubois et al., 2002). The benefits of strong social capital are well researched and are often positively connected to the stability of society in general. Where social capital is not maintained, or where it lacks in strength, deficiencies usually result in social breakdown. An important ingredient of social capital, in addition to that referred to by Putnam (1996), is what is generally known as the sense of place. This term, although variously defined, is often used in relation to the characteristics that make a place special or unique, and/or encourage a feeling of human attachment and belonging. A strong sense of place is therefore associated, in a reciprocal fashion, with strong social capital; which, in turn, is an important determinant of community stability and human well-being. Much of the socio-spatial behaviour of people is voluntary and adds to a particular sense of place. However, it can occasionally be 'forced' on them. This in a post-Apartheid South Africa is often the consequence of the large-scale movement of people to low cost (social) housing estates where they have little or no choice in their eventual place of settlement. Whereas the provision of formal low cost housing in South Africa is no doubt an essential factor in the social well-being of the urban poor, the resettlement of people and communities is probably one of the key contributing factors in upsetting community social capital and people's sense of place (Herbert, et al., 1997). This holds an unintended human well-being paradox for the provision of low cost housing in South Africa, as many societies, in problems such as crime, violence, conflict and social instability, display ample

evidence of what happens when community social capital and the sense of place are disturbed. This research aims to explore the determining role of social capital and the sense of place of the inhabitants of the Zanemvula neighbourhood. These findings will be used to debate current housing policy with regard to sustainable human settlements in South Africa.

Enactment of citizenship by creative activism in an immigration neighborhood of Madrid

Eva Youkhana (Interdisziplinäres Lateinamerikazentrum), Christian Sebaly (University of Bonn), Christian Sebaly (University of Bonn)

Madrid is undergoing an urban transformation process. Economic growth primarily backed by the real estate and service sectors has introduced the city as an international hub for business and commerce. To demonstrate the new centrality neoliberal urban governance strategies such as revaluation and progressive tertiarisation transform the historic city center to an arena for consumption, urban spectacle and tourism. At the same time demographic pressure and segregation reconfigure the dynamics of the socio-spatial urban fabric. The socially marginal working class neighborhood Lavapiés is one case in point. The construction of cultural institutions, rehabilitation projects, redesign of the public space and control of communal places foster the image of Lavapiés as a cultural destination and provoke changes in social tenancy, as well as gentrification and displacement of low endowed people such as immigrant groups. As a consequence the replacement of traditional structures and conventions provoke resistant spatial practices and make Lavapiés a highly contested space. To counteract rehabilitation programs to commercialize and control the city and thus repel heterogenous urban livelihoods street and action art is increasingly used to symbolically re-appropriate the urban space and thus articulate urban citizenship from below. As such, street and action art is a strategy to for those who are widely excluded from hegemonic social, political, cultural and economic participation. Alternative cultural expressions are nowadays synonyms for the countervailing power of the subalterns. This was nicely documented at the example of the symbolic re-appropriation of North American cities since the late 1960s through Graffiti. While Graffiti has been used mainly by young artists to allow for the articulation of political and other forms of self-manifestations, there is a variety of street and action art used by activists and migrant groups to escape from voicelessness, to articulate exclusion and the lack of rights and access to resources. By this emancipatory activism the current politics of place undergo radical changes from a capitalistic

appropriation towards new forms of urban belonging beyond normative categorisations of social difference.

Capital Flows and Captive Animals: Rural-Urban Intersections in Delhi, India

Pratyusha Basu (University of South Florida)

As the showcase of India's claim to being a rising economic power, the capital city of Delhi has also become the site of governmental and middle-class anxieties related to the continuing presence of rural migrants and informal economies. A key aspect of these informal economies are small-scale dairy farmers who have proved especially resistant to removal from the city. More recently, the attention has shifted from dairy farmers to stray cattle associated with them, so that it is not just rural-urban boundaries that are sought to be policed but also human-animal intersections. How does the removal of animals become connected to the production of urban space? Is India merely replicating Western forms of the disciplining of nature through urbanization, or is this a contextual production of urban utopias via the suppression of rural others? This paper examines how urban dairy farming becomes represented as an interruption to the scale and speed of urbanization demanded by the global economy. In the process, it seeks to map the rural-urban intersections that constitute Delhi, highlighting the role of villages as internal others, leaving persistent traces and hence inserting doubts about the ability of urbanization to erase rural pasts, and as external others, marking the boundaries of urban space and hence enabling urbanization to become visible. Drawing on Lefebvre and Foucault, this paper discusses how planning for urban utopias leads to the production of more-than-urban heterotopias. In the process, it reflects on the irony of marginalization being central to urban identity formation. The paper also considers how the notion of the 'right to the city' requires a consideration of the right to frame urban nature as a site for the production of small-scale livelihoods rather than primarily as site for consumption of recreational and therapeutic values. This paper contributes to studies being conducted on processes of class-based segregation in Asian megacities. It also seeks to analyze the extent to which the notion of 'desakota,' while eminently useful in the context of the coupled urban-rural systems that characterize Asia, may become complicated by the desires of state officials and middle-class citizens for a more purified and disciplined urban space.

Shrinkage Utopias in the Urban Rustbelt

Alessandro Coppola

Most inner-cities in the Midwest and Northeast of the United States have been declining for over 50 years: extensive abandonment, fall in real estate values, poverty concentration, decline in income and economic activity are some of the problems currently stressing already distressed local administrations. After decades of neoliberal hegemony, the failure of traditional urban renewal programs has created a receptive environment for new planning strategies aimed at smart-shrinking the city, introducing urban agriculture, returning unused land to nature and relocalizing part of the economy. The formulation and implementation of these strategies tend to form a new narrative presenting interesting references to past urban and planning utopias, re-actualized in the context of global environmental and economic crisis and change

Nouvelles stratégies d'attractivité urbaine : conséquences sur l'identité des lieux et la territorialité des habitants à partir de l'exemple berlinois

Elisabeth Dury-Czekaj (Université de Reims)

L'attractivité est l'une des particularités de l'espace urbain parmi les plus difficiles à expliciter, et a fortiori à évaluer, notamment parce qu'elle est immédiatement sensible à l'individu. Or, il est aisé d'envisager l'espace urbain comme un ensemble hétérogène où s'articulent lieux de forte attractivité et lieux de faible attractivité. Dans cette perspective, les enjeux liés à l'image envisagée comme vecteur d'attractivité et de dynamisation locale sont au cœur des préoccupations des aménageurs. Ainsi, les projets de restructuration de la région métropolitaine berlinoise se succédant depuis 1990 n'ont eu pour autre but que de réorganiser l'espace urbain en statuant aussi sur la vocation de certains lieux. L'examen du dernier en date (IBA 2020) révèle que l'époque du primat de l'économique dans les problématiques d'attractivité est révolue. Les effets induits des attributs métropolitains classiques font désormais consensus. Mais en même temps, on constate un abandon progressif des réalisations de prestige en tant que leitmotiv exclusif des stratégies de valorisation urbaine. Plus encore, ils sont quasi systématiquement couplés à un usage plus prosaïque de l'espace urbain, posant alors la question de la finalité de la production de lieux attractifs. A Berlin, la tension est constante entre nécessité de rehausser qualité de vie des habitants et maintien en parallèle d'une participation à la compétition internationale. L'objectif de cette

communication est donc d'évaluer les conséquences territoriales (pratiques, représentations, production) à l'échelle individuelle et collective des stratégies d'attractivité conçues comme valorisation et mise en concurrence des lieux urbains. A partir d'un travail d'enquête réalisé à Berlin (9 lieux), trois axes seront développés : identifier l'adéquation entre le sens qu'un habitant confère à un lieu et les projets de valorisation dont ce lieu fait ou a fait l'objet ; analyser en retour, comment est reçue la matérialisation concrète de l'identité urbaine proposée ; montrer comment cette diversité peut être intégrée dans la construction d'une identité collective demeurant in fine l'objectif des aménageurs.

Public Space Invaders : A collaborative research on collective urban activism

Romain Minod (Quatorze), Jon Richter (Quatorze)

key topics : Public Space Invaders, collaborative research, collective urban activism, Paris, Madrid, Berlin, network processes, self-organization, heterotopoleis The work of interdisciplinary collectives, built at the margins of european metropolitan cities, is an empirical and diverse phenomena. Finding their roots in the early sixties - with radical american groups like 'Antfarm' or european avant-garde groups like 'Archigramm' - those collectives work on an unexpressed heterotopian paradigm with similar methods, mostly based on activism. This input presents early results of an ongoing collaborative research about the so-called Public Space Invaders. How do they organize? What are their methods? What is their contribution to the broad public? In a first step (demography) collecting the raw data from Paris, Madrid and Berlin, the overview of the questionnaires allows us to describe a network topology between people, projects and collectives. An interactive online visualization helps to understand their intertwinability. In a second step (chronography) analyzing the inner formation of projects, the results track down the tempo-spatial conditions by which activated resources (people, institutions, ideas, abilities) transpose their environment. As the entire range of research findings on Public Space Invaders cannot be publicized yet, this input focuses on a peculiar question : how does the political engagement of those self-organized civil society collectives - in terms of project actor's commitment to public institutions, private sponsorships or users - structures the methods, the networking processes and sometimes even the collectives themselves? One relevant collective of each chosen playground will be taken as a case-study in regard to this issue : Recetas Urbanas in Madrid, Exyzt in Paris and Raumlabor in Berlin. In a third and last step (theorization) the analysis of these three collectives,

understood by the prism of the different projects they've been building for almost fourteen years, will be an attempt to sketch the concept of heterotopoleis.

UDC 34-02 - Urban utopias and heterotopias: Theorizing, analyzing, and evaluating urban spaces 2

Chair: Christina West, Thomas Doerfler

What's real about real utopias in different urban spaces?

Andre Carmo (University of Lisbon), Isabel Andre (University of Lisbon - CEG)

Oscar Wilde once said 'a map of the world that does not include Utopias is not worth even glancing at, for it leaves out the country at which Humanity is always landing. And when Humanity lands there, it looks out, and, seeing a better country, sets sail. Progress is the realization of Utopias'. This remarkably vivid description captures the underlying spirit of a currently ongoing project - Real Utopias in Socially Creative Spaces (RucSaS). Its main goal is to explore and understand, through the study of different spaces (i.e. abandoned industrial sites and portuary zones, multi-ethnic neighbourhoods, decadent bohemian areas, small rural cities), the configuration and development of a number of socially creative places that from our perspective configure real utopias, as they are able to reconcile economic development, social inclusion and territorial cohesion. Obviously this paradoxical understanding involves a tension between dreams, hopes and praxis, meaning that although anchored in the real, therefore, having to deal with a wide array of obstacles and limitations, somehow, these spaces seem to give us clues and possibly inform the navigation towards a more just and egalitarian society. Real utopias exist within a wider context characterized by the existence of an ever growing mobility of people, information and capital, an increasing uncertainty associated to a reflexive risk society, an intensification of the role played by knowledge as generator of power and wealth, and a neoliberal agenda that still manages to strive, despite its obvious contradictions, thus continuing to dismantle welfare states and brutally attack societies throughout the developed western world. This context has a twofold character as it seems to generate adversities, threats and risks but also various kinds of opportunities for social innovation. Arguably, real utopias correspond to the places/communities that are able to minimize the

and critical thinking. This paper focus urban creativity in Lisbon and discusses the links between culture and creativity and the role of different city centre spaces in stimulating urban creativity, e.g. the production of new and renewed places. Nowadays the linkage between culture and creativity - especially through arts - is a necessary condition to urban development. Heritage is an important amenity but its real added value doesn't depend only on its rarity and aesthetics but especially on its social appropriation. Urban spaces such as monasteries, palaces or ancient ethnic quarters reach special relevance if they assume a creative function. To conciliate the old and the new, conservation and transgression is a real challenge and a permanent tension for urban agents. One of the most important levers to stimulate urban creative activities is the need to regenerate old industrial and port areas. These ruin spaces seem to have a special capacity to attract artists. Some conditions are obvious such as the availability of space, the architectural features or the location. But other appeals are not so easy to detect such as the ambiance, i.e. distinctive and cherished features. A second lever of urban creativity is the restructuring of old bohemian districts where former demand decreases leaving many free spaces being progressively appropriated by creative people and businesses. The third stimulus to urban creativity is cultural mixing, namely popular old districts where ancient residents coexist with immigrants from different cultural origins. Over the last few years, public authorities and grassroots' movements have been really engaged to stimulate urban creativity in Lisbon and nowadays very interesting experiences can be witnessed. The initiatives are focused on competitiveness, e.g. cultural tourism and creative industries, others on social cohesion and citizenship strengthening. Curiously, with different goals there is convergence somehow as far as actions are concerned. This paper will present 3 illustrative cases where social tensions coming from diverse interests seem to be overcome through the mobilization of cultural resources and artistic initiatives. These cases focus: (i) the challenges faced by abandoned industrial areas where the real estate crisis has forced to substitute luxury housing by studios for young artists and creative projects with precarious leases (LxFactory) (ii) the merging between post modern cultures and life styles in a bohemian ancient neighbourhood from the 16th century (Bairro Alto); (iii) the emergence of artistic grassroots? movements in a multiethnic area in the city centre (Mouraria).

Creative Lisbon: Tensions between memories and desired futures

Isabel Andre (University of Lisbon), Mario Vale (University of Lisbon)

Creativity is neither a historical inheritance nor just a vision of the future. Nevertheless to stimulate novelty memories are important as well as intuitions

Lifestyle markets in Cape Town: Urban consumption utopias and the construction of identity

Bradley Rink

In the past several years, the city of Cape Town has witnessed a proliferation of consumer spaces that identify as 'markets' -- encompassing farmer's markets, organic markets, community markets, and lifestyle markets. With roots in traditional farm-to-table consumer practices, the range of market environments in Cape Town create opportunities for buying and living a 'local' lifestyle. This paper argues that the recent growth of such markets is a phenomenon situated at the intersection of consumption, urban regeneration, food pathways, identity and lifestyle. This paper attempts to identify, categorise and unpack these various retail typologies as lifestyle 'market' environments. Lifestyle markets are shaped around the production and consumption of foodstuffs and craft, but also serve as sites for creating and performing multiple urban identities. While attempting to reassert the connections between food and craft producers and the consumers they serve, lifestyle markets are embedded in complex negotiations of urban space and identities. This research attempts to locate and define the lifestyle market as a retail typology as well as to begin to interrogate how such markets locate themselves within an unstable discourse of 'the local' that is central to lifestyle market identities, while resting on more complex connections within global scales of consumption and the production of urban space.

Kelowna, British Columbia, Canada: A neoliberal utopia of unlimited exploitation?

Tina IL Marten (University of British Columbia Okanagan)

In the early millennium, the Canadian mid-sized city Kelowna, located in British Columbia's Okanagan Valley, experienced an economic boom of unprecedented proportions. Highrises were built in select downtown areas, accompanied by discourses of gentrification and rejuvenation. At the same time there were adjacent areas that were actively deprived of economic intervention. The result was a gentrified area, but devoid of people, and a derelict urban area inhabited by a marginal and transient population. Whereas some heralded this building boom as a great transformation and successful economic development, I argue this makeover benefited only a select few. I further challenge the resulting urban reconfiguration did not rejuvenate Kelowna's downtown, but instead exacerbated existing spaces of inequality and poverty. For this research, I

examined the role of local elites in neoliberal urban redevelopment. I demonstrate that Kelowna's boom and transformation have not been coincidental, but rather carefully concerted efforts by Kelowna's economic and political elites at economic development for their sake of profit accumulation. Creating neoliberal opportunities for growth and development take effort and political will. Neoliberal agents of change, members of economic and political elites, purposefully orchestrate situations into which neoliberal policies can be inserted. Thus, they do not only manipulate economic, political, and social realms in preparation for neoliberal assault, but simultaneously foster a neoliberal hegemonic discourse that supports their goals. I explain, using re-developments in Kelowna's downtown as a case study, how this city's agents of change created and used neoliberal power networks. I analyzed the involvement of five key agencies, Kelowna's Economic Development Commission, Chamber of Commerce, Downtown Kelowna Association, Urban Development Institute, and the City itself. Through my qualitative investigative empirical research, I uncovered that the executives and members of these agencies are connected in a far-reaching powerful network, linking local capital to global capital. My work demonstrates that Kelowna's neoliberal agents acted as a united front, unified in their endless pursuits of profit and capital accumulation. Aided by neoliberal discourses and policies, they pushed for fundamental change to the local governing body. During the neoliberalization of the City of Kelowna, they sometimes collaborated and at other times competed. And, as I further demonstrate by uncovering the connections and mechanism of their neoliberal growth machine, they continually strived to create possibilities and conditions of never-ending economic development. My case study reveals that in Kelowna only a select few benefited from the neoliberal urban redevelopment, and that inequality and poverty are indeed accompanying outcomes of this kind of urban reconfiguration.

Post-apartheid Racial Integration in Grahamstown: A Time-geographical Perspective

Philippa Irvine (Rhodes University), Roddy Fox (Rhodes University)

This research is situated within the context of the post-apartheid era in South Africa, which includes the dominant ideologies and policies that have shaped the urban landscape of the past and present. It investigates the extent and patterns of integration that exist twenty years after the country's political transition and it uses Grahamstown, a small education and cultural centre in the Eastern Cape Province, as its case study. The investigation incorporates the traditional geographical focus of residential and educational integration, using conventional means of investigation such as segregation indices, dissimilarity indices and maps. However, in identifying the broader nature of 'segregation' and 'integration', the study moves beyond these narrow foci and approaches. It also adopts the time-geographical framework to reveal the dynamic use of urban space that reflects the lived space of selected individuals from the white community of Grahamstown: the extent and patterns of their behavioural integration or spatial linkages. Together, these approaches reveal that Grahamstown is still a city divided by race and, now, class. Schools and residential areas remain tied to the apartheid divisions of race and the white community exists almost entirely within the bounds of apartheid's blueprint of urban space. Rhodes University, which is located within Grahamstown, has experienced admirable levels of integration within the student body and within the staff as a whole, but not within the staff's different levels. In essence, where integration has occurred it has been unidirectional with the black community moving into the spaces and institutions formerly reserved for whites. The white community have retained the positions in space, society and the economy they enjoyed before the political transition and have little contact with the spaces and educational institutions formerly reserved for other race groups during both their weekday and the weekend activities. The limited behavioural integration or spatial linkages are shown to be tied to city structure and the perceptions of 'otherness' held by the individuals interviewed. The study argues that the slow pace of change is related to the nature of South Africa's democratic transition

and it's attending political and economic policies. Key words: Grahamstown, integration, segregation, race, South Africa, time-geography

Township of To-Morrow? Cosmo City and inclusive visions for post-apartheid urban futures

Christoph Haferburg (Universität Erlangen-Nürnberg)

20 years after the scrapping of the Group Areas Act, African urbanity in South Africa is no longer confined to the townships of the past. Still, a major challenge in urban development lies in the persistent fragmentation of the cities. While urban integration was prominent in planning and research in the 1990s, this discourse has almost ceased to exist in the past couple of years. Bond (2000), Pieterse (2006) and Pillay (2008) have been sceptical on the possibility of bridging the divide between the various residents and the different "communities" under current urban conditions. Polls have shown distrust and little interaction between the various groups in South African society. This lack of social cohesion is reproduced in the neighbourhoods, where the separation of rich and poor has become the new principle of fragmentation. Against this background (and based on fieldwork and as well as on a critical reflection of recent publications) the proposed paper will highlight and discuss two new approaches towards South African urban development. Both approaches have discursive and practical elements, and both levels will be addressed. The first approach has been centered on "Cosmo Cities". These developments are supposed to fight the housing backlog by public-private partnerships, while promoting at the same time integration by offering low-cost and middle class housing within a single suburb. The second approach is the discourse on seeing South African cities as African cities (Swilling et al. 2003, Simone 2004) – including the attempt to re-think the latter. To a certain extent, planning initiatives that create specific types of urban space respond to this discourse (Wafer 2010). On a more conceptual perspective, the paper will assess the potential of socio-spatial integration in a "multi-cultural" society through the synopsis of both concepts.

Globalization and the Blurring of Gendered Spaces: Rhetoric or Reality

Tanusree Paul (Jawaharlal Nehru University)

The Indian cities have been undergoing remarkable socio-cultural transformations alongside major economic shifts leading to reconfiguration of the

spatial contours and the emergence of a 'new' urban middle class, the 'newness' of whose identity is defined by global aspirations, white-collar jobs and a new culture of consumption. In this context, the location of women posit interesting field of enquiry primarily because women have been fervently projected as epitomizing this new found modernity. This new 'iconic' women have been envisaged as having access to technical and higher education, professional corporate jobs, greater autonomy etc and portrayed as privileged signifiers and transmitters of new India. However, such an avant-garde envisioning of women needs to be explored with scepticism. Located in this context, this paper tries to explore how gendered spaces are implicated in the new urban spaces upwelled by globalization, reflecting on Kolkata, which posits an intriguing case study since in this city spatialization of gender marked an important locus of the formation of cultural identity of the Bengalee community and socio-political consciousness since colonial era. Spatiality of gender became inherent in the ways domesticity was organized around the binaries of space, the public and the private, of which women came to embody the private and the home. This paper attempts to understand to what extent the spatial transformations in Kolkata, with coming up of new spaces viz. vivacious consumption spaces, specialized economic enclaves etc. have been able to flout the andro-centrism embedded in the existential connotations of space. The study is based on a semi-structured questionnaire survey of about 360 working women in various sectors of the reconfigured urban economy and participant observation by simply hanging around in the city to understand the processes instrumental in the engendering of the public spaces. The study reveals that the interplay between liberalization and female subjectivity is underlain by nuanced subtexts. Although women have gained access to liberating spaces and opportunities through spatial transformations consequent upon globalization, their cultural identities as women have not been deconstructed. Women still seem to be essentialized around their sexualities and reproductive roles and their access to and engagement with the public space still continues to be shaped by notions of respectability; which, in fact, is the constitutive element of symbolically authorized 'middle classness'. Moreover, since it is through these endeavours towards such productions of respectability, that the direct physical control over women gets manoeuvred through tacit exclusionary spatial control, the avant-garde depiction of new urban developments as erasure of social differences and cultural estrangements appear to be some sort of an utopia.

From the “Gay Village” to the “(Euro)Pride Park”: heterotopical spaces in Rome and a new urban governance against the “homophobic emergence”

Cesare Di Feliciano (Sapienza- Università di Roma- Dipartimento MEMOTEF)

This paper analyzes the spatial evolution of the two most important symbols of the LGBT mainstream community in Rome: the 'Gay Village' and the 'Gay Street', referring to the Foucaultian concept of 'heterotopias'. It attempts to show the manner in which, at the very beginning, the conception of these spaces presented the same features identified by Foucault when theorizing 'heterotopias'. The analysis of their spatial evolution needs a specific focus on the parallel change in the urban governance of (other) sexualities, centered on the 'homophobic emergence'. Based on interviews with the main 'creators' and 'users' of these spaces, the paper demonstrates how, although responding to the material needs of the urban LGBT community, their construction was used by local institutions to promote an urban governance model based on the idea of 'danger', 'safety' and the privatization of spaces. This double process joined the top with the 2011 Europride, when a new (temporary) and deeply heterotopical space was opened (the Pride Park) and local institutions promoted the image of 'Rome- Capital of welcome and tolerance', in an attempt to dismiss the 'homophobic emergence' that had featured on the media discourse in recent years.

UDC 34-04 - Urban utopias and heterotopias: Theorizing, analyzing, and evaluating urban spaces 4

Chair: Christina West, Thomas Doerfler

the undetermined space. how urban overall concepts – manifestos of architectural modernism – are transformed in the everyday life

Markus Vogl (Akademie der bildenden Künste Wien)

Within the debate of the architectural Avant-garde in late 1950ies, architects started to challenge the attributes of modernism - i.e. rationalism, functionalism, neutrality and universality - to offer alternatives to the modernist paradigm, that was promoted by the CIAM (Congrès International de l'Architecture moderne). But a new Charta for Housing in continuation of the Charta of Athens was never implemented in the architectural debate. In fact this younger generation scratched only the modernist surface and merely changed the form of architecture and urbanism. The presentation will focus on the developments of large housing estates that were built in the last 50 years, which seem to disregard genius loci and local traditions and are often perceived as big, ugly, overwhelming, generic and soulless. The trans-disciplinary analysis of three housing estates in Berlin and Budapest, designed and built in three different political systems will help to understand the particularity of these in relation to social, political and economical circumstances and aesthetic debates. The focus on transformation processes from the urban vision till the completion of the housing estate and the actual life situation within the estate will create a characteristic biography for each neighbourhood, that is always related to two overall concepts: the overall concept of habitat, which is based on cultural, economical and social developments in the specific society, and the urban overall concept of architectural modernism, based on cultural, technological and social ideas of an avant-garde in the 1920ies. Yet a close look to the everyday life in these neighbourhoods with qualitative studies proves that the lack of defining the intermediate housing scale asked for new and different tactics from the inhabitants to appropriate the built environment.

The discursive construction of the city, the urban and the planner in planning education

Moa Tunström (Royal Institute of Technology (KTH))

What is the city, what is its function today and what meanings are attached to 'urban planning'? The city and the urban are today contested and dissolving both spatially and conceptually through phenomena such as urban sprawl, city marketing and the spreading of an 'urban lifestyle' to the countryside. Urbanity is often defined by elusive concepts such as pluralism, dynamism, density, intensity etc. and the 'good city' is sustainable, attractive, compact, lively etc. These elusive concepts are of course normative and political; however, this is seldom brought up in planning discussion (see e.g. Gunder 2004 and Tunström 2009). Often the discourse is instead unquestioned, and key concepts such as sustainability, urbanity or compact city are used without questioning in constructing the images and stories of urban development that are central planning tools. Planning education is also an arena where images and stories of the city and the urban is constructed and reconstructed, and where the planning practitioner is shaped. The purpose of this paper which is based on an ongoing research project, is to discuss what ideals, norms and values regarding the city, the urban and urban planning that are constructed in urban planning education in Sweden and the UK, and how they are negotiated among students. This means investigating the discursive constructions of urban planning problems and solutions, as well as the constructions of the professional role of the planner. What urban planning issues engage the students, and what urban planning issues are presented to them in the education? The empirical material consists primarily of group interviews with urban planning students in Sweden and the UK. A more elaborated understanding of the shaping of the city and the urban through discourses can indicate both the importance of norms and values in urban planning, and ways to handle them in practice (see e.g. Plöger 2001, Throgmorton 1993 and Tunström 2009). It also relates to possibilities of a planning education and practice encouraging the 'reflective practitioner' instead of one that risk underestimating the role of norms and values (Schön 1983, see also Poxon 2001, Richardson 2002, Sandercock 1998).

GCG01 - Land cover and land use changes in Studinet catchment (Eastern Romania)

Iacob Ana-Maria (Alexandru Ioan Cuza University)

The present research aims at a local comprehensive analysis of the changes that have occurred over the years on land use, based on a case study in Eastern Romania: Studinet catchment (9669 hectares). In this area, the components of both the natural system and of the anthropic one have stimulated accentuated erosion, especially during the last two centuries. The general monocline structure accounts for the development of the cuesta relief, implicitly for the morphologic, morpho-dynamic and land use asymmetries. From a bio-pedologic viewpoint, two aspects are important: the reduced percentage of forested surfaces and the high percentage of eroded soils. The agricultural economy of the area is characterized by a faulty land use, with an 'atomization' of the agricultural exploitations and the frequently farming up and down-hill. In order to obtain the information necessary to shape the profile of the research area we made use of the diachronic or comparative analysis of different categories of land. Therefore, we analyzed three distinct aspects: evolution and present share of the forest area; weight and fragmentation of the arable land; expansion of xerothermophile shrubs. Arable lands were analyzed at the maximum details level of orthophotoplans (0.5x0.5 meters), in order to highlight the subsistent farming system in small plots, improperly oriented on slopes. Also, to highlight the changes that have occurred on land use, an estimation was performed of the natural expansion of forests compared to the evolution of population and forest dynamics area between 1772 and 2010. To emphasize the need for reforestation, we carefully analyzed all the morphographic components and their influence on the use of land. The exploitation of GIS techniques and the use of aerial photos allow the diachronic analysis of large land surfaces. This analysis allows comparing the current land use with the natural land cover and emphasizing the existing discrepancies and the potential imbalances. Any change in the size of an environmental component or in its functions generates imbalances that may lead to a degradation or disorganization of natural systems. The impact of human activities is the most appropriate example. The society initially evolved in equilibrium with the nature, creating its own habitat,

appropriate to the needs of each stage of development, but the human pressure progressively increased, forcing the relationship with the natural environment. The perspective of globalization creates a more complicated context, but it is easy to estimate that after thousands of years of struggle for knowledge and mastery of natural forces, the society is obliged nowadays to fight against problems whose responsibility belongs to the humanity itself.

GCG02 - Villes et ports méditerranéens dans la globalisation

Sebastien Antoine (Université de Bourgogne)

"La position de la ville portuaire dans les différentes chaînes et réseaux de production, ainsi que la manière dont ces derniers s'inscrivent dans la "ville globale", comprise, suivant Peter Taylor, comme un ensemble de villes inter-reliées par des firmes de services avancés aux entreprises, n'est pas bien connu. Si les villes portuaires cherchent, en général, à développer des services avancés reliés au transport maritime, du point de vue de la ville globale, les services avancés de très haut niveau sont associés à une économie d'urbanisation et non pas de spécialisation. Autrement dit, une grande ville a vocation à être reliée à une autre grande ville plutôt qu'à un port ou une industrie particulière. Ce travail propose d'évaluer la diversité, ou, au contraire, la spécialisation dans le transport et la logistique, du secteur des services avancés aux entreprises dans différentes villes portuaires méditerranéennes, en considérant cette dernière région en voie d'intégration dans la globalisation. Une méthode, développée par le laboratoire GaWC, basée sur la localisation des transactions entre les producteurs de services avancés et les industries clientes de ces services, permet d'articuler les échanges internationaux (commerce, industrie, transport) à la ville globale, et de cartographier des réseaux de villes à différentes échelles (régionale, nationale, européenne et mondiale).

GCG03 - Future Climate Changes under Representative Concentration Pathways using HadGEM2-AO Climate Model

Hee-Jeong Baek (National Institute of Meteorological Research/KMA), Johan Lee (National Institute of Meteorological Research/KMA), Hyoshin Lee (National Institute of Meteorological Research/KMA), Da-Hee Choi (National Institute of Meteorological Research/KMA), ChunHo Cho (National Institute of Meteorological Research)

NIMR/KMA is participating in CMIP5 long term experiments jointly with Met Office Hadley Centre using HadGEM2-AO, which comprises an atmospheric GCM at N96 and L38 horizontal and vertical resolution, and an ocean GCM with a 1-degree horizontal resolution (increasing to 1/3 degree at the equator) and 40 vertical levels. A pre-industrial control simulation with fixed CO₂ concentration of pre-industrial value of 286.3 ppm and 1860 land cover has been run for 1000 years to serve as the initial conditions for historical runs. A historical (1860-2005) simulation is initialized at 500 year from the pre-industrial control and performed using the historical record of anthropogenic changes such as GHGs, aerosols, land cover and natural forcing such as solar and volcanic changes. Then model state at 2005 is used as the initial condition for 4 future RCP simulations for the period 2006-2099. The HadGEM2-AO simulation for of global and annual mean surface air temperature (SAT) well captures the observed multi-decadal variation throughout the whole simulation period, although the simulated SAT is about 0.2° warmer than observations for the period 1860- 2005. The simulated SAT increase over the historical 1860-2005 period is 0.54° which compares the observational based estimate of 0.66° using HadCRUT3. Projected changes during the 21st century are shown as differences from the baseline period (1980-1999) for global surface temperature, precipitation and Arctic sea-ice cover, indices of climate extremes, etc. The RCP2.6/ 4.5 /6.0/ 8.5 scenarios respectively yield global averaged warming of 1.3/2.6/2.7/4.2° and precipitation change of + 2.4/4.3/3.5/4.8% for the period 2080-2099. Future climate changes over East Asia (100-150°E, 20-50°N) are also analyzed. 4 RCPs scenarios show East Asian temperature and precipitation in the 21st century will increase with larger amplitude than global mean. Surface soil moisture over East Asia is projected to decrease in most parts of the region because evaporation will increase with rising temperatures.

GCG04 - The effects of urbanization on the nature of thunderstorms, observations from Southeastern US cities.

Mace Bentley (Northern Illinois University), J. (Tony) Stallins (University of Kentucky), Walker Ashley (Northern Illinois University)

This study examines how urbanization augments warm-season convection among a range of cities in the Southeastern U.S. By visualizing convective development via high-resolution, radar reflectivity and lightning data, we illustrate that demographic and land-use changes feed back to local atmospheric processes and promote local environments conducive to thunderstorm formation. Composite radar data for a 10-year, June-August period are stratified according to specific 'medium' and 'high' reflectivity thresholds. As surrogates for potentially strong (medium reflectivity) and severe (high reflectivity) thunderstorms, these radar climatologies can be used to determine if cities are inducing more intense events. Results demonstrate positive urban amplification of thunderstorm frequency and intensity for major cities. Mid-sized cities investigated had more subtle urban effects, suggesting that the urban influences on thunderstorm development and strength are muted by land cover and climatological controls. The investigation determined that the degree of urban thunderstorm augmentation corresponds to the geometry of the urban footprint.

GCG05 - Promoting Complementary Currencies for Sustainable Local Economies in Ecuador

Erick Brenes (University of Calabria), Javier Felix (Pachamama Foundation)

In 2008, the people of Ecuador established a new constitution that linked economy to the principles of "efficiency, solidarity, sustainability and quality." The longest chapter of the new Constitution, and at its beginning it declares *sumak kawsay* (Quechua for "well being") as the sole aim of the regime of development. Not only are the benefits of development to be distributed, but the means of production as well. This new legal framework has created and outstanding setting for the creation and implementation of complementary currency (CC) projects in the country. Beside this legal opportunity, Ecuador has an excellent country wide network of grassroots organizations that promotes financial inclusion and popular financial methods like credits, savings and solidarity among others. Based on the successful experiences of the Social Trade Organization (STRO) in the Latin American region and with their support, Pachamama Foundation has been supporting (CC) methods and projects to promote sustainable local economies in the country. Along with Pachamama

Foundation one of the regional networks known as REFLA (for the acronym in Spanish for Red de Estructuras Financieras Locales Alternativas) has promoted the implementation of two complementary currency projects in order to stimulate local resilience. The local monetary approach In a first stage, a Pachamama advisor evaluated the financial and administrative capacity of the implementing organization to back and administer the CC. Next, and considering the 'three-dimensional model' developed by the ICLEI for the Agenda 21 Global Policy, developed the feasibility study. Based on the information compiled in the feasibility study, a project proposal was written and socialized among stakeholders. At this point, it was of crucial importance to write the project proposal taking into consideration the local knowledge of the economic, social and environmental stakeholders. This is done in a participatory way with the local partner, assuring full understanding of the scope and limitations of the future project. The approach consists of local applications and combinations of the three methods detailed in table 1. A major feature in almost every project is the transversal use of the CC printed or virtual to re-design local social, economical and environmental relations, where possible in a more sustainable way. While trying to achieve this objective, the local economy will become more stable (resilient) while at least, maintaining production and reducing environmental degradation.

GCG06 - Relationships Between Chironomid Taxa and Lake Depth in Bosten Lake, Xinjiang, China: Results from an In-lake Dataset

Jianhui Chen (Lanzhou University), Fahu Chen (Lanzhou University)

Significant relationship between chironomid distribution and water depth has been recognized for a long time. However, few studies have been done on this topic in arid region - where chironomid community is usually mainly controlled by water salinity. Located in arid NW China, Bosten Lake, the nation's largest inland freshwater lake (1000 km²), gives us a unique opportunity to investigate the chironomid taxa - water depth relationships in arid region. Totally, 41 surface sediment samples from different part of the lake have been retrieved for chironomid analysis, 37 of which contain enough headcapules (?50). The range of water depth is from 4 m to 17 m. 12 taxa with an average abundance of more than 1% are used for further analysis. From visual observation on the percentage-versus-water depth diagram, it is evident that when water becomes deeper, the abundance of 4 individual taxa (chironomus sp1, microchironomus, cryptochironomus and stictochironomus) increases, 4 (Tanytarsus, Polypedilum nubifer, Cricotopus, Psectrocladius sordidellus) decreases and 4 unaltered. PCA

analysis demonstrated that the first axis can explain 76.8% variance of chironomid community. And significant relationship was revealed by correlation analysis of PCA-1 scores and water depths ($R^2 = 0.8495$). For the validation purpose, we have compared the chironomid-based lake level reconstruction to diatom-based water salinity reconstruction. Given that both the lake level and salinity are effective moisture proxies in arid region, the overall agreement of these two reconstructions during the recent past gave confidence about our ecological interpretation. Furthermore, the 4 deep-water taxa and 4 shallow-water taxa found in this study were also labeled as profundal and littoral taxa, respectively, in relevant literature from Europe and North America.

GCG07 - Innovations vs. regional polarisation of Poland's socio-economic growth

Pawel CHURSKI (Adam Mickiewicz University), Joanna Dominiak (Adam Mickiewicz University in Poznan)

Pawel Churski Joanna Dominiak Institute of Socio-Economic Geography and Spatial Management Adam Mickiewicz University Innovations vs. regional polarisation of Poland's socio-economic growth The process of social and economic growth is naturally accompanied by spatial and structural diversity. Lack of uniformity and the numerous accompanying aspects are commonly recognised as the process? characteristics and, on the other hand, the reason for limitations of developmental processes. However, the very fact that the level of growth is diversified in space is not an impediment to the growth. Development is hampered by too large differences in the growth level which may result from the aggravating polarisation; it boosts the growth areas, at the same time stagnating peripheral areas. Similarly, the numerous aspects themselves do not limit developmental processes. Such limitations may stem from too advanced growth diversity with respect to specific aspects or deficits thereof: such deficits in a specific aspect limit opportunities to achieve optimum growth effects in the remaining aspects and the overall growth process. Innovations are among the aspects affecting contemporary diversity in economic growth. Innovations tend to be among the most important factors contributing to the growth of the modern knowledge economy. Economic innovations are a source of regions? competitive advantage and significantly condition the regional diversity in socio-economic growth. The goal of the analysis is to evaluate the importance of innovations in the emergence of growth and stagnation regions in Poland. The research process consists of two stages: Polish administrative units (voivodeships) arranged as economically weak or strong following a cluster

analysis based on the following aspects of socio-economic growth: (1) population and settlement, (2) structure of the economy and the labour market, (3) the technical infrastructure and spatial accessibility, (4) the financial situation and the level of affluence. Stage two consists in identifying the relations between the regional diversification of innovations and the distribution of growth and stagnation regions in Poland. This is achieved by means of canonical correlation. The level of innovations in Polish regions is identified in compliance with the Oslo Manual in the following arrangement: (1) R&D activity, (2) activity for the benefit of innovations and (3) results of innovative activities. The poster is an element of stage one of a research project conducted by the National Science Centre (NN306791940): Socio-economic growth vs. development of economic growth and stagnation areas carried out by a Team including the authors.

GCG08 - Evolution of Romanian Geopolitical Thinking

Dragos Frasineanu (Spiru Haret University), Mihaela Frasineanu (Spiru Haret University), Liliana Guran-Nica (Spiru Haret University)

Evolution of Romanian Geopolitical Thinking Even though not very largely visible on the international scene, because few works have been translated, the Romanian geopolitical thinking may contribute to the development of the field by a whole ensemble of theoretical and applied writings. From a historiographer's perspective, the Romanian geopolitics has passed, during its evolution from a domain of knowledge with quite a limited sphere of interests to a largely opened scientific field, through three stages. The first of these stages began between the First and the Second World Wars and ended in 1945 and was marked by the emergence of the first ideas, concepts and theories, the structuring of first geopolitical research nuclei and crystallizing of what later came into a science; it was a period of accumulation and clarifications. Otherwise said, this first stage can be considered as classical. The marking stones of the Romanian geopolitical thinking during this first stage were in agreement with time specific requirements, the orientation of the studies being purely defensive. Consequently, the main directions aimed to the defense of the newly acquired status of national and unitary state. The response to external threats was given by studies that focused on the continuity of the Romanian people across the Carpatho-Danubian and Pontic territory. The so-called "expansionist" policy of Romania was reflected in geopolitical studies as a wish to identify a position that could be recognized on both regional and continental scales. As compared to other geopolitical schools, that were trying to demonstrate the status of great power of the generating countries or their superiority, The Romanian Geopolitics

was insisting on the defending of the national values. The development of the newly constituted academic discipline during the first half of the 20th century was brutally stopped at the end of the WW II. The political changes Romania suffered after 1945, materialized by a communist regime and the engulfing of the country in the Soviet sphere of influence, have determined the total banning of geopolitics. The veil of "academic total silence" and a deadly "anathema" thrown by the communist regime covered the Romanian geopolitics for a long period of time. The third stage of the Romanian geopolitics development can be considered its "rebirth" and started at the beginning of the 1990s as a consequence of the dissolution of the communist system, recording a strong connotation in the political debates of the time that has finally moved back into the academic field. Nowadays, as like as during its first stage of development, the Romanian Geopolitics can be defined by its national character, since it identifies its priorities in the large number of problems Romania is facing to.

GCG09 - Phenotypical variation in *Leucocytherella sinensis*, Huang, 1982 (Ostracoda) – a proxy for water chemistry in Tibetan lakes?

Sascha Fürstenberg (Friedrich-Schiller-Universität, Jena), Peter Frenzel (Institut für Geowissenschaften), Ping Peng (Institute of Tibetan Plateau Research), Claudia Wrožyna (Karl-Franzens-Universität Graz)

Leucocytherella sinensis is an ubiquitous ostracod endemic to the Tibetan Plateau. Ostracod sampling in about a dozen of lakes in southern Tibet showed this species to be the most abundant one, sometimes up to more than 90 % of the ostracod association. Such low diversity associations are hard to interpret using population ecology alone. A clue to palaeoecology may be environmentally driven phenotypic variation. *L. sinensis* displays several morphological forms, characterised by different grades of node formation and ornamentation on their valves. This feature is so distinct that several junior synonyms were described from this species by different authors during the past 30 years. *L. sinensis* is a member of the ostracod group of Cytheracea known for node formation caused by water chemistry. We assume a phenotypical variability driven by water chemistry for *L. sinensis* also. In order to identify the driving factors, we investigate *L. sinensis* populations from samples representing different water chemistry, water depth, and habitats of selected southern Tibetan lakes. The analysis comprises the grade of node formation (number, size, spines), valve size and shape, as well as the sex ratio of associations. First results show a connection between nodding and conductivity of the ambient water. Surprisingly, nodes are not most common in low conductivity populations but highest within

the beta-oligohaline range. Looking onto Ca^{2+} concentrations, however, highest values are present in the sampled freshwater environments. Ca^{2+} is of crucial importance for osmoregulation, regulating the penetration of water into the body fluid under hypoosmotic regulation. An excess water inflow during moulting of the ostracods may cause blowing up of nodes in the not yet calcified cuticula. Biomineralization of such pathological nodes on the body surface will stabilize and conserve those structures as already known from *Cyprideis torosa*, another cytheracean ostracod with nodes. *L. sinensis* associations of the highest studied salinity (beta-mesohaline range) show rather smooth valves with a reduced reticulation. We assume a combined effect of salinity and Ca^{2+} ion concentration on the formation of nodes in *L. sinensis*. The number of nodes increases as the proportion of noded individuals within the population with decreasing salinity, but a high Ca^{2+} availability reduces the node formation. Together with the smoothed reticulation at high salinities, the nodding phenomenon can be used tracing salinity changes for *L. sinensis* assemblages from Holocene lake sediments. It has to be taken into account, however, that changes in ion composition, especially the proportion of Ca^{2+} ions, may alter the salinity effect. So far, no direct salinity estimation but the detection of trends in the geological past are possible.

GCG10 - Megadrought, population collapse and soil erosion: The role of epidemics in environmental change in central México 400 to 500 years ago

Klaus Heine (Universität Regensburg)

Recently, there has been growing interest in historical megadroughts, arising from a variety of motivations; these include documentation of the past climatic record, impact of such climatic events on past environments and civilizations, the possibility of future megadroughts, and their interaction with the greenhouse effect (Hunt & Elliott 2002, Rees 2005). Here I show that the 16th century Mexican megadrought caused a population collapse resulting in abandonment of cultivated areas with consequences for soil erosion processes and environmental change. The relationship between climate and accelerated soil erosion (sediment yield) in central Mexico was modulated by population fluctuations in the areas of summer-rain-fed agriculture. In the 16th century, in central Mexico a climatically (megadrought) driven epidemic (cocolitzli) caused a population collapse which in turn resulted in an abandonment of cultivated land, reforestation/recovery of natural vegetation and retardation of soil erosion processes. There is no evidence from any central Mexican site that we have

investigated, to suggest that climatic change and/or climatic hazards (e.g. droughts) had had a significant, direct impact on erosion rates.

GCG11 - Summer monsoon history in SE-Tibet displayed in tree ring parameters of *Larix griffithii* and *Juniperus tibetica*

Philipp Hochreuther (University of Erlangen-Nuremberg), Jussi Grießinger (University of Erlangen-Nuremberg), Achim Bräuning (University of Erlangen-Nuremberg)

South- and Southeast Asia is home to more than one third of the world's population, with the monsoon system as the main provider of precipitation. The hydrological dependency and thus vulnerability of the region, in combination with the variability that inherits the system on a year-to-year basis means, as a consequence, great risks to the whole region. The reconstruction of patterns evolved by three different monsoonal branches poses therefore an important and challenging task since spatio-temporal availability of instrumental climate data is sparse in High Asia. Our paleoclimatic approach to disentangle and to reconstruct monsoonal activities in southeast Tibet is tackled by using different dendrochronological parameters. Each is known to react specifically to a set of climatic and environmental parameters. Within this multiproxy approach are time series of tree-ring width (TRW), maximum latewood density (MXD) and stable oxygen isotopes ($\delta^{18}\text{O}$). First results show high synchronicity between ring width and MXD in cases of extreme events, whereas the oxygen isotope variations display long-term variability of summer monsoon precipitation. For the calibration period with instrumental data, the linkage between low ring width, low MXD and increased summer monsoon activity was proven. The established time series also reveal information about global climatic periods of the late Holocene like Little Ice Age (LIA). An additional research goal is to gain knowledge of the behavior of monsoonal temperate glaciers regarding a changing climate. To achieve this, geomorphological and sedimentological data will be combined with dendrochronological material, in order to reconstruct glacial fluctuations and the climatic conditions under which they occurred.

GCG12 - A Study on the Near-Surface Wind Speed Change in South Korea during 1954-2010

Seungho Lee (Konkuk University), Jun Suk Hong (Konkuk University)

The wind is involved in the movement of material as well as has close relation directly or indirectly with other climatic elements such as evaporation,

temperature etc. Besides it has relation with large scale circulation concerned with climate changes. In this study near-surface wind speed change will be analyzed, and discussed whether this wind speed change is the phenomena caused by the urbanization or the change of temperature difference of the continent and ocean due to increasing temperature. The study are used the 14 weather stations (Seoul, Incheon, Gangneung, Ulleungdo, Chupungnyeong, Jeonju Daegu, Pohang, Ulsan, Gwangju, Busan, Mokpo, Yeosu, Jeju) in South Korea retaining long term observation data where the 57 years?(1954-2010) data are available. The data are for the monthly and seasonal mean wind speed which is derived from carrying out quality management and homogeneity test. In addition, the changes for the number of days not only with strong wind of more than 14 m/s in maximum instantaneous wind speed but also with calm of less than 0.5 m/s will be reviewed. The trend of wind speed change and the change of the number of days with phenomena related with the wind in the Korean Peninsular region will be reviewed to investigate the effect of climate change on the wind speed change. ""This work was supported by the National Research Foundation of Korea Grant funded by Korean Government (NRF-2010-330-B00278).

GCG13 - The variation characteristics of Ca, Mg, Sr concentrations and the ratios of Mg/Ca, Sr/Ca and Mg/Sr in soil infiltrating water overlying

Furong cave, Chongqing, China, Junyun Li (Southwest University), Wang Jianli (Southwest University), Li Tingyong (Southwest University)

Abstract: In order to track the deposition mechanism of trace elements in the speleothems, a continuous monitoring program was performed in Furong Cave, including the overlying soil. In this paper, the transportation of Ca?Mg'Sr in the soil infiltrating water, which was the transition process from local precipitation to cave drip water, was detected. The soil and soil infiltrating water overlying Furong Cave were sampled from January to December in 2010. The concentration of Ca, Mg, Sr, in soil infiltrating water had been analyzed and the ratios of Mg/Ca, Sr/Ca and Mg/Sr had been calculated too. The data show that the discharge of soil infiltration water approximately corresponded with the local precipitation amount synchronously. Although the residence time of soil infiltrating water influenced the concentrations of Ca, Mg and Sr in soil infiltration water, it affected element Sr more. While, the seasonal variation of biological activities on ground and in soil, together with temperature changes, influenced more on elements Ca, Mg, than that to element Sr. This difference was further

approved by the different correlation between the elements in soil infiltrating water, which with the $R=0.82$ and $R=0.88$ for Mg and Sr, correlated to Ca respectively and $R=0.67$ for Sr correlated to Mg. The concentrations of Ca, Mg and Sr in soil infiltration was increased from the surface layer to the deep layer in the same soil profile. This was due to the increasing interaction between soil water and minerals by the added infiltrating length and the different element concentration of soil minerals through out the soil profile. Because of the different influence on Mg and Sr which induced by the residence time of soil infiltrating water and seasonal temperature variation, there was a negative correlation between the ratios of Mg/Ca and Sr/Ca ($R=0.61$). The peak values of Mg/Sr ratio was presented in the months of July and August, which with the highest air temperature during 2010, and occurred in April too, during which the air temperature was relatively low while the rainfall increased evidently, compared to the rainfall during the period from January to March. It demonstrated that the residence time of soil infiltration water and the amount of precipitation besides air temperature impacted the ratio of Mg/Sr in soil infiltration water. Key Words: Furong cave, Soil infiltration water, Ca, Mg, Sr, Ratio of elements.

GCG14 - Spatial and temporal trends of Climate Extreme Indices in the Caucasus Region

Ina Keggenhoff (Justus-Liebig-University Giessen), Lorenz King (Justus-Liebig-University Giessen), Mariam Elizbarashvili (Tbilisi State University), Nato Gogatishvili (Tbilisi State University)

The mountainous ranges and adjacent lowlands of the Caucasus react highly sensitive to recent climate change. Thus, a change in extreme climate patterns in this region is also very likely. It may lead to an increase in intensity, duration and frequency of extreme climate events and in the risk of hydro-meteorological hazards like droughts, flash floods and landslides. This study analyses recent temporal and spatial trends of extreme temperature and precipitation indices in the Caucasus Region. The daily minimum and maximum temperature data used for this study encompass over 40 station records with observations for the period 1946-1997. Daily precipitation time series from over 80 stations were analysed for the observation period 1940-1991. The 52-year analysing periods were chosen to optimize data coverage for the different climatic zones throughout the study area. Quality and homogeneity testing as well as the trend analysis for 22 precipitation and temperature extreme indices have been processed using the open source software RClimDex 1.0. These Climate

Extreme Indices (CEIs) are approved as core indices by the CCI/CLIVAR/JCOMM Expert Team on Climate Change Detection and Indices (ETCCDI) (<http://cccma.seos.uvic.ca/ETCCDMI>). Additionally, selected indices were investigated regarding decadal space-time patterns and the correlation between altitude and trend intensity per decade across the study area. An increase of minimum and maximum extreme temperature was observed as well as a decrease in the frequency of cold days and nights. Extreme precipitation patterns show an increasing trend especially in heavy precipitation events for most of the stations, which indicates that more hydro-meteorological events can be expected in future.

GCG15 - Endogenous capital of towns as the way to overcome peripheralization (an example of the small towns in Wielkopolska)

Barbara Konecka - Szydłowska (Adam Mickiewicz University)

Endogenous capital of towns as the way to overcome peripheralization (an example of the small towns in Wielkopolska). In contemporary socio-economic conditions endogenous capital, often described as endogenous potential or endogenous resources, becomes an important factor for development of small towns. That is why Polish spatial policy should appreciate the role of small towns, and the significance of sustaining and strengthening their functions in spatial organization of social life. The process of reconstruction and sustaining the economic potential of small towns should be based first of all on the endogenous resources thereof. It will be necessary to support regional self-governments? activities involving local communities and institutions of local development aimed at undertaking common initiatives for local development and co-operation with bigger urban centers (Korcelli 2007, Heffner 2008, National Development Strategy 2007-2015, National Spatial Arrangement Policy until 2033). The aim of this paper is a comparative analysis of employing the endogenous capital in development of small towns. Recently many small towns seek for an idea how to shape new and unique branding leading to greater promotion and eventually development in local tradition and identity. All of these actions should result with overcoming the threat of peripheralization both in local/ regional as well as national/international dimensions. In this paper, the endogenous capital of small towns is identified as local property and production base (economic endogenous capital), natural and landscape resources (natural endogenous capital) and local tradition and identity (social endogenous capital). Analysis comprises the stages of local strategy implementation employing the endogenous capital in broad sense. It is the local self-government, who plays

the leading role in building the local development strategy and creating the town's brand based on endogenous resources. It should be highlighted that also the participation of inhabitants and local organizations or associations is as much important. The role of endogenous capital in small towns? development is carried out on example of small towns in Wielkopolska voivodeship, which is characterized by the largest number of small towns among all Polish regions. The centers are diversified in many ways- due to their geographic location, size and administrative functions. Methodology of research is applied equally to all centres under scrutiny. In the first stage, an analysis of web-sites and official documents such as development strategies and plans have been researched. In the second stage the in-depth interviews with public persons: mayor, representatives of promotion department, members of local associations and organizations have been carried out. Press articles and publications are complimentary to this material.

GCG16 - Future change in mean and extreme temperature indices over the Republic of Korea using high-resolution regional climate model

Kyoungmi Lee (National Institute of Meteorological Research), Hee-Jeong Baek (National Institute of Meteorological Research), Su-Hee Park (National Institute of Meteorological Research), Hyun-Suk Kang (National Institute of Meteorological Research), ChunHo Cho (National Institute of Meteorological Research)

The climate of Korea has experienced a gradual warming throughout the 20th century. Negative impacts of climate change on society and ecosystems are mostly expected to arise from extreme events. The changes in extremes have impacts on human activities such as agriculture, human health, urban development and planning and water resources management. The behavior of these extremes can be quite nonlinear. Therefore, it is important to examine changes in frequency and magnitude of climate extremes as well as changes in the mean state. This study focused on the spatio-temporal changes of temperature indices over the Republic of Korea using daily mean, maximum and minimum temperature data from a regional climate projection at 12.5km grid spacing. Seven temperature-based indices are selected to comprehensively consider the frequency and intensity of extreme events. In addition, the linear trend method is used to detect the statistical significance of trends in these indices. The Arcgis9.3 software was used to analyze the changes of spatial distribution. The regional climate model (HadGEM3-RA) reproduced by National Institute of Meteorological Research (NIMR) was nested in HadGEM2-AO (a

GCM of Hadly Centre). HadGEM3-RA simulations projected climatic changes under the IPCC RCP scenarios. A reference (1971-2000) and a future climate (2070-2099) time slices are simulated to calculate changes in relevant climatic variables. For the validation of the reference simulation covering the period 1971-2000, we used the climate observations from 57 stations with long-term time series and few missing data maintained by the KMA (Korea Meteorological Administration). Based on the validation of a reference simulation against a dense network of station observations, the model reproduces the PDF of daily maximum and minimum temperature distribution reasonably well. The temperature indices show overall good agreement with those from observations. Indices based on daily minimum temperature show a considerable change towards warmer climate conditions while indices based on daily maximum temperature do not reveal any distinct trend, implying an asymmetric response of daily minimum temperature and daily maximum temperature to global warming. In the future projection for the 21st century, the degree of warming is sharply accelerated. The hot days and tropical nights at the end of the 21st century is expected to have much higher values than the present (1971-2000), while frost days are projected to decrease noticeably. In addition, the decreases of heat degree days and increases of cooling degree days are projected due to rise of temperature. In the future, the most areas of Korea except for Taebaek Mountains are projected to include in the subtropical climate region. * This research is supported by a project, ""NIMR-2012-B-2"".

GCG17 - A land use switching model under climate change in perennial crop industry

Sangjun Lee (Michigan State University), Jinhua Zhao (Michigan State University), Suzanne Thornsby (USDA Economic Research Service)

Farm income will be at risk if crop yield declines or fluctuates greatly under climate change. Among many potential adaptation options, land use switching is one of most widely acknowledged strategies with farmers seeking the land use which maximizes profit. Land use conversion includes multiple layers of cost and uncertainty. These barriers are inherently greater for perennial crop production where land use change often requires significant investment or establishment costs and the investments are often irreversible. Furthermore, future returns from current and alternative uses are typically uncertain. These characteristics of land use change can be conceptualized using the real option approach, and a growing body of literature has employed this approach to examine land use change or production restructuring problems in agriculture. Traditional real

option modeling, which relies on continuous stochastic processes, may not capture the extreme events underlying climate change impacts on agriculture. Moreover, impacts of climate change on yield are highly nonlinear, potentially resulting in drastic yield declines beyond certain climatic thresholds. These fat-tailed uncertainties are not well identified by standard continuous stochastic processes (e.g. geometric Brownian motion) which are typically employed in real option modeling. We developed a real option land conversion model under climate change using Lévy processes, which are a natural extension of Brownian motion. Specifically, we assume a grower's profit stream to be a mixture of jumps with Brownian motion with drift. While Lévy processes can incorporate the heavy tail phenomena into the real option modeling, these models are highly intractable to obtain numerical approximations as well as analytical solutions. In order to circumvent this, we employ spectrally negative jump diffusion with Poisson-arrival and exponential-size jump distribution, which can approximate a fairly flexible class of the Lévy processes. Since an exponential distribution has a higher peak and fatter tail than the corresponding normal distribution, it can better capture heavy-tail phenomena. When the profit stream follows a geometric Lévy process as a special case, our model allows for analytical expressions for optimal switching thresholds. Our preliminary results indicate that a drastic drop of return under a current land use may induce an early land conversion to an alternative land use which is less vulnerable to climate change. Hence, our model suggests that it is optimal to adapt earlier rather than later and that intense and frequent jumps will invoke early actions. The model was evaluated using the tart cherry industry in Michigan (USA). Tentatively, this empirical application suggests that the proposed model fits the example industry well and can be extended to other industries which have similar characteristics.

GCG18 - Analysis of climate change in selected regions with tart cherries orchards in Central Europe and Michigan (USA) based on regional climate model simulations

Malgorzata Liszewska (Interdisciplinary Centre for Mathematical and Computational Modelling), Krystyna Konca-Kedzierska (Institute of Meteorology and Water Management), Julie A. Winkler (Michigan State University), Pang-Ning Tan (Michigan State University), Zubin Abraham (Michigan State University), Perdinan Perdinan (Michigan State University), Sharon Zhong (Michigan State University)

Potential climate change was analysed for several areas in Poland and Michigan (USA) where commercial tart cherry production is a major component of the

local economy. We used results of regional climate model simulations carried out in the frame of the ENSEMBLES EU project for Central Europe and as part of the NARCCAP project for Michigan (USA). Verification analysis for temperature and precipitation was performed for the reference period of 1971-2000. European simulations with boundary conditions from the ERA40 re-analyses were compared against the EOBS gridded data, and North American simulations driven by the NCEP re-analysis were compared to North American Regional Reanalysis and to observations at individual climate stations. To illustrate the pattern similarity between the considered set of models/simulations and observations, Taylor diagrams, portrait charts, as well as the climatic diagrams of Walter & Lieth are presented. As expected, there is much better agreement for the temperature fields than for precipitation. Simulated temperature correlates with observations at the 0.95 to 0.99 level for Central Europe. Similar results are seen for the NARCCAP simulations for Michigan. Changes in climate parameters in future periods up to 2050 and 2100 (for Poland) and 2041-2070 (for Michigan) were assessed. Also demonstrated are climate indexes for the regions: frequency of dry and wet days, iced, frost and summer days, growing season length, strong wind days and percentiles. Climate indexes for the future periods are examined with respect to estimates for the reference period.

GCG19 - Le Grand Alger: Vers une nouvelle spatialité entre la métropolisation et les perspectives de développement durable.

Tarek Medjadj (Université de M'sila)

Le Grand Alger : vers une nouvelle spatialité entre la métropolisation et les perspectives de développement durable. 1) Auteur: Mr MEDJADJ Tarek, Maître assistant, université de M'sila, Algérie La métropolisation, en tant que phénomène récent, ses conséquences sont multiple sur l'aménagement des territoires. La « compétition » entre les grandes villes du monde se concrétise jour après jour. Alors, la capacité de tirer le monde des affaires semble le critère économique qui peut justifier ce phénomène. Cependant, les incidents sur la ville et son fonctionnement s'affichent bien dans son niveau de métropolisation. Aujourd'hui, on trouve les grands pôles urbains telles que : Paris, London, New York'etc. accaparent le pouvoir de décision et de finance à l'échelle mondiale. Tandis que, d'autres villes du sud telle que : le Caire, Mexico, New Delhi'etc. ont la même taille mais elles ne remplissent pas les conditions qualitatifs en matière de fonctions métropolitaines internationale. D'autre part, on ne peut pas affirmer que la métropolisation est-elle liée uniquement à la mondialisation. Mais d'autres

facteurs locales peuvent intervenir en tant qu'atouts ou contraintes pour lancer le processus de la métropolisation. La ville d'Alger comme objet d'étude son poids économique, politique et démographique est considérable à l'échelle nationale malgré les pertes et la régression de son rôle sur le plan international depuis quelques années. Elle se retrouve aujourd'hui devant le fait accompli, la nécessité d'adapter son développement urbain avec les normes de développement durable notamment après l'adhésion à l'initiative des villes durable (IVD). Nous voulons s'interroger si cela va dans le sens de renforcer la métropolisation d'Alger. Mais avant de lancer ces hypothèses nous devons faire un diagnostic si les conditions de performances minimales au seuil pour être métropole sont-elle remplies ou Alger figure parmi « les métropoles incomplètes » ?

GCG20 - Drought induced variability of radial increment, carbon isotope composition and wood anatomical parameters of *Fagus sylvatica* in the climatologically exceptional year 2011

Cathrin Meinardus (University of Erlangen-Nuremberg), Volker Raffelsbauer (University of Erlangen-Nuremberg), Timo Hetzer (University of Erlangen-Nuremberg), Achim Bräuning (University of Erlangen-Nuremberg)

From a climatological point of view, 2011 was an exceptional year in Germany: Spring-time was the driest since the record began in 1893. March, April and May were very sunny and showed abnormally high temperatures. During the summer months, temperatures fluctuated strongly, while the amount of precipitation in June, July and August was higher than average. In contrast, autumn, especially October and November, was remarkable dry again. Since the frequency of such climatic extreme years is expected to increase in the near future, it is important to investigate the effects of climatic extremes on forest ecosystems and on individual tree species. Common beech (*Fagus sylvatica*) is one of the economically and ecologically major tree species of central European broadleaved forests. However, it is known from dendroecological studies that common beech reacts sensitive to drought events and responds to severe water deficiency by forming a narrow tree-ring in the current season or in the following year. The future occurrence of common beech at some very dry sites might be endangered under possible future climatic conditions. We investigated *Fagus sylvatica* at different sites along a moisture gradient in northern Bavaria (Southern Germany). In this study we combine several methods to examine how dry periods are reflected in different wood parameters. Changes in radial increment were measured using band dendrometers. By quantitative analyses of

wood anatomy, we evaluated how vessel size and other wood anatomical features are influenced by drought in different phases of the growing season. Another important indicator of drought induced stress to trees is variations of stable carbon isotopes ($\delta^{13}C$) in tree rings, which we analyzed intra-annually to obtain a high temporal resolution. Hence, analyzing the growth reactions of common beech to the climate parameters during the climatically still unusual year 2011 in comparison with years showing average climatic conditions might indicate how *Fagus sylvatica* may cope with changing climate conditions.

GCG21 - Geo-Spatial Analysis of Occurrence and Factors of Vulnerability to Malaria with Changing Weather Patterns in a Traditional Nigerian City

*Olawale Oluwafemi (National Space Research and Development Agency),
Oluwaseun Temitope Oluwadare (National Space Research and Development Agency, Nigeria),
Oludotun Olagundoye (Obafemi Awolowo University Ile-Ife)*

Health and climate have close affinity since antiquity. Several studies have affirmed that climate and weather can affect communicable disease patterns since disease agents and their vectors are distinctly cognizant of climatic variability. This study analysed the seasonality of climate, spatial patterns of malaria occurrence, people's perception of transmission and prevention of malaria, and the factors of vulnerability to malaria in a traditional Nigerian town, Ile-Ife. Questionnaire was used to obtain information on people's perception of malaria. Data on malaria occurrence (2004-2007) was obtained from hospital records. Field observation, questionnaire and satellite imagery were used to ascertain the behavioural and environmental factors of vulnerability to malaria. Ile-Ife town comprising of two LGAs was stratified into the 21 existing administrative wards (neighbourhoods); in which 200 questionnaire were administered to households based on their population. Remote Sensing and Geographic Information System analytical operations employed with ArcGIS 9.2 include land-use/land-cover classification, query, overlay and Inverse Distance Weighted (IDW) using SPOT 5 XS (5m resolution). Data show that there exists spatial variation in the occurrence of malaria with the highest cases recorded at Ilare1 (73), while Yekemi, Akarabata, Okewere1 and Modakeke2 have no reported case. Also, intra-annual variation in the occurrence of malaria shows that highest cases recorded between July and December (230) and it is attributable to high temperature, relative humidity, heavy rainfall, and availability of domestic and peri-domestic sources of mosquito breeding. Chi-square analysis was used to determine people's perception about mosquito-prevention

practices in the study area. Three mosquito prevention practises were reported - the use of mosquito repellent (30%), insecticide (20.5%) and bed-net (7.5%). Also, 63.5% of respondents have a wrong knowledge of mosquito breeding. Some observed environmental and behavioural factors make people vulnerable to malaria; for instance, 57.5% of households have temporary pools of water and water containers favourable for the breeding of mosquitoes around their dwellings. Also, 56.5% of the housing units surveyed do not have good drainages and 62.5% with no proper means of refuse disposal. The study concludes that the occurrence of malaria varies over space, and that certain environmental and behavioural factors make people vulnerable to malaria. Also variability in weather and climate greatly influences the seasonality of malaria transmission. Hence, malaria prevention efforts should take cognisance of spatial peculiarities as well as access to resources. Key words: Geo-spatial; climate change; prevention; malaria occurrence; Nigeria.

GCG22 - The International Urban System between Korea and Japan in Terms of Enterprises Alliances (1990-1995)

Jonghuyn Park (Hosei University)

The urban system consists of node and linkage, which are indispensable to study the changing process of the urban system. This study examined interurban linkages in the international urban system between Korea and Japan through interfirm alliances during 1990-1995. The data used in this study were obtained from the three major economic newspapers in Japan published by Nihon Keizai Shimbun, Inc., which are The Nihon Keizai Shimbun, The Nikkei Industrial Daily, and The Nikkei Marketing Journal. The results are summarized as follows. 1. According to the indices by the Murayama model, the overall pattern of development of interfirm alliances suggests that : (1) enterprises based in the world cities (Tokyo, Osaka, and Seoul) play the most important role ; (2) the linkages among the other cities are still weak ; and (3) the alliances associated with the enterprises based in Tokyo and Seoul has particularly developed. 2. A discriminatory analysis of relationships between industry group and inter-urban linkages revealed that: (1) within the inter-world city linkages, the alliances of enterprises engaged in various industries developed, especially the machinery manufacture industries; and (2) as regards the inter-nonmetropolitan city linkages, alliances are not found in the industries associated with the producer service, such as banking and insurance, and transport and communications. 3. Various factors have brought about concentration of the alliances among the world cities in Korea and Japan, especially, among the big

business groups (kigyoshudan) located in Tokyo and Seoul, with their strong networks with subsidiary and affiliated firms.

GCG23 - Trade and Social Networks of Informal Cross-Border Traders in the Greater Mekong Sub-region: Strategies for Survival in a Globalising World

Lada Phadungkiati (University of Sydney)

The research examines the form and degree of which globalisation and regionalisation have affected trade operation of informal, cross-border traders especially by creating change in border and cross-border trade governance scheme. Through ethnographic fieldwork, it investigates trade and social networks as strategies that local people use to overcome difficulties and benefit from opportunities that created by these processes. Increased regional economic integration in the Greater Mekong Sub-region (GMS) reinforced by ASEAN Free Trade Area (AFTA) has created several changes in cross-border trading activities. Firstly, governments have promoted trade liberalisation through initiatives aimed at facilitating and streamlining cross-border trade. Improvements in transport infrastructure and the removal of trade barriers, for example, have contributed to significant increases in cross-border trade in the GMS. At the same time, however, governments have attempted to regularise and channel flows of trade. This blend of trade liberalisation on the one hand, and increased regulation and formalisation of trade on the other, characterises a new phase of border governance in the GMS. At first sight, it appears that male-dominated, large-scale, cross-border traders who use formal trade channels are the winners in this new trade landscape, while female-dominated, informal cross-border traders who usually conduct trade in smaller scale are the losers. However, there is evidence that a significant number of informal cross-border traders survive and are doing well. Furthermore, there has been a continuous inflow of newcomers into the market. Various authors highlight that networks between cross-border traders and kin and non-kin actors are essential to their survival. However, most of these studies do not provide a complete picture of these trade networks and relationships. Gender relations within networks are rarely given attention, and most studies do not place informal cross-border trading within the context of globalisation and regionalisation. The research use Thai-Lao border at Mukdahan and Savannakhet Provinces of Thailand and Lao PDR as a case study. This area has been selected as it has been one of the main border crossings between Thailand and Laos since many decades. Since 1998, the area has regained importance as an important node in the so-called

'East-West corridor' in the GMS, promoted by the Asian Development Bank and other regional players. As a result, trade and social relations have been changing rapidly in the area. In-depth ethnographic fieldwork gives insight into the strategies used by old and new actors in the area to adapt to these changes.

GCG24 - Indian Summer Monsoon Variability and its Physical Mechanisms in the last Millennium

Stefan Polanski (Freie Universität Berlin), Franziska Hanf (Freie Universität Berlin), Daniel Befort (Freie Universität Berlin), Franziska Menzel (Freie Universität Berlin), Ulrich Cubasch (Freie Universität Berlin), Gregor Leckebusch (University of Birmingham)

The last Millennium is the best documented climate period affected by variations in external forcing and an internal variability in the highly nonlinear climate system. According to that the Indian Summer Monsoon and its high variability on different time scales plays an important role, studied in the interdisciplinary HIMPAC project (Himalaya - Modern and Past Climates). In order to understand the forcing mechanisms, feedbacks and amplifiers concerning monsoon variability of the last 1000 years, the five ensemble members of the full forced simulation of the Millennium experiment (Jungclauss et al., 2010), using the coupled COSMOS Earth System Model (ECHAM5/JSBACH-MPIOM/HAMOCC) in a T31L19 spatial resolution, have been statistically analyzed to detect strong wet and dry periods of monsoonal rainfall due to interannual rainfall anomalies and special monsoon indices within the South Asian monsoon region. Later the selected periods of extreme rainfall events have been simulated in a higher spatial resolution with the uncoupled atmosphere version of COSMOS Earth System Model (ECHAM5) in a T63L31 resolution. The focus is on the monsoon variability of 200-years-long time slices within the Medieval Climate Optimum (900-1100 AD), the Little Ice Age (1500-1700 AD) and the Preindustrial (1800-2000). A comparison with paleoclimatic reconstructions from Dandak and Jhumar cave record (Sinha et al., 2011) helps to verify the model results, and the model has been used to check the consistency of the proxy data. In addition high resolution regional climate model simulations with COSMO-CLM will be carried out for the selected time slices driven by the ECHAM5 simulation results.

GCG25 - Changement climatique et dynamique de la végétation dans les Andes du Chili central, depuis le milieu du XXe siècle:

L'exemple de la Vallée de Yerba Loca

Jorge Quense (Universidad Catolica de Chile)

Les milieux oroméditerranéens sont considérés comme particulièrement sensibles aux changements climatiques. Deux questions sont posées dans ce contexte : quelles sont la nature et l'ampleur des modifications climatiques à l'échelle régionale (climat et enneigement) au Chili central, depuis les années 70 ? Quels sont les changements de la végétation en montagne (dans la tranche d'altitude 1.500 - 2.500 m), en particulier au niveau de la limite supérieure de la forêt à *Kageneckia angustifolia* ? Les données climatiques enregistrées les 30 dernières années aux stations d'El Yeso (2.500 m) et de Los Bronces (3.500 m), montre une croissance d'environ 1 °C pour la température moyenne annuelle, réchauffement plus marqué à El Yeso, au niveau des températures minimales. Pour l'enneigement, il est montré une haute variation interannuelle de la couverture de neige et une élévation de la limite de la neige durant les dernières décennies, d'environ 300 m. Ces résultats, sont accompagnés d'une augmentation faible du NDVI. Au niveau de la vallée Yerba Loca, l'étude diachronique de l'écotone supraforestier montre des transformations vers une augmentation de la superficie des espaces forestiers et leur densification.

GCG26 - Dating coastal landforms in Central Chile by cosmogenic nuclides: In situ ¹⁰Be ages of a wave-cut platform and a depositional marine terrace

Gilles Rixhon (University of Cologne), Helmut Brückner (University of Cologne), Tibor Dunai (University of Cologne), Dieter Kelletat (University of Duisburg-Essen), Simon Matthias May (University of Cologne)

Cosmogenic nuclide dating significantly evolved during the last two decades. It was applied to glacial geomorphic settings in most cases, providing a reliable temporal framework for the timing of the deglaciation in many parts of the world. By contrast, the potential of using cosmogenic nuclide dating in the context of coastal environments was hitherto disregarded. Although in particular marine terraces may record the complex interplay between Quaternary sea-level fluctuations and active tectonics, they were barely investigated with this dating technique. Provided that reliable ages for their formation are available, they allow inferring long term uplift rates in coastal areas. However, dating Pleistocene marine terraces (MIS 5 or older) remains challenging since conventional dating

methods (¹⁴C, U-series, ESR...) all have their specific limitations. In this contribution we explore the potential of in situ-produced cosmogenic nuclides in the littoral environment by dating two Pleistocene coastal landforms in northern semiarid Central Chile, found at comparable altitudes above mean sea level, but formed by the interplay of different processes: a wave-cut, abrasive marine platform and a depositional marine terrace. Recently, Saillard et al. (2009) published ¹⁰Be exposure ages for a sequence of 5 wave-cut platforms in the Altos de Talinay, based on quartz-rich surface samples. However, such surface samples and the resulting exposure ages are highly sensitive to denudation processes, which might have been significant during more humid periods throughout the Pleistocene. Thus, in this study, the sampling strategy comprised depth profiles, allowing for constraining the evolution of ¹⁰Be concentration with depth and, importantly, the determination of both exposure times and denudation rates. From the sediments of the depositional marine terrace, we collected 6 quartz-rich samples (i.e. quartz pebbles or gruss from weathered granite boulders) from the surface to a depth of 3 m. From the erosive marine terrace, we extracted 6 bedrock samples from the Holocene cliff (from the subsurface down to a depth of ~10.5 m), where quartz veins cropped out at different levels within folded micaschists. Since the bedrock was directly sampled, the latter sampling technique avoids problems with inheritance (i.e. nuclides accumulated prior to the exposure episode), which may interfere in our sediment samples from the depositional terrace. This study, therefore, provides an interesting methodological comparison regarding (i) the sampled material (bedrock and sediment), and (ii) the forming process, and may help to advance the cosmogenic nuclide dating technique. Reference: Saillard, M., Hall, S.R., Audin, L., Farber, D.L., Hérail, G., Martinod, J., Regard, V., Finkel, R.C., Bondoux, F., 2009. Non-steady long-term uplift rates and Pleistocene marine terrace development along the Andean margin of Chile (31°S) inferred from ¹⁰Be dating. EPSL 277, 50-63.

GCG27 - Microfaunal investigations in the Quebrada Pachingo coastal swamp (Bahía Tongoy, northern central Chile) – Late Holocene environmental changes and their potential causes

Juliane Scheder (University of Cologne), Simon Matthias May (University of Cologne), Anna Pint (University of Cologne), Helmut Brückner (University of Cologne), Dieter Kelletat (University of Duisburg-Essen), Gilles Rixhon (University of Cologne)

Chile belongs to one of the seismo-tectonically most active areas of the world. Moreover, its coastline is directly exposed to the influences of (i) the Humboldt Current, causing aridity in the north, (ii) the Westerlies, responsible for remarkable rainfall and humidity in the south, and (iii) the El Niño Southern Oscillation (ENSO), resulting in a high climatic and, consequently, geomorphological variability. The northern part of the central Chilean coastline provides few geological archives suitable for the study of Holocene environmental changes. By means of the microfaunal analysis of a sediment core from the Quebrada Pachingo coastal swamp (Bay of Tongoy, central Chile; 30°18'11" S; 71°33'49" W), this contribution intends to detect late Holocene palaeoenvironmental changes and aims to discuss their potential causes. Situated in the transition zone between the hyper-arid northern and the humid southern part of Chile, the study area is assumed to be particularly sensitive to late Holocene climatic variations. In addition, the high seismo-tectonic activity along the Andean subduction zone involved significant vertical crustal movements, resulting in the formation of uplifted marine terraces and beach ridges throughout the Pleistocene [1]. Ongoing coastal uplift during the Holocene [2] is reflected by the succession of fluvial terraces close-by. Possible earthquake-related tsunami events are assumed to have provoked changes in late Holocene palaeoenvironmental conditions of the coastal marsh of the Quebrada Pachingo as well. According to variations in the occurrence of different ostracod species and their characteristics, significant environmental changes took place in the study area within the last millennium. At around 1000 cal AD, a coastal brackish water body characterized the Quebrada Pachingo river mouth. After ~1000 cal AD, palaeoenvironmental conditions were suddenly dominated by a freshwater habitat. Later, salinity again gradually increased, suggesting a recovery of the marine influence in the coastal swamp. It is assumed that either a rapid coastal uplift due to a major earthquake or a severe flooding event caused the described change of the microfaunal association. Although intercalating sand deposits within the sedimentary succession may suggest tsunami inundation, they could not definitely be verified as tsunamites

due to the lack of marine faunal elements within the strata. [1] Pfeiffer, M., Le Roux, J.P., Solleiro-Rebolledo, E., Kemnitz, H., Sedov, S. and Seguel, O., 2011. Preservation of beach ridges due to pedogenic calcrete development in the Tongoy palaeobay, North-Central Chile. *Geomorphology* 132(3-4), 234-248. [2] Ota, Y. and Paskoff, R., 1993. Holocene deposits on the coast of north-central Chile: radiocarbon ages and implications for coastal changes. *Revista Geologica de Chile* 20(1), 25-32.

GCG28 - Shaping the Territorial Cohesion – the example of Wielkopolska

Katarzyna Szkudlarek (Adam Mickiewicz University)

A process of integration with the European Union can be regarded as one of the most important causes of the widespread interest in the regional development in Poland. The European Union seeks in its regional policy to increase the level of cohesion in three dimensions: economic, social and territorial. Each of these dimensions is analysed at the level of states and regions, such as NUTS II (in Poland - 16 voivodeships) and NUTS III (in Poland - 66 subregions). It is assumed that the increasing cohesion may lead to improvement in competitiveness of the regions of the European Union. Moreover, it should be noted that the emphasis is increasingly on stimulating endogenous development by providing support to areas of comparative advantage rather than compensating regions for disadvantages (Fifth Report on Economic, Social and Territorial Cohesion, 2010). When Poland joined the EU on 1st May 2004, all Polish regions were below the threshold of 75% of the EU average in gross domestic product (GDP) per inhabitant. As a less developed country Poland has become one of the main beneficiaries of the financial tools of EU regional policy, which include the Structural Funds and the Cohesion Fund. It must be emphasized that the main source of funding for regional policy in Poland are the EU funds. The EU financial perspective 2007-2013 is first full period of implementation of regional policy in Poland. The creation of sixteen separate Regional Operational Programmes is indicative of partial decentralization of development policy in Poland in 2007-2013. The aim of this presentation is to assess the impact of realisation of regional policy on the shaping the territorial cohesion of Wielkopolska voivodeship in years 2007-2011. In addition, an attempt has been made to diagnose the role of Poznań agglomeration in this process. The research procedure is composed of three stages. In the first, an operational definition of territorial cohesion is given, which allows to systematise projects co-financed from the EU funds over the years 2007-2011 by criterion of

intervention direction (within each of three dimensions of cohesion: economic, social and territorial). This evaluation has been based on the analysis of projects conducted in the Regional Operational Programme For Wielkopolska 2007 - 2013 (WROP), both the completed ones and those in progress. WROP is the main instrument of the regional policy in Wielkopolska. It makes it possible to determine the directions of intervention granted from the EU funds and outlays devoted to increasing territorial cohesion in Wielkopolska. In the second stage, selected diagnostic measures for territorial cohesion are subjected to effectiveness analysis (based on the product and result indicators). Then, the empirical results make it possible to assess the real impact of intervention granted from the EU funds on the territorial dimension of cohesion in Wielkopolska.

GCG29 - Local Assessment of Urban Vegetation in the Context of Global Climate Governance

Jan Tigges (Humboldt-Universität zu Berlin), Tobia Lakes (Humboldt Universität zu Berlin), Patrick Hostert (Humboldt Universität zu Berlin)

To date discussions move ahead on carbon regulation towards mitigation of climate change. To a great extent such global change is analyzed in the perspective of its local effects. Whereas recent research mostly disregards the opposite point of view concerning the importance of local urban vegetation in the context of adaptation and mitigation strategies of global climate change. In the matter of climate relevant functionalities of carbon storage, urban vegetation has recently gained more attention in the role of a regulating ecosystem service. The assessment of such service is challenging as field measurements of vegetation lack up-to-dateness and a consistent area-wide basis. Moreover field measurements do not offer a unique representative value of an ecosystem service as it is manipulated by different stakeholders. Stakeholders differ in their assessment of a service due to individual interests and different scales of acting. Therefore the aim of this case study is to discuss a remote sensing and modeling approach to assess urban vegetation in the city of Berlin (Germany) as a proxy for carbon storage concerning different stakeholders? strategies on climate change. The discussion considers different stakeholders? interests, possibilities and problems of adaptation and mitigation of global climate change, among those are such public awareness, planting strategies, green economics as well as addressing public and private space. A remote sensing and modeling-based approach addresses measurements of carbon storage of urban trees to provide a spatial up-to-date and consistent area-wide basis. This basis of field

measurements is confronted with urban stakeholders considering their individual evaluation of urban vegetation as a climate regulating service. Regarding the evaluation is to first say that a high quantity of urban vegetation might act as a global carbon sink itself. The second is to point out that urban vegetation offers various ecosystem services which act as complementary climate regulators, as cooling & shade of trees can reduce energy consumption of urban housings as well. The third is to say that the urban share of total carbon storage of urban vegetation might be low. Nevertheless urban stakeholders can function as a seedbed inducing and diffusing socio-ecological and socio-economic behavior towards climate governance on a global scale.

GCG30 - Coastal onlap and landward migration of a Holocene barrier sandbar (Amrum Kniepsand/ German North Sea) investigated through GPR and sedimentological data

Tanja Tillmann (Goethe University), Jürgen Wunderlich (Goethe University)

Barrier sandbars and barrier islands are geologically young, highly dynamic and represent a complex coastal system that includes a number of different but closely related sedimentary depositional environments with geomorphologic elements of varying origin, genesis and evolution. Barrier sandbars are exposed ridges of sand that are built offshore by wave action. The so-called Kniepsand on the island of Amrum represents one of the widest beaches in Europe. The Kniepsand originally belongs to a system of sandbars lining the North-Frisian coast. Some of these sandbars are already attached to the mainland (e.g. St. Peter-Ording-Sand and Westerhever-Sand). The offshore sandbars of Japsand, Norderoogsand and Süderoogsand are located in front of the western coastline of the North-Frisian Island and the Halligen and fulfil the function of natural coastal defence dissipating the energy of the incoming deep-water waves of the North Sea. Barrier sandbars are usually investigated through the use of aerial photos and borehole data. Therefore, the processes of evolution and the internal structure of sandbars are often unknown. That is why this study chooses an integrated approach using high-resolution ground-penetrating radar (GPR) and sedimentological analyses of shallow sediment cores drilled at selected sites along the radar profiles. A geophysical Survey Systems Inc. radar system, SIR-2000 coupled with a 200 MHz antenna, was used. Based on these data a sedimentary model was generated that describes the process of barrier sandbar migration and the attachment to the Pleistocene island core. According to historical maps and nautical charts of the sixteenth and seventeenth century, the Kniepsand used to be a solitary barrier sandbar located well in front of the

island's west coast without any connection to its Pleistocene core consisting of Saalian moraine deposits. The presented model shows how the Kniepsand has welded onto the Pleistocene island core of Amrum. Before the barrier sandbar was connected to the island, tidal flat deposits had been accumulated in a low energy environment. Tidal flat deposits show a general coarsening upward trend and turn into overlying coarser grained beach deposits. Old cliffs formed through several storm surges are also preserved in GPR data. Normally, the former structure of the barrier sandbar will be lost as its sediment is welded onto the island core to form the contemporary sandy beach. The study indicates that GPR-data make it possible to reveal the structure of the former sandbar and to figure out and understand the barrier sandbar attachment process.

GCG31 - Calibration and validation of the hydrodynamic model DYRESM to estimate future impacts of climate change on aquatic ecosystems

Stefan Weinberger (University of Munich), Mark Vetter (University of Munich)

Modelling the thermal structure and heat content of lakes in climate change is getting more and more important as a fundament for ecological lake models. Various studies demonstrated the strong impact of climate change on environmental systems, including the ecosystems of lakes. Anyhow there are several gaps in understanding the complex interaction of atmosphere and hydrosphere as well as in modelling their impact on aquatic ecosystems. When using a hydrodynamic lake model for ecological studies, the careful calibration and validation is an essential condition. The results of the validation process and the following statistical analysis will be presented in this contribution. Afterwards the hydrodynamic model is suitable to estimate future trends in the development of the lake's thermal characteristics, e.g. vertical thermal stratification, Schmidt stability or thermocline shift, which have a significant influence on the aquatic ecosystem. Therefore it is advisable to use data of existing regional climate models, e.g. REMO on the basis of different IPCC emission scenarios. Finally the hydrodynamic model can be coupled with an aquatic ecological model to support the future water quality management. We are working with the one-dimensional hydrodynamic model DYRESM (Centre for Water Research 2010), which is a process based model using a Lagrangian layer scheme. It was established successfully in different investigation areas around the world, in Middle Europe for example at Lake Constance. The input parameters of the model are provided by the meteorological network of the DWD and the Bavarian environmental agency. The calibration covers a period between 2001 and 2007,

the validation between 2007 and 2011. As study object we selected the pre-alpine, 83 metres deep, currently dimictic Lake Ammersee, which is located 30 km south west of Munich. This lake was chosen due to the fact that in our opinion it could be representative for many other lakes in the northern foothills of the Alps considering their similar geogenic, climate geographic and limnologic character. There is no other lake in Upper Bavaria where such a large calibration and validation of a hydrodynamic model was achieved. To quantify the current model error when comparing the modelled data with the measured data during model calibration and validation at Lake Ammersee, we calculated the root mean square errors (RMSE), mean absolute errors (MAE) and coefficients of determination in different depths. This statistical analysis we will also present in this contribution.

GCG32 - PM10 concentrations in Bavarian cities and their relation to local meteorological conditions and large-scale circulation types

Claudia Weitnauer (University of Augsburg), Christoph Beck (University of Augsburg)

PM10 concentrations in Bavarian cities and their relation to local meteorological conditions and large-scale circulation types Claudia Weitnauer¹⁾, Christoph Beck¹⁾, Jucundus Jacob¹⁾ ¹⁾ Universität Augsburg, Institut für Geographie, Universitätsstraße 1a, 86135 Augsburg, claudia.weitnauer@geo.uni-augsburg.de Numerous studies have shown that local PM10 concentrations depend not only on PM10 emissions but as well on the local meteorological conditions (e.g. air temperature, windspeed, precipitation, global radiation) and the large-scale circulation characteristics, as for example reflected in occurrence frequencies of circulation- or weather types (e.g. Beck 2011). This has become evident for instance during the exceptionally warm and dry year 2003 - with significantly increased frequencies of anticyclonic circulation types over Central Europe - when critical thresholds of daily mean PM10-concentrations ($> 50 \mu\text{g}/\text{m}^3$ on more than 35 days per year) have been exceeded at 140 out of 366 stations in Germany (Umweltbundesamt n. d.). Against this background it can furthermore be expected that possible future climate changes in mid-latitudes, as projected by different global climate models, will in turn lead to changes in PM10 concentrations. In this contribution we present first steps towards the estimation of possible future - climate change induced - variations in local PM10 concentrations in Bavaria. To this end the relationships between local PM10 concentrations in different bavarian cities and local meteorological variables and large-scale circulation characteristics respectively are analysed during the period

1979-2010 on the basis of daily PM10 and meteorological data and daily circulation types by means of multiple linear regression models and synoptic downscaling approaches (e.g. Philipp et al.2010). Based on these initial analyses it is further intended to develop robust downscaling models for estimating possible future - climate change induced - variations in local PM10 concentrations in Bavaria from scenario runs of global climate models. References: Beck, C. (2011): Monthly mean PM10 concentrations in Augsburg (Germany) and their relation to large-scale atmospheric circulation types. Geophysical Research Abstracts Vol. 13, EGU2011-12920. Philipp, A., J. Bartholy, C. Beck, M. Erpicum, P. Esteban, X. Fettweis, R. Huth, P. James, S. Jourdain, F. Kreienkamp, T. Krennert, S. Lykoudis, S.C. Michalides, K. Pianko-Kluczynska, P. Post, D.R. Alvarez, R. Schiemann, A. Spekat & F.S. Tymvios (2010): Cost733cat - A database of weather and circulation type classifications. J. Phys. Chem. Earth, 35 , 360-373. Umweltbundesamt (n. d.): Episodenhafte PM10-Belastung in der Bundesrepublik Deutschland in den Jahren 2000 bis 2003.

GCG33 - The Effect of Caspian Sea Level Changes on Bed Rivers Morphology

Mojtaba Yamani (University of Tehran)

Bed Rivers may reflect the influences of erosion, tectonic and climate changes. Meanwhile, a factor perhaps more important role in these changes, the effects of tectonic and base level of rivers estuary. In this study, the role of Caspian sea level changes in the pattern of the channel bed rivers in south of Caspian Sea has been studied. Research problem is that the river beds of the Caspian coastline near the estuary are deep cutting. Purpose is the role of factors on base level changes and geomorphologic changes of the river beds. Digital topographic maps, aerial photos and geological maps have formed physical tools of this research. Detailed field work for obtain of sections and longitudinal profile of river bed and record their locations using GPS and other geometry tools has been done. Data in GIS environment and AutoCAD software are processed. Also, the pattern of river channel based on the findings and theoretical principles of classification and finally, the interplay of the Caspian Sea water level fluctuations and tectonic effects Alborz combined with other data and analysis has been. The results show that short-term changes in water level of the Caspian Sea near the mouth rivers (up to 5 km from the shoreline) to have been affected. This impact in east of Sefidrood river that the Kenik is closer to the beach and coastal plain is wider than the West and Northwest, is more. On

the other hand, the Alborz uplifting against South Caspian Plate subsidence comes up in the drainages and about 10 km distance after leaving the mountains to be influenced and deep rivers in this area has been.

GCG34 - Measuring superficial changes of glaciers as an evidence for global warming (Central Alborz, Iran)

Mojtaba Yamani (University of Tehran)

At the present time, among all Quaternary landforms, mountain glaciers present more clear evidence of global warming. Increase in average annual temperature resulted in ascension of snow lines and decrease in area extent of glaciers located in cirques and mountain valleys. The glacial evidences make the exact measurement possible. In this research Alborz mountain glaciers in the North of Iran are considered as the case study. Several cirques can be observed adjacent to the peaks above 4000 meters in this mountain range, with the remained evidences of Late Wurm glaciers. Among them Alamkuh glacier has a length of over 5 kms and is still active. To determine the glacier movement and thaw rate, 15 indices were placed in the surface of the glacier as bench marks (BM). The location and altitude of these indices were recorded by T16 Teodolite. Then during 2002-2008 time interval, measurements were carried out annually at the end of September. The results show that this glacier moves some 220 centimeters annually. Also measurement of surface thaw range of this glacier via BMs and drawing cross sectional profiles show that the glacier has an average depression about 15 to 20 centimeters per year. Moreover, measurement of the distance between the BMs reveals that the area of this glacier decreased in the studied time interval. The results evidently indicate the effects of global warming in the studied area, so that the complete melting of glacier is expectable in the next few decades.

GCG35 - Modeling studies of impact of climate change on vegetation NPP in Poyang lake wetland

Xia Zhou (Guangzhou Institute of Geography), Yingshi Zhao (College of Resources and Environment, GUCAS)

Wetlands are one of the main ecosystems of the earth, and play a key role in global carbon cycle and in global climatic change. In this process, wetland vegetation plays a significant role, because it can fix atmospheric CO2 with high efficiency. While, the impact of climate on wetland vegetation is also a complex process. It will be helpful for understanding and management of wetland through

studying these processes. In this paper, the impact of climate change on NPP was explored using a process-based model in Poyang lake wetland. The model originates from an atmosphere-vegetation interaction model (AVIM) developed by Ji. To improve its applicability in the study area, the AVIM was modified so that its submodules such as the physical process model and plant growth model could appropriately reflect the characteristics of wetland. Three meteorological factors, temperature, precipitation and humidity were selected for single factor analysis. The results reveal that the effects of Meteorological factors on vegetation NPP is non-linear. Temperature has negative impact on the NPP, while precipitation has a positive effect on the NPP. There is a relatively weak correlation between NPP and humidity. While the responses of different types of grassland on climate changes are different. In order to reveal the integrated impact of meteorological factors, the scenario analysis was used. Eight scenarios were simulated based on the changes of the temperature, precipitation and humidity as following, scenario one: +2', +20% and +20%, scenario two: +2', +20% and -20%, scenario three: +2', -20% and +20%, scenario four: +2', -20% and -20%, scenario five: -2', +20% and +20%, scenario six: -2', +20% and -20%, scenario seven: -2', -20% and +20%, scenario eight: -2', -20% and -20%. The results show that the impact of Meteorological factors on the growth of vegetation is integrated, and the impact could be changed during the different stages of vegetation growth.

UDC01 - Romanian demographic issues during post-communist period. Case study: Burnas Plain.

Madalina-Teodora Andrei (Faculty of Geography), Florin Vartolomei (Spiru Haret University), Costin Dumitrascu (Spiru Haret University)

In post-communist period, Romania's population has undergone significant changes. Burnas Plain, located in the south, falls into the same trends of national demographic trends. In this studied area were found the changes in population dynamics, both in the terms of number of population, as well as the natural and migratory movement of population. The trends are the decrease in values of demographic indicators. Significant changes are observed in the population by aging population, decrease of the working population contingent (mainly due to international migration), emergence of new minorities that were not specific (eg. Chinese). All demographic changes have led to changes in the social and economic life, thus creating different conditions and new demographic trends.

UDC02 - Craiova – Main Urban Pole within the Development Region South West Oltenia (Romania)

Alina Vladut (University of Craiova), Sorin Avram (University of Craiova), Cristiana Vilcea (University of Craiova)

In the attempt to harmonize the Romanian legislation with the EU legislation regarding the local public administration, the settlement system undertakes some transformations in order to use the funds more efficiently and to achieve the decentralization of the administrative decisions. Even if in terms of theory or rapports sent to EU, statistical data are quantified and rendered at the level of the development region / NUTS II, these regions do not have juridical personality and, consequently, there emerge numerous dysfunctions of the local public administration. This study is focused on the influence of the main urban pole of Craiova at the level of the Development Region South-West Oltenia. This is one of the eight development regions of Romania, covering a surface of 29,212 km² and being composed of five counties (Dolj, Olt, Vâlcea, Gorj, Mehedin'i). Within the settlement system of the Development Region South-West Oltenia, the urban pole of Craiova detaches as the city with the highest rank. The central position within this region played a fundamental role in the development and becoming of the city as the main urban pole of attraction. This research quantifies the effect of Craiova city upon the social-economic and spatial components using representative indicators. In the first stage of this research we established the urban influence area using methods of spatial analysis, in order

to analyses the types of urban attraction. The results of the research outlined the existence of two concentric areas, one of peripheral influence, where the attraction of the urban pole is reduced, and the second one, identified with the metropolitan area, where the urban attraction is strongly felt. Finally, we analysed the spatial dysfunctions by reporting the internal structure of the study area to the community policies regarding territorial disparities.

UDC03 - Urban image features in Craiova municipality, Romania

Amalia Roxana Badita (University of Craiova), Liliana Popescu (University of Craiova)

Despite many changes in the last years, it is known that the urban image can be still measured with the help of landmarks as it was described by Kevin Lynch. However, the city image is increasingly exposed to recent progresses and transformations of infrastructures and land use. This article aims to outline the perception of the urban image at micro- level scale with the help of data analysis resulting from several types of surveys (VPS- Visual Preference Survey, Community Image Survey) conducted in Craiova municipality, Dolj County, Romania. Based on a technique first developed by Anton Nelessen and Associates of Princeton, New Jersey, the community image survey and the VPS (both having similar patterns) represent the process that allows the community to participate in the assessment of its environment and develop a new common vision for the future. By ranking various different images of places, spaces, and land uses, which exist or do not exist, people from Craiova express their perception on the urban image and also what type of community they want to see in the future. The results show that the landmarks presented by the residents of Craiova municipality are those related to the built areas, emerging in this way the issue of a superficial spatial knowledge of the city. Consequently, we propose principles for improving both the sense of place and the sense of time from a new modern perspective.

UDC04 - Périurbanisation et promotion sociale: des cheminements parallèles?

Atika Benazzouz (EPAU), Hassina Cheballah (EPAU)

Si la dynamique urbaine est générale à toutes les villes algériennes, elle affecte bien plus la bande septentrionale et encore plus la région d'Alger. Pôle politique et économique, Alger sécrète et subit son étalement urbain dont l'amorce fut perceptible dès la mise en oeuvre du Plan de Constantine (1959/1963). Ainsi,

entre 1966 et aujourd'hui, son emprise a été multipliée par 5 ; elle passe de 15325,3 hecets à 80900 hecets avec un taux d'urbanisation de 94,67%. Depuis deux décennies environ Alger se dépeuple. A cet effet, pour la première fois de son histoire récente (en 1998), les communes centrales et péri-centrales connaissent un net fléchissement du taux d'accroissement de leur population; cette tendance est confirmée par le RGPH de 2008. Si ces désaffections soulagent ces espaces exiguës, engorgés et surpeuplés elles vont se traduire sur les espaces périphériques par un apport d'une nouvelle population. Les enquêtes menées sur le terrain indiquent que 34,82% de leur population sont originaires des communes centrales d'Alger. Cette mobilité résidentielle motivée,

- Par un foncier rendu accessible grâce à la rétrocession des RFC ou les offres introduites par les particuliers
- Par l'aspiration à plus d'espace et un rapprochement de la nature
- Par le désir d'affirmer et faire reconnaître sa réussite, son statut social, Aura pour conséquences :
- Une occupation des terres agricoles que de nombreux textes officiels ont tenté de protéger en vain ; le monde rural connaîtra un profond bouleversement.
- La conquête et la formation d'espaces périphériques, sans articulations avec le centre urbain existant et sans structuration d'ensemble qui inéluctablement progresse en s'étirant le long des principaux axes de communication.
- Une croissance démographique spectaculaire des communes périphériques du à un exode urbain.
- Une recomposition spatiale et sociale, celle de l'espace urbain mais aussi celle de l'espace rural.

UDC05 - les mutations des tissus centraux et péri-centraux à Alger

Atika Benazzouz (EPAU), Larbi Sidi Moussa (EPAU)

L'adaptation d'une ville aux transformations de société est un processus de développement historique. En Europe, à partir des années 70 du siècle dernier, spontanément mais surtout à la suite d'actions programmées, les tissus urbains et périurbains des principales villes se sont transformés, rénovés, renouvelés. Obéissant en priorité à des impératifs socio-économiques, ces opérations ont concerné des quartiers généralement centraux et péri-centraux dont les tissus ont été profondément transformés. Alger capital d'un pays en transition pluriel offre aujourd'hui l'image d'une ville hétérogène et désordonnée. Elle est la parfaite illustration d'un développement non planifié et mal géré qui a généré l'apparition au sein de certains quartiers en raison d'un entassement de population, de poches de pauvreté et d'exclusion source de conflits, générateurs de violences et destructions. Un examen de la configuration urbaine de la ville révèle un espace divisé en deux entités : un centre et un péri-centre,

plus ou moins organisé, constitué de quartiers d'époque coloniale qui dépérit et se vide et une périphérie de grands ensembles et de lotissements anarchique et en extension permanente. Les quartiers centraux présentent un degré de désorganisation et de vétusté très prononcé ; d'immenses poches oubliées, offrant l'image d'un amoncellement de bâtisses en ruines abritant des entrepôts et/ou de petites unités industrielles dont le maintien en place va à rencontre de toute logique (économique, fonctionnelle et esthétique...). Par ailleurs, les anciens faubourgs de la ville à vocation agricole initiale, en raison de l'extension de la ville, occupent aujourd'hui une position privilégiée, en totale contradiction avec leur contenu actuel, lieu stratégique pour l'implantation d'une éventuelle future centralité de la ville. Faut-il détruire ces quartiers et les reconstruire ex-nihilo? Faut-il au contraire les conserver en les réhabilitant - Aujourd'hui, l'avenir et l'équilibre de la ville impose nécessairement une réflexion approfondie et fondamentale sur le devenir de ces quartiers. La reconquête de ces portions et leur réaménagement peut-il participer à la recomposition des fragments de la ville et permettre de doter ALGER d'un centre en mesure de lui assurer le statut de métropole auquel elle aspire.

UDC06 - Tunisia Election of 2011 and regional disparities

Ali Bennisr (Faculté des Lettres et Sciences Humaines)

The elections of 2011 in Tunisia, showed spatial and social divisions in the country. Two Tunisia emerged from these elections: modern Tunisia and traditional Tunisia. These divisions reflect the regional disparities in the country.

UDC07 - The Border Experience: Tracing the urban journeys of cross-border commuters in the Hong Kong Guangdong border region.

Jonathan Burrow (University of Oulu)

Immigration and passport control is a highly symbolic and regulated experience, which can carry with it feelings of both anxiety and relief for the traveler. This poster will explore the daily experience of cross-border commuters' between Hong Kong and Shenzhen special economic zone in Guangdong Province. Both part of the dynamic Pearl River Delta urban region. For these individuals presenting their identity documents for inspection is part of everyday life. The Hong Kong Guangdong border is an international strength barrier within a rapidly expanding urban region, a barrier that utilizes the latest biometric

technology to identify and determine who can cross it. The daily journeys of cross-border commuters rarely cover at more than a hundred kilometers or take more than an hour but transact two distinct jurisdictions under the eye of a single nation state, a state in which different groups of people are given distinctly different mobility rights at the barrier. Cross-border commuters through their, business, social and education activities are both benefices and servants of the change in systems that occurs as they cross this increasingly intra-urban barrier. Each border commuter's journey and experience is unique and this poster selects a sample of border commuters who's lives show the dynamic nature of the this region and its rapid transformation from agricultural backwater to a global manufacturing centre in a couple of decades. This poster is based on three months intensive fieldwork and in depth interviews conducted in the region for my Masters of Applied Anthropology as Macquarie University in Sydney, Australia. This poster will be built around a map of the urban region, layered with details of the commuters' journeys. As an interactive element, viewers will be able to use their smart phones to scan QR codes on the poster for more extended information about particular points in these commuters' journeys, allowing the viewer to take with them and consider ideas around the border experience on their own journeys home from the congress.

UDC08 - Analysis of Spatial localization in educational equipment for the city of Tome, Chile

Carolina Rojas (Universidad de Concepción), Helen De la Fuente (Universidad de Concepción), Matias Casanueva Lermada (Universidad de Concepción), Constanza Villarroel (Universidad de Concepción)

Tomé is a coastal city of Chile located in the Bio Bio Region just over 32 km of the regional capital Concepción. It has an area of 1495 km² with a population of 55,000 inhabitants, who are unequally distributed in the territory with supremacy of the Urban (87.64%) versus the Rural (12.36%). This striking and uneven distribution of the population will greatly influence the distribution of all types of services and in educational facilities. Tomé has conditions that make spatial distribution of education, must deal with complexities between the dispersion of the population and accessibility to the offer in education. It proposes to work with socio-analysis of the distribution of equipment, which allows comparison of distribution situations between territorial units, which is the first approach to reveal differences in space, in addition to assessing the welfare of the population distribution and equity of resources. For the identification and characterization of patterns of inequality and spatial expression in the municipality of Tomé,

statistical and graphical tools for data analysis were done, applying a set of indicators, alluding to the quality of education of educational institutions to national level as rate student - teacher, SIMCE results, provision of educational and assessment with the inequality index Sergeant Florence, spatial and temporal accessibility, among others. Through this work and its relation to location theory, we understand the educational distribution, there are places that act as a center, gaining a valuable social, symbolic and economic, where large flows of people converge more distant from the center periphery and disadvantaged areas synonymous with accessibility, resource allocation or quality of education as is the case of Tomé. The location-based planning uses the concept of accessibility, because inevitably there will be an unequal geographical access to any public services. This in practice means that some populations are better placed to take advantage or disadvantage imposed by geographical distance. Thus, if the population is most favored, this creates the strengthening of human capital, and social, one of the pillars for sustainable land development and important aspect to consider in developing countries like ours.

UDC09 - Defining two new paradigms in planning

Pablo Coquillat Mora (Universidad Politecnica de Valencia (UPV)), Universidade de São Paulo (USP)

Defining two new paradigms in planning The text proposes to discuss how to set links between two contemporary paradigmatic phenomena: urbanization of the planet and the uncontrolled population growth, emphasizing the necessity of incorporating interdisciplinary new tools to understand and reformulate the urban planning. At the starting point, the analysis attempt to state two new paradigms: overpopulation and urbanization. Through the text of Thomas Kuhn, *The Structure of Scientific Revolutions* (KUHN, 1998), we seek to demonstrate how the current urban planning instruments are inadequate for the definition of existing urban structures. Likewise, it is proposed a review of these instruments and the theorization of different scientific and social instances, and how they must incorporate these new paradigms to the discourse on planning. Secondly, it will be identified the urbanization-overpopulation binomial through data from contrasted sources on current processes of territory occupation, pointing out, mainly, experiences in the developing regions. It will set out the political, economic, social and spatial links established with the new paradigms, primarily pointing to the mechanisms of globalization and the production of capitalist space that generate them. Then, it will be explained the way in which urbanized overpopulation is organized in the territory: the formation of megacities, recurrent

million-plus cities, urban galaxies organization, hermaphrodite structures between the rural and the urban, the systems of chinese regional cities, or the Zwischenstadt ('intermediate city'). All of them will compose a kaleidoscope of references from the successes and failures of recent urban experiences that are being carried out in regions of the Third World. Finally, it will be described the principles on which the planning should be reformulated to incorporate the rules of a new situation which results in increased poverty and inequality, the informality of occupation processes of the territory, the rapid and uncontrolled changes in the production of the space, as well as the new positioning about the climate challenge. KUHN, T. S. A Estrutura das Revoluções Científicas. São Paulo: Editora Perspectiva S.A., 1998.

UDC10 - Méthode de la synthèse trichromatique sans partition en classes: Les résultats d'une application aux pays arabes

Mohsen Dhieb (King Abdulaziz University)

En cartographie, la méthode de la synthèse trichromatique de J. Bertin permet de visualiser la part relative de chacune trio de variables reliées sémantiquement (Bertin J, 1999). La combinaison résultante des trois couleurs primaires soustractives offre des tonalités ternaires changeantes, exprimant ainsi la dominance ou l'effacement, la forte ou la faible représentativité d'une (ou de deux) variable(s). La méthode Bertin est basée sur des paliers de valeurs distincts et discrétisés. Si la mise en classes regroupe en catégories distinctes des objets géographiques ayant des valeurs voisines, elle ne permet pas toujours de saisir les nuances des couleurs. De plus, la mise en classes cumulée au niveau de chaque modalité ou variable peut ne point être fidèle à la position précise de certains objets s'ils sont au bas ou en haut de la classe de valeurs (sur ou sous représentation). Ce sont là des biais qui s'ajoutent aux difficultés de perception des couleurs combinées. Or, nous savons que Waldo Tobler, a expérimenté la méthode de non partition en classes des séries de chiffres, arguant du fait que la non mise en classes permet de représenter la valeur réelle des objets. Pour lever quelques biais de la méthode de la synthèse trichromatique nous avons entrepris de combiner cette méthode avec celle de Tobler, et notamment lorsqu'il s'agit d'évolutions. Notre démarche est étayée à travers une étude du monde arabe. La cartographie analytique et synthétique des variables socio-économiques comme la structure par âge et la structure des activités économiques s'avèrent très utiles pour une meilleure compréhension du positionnement des pays arabes les uns par rapport aux autres. La place de chaque pays dans le continuum de couleurs ternaires, au sens scientifique du

terme, est un bon indicateur de sa structure économique et sociale. Les images résultantes de la synthèse trichromatique non classée offrent une meilleure lecture que certaines représentations classiques et permettent les analyses spatiales utiles. Les différences chromatiques entre les pays ne mettent pas seulement en valeur les décalages, mais aussi, dans leurs nuances, les atouts pour une éventuelle restructuration. Nous pensons mieux étudier les ensembles géographiques régionaux grâce à cette nouvelle méthode cartographique.

UDC11 - Cultural Industries in Xi'an?A 2009 Survey of Spatial

Dongqian Xue (Shaanxi Normal University)

The cultural industries have attracted increasing attention from researchers and policy-makers in recent years'because the research of regional distribution of cultural industries is not only conducive to understanding the development status of the cultural industries in this region, but also is a guidance of government decision-making. After classified the cultural industries in Xi'an, this paper examines more than 1980 cultural industries enterprises in urban area in 2009, then based on the point pattern analysis methods, we obtain the Cultural Industries' concentration index of ten areas through function. According to the present development of Cultural Industries in Xi'an?then the studied region is divided into three types: Core Area, Potential Area and Dispersion Area. Through analysis of geographic concentration and Kernel density, it founds that at present the characteristics of spatial distribution of cultural industries in Xi'an urban area, besides, the different type areas have their special concentration or dispersed mode and the location factors that affect the distribution of cultural industries enterprises.

UDC12 - From Haiti to Brazil – the new migratory flow

Duval Fernandes (PUC Minas), Andressa Faria (PUC Minas)

Brazil has been known as a country of emigration for a long time, once more than 4 million Brazilians lived abroad in the 2000s. With the economic crisis of the central countries, many Brazilians have decided to return to their country of origin and Brazil gets to know the reverse movement, the reflux of its citizens who have returned. At the same time that the return occurs, a new migratory flow begins: the increased immigration towards Brazil. On the northern border the movements have always been unimportant, restricted to the moving of some Brazilians who are in search of easy enrichment with the gold in French Guiana, Suriname, Venezuela or go to Bolivia by taking lands not far from the border.

However, a new flow, of no more than two years has begun to be produced: the immigration of foreigners from the Caribbean, by the border between the countries of the Legal Amazon. They are mostly Haitians seeking a better life away from their country of origin which is the poorest in the American continent and whose social and economic situation was strongly aggravated by the earthquake that struck the country in January 2010, killing more than 150,000 people, culminating in a large number of homeless and reducing to rubble a major portion of the housing and governmental infrastructure, deeply worsening the humanitarian situation of this nation. In the beginning just a few dozen arrived in Brazil, but in March 2011, this number exceeded the thousands and at the end of 2011 the total number of Haitians in Brazil exceeded 4,000 people. The characteristics of this flow are already known and they have arrived in Brazil with well-defined paths. Nevertheless, this is a new situation for the government and the Brazilian society and presents challenges to governance in terms of international migration towards the country. What we propose in this paper is to systematize the information on this new migratory flow, the routes to get to the Brazilian territory, the profile of immigrants, and comment on something about what this demand brings as challenges to the new realities that the world is facing with the human movement due to environmental grounds and, above all, the responsibility to ensure, first, that human rights of these immigrants are respected. We will use as sources administrative records provided by the National Immigration Council (CNIg- Conselho Nacional de Imigração) of the Ministry of Labor and Employment (MTE - Ministério de Trabalho e Emprego), and other agencies of the Federal Government, in addition to data collected by civil society organizations.

UDC13 - Urban Regeneration Practices in the U.S., Germany and Austria

Yvonne Franz (University of Vienna)

Cities are embedded in ongoing transformation processes that are triggered and influenced by a mixture of political, economic, demographic and social changes. Cities constantly have to reinvent themselves while at the same time preserving their urban and cultural identity. If they do not, they remain stuck in a status quo and are at risk of facing severe challenges like shrinkage or artificial conservation; they lose their attractiveness and are finally unable to compete with other cities in global competition. Urban revitalization in terms of physical rejuvenation plays a crucial role in attracting future and existing residents, especially in times of urban renaissance. The potential for physical rejuvenation

differs within the specific context of a city. Investments for urban renewal cannot be covered solely by public funds on federal, state or communal level. Private public partnerships become more and more important not only for large scale developments. The investments of all actors who are involved in the urban revitalization processes have an impact on the economic and social structure of cities, too. Gentrification can be a potential outcome. Additionally, the dynamics of modern transformation processes are on the increase and demand comprehensive concepts and steering strategies. This poster will visualize different urban revitalization approaches and outcomes in the US-American, German and Austrian context. Vienna, Berlin and New York City serve as practical examples in this poster.

UDC14 - Indicators, planning and urban observatory network in Mexico

Oscar Frausto (Universidad de Quintana Roo), Thomas Ihl (Universidad Nacional Autónoma de México), Justo Rojas (CESAC), Esteban de Jesus Vazquez Rodriguez (Universidad de Quintana Roo)

Indicators are regarded as important tools for the implementation of Monitoring of the Agenda habitat in Mexico. Since the beginning of the debate about indicators in 1992 different concepts have been developed. Some of the existing indicator sets have been tested already. The results have led to the conclusion that the indicator concepts of the "first period" need to be improved. One of the most important outcomes of the experiences made until now is that it is almost impossible to develop indicators or indicator sets, suitable for every spatial area or different regions. The results of the program of the UN Habitat Mexico confirm this fact. In the present contribution 44 experiences of sustainability indicator development for the Mexican Urban Observatory Network context are presented, the analysis time is for 2000 - 2010. The examples from Mexican cities underline the necessity to develop indicator concepts based on the specific problems and goals for the region without neglecting the global principles of sustainability. Furthermore, the description of both case studies (methodology of selection, indicators and her application) illustrates the problems and challenges of indicator concepts for a specific region. Finally the author gives some recommendations for the development of sustainability indicators for the National Urban Observatory Network for the Mexican cities planning.

UDC15 - Possibilities of e-health technologies to support health care in rural areas

Karsten Gödderz (University of Bonn)

Demographic change imposes different challenges on our society making it older and fewer in number, hence causing a change in demand and supply of health care services in the future. Rural areas in particular face difficulties providing health care for the scarce population at high quality. E-health technologies have been widely discussed, yet not implemented in Germany to face these challenges. Certain resentments against implementation of e-health technologies exist, opposite to other countries facing similar problems such as the US or Scandinavian countries. Following the paradigm of Gesler/Kearns (Geography of Health) the study sets out to investigate the acceptance of a specific technology (Home telemonitoring for patients with heart disease) among patients and practitioners aiming at everyday geographies of both groups via qualitative research. Furthermore, the possibility of implementation regarding the views of health care systems' stakeholders was investigated. The study focused on the experiences made in the 'Partnership for the Heart project' (Köhler), set in the north of Brandenburg, Germany, an area highly affected by demographic change. Even though a qualitative single case study has been conducted, certain general characteristics for telemonitoring can be established. The results show that patients are extremely positive towards the implementation of telemonitoring devices at home to support their health care. Treatment at home, a place connected with a certain sense of place, improves quality of life by creating a feeling of security and enabling patients to follow their everyday activities. The high rate of acceptance cannot be found for practitioners, however. Resentments towards implementation of technology into the treatment process remain constituted by the fear of a thorough change in a practitioner's working culture towards a technical and impersonal treatment and a loss of their economic foundations. A similar refusal of this technology was discovered for some stakeholders within the system of health care in Germany due to a missing proof of medical efficacy and utility of telemonitoring, leaving them with scepticism towards its implementation. However, viewpoints vary from opposition to endorsement. In addition, the results pointed out that telemonitoring cannot be the sole solution for rural areas facing demographic change since it is always considered as an additional means of treatment. Nevertheless, it can contribute to providing expertise and treatment in remote locations, thus supporting supply in these areas. For patients, the telemonitoring shall lead to a more stable condition, leading to fewer hospitalisations and thus

to a lesser demand in health care services, mitigating the challenges of demographic change by reducing the workload on practitioners in rural areas. If designed similar to the PfH project, these goals seem reachable.

UDC16 - Urbanization in Rajasthan (India): A Demographic Transition

Sawan Kumar Jangid (M.L.V. GOVT. COLLEGE, BHILWARA)

Urbanization in Rajasthan (India): A Demographic Transition Sawan Kumar Jangid Department of Geography M.L.V. Govt. P.G. College, Bhilwara-311001 (Rajasthan), India sawan.jangid@yahoo.com Abstract 32nd International Geographical congress cologne (Germany) 2012, 26-30 August 2012 This paper investigates how urbanization and demographic transition interrelate with each other via merits of population concentration and demerits of it. Urbanization is an index of transformation from traditional rural economies to modern industrial one. It is a long term process. This paper endeavours to illuminate on the process of urbanization in Rajasthan over a century with emphasis on level, tempo of urbanization and urban morphology using Indian Census data during 1901-2001. It will try to trace urban problems and related policy issues. At the moment, Rajasthan is among the state of low level of urbanization. Number of urban agglomeration has grown from 135 in 1901 to 222 in 2001. Number of population residing in urban areas has increased from 15.50 lakh in 1901 to 132.14 lakh in 2001. Only 23.39% of population was living in urban areas as per 2001 census. Over the years there has been continuous concentration of population in class I towns. On the contrary the concentration of population in medium and small towns either fluctuated or declined. The graduation of number of urban centres from lower population size categories to class I cities has resulted top heavy structure of urban population in Rajasthan. Rajasthan's urbanization is often termed as over-urbanization, pseudo-urbanization. The big cities attained inordinately large population size leading to virtual collapse in the urban services and followed by basic problems in the field of housing, slum, water, infrastructure, quality of life etc. Urbanization is a product of demographic explosion and poverty induced rural - urban migration. Urbanization is occurring not due to urban pull but due to rural push. Globalization, liberalization, privatization are addressing negative process for urbanization in Rajasthan. Policy relates to proper urban planning where city planning will consist of operational, developmental and restorative planning. Redirection of investment is recommended to develop strong economic base for small and medium city neglected so far so that migration flows are redirected to small and medium cities.

UDC17 - Electoral aspects of the socio-political variability of big cities in Poland

Katarzyna Kulczynska (Adam Mickiewicz University), Elzbieta Bilaska-Wodecka (Jagiellonian University)

Urbanisation is regarded as one of the most important factors shaping electoral behaviour in Poland over the last two (post-1989) decades because here have appeared parties on the political scene in that period that captured much higher support in towns than in rural areas. Also, the biggest cities have shown the highest voter turnout in parliamentary elections. Among factors affecting the voter turnout and the spatial variability of electoral results at the regional level, apart from historical and socio-economic determinants, one can also find a religious element. Do those regularities appear in big cities as well? The subject matter of the analysis reported here was differences in the voter turnout and the results of parliamentary elections at the start of the 21st century in Poland's biggest cities. The analysis was also conducted in the intra-urban space with electoral districts or their sets (city quarters) as objects of study. This type of analysis, therefore, can be regarded as a specific form of socio-electoral ecology. Also considered at this level of analysis was the influence of socio-religious differences in the Roman Catholic Church. Differences (inequalities) in the support structure within those small territorial units are considered in socio-economic terms (e.g. as differences in religiousness). It should also be noted that this urban type of electoral behaviour tends to spread into the rural areas adjacent to a big city, which is a result of the process of their suburbanisation. A special role in the structure of big cities is played by so-called closed electoral districts (set up in hospitals, police jails and prisons, and nursing homes). Those units tend to acquire a politically distinct sense of place. Religion as a factor explaining electoral behaviour patterns is still significant in Poland, as opposed to some European states like the Netherlands or the Czech Republic, although its impact seems to decline gradually. In the case of Poland, the effect of religious factors on the election process can be seen in: (a) a clear relationship between the level of religiousness and the voter turnout (the higher the level of religiousness, the more steady the voter turnout throughout the years); (b) strong and persistent support for right-wing parties in areas showing a high level of religiousness, and (c) persistent support for left-wing parties in areas where the level of religiousness is low.

UDC18 - Neighbourhood environment: Implications for childhood obesity

Ana Lourenço (University of Coimbra), Helena Nogueira (University of Coimbra), Isabel Mourão (University of Coimbra), Vitor Rosado (University of Coimbra), Cristina Padez (University of Coimbra)

Introduction Over the last decades, the prevalence of childhood obesity and overweight has increasing in developed and developing countries, becoming a serious worldwide public health problem. In Portugal, the prevalence of overweight reached 20,3% and obesity 11,3% among children aged 7-9 yrs. Many studies have identified associations between parental perceptions of the neighbourhood attributes and childhood weight status (Timpero et al., 2005): positive perceptions of safety, proximity of free or low cost recreational facilities, public transport options, existence of sidewalks and facilities to bicycle can potentially reduce childhood obesity rates because time spent outdoors is significantly associated with physical activity participation. Our main aim was to analyze the links between parental perceptions of the neighbourhood environment and weight status among children aged 3-9 yrs. **Methods** Data were collected between October 2002 and June 2003 in 24 kindergartens and elementary public schools in Aveiro. 1117 children's weight and height were obtained using standardized anthropometric methods. Body mass index was calculated and the cut-offs points published by Cole et al. (2000), were used to define overweight and obesity. Parental perception of the neighbourhood environment was measured using responses from the Environmental Module of the International Physical Activity Prevalence Study questionnaire. Parents indicated how much they agreed or disagreed with 15 statements about traffic safety, crime, sport and recreation facilities, aesthetics, streets connectivity, access to public transport and social environment. Chi Square was used to test differences in the proportions; and logistic regression to examine associations between neighbourhood environmental attributes and weight status. **Results** The prevalence of obesity (including overweight) in our sample was 29,0%. We found that girls have significantly higher values for obesity than boys (17,3% and 11,7%, respectively). Logistic regression analysis showed that children whose parents agreed that the crime rate in their neighbourhood allow walking in safety during the day were less likely to be obese and overweight (OR=0,63; 95% CI 0,41-0,96; $p<0.05$). **Conclusion** Our results suggest that perceptions of neighbourhood safety were predictive of 3-9 yrs children's weight status. We found that living in a neighbourhood perceived as safe decreased the risk of excessive weight, suggesting that the promotion of a high-quality social

environment may be a possible way to prevent childhood obesity. This result is consistent with prior longitudinal studies on neighbourhood safety conditions and adiposity, as well as with other cross-sectional studies, highlighting the crucial role of local perceived safety on children's weight status. Key Words: Childhood obesity; Parental perceptions; Neighbourhood environment; Aveiro; Portugal.

UDC19 - The process of demographic and economic polarization in the Republic of Macedonia

Biljana Apostolovska Toshevska (Faculty of Natural Science and Mathematics - Skopje), Biljana Apostolovska Toshevska (Faculty of Natural Science and Mathematics - Skopje), Dejan Iliev (Faculty for Natural Science and Mathematics, Institut of Geography)

Demographic and economic development in the Republic of Macedonia is characterized by high dynamics, and an imbalance in development. Unequal social and economic development is one of the main negative features of development, especially during the transition period in which the regional development has been marginalized the expense of market development and stabilization and restructuring of the economy. No less important component of the development is the problem of concentration and dispersion of population and economic activities in the area causing the appearance of demographic and economic polarization in the country. Today the degree of the population and economic development in the Republic of Macedonia shows certain differences on the regional level, according distribution of the population, investments, GDP and etc. From the available social and economic indicators can be concluded that the Republic of Macedonia has the characteristics of a country with a mono-centrism model of development where the Skopje region stands out as the core of development, while other regions stagnate or grow with less intensity compared to the previous one. Therefore, this current problem requires finding solutions to reduce disparities in regional development and harmonization of the same.

UDC20 - GIS based land suitability evaluation for spatial planning using AHP method at Shandiz urban region, Northeast Iran

Mehrnoush Afshari (Islamic Azad University), Mohammad Reza Mansouri Daneshvar (Islamic Azad University)

The present study evaluated the land suitability for spatial development of Shandiz urban region on the basis of analytical hierarchy process (AHP) and geographical information system (GIS). Based on this method, the area and percentage distribution of land suitability were calculated and it was found that 12 landforms (22.5% of the region) is under the high and moderate suitability to spatial development. Our results revealed that the regions with high suitability spatial development are located in the middle and south parts of the study area. Our study presents a map of land suitability for spatial development of the region, which will aid in planning appropriate, quick and safe mitigation measures and future development strategies based on the identification of the region. As a result we develop and apply a systematic regional planning approach to identify geographic priorities for on-ground natural resource management actions that most cost-effectively meet multiple natural resource management objectives. Our systematic regional planning approach utilizes integer programming within a structured multi-criteria decision analysis framework.

UDC21 - A functional, ranking-based, land planning methodology for resource optimization, in resource deprived areas: A Spanish Applied case.

María Asunción Martín Lou (CSIC), María J. Lozano de San Cleto (Real Sociedad Geográfica), Alberto Míguez Iglesias (ESCUN)

The object is to create a functional map presenting a global and actual view of the land, as a planning tool to distribute and optimize resources over 'sustainable influence areas'. To get the functional ranking, a synthetic index is created by mixing a correspondence point analysis (McGranahan, D., et al 1972) and a CRITIC multi-criteria weighting system (Diakoulaki, et al 1992). In said synthetic index we have included any basic facilities available: culture centres, sport areas, schools and health services (EIEL, 2009), as well as other land features: demographical (absolute population and density) data, accessibility (road network) and economic activity (number of financial entities). Its global analysis facilitates determining the functional ranking and influence area of the municipalities, object of the land planning. This methodology is applied in the

Autonomous Community of Castilla y León, a connecting area for trading flows between Northern and Southern Spain and between Portugal and other European regions. Its 94,223 km² of area (18.6 % of Spain) makes it the first largest region in Europe. Its population in 2010 amounted to 2,559,515 inhabitants (5.69 % of Spain), with a density of 27.16 inhabit/km² and 2,248 municipalities. To obtain the functional ranking, any municipalities over 50,000 inhabitants were excluded and the mean rate became 646 inhabitants per municipality (1,446,018 inhabitants distributed in 2,239 municipalities). Due to this atomization of the population, this kind of tool is needed to reach some resource managing policies to insure the population has access to basic services.

UDC22 - The governance and development strategies: Work and Timorese youth

Gabino Moraes (UNESP/FAPESP)

East Timor is a small Southeast Asian country that gained independence in 2002, and since then it has enjoyed the support of different international social actors like the UN, the World Bank, International NGOs, among others. What synergistically orchestrate development strategies. In Timor, half the population of about 1,066,582 inhabitants, have less than 15 years and the fertility rate is at approximately 8.3 children per one. This summary aims to investigate the role of governance as a strategy for urban development. Where the question of labor and employment policies for young people present themselves as a central issue. The theoretical framework underlying this research is related to studies on governance and territorial development that has been produced within the international context and geography in Brazil, the specificity of UNESP, in Rio Claro. The governance and development strategies are the core of East Timor today. 'Due to this process of nation building, it is important to note that the various social actors involved in foreign and local projects to promote these strategies have different ideas about how to promote them' (Guedes and Mendes, 2005 and Silva and Simião, 2006). But in a scenario of high population growth rate of an intense process of urbanization and a low prospect of employment growth, with a rapidly increasing young population (World Bank, 2007 and 2008) the development of these strategies is inevitable. The methodology is based on the diagnosis of the material: 'East Timor Force Survey 2010'. Joint initiative of the Secretary of State for Vocational Training and Employment (SEFOPE) and National Directorate of Statistics (DNE), which represent the first attempt of this kind, held in East Timor after independence. It

covered 4,665 households spread across 311 fields through East Timor. Detailed information on the economic activity of 17 000 people in each household was collected. With emphasis on the economic conditions of people aged 15 to 29 years. Of these, about 51,000 are employed and 6,000 unemployed. This data collection provides an important set of labor statistics, including data on employment, unemployment and underemployment. In order to provide a real monitoring of labor market policies in East Timor. Finally, it is expected that the results of this research can contribute to the analysis of governance strategies for urban development in Dili. Pointing diagnoses facing the Timorese urban space, and the country, with regard for youth employment.

UDC23 - Analyse du changement de l'occupation du sol par automate cellulaire à Menzel Bouzalfa (Cap Bon_Tunisie)

Monaem Nasr (Laboratoire SYFACTE), Mohsen Dhieb (King Abdulaziz University)

Nous nous proposons d'étudier les dynamiques spatiales et les mutations agricoles des différents modes d'occupation du sol à Menzel Bouzalfa, ancien bourg rural situé dans la plaine de Grombalia (Cap Bon_Tunisie). Caractérisée par son activité agricole notamment agrumicole, cette ville a connu des changements remarquables et des mutations profondes au niveau de son occupation et utilisation du sol. Il s'avère indispensable dès lors de penser à la modélisation prospective, à l'aide des Automates Cellulaires, de la masse d'informations relative à l'évolution de la région de Menzel Bouzalfa pour mieux gérer et organiser cet espace dans le futur en mettant l'accent sur le bâti comme expression de l'étalement. Dans ce cadre, un modèle de type automate cellulaire est nécessaire afin de produire des images du futur de l'espace périurbain et rural. La production d'images différenciées du futur des modes d'usages du sol et des structures paysagères selon différentes hypothèses est envisagée à travers une approche prospective spatialisée. Elle est effectuée à travers des scénarios élaborés selon une démarche participative auprès de différents acteurs et le développement d'un modèle de type automate cellulaire (SpaCelle). Ce dernier est une application programmée dans le but de répondre à une problématique semblable à celle à l'évolution de l'occupation du sol dans l'agglomération rouennaise.

UDC24 - Human-Environment Interaction: Analysis of the transformation of urban space in the city of Coimbra in the time period 2000-2010

Diogo Neves (Universidade de Coimbra), Viviane Neves

Within our current life cycle and increasingly global society we live in, frequently and profound changes begin to occur more constant in our daily lives. If, then, for some authors this movement for change that we witness in the contemporaneity space is an inherent characteristic of the time we live in and so we have to get used to them. We can not deny that his understanding comes understanding many phenomenon in the composition space. The way in which our cities and towns are now surely is the fruit of our past relationship to it, but we can not deny the future importance of the constant transformations that urban centers are within our day-to-day. With this we affirm that although the past has key role to understand the contemporary, certainly our contemporary relations will generate reflections on the spatial structure of the future. Sometimes we see that man as an agent of transformation of urban space and the environment in which they are inserted does not realize the possible consequences of (beneficial or not) of their actions. Thus, we must have a clearly established these spatial changes in our cities and towns for in the future, we can better absorb the effects and consequences in the spatial structure. So, in this work we propose to make a list of the main processes of urban change in Coimbra occurred in the last decade (2000-2010) to understand the dynamics of use and occupation of land in the urban center and to generate benefits to a future analysis of its features and potential benefits from the processes of transformation of the urban space of Coimbra.

UDC25 - Location of facilities and the vulnerability in Andean Cities: The Case of La Paz

Javier Nuñez Villalba (II GEO-UMSA)

Latin America is a unique place in terms of the phenomena affecting the world such as global change, migrations, and new democracies, since these phenomena are more drastic in this region. In terms of population for example, according to the United Nations Population Fund, the worldwide population will increase to 5 billion people, with the most significant growth in developing regions such as Latin America (where eighty percent of the planet's urban population is concentrated). Because the high concentration of population in

urban areas, according to Pelling (2003), is only 1 % of the terrestrial surface, cities such as those in the Andean region become key places for the analysis of global change. Difficult geographic conditions (accessibility, climate, topography, etc.) in the Andean region have not impeded the construction of immense urban cities such as Quito and La Paz, which are both characterized by accelerated growth that is expanding through valleys and mountains. This growth multiplies both human and natural threats, however due to constant landslides in places with highest slopes (that cause entire neighborhoods to disappear) it is often believed that the most significant threats are natural, without taking into consideration the urban planning that allowed for these areas to be occupied in the first place. An analysis of the plannification of these urban areas, through a sequence of aerial photographs and satellite images shows the true vulnerability of these urban areas.

UDC26 - Spatial Pattern of Occurrence and Factors of Vulnerability to Cancer in Ile-Ife, Central Western Nigeria: Using GIS and Remote Sensing

Oludotun Olagundoye (Obafemi Awolowo University Ile-Ife, Osun State), Olawale Oluwafemi (National Space Research and Development Agency), Akinola Akinwumiju (Bunmak Systems Limited)

This study analyses the spatial patterns of cancer occurrence, accessibility of cancer patient to treatment centre and factors of vulnerability to cancer in Ile-Ife city, Central western Nigeria. The study area constitutes 21 administrative units (wards). Handheld Global Positioning System (GPS) receivers were used to determine the exact location of cancer patient (cancer neighborhood) using their residential addresses as recorded at the registry between 2000-2010. 200 heads of household were randomly selected from the administrative units for questionnaire interview to serve as attribute data. Cancer occurrence data (2000-2010) obtained from cancer registry, Obafemi Awolowo University Teaching Hospital Ile-Ife, Nigeria. IKONOS multispectral imagery (1.1m resolution) was used to perform landuse and landcover classification, query, buffering, overlay, point density analysis and spatial interpolation (Inverse Distance Weighted) using ArcGIS 9.2 software. Data shows that 2778 cancer cases were reported to the Obafemi Awolowo University Teaching Hospital from various regions of the country while 535 cases were reported at Ile Ife for the period of ten years. Also, 21 cancer types were reported in the study area with the breast cancer having the highest (13.6%), stomach (9.3%), abdominal (8.7%) while brain cancer having the lowest (1.7%) among others. Six landuse and landcover classes were

determined, light forest (37%), built up area (35%), gallery forest (15%), water bodies (5%), bare soil (5%) and bare rock (3%). Also, several observed environmental factors make people unsafe to cancer. The study identified household with close proximity to communication base station (83%), 67% of the household have refuse dump around their dwellings, households with sawmills around their dwellings 30%. 31.5% of the households interviewed have their major source of water close to dumpsite and 13% of respondents have source of water close to pit latrines. Also, certain behavioral factors observed includes alcohol drinking 56.6%, 52% engaged in smoking habit while 55% involved in bleaching cream usage among others. Chi square analysis was used to test validity of the assertion that refuse dumping and tobacco use induces the occurrences of cancer. However, significant association exists between dumpsite and cancer ($\chi^2 = 0.132$; $p < 0.05$). Also, significant association exists between tobacco use and cancer ($\chi^2 = 0.220$; $p < 0.05$). The study concluded that cancer is a spatio-temporal disease and can be attributed to the effects of carcinogens or infectious agents and recommends that cancer prevention effort should take into cognizance the rate of urbanization and awareness programmes for the citizenry. Key words: cancer; carcinogens; prevention; GIS; Central western Nigeria.

UDC27 - Geo-Spatial Patterns of Primary Health Care Facilities in a Traditional Nigerian City

Olawale Oluwafemi (National Space Research and Development Agency), Adekola Olaitan (Standard Mineral Exploration Company, Abuja Nigeria), Nicholas Elugoke (National Centre for Remote Sensing, National Space Research and Development Agency), Kehinde Adebawale (National Space Research and development Agency, Abuja)

This study situates the distribution of primary health care facilities in a traditional Nigeria city, Oyo town, within the context of geography, accessibility and population of the city. Hence, the study analyses the spatial pattern of primary health care facilities among 14 administrative units in the city. Also, the ownership structure of facilities and the relationship between population and distribution of health care facilities in the city are analysed. The list of primary health care facilities and ownership in Nigeria obtained from the Department of Health Planning and Research, Federal Ministry of Health served as database for the analysis of the spatial patterns of distribution and ownership of primary health care facilities in Oyo city. Also, the National Population Commission census figures provided information on the population of the city. Handheld

Global Positioning System (GPS) was used to determine the locations of 34 existing primary health care centers within the study area. Field observation, questionnaire and IKONOS multispectral imagery (1.1m resolution) acquired from National Centre for Remote Sensing were used to ascertain the road network, built-up areas, location of primary health care facilities, spatial coverage and population as factors of accessibility to primary health care facilities in the study area. Remote Sensing and Geographic Information System analytical operations employed using ArcView 3.3 include proximity analysis (buffering), overlaying and querying. Data show that there exists inequality in the distribution of PHCFs among the various administrative units in the city with Owode having highest distribution of 17.6%, followed by Sabo 14.7% and Apaara with no PHCF. The study identified three categories of PHCFs in the study area- Comprehensive Health Centre (38.2%), Health Centre (38.2%) and Basic Health Centre (23.6%). It is observed that the patient-physician ratio is (1:15), population-physician ratio (1:7035), patient-nurse ratio (1:5) and population-nurse ratio (1:2438) for the three categories of PHCFs. Although the government dominates the ownership of health care facilities in the state, but private organizations dominated the ownership in Oyo city with 58.8%, and government 41.2%. The study concludes that primary health care facilities tend to be located closely to the elite population in the city. Also, Comprehensive Health Centre (CHC) which is the highest level of PHC is haphazardly located and does not conform to the population variation and distribution within the city. Hence, appropriate authorities should endeavour to achieve a more equitable distribution of primary health care facilities in the city, taking into consideration geography, accessibility and population so as to engender equity and social justice. Keywords: Geo-spatial, spatial pattern, primary health care facilities, Oyo city, Nigeria.

UDC28 - The impact of inter urban distances on rural economy: A network theory approach

Ajith Padmanabhan (Bernstein Center Freiburg)

The spatial distribution of cities in a region play an important role in shaping up the overall economy of the region. Hitherto, network theory has been utilised to understand the advanced capitalist urban networks. In developing economies with significant dependance on agriculture they can play an important role in the shaping up of the rural economy. In the poster to be presented, the effect of urban spatial distribution on the overall economy is studied from a network theory perspective. A network of cities are built with cities as the nodes.

Parameters like transport, distances, communication facilities are defined by the strength of the connections between the nodes. Simulation of such a system highlights the advantage a widespread urban spatial distribution (smaller cities spread out throughout the region and more in number) compared to a concentrated urban spatial distribution (bigger cities and fewer in number) provides. Specific examples are chosen and the conclusions are verified. The states of Tamil Nadu (widespread spatial distribution) and Maharashtra (concentrated urban distribution), the two most urbanised states in India are analysed with reference to the model. References: Loretta Lees, Rematerializing geography: The 'new' urban geography, Progress in Human Geography February 2002 26: 101 - 112

UDC29 - From the origin of the environmental speech to the collapse of the public space: The paradox of the sustainable neoliberal city in Brazil

Fernando Pinto Ribeiro (Universidade de São Paulo)

This article proposes to advance the debate about the territorial implications instituted by the neoliberal ideology in Brazilian cities, in order to establish a link between this ideology and the growing environmental speech linked to the spheres of the State and the market. The intention is to analyze a space that is reproduced according to a logical of development in which the neoliberal State and the market make use of the environmental matter as a business strategy. The objective is to evaluate, in the Brazilian metropolitan context, some indicators that show how the environmental issue articulates with the urban issue from the dispersion of housing enterprises with sustainable character. With eminently historical character, the Brazilian urban pattern implies the selective modernization of the cities, without, however, breaking the social structures that have existed since the colonial era, when the ruling elite consolidated its appropriation of the means of production, the State and the land. Such a deepening implies an increase of poverty and urban environmental degradation, with irregular occupations on the banks of the rivers, lakes and catchments, on the tops of the hills, dunes and other vegetation areas. Also, with regard to the collapse of public policy, which gives space to the enterprisation of the urban management with a focus on competitiveness and on the search for private investments. With regard to the real state / housing sector, the intensification of competitiveness will use the urban problematic itself in order to develop marketing strategies, among them, the environmental one, marked by the dispersal of enterprises considered 'sustainable'. We take as example the

so-called 'Ecovilles', nomenclature used to characterize many private closed projects in Brazil, which adopt technologies with 'green' certificate, or that have a further location from the major urban centers. This is the case of new developments in Curitiba, Porto Alegre, Campo Grande, among others. In Florianópolis, another example is the emergence of the sustainable housing enterprise Cidade Pedra Branca and Sapiens Park, large investments that add environmental concepts together with elements associated with social and economic sustainability. The speech always seems to be the same: its function is to meet current and future environmental demands, through specific engineering mechanisms in order to rationalize the nature resources and improve waste treatment. On the urban side, green areas are designed and areas with mixed zoning are planned, in order to discourage the use of the car through a greater accessibility to urban services. Finally, the elements that have been summarized here intend to stimulate the debate about the urban implications and practices of sustainability in Brazil.

UDC30 - Influence of Industrial Area against Congestion in the Bogor highway

Dimas Raharjo (University of Indonesia)

Abstract The high price of land, home or the living cost in Jakarta creates an alternative that Bogor city (Suburban) as a place of living for the workers earning their living in Jakarta. This case makes Bogor Highway has a very important role as an access between Bogor and Jakarta. Although there are Jagorawi toll and railways commuter trains connecting the two cities, Bogor Highway remains as the top choice for the people having an interest in the eastern part of Jakarta or those having private vehicles are reluctant to spend extra money for toll charges. Bogor Highway is a primary arterial road becoming one of the locations of traffic congestion in Jakarta. With the road conditions in only about 7 meters per segment, it is not proportional for the volume of the vehicles passing by the highway. The problems presented in this study is how far the industrial area in Bogor highway affects congestion, because the landuse along the Bogor highway region is dominated by industry, There are approximately 400 industries scattered along corridor of Bogor highway with spreading pattern diversity. The method used in this study is the method of the observations done during the rush hour at 6:00 to 8:00 AM and at 5:00 to 07:00 PM. The observations were made to obtain data required in this study, such as the volume of passing vehicles, the type of passing vehicles, the points congestion, travel time of vehicles, the average speed of vehicles, road conditions, the number of crossing

people, which will be connected with the existence of regionally industrial linkages, shopping centers, residential and public facilities such as hospitals, bus terminal, schools, place of worship and amusement center which are quite a lot along the Bogor highway. The purpose of this study is to analyze how far the industrial area contributes to the congestion on the Bogor highway. Therefore, the action planning program can be structured to handle the existing problems of congestion on the Bogor highway. Keywords: industrial area, congestion, landuse, suburban.

UDC31 - Urban networks and the medium-sized cities in the Brazilian Amazon

Douglas Sathler (UFVJM)

In the past decades, the Amazonian urban networks have been developing with the emergence of middle size cities and the multiplication of new towns and small urban agglomerations along the main regional roads and rivers. Even though there is an urban hierarchy that seems to be similar to those of other country's regions, with regional and local centers clearly established, the various urban hierarchic levels have different demographic, spatial and socioeconomic dynamics. Within this context, the debates on the legal Amazon's intermediate cities? role and meaning become more significant, in light of the theme's relevancy in the urban and public policies study field. Thus, the present study dialogues with the conceptual issues concerning the sprouting of medium cities in the Amazon, considering the different existing types: the cities of rubber, of the great mining company, of the (un)organized gold mining, the agro-industrial activities and those of the colonization processes.

UDC32 - Facing the 'Zwischenstadt' – The transboundary 'Zwischenstadt' Alpine Rhine Valley and its challenges for a sustainable regional development

Julia Scharing (Institut für Geographie), Stefan Obkircher (Institut für Geographie), Janine Fellner (Institut für Geographie), Lukas Weiß (Institut für Geographie)

The poster abstract submitted for the IGC 2012 Conference in Cologne examines the challenges and opportunities associated with sustainable regional development in the trans-boundary Zwischenstadt Alpine Rhine Valley. Urban sprawl, increasing land use as well as high economic and population growth rates are amongst the processes that characterise the Alpine Rhine Valley. In

total 450.000 people, distributed amongst small or medium sized cities, live in this area. Decades of progressive sprawl have led to a singular continuous settlement ribbon. The Alpine Rhine Valley is the border region between the Principality of Liechtenstein, Switzerland and Austria and therefore features numerous types of boundaries. The region is organized in a polycentric manner, characterised by multiple functional relations. Despite of high volumes of cross-border commuting, a common living environment has not formed yet. As a result of the increased coalescence of spatial structures and growing functional relations, existing boundaries are becoming less defined. New 'spaces' emerge, in which socio-ecological and physical boundaries are not yet, or no longer, defined (Davy 2002). The structures and developments described above correlate with the concept of Zwischenstadt, defined by Thomas Sieverts in 2001. The term Zwischenstadt describes landscaped cities and urbanised landscapes. It is neither city nor landscape; it has elements of both spatial categories. Extrapolating from analyses by Ben Davy (2002), which also associate the Zwischenstadt, with the creation of 'spaces of hope for future development', such spatial phenomena can also be interpreted as 'spaces of possibilities'. Based on this consideration the following hypothesis is suggested: The Zwischenstadt Alpine Rhine Valley has unique qualities that could be harnessed to create 'spaces of possibilities' that promote sustainable regional development. The poster identifies key 'spaces of possibilities' in the Alpine Rhine Valley. Examples include 'spaces of identity', 'spaces of culture', 'spaces of participation' and 'open spaces'. Different 'spaces of possibility' are investigated on the poster, by means of a SWOT-analysis and related to their impacts on sustainable development. All shown examples are preliminary results of the research project 'Alpine Rhine Valley Perspectives', carried out at the Institute of Geography, Innsbruck. Surveys are conducted in a qualitative-participatory setting; methods include think tanks and qualitative interviews. These are supported by net- and mental-mapping, photographic documentation, film interviews and participatory observations. Another focus is placed on statistical analyses of municipal, land-use and demographic data. In the conclusion learning effects extracted from case-studies of other Zwischenstädte are illustrated and an overarching development vision is articulated, based on previously identified 'spaces of possibilities'.

UDC33 - The impact of urban growth on agricultural households – A GIS-based integration of land use and household survey data from Moshi/Tanzania

Johannes Schlesinger (University of Freiburg), Axel Drescher (University of Freiburg)

Today, Africa is the world's least urbanised, but fastest urbanising continent. This urbanisation process to a large extent takes place in medium-sized cities. These cities are highly dynamic and often characterised by manifold transformation processes. One of them is the conversion of areas traditionally shaped by agricultural activities into zones fulfilling urban functions. Yet, agriculture in these areas of transformation contributes to the overall food security of cities in Africa. Furthermore the ongoing transformation processes shape the socio-economic situation of urban and periurban farmers and play an important role in the spatial development and planning efforts in cities. The so-called 'periurban' becomes more important as cities grow and as these areas become the battlefields of conflicting interests. This case study concentrates on the changes of the importance of urban and periurban agriculture along the rural-urban continuum in medium-sized Moshi, a municipality of about 180.000 inhabitants located on the foothills of Mt. Kilimanjaro, Tanzania. With an innovative GIS-based transect approach, changes along the rural-urban continuum can be analysed and visualised. A twofold approach was applied to get a comprehensive data set on the importance of agriculture for the livelihoods of Moshi's inhabitants on the one hand and about the spatial and temporal changes of land use patterns along the rural-urban continuum on the other hand. Therefore four transects from the city centre to the periurban areas of Moshi have been identified, each eight kilometres long and a hundred meters wide. Within those transect polygons, a Geographical Information System (GIS) was applied to sample about 400 households that were interviewed with a standardised questionnaire to assess the importance of agricultural activities for the individual households. Secondly, the land use patterns within these transect were mapped based on high-resolution satellite imagery and in situ methods. The land use data was imported into a GIS and a database was set up containing information on land cover, crop production systems and size of plots. The GIS then was supplemented with the geocoded household data generated through the household survey. Other information such as census data and results of the interpretation of satellite image time series were also incorporated into the GIS. Several spatial indexes could be developed for every respective scale unit. These integrated spatial indexes cover aspects of agricultural

activities such as land use intensity, involvement of households in agricultural production and its economic importance for the households. Spatial and temporal changes along the rural-urban continuum can be identified and appropriate measures addressed. This method helps understand the transformation processes that come along with spatial growth of medium-sized cities and can therefore support future policy options.

UDC34 - Coping with a changing supply of services of general interest: Long-term strategies of the population in two aging regions in Germany

Alexandra Tautz (Johann Heinrich von Thünen Institute)

In Europe, the debate about the demographic divide between growing metropolises and shrinking rural peripheries, combined with a deepening of social disparities across the continent, is ongoing. In declining and ageing regions one major topic discussed is the question of how to ensure services of general interest (SGIs) in future. Due to constraints within the municipal budgets the situation often worsens and SGIs in rural areas are reduced or shut down completely. At the same time the provision of SGIs has changed. Many mobile and internet-based offers extended their range. That is why the assumption that the quality of life in peripheral rural areas is generally declining needs an empirical verification. In Germany, the debate so far focused on shrinking cities and regions in Eastern Germany but the issue has now reached Western Germany as well. The two rural areas with the oldest population compared to the national average include the regions Osterode am Harz and Lüchow-Dannenberg. Here aging is the result of different selective in- and out-migration processes of the past four decades. Both regions are also characterised by a long-term population decline and were chosen because of their different settlement structure. The latter is essential for the organisation of SGIs. The research project to be presented is in its initial stage and is designed as a doctoral thesis at the Institute of Rural Studies of the Johann Heinrich von Thünen Institute (vTI). It aims to investigate coping strategies and capacities of different population groups with respect to the thinning out of SGIs. The issues to be addressed within the project, through comparative case studies, include: What kinds of strategies are pursued by different population groups over the course of their lifetime to cope with a changing supply of SGIs? What kinds of coping capacities can be activated to compensate perceived deficits? The focus of the investigation are senior citizens, especially young elderly people (50 years and older). By applying different methods (a standardized questionnaire survey

and in-depth biographical interviews with senior citizens) it is planned to pay particular attention to coping capacities and strategies in the life course, as this is an under-researched issue in the debate so far. Previous research projects have not addressed the longer-term developments of coping and adaptation of the rural population. Though, one can assume that in rural areas the examination of facilities and services of general interest takes place constantly during the course of life and is a vital part of living in such places. This knowledge, a typology of coping strategies and capacities, is necessary for both the scientific community and regional planners to steer and provide user-specific SGIs. Finally, the project wants to put the debate of 'deserted villages' into perspective.

UDC35 - The puzzle of measuring the urbanization process: Coincidences and divergences between various sources of spatial information (test on Andalusia)

Miguel García Martín (Universidad de Sevilla), Arsenio Villar-Lama (Universidad de Sevilla)

The various maps on land use raised in the last decades have drawn and measured the process of urbanization. However, depending of the source of information there are notable differences in the localization and quantification of this phenomenon. The choice of one or other methodological parameters -data source, scale, capture, interpretation of the urban land?- explains these contrasts. This work aims to quantify these differences by comparing four different sources: the Corine Land Cover (CLC), the land use map and land cover types of Andalusia (MUCVA) and data gathered in authors' doctoral theses. In contrast with the media, that usually publishes questionable indicators about the urbanization process, this research underlines the caution in expressing the dimension of a complex phenomenon with fuzzy boundaries. **KEYWORDS:** urban-altered land, process of urbanization, Corine Land Cover, Map of uses and land covers of Andalusia, Geographic Information Systems, Andalusia.

UDC36 - A Study on the Rules of Rural-urban Migration during China's economic transitional period

Guoxia Wang (Shanxi University)

Abstract: Since China's Reform and Opening-up there have been great changes and some rules are demonstrated in the rural-urban migration in China in the

aspects of migration demographic characteristics, migration approach, spatial pattern and so on. Chinese scholars have been paying more attention to case studies of migration due to more availability to migration data since 1980's and making considerable accomplishments, but little progress has been made on migration theories. By doing a tentative work, the author concludes three migration laws by extending and integrating the present research results. 1. The migration motivation and the spatial pattern of migration follow the Economy-incentive Rule. The economic factor acts as the main driving factor of rural-urban labor force migration. The migration destination is adjacent to the migration departure. The spatial pattern of inter-provincial migration demonstrates a polarization trend. 2. The demographical features and the migration behavior demonstrate the Human Capital Differentiation Rule. Most migrants are elites in rural areas. The migration distance varies according to the migration's population: first an inverse increase and then an accelerative increase. Migrants with high human capital value tend to migrate to the urban areas with their family members. The new generations of urban migrant workers more desire to integrate into the city than their peasants. 3. The migration patterns and the employment selection follow the Social Relationship Rule. The chain migration is the most common migration pattern and their access to employment information still relies upon their social networks. In the future, a large-scale rural-urban migration will continue with the economic incentive still being one of the important factors affecting the population migration. Since urban areas centering metropolitans will continue to promote China's economic development and play an significant role in the process of urbanization, the places such as the cities in eastern China and the large and medium cities will continue to be ideal destinations for migration workers. But with the implementation of China's policies on regional balanced development and other related efforts, the trend of large-scale inter-regional migration will be on decline and rural labor force will move to central and western regions or smaller cities (towns). Although the new generation of farmers have a strong will to live in cities, China's present institutional arrangement can not realize their dream at once so the migrant workers will continue to move between urban and rural areas. But the population who choose to live in the cities is predicted to rise. **Key words:** rural-urban migration, migration rules, China

UDC37 - Concept and Prototype of Map of Land Use Neighborhoods. Case Study of Warsaw Metropolitan Area (Poland).

Piotr Werner (University of Warsaw)

Land use is defined as spatial distribution of forms of land cover patches, utilized or not by man within framework of the spatial and mutual relationships. The term refers to the functional character of given terrain and is identified also with the socioeconomic description of the surface. The observed dependency of land use and neighboring land cover patches is pointed out in many publications from geography or spatial economy; i.e. the economic utilization of observed lot (or patch) has the smaller consequence for future than the existing land use in its neighborhood. Either the situation, existing neighborhood or predominant land use types in given, whole region are the factors stimulating of further land use changes of the observed lot (Hagoort, 2006). The majority of land use models come from geography. The research field of land use changes is interdisciplinary and forces the application of integrated tools based on simulations; GIS software obviously has become the tool of simulations and geovisualizations of the models' results. The aim of the concept is to verify the hypothesis stating that existing spatial pattern and the range of area with different classes of land use show defined tendencies for further spatial development according to the geographical model (Hagoort, 2006, after Tobler 1979). The application of the neighborhood indicator in analysis of land use changes is the idea of combination of the method of map algebra and two-dimensional cellular automata. The neighborhood indicator is reversible and calculated as the result of the expression of the ordered, numbered, nominal classes in the surrounding. The analysis is based on the one-to-one relation between the each unique configuration of neighborhood land use classes and the calculated Neighborhood Coefficient (NBC, Werner, 2009, 2011). Thus the intermediate map of neighborhoods can be obtained. It is possible to make the spatial comparisons of the new intermediate map of the NBCs and the map of land use classes. And what is more and gives the interesting results - it is also possible to analyze the successions of neighborhoods. Bibliography: Hagort, M J. 2006. The Neighborhood Rules. Land use interactions, urban dynamics & cellular automata. Utrecht : Netherlands Geographical Studies, 2006. Werner, P. 2009. Application of Cellular Automata and Map Algebra in Studies of Land Use Changes. The Neighborhood Coefficients Method. Geoinformatica Polonica. 2009, vol. 9, pp. 7-20. UDC38 - A spatial autocorrelation analysis of the residents' living distribution by groups in Beijing based on their social characteristics

Jianhui Yu (Chinese Academy of Sciences), Wenzhong Zhang (Chinese Academy of Sciences), Dai Wang (Chinese Academy of Sciences)

On the background of continued expansion and population growth of Beijing, the distribution of people's spatial living is becoming more and more important and gets increased emphasis by researchers. Based on the large-scale survey from 2005 to 2009, this study used the method of ecological factor analysis and spatial autocorrelation analysis to give the spatial living distribution of different groups of residents in eight districts and the suburbs of five representative regions including a total of 134 communities. Using the ways of Principal Component Analysis and Cluster Analysis, the thesis tries to identify all the residents' characteristics into two main integrated factors, which are the level of potential for the future and the level of existing standard of living. Then the paper divides all the residents into five groups with those factors, i. e., the groups of low-potential and poor-status persons (type I), high-potential and poor-status persons (type II), high-potential and medium-status persons (type III), medium-potential and medium-status persons (type IV) and high-potential and excellent-status persons (type V). By using spatial autocorrelation analysis, the paper reveals that the groups of types II, IV and V people have the most significant living aggregation from the view of global spatial autocorrelation. From the view of local spatial autocorrelation, the article finds that the groups of types I and II people obviously cluster to the eastern and northeastern parts of the city. The group of type I has the largest proportion in the communities of Heizhuanghu, Tongzhou and Dougezhuang. The group of type II is concentrated in a fan-shaped region with Dongzhimen Street as the center. Most people of type IV live in the inner city. The groups of types V and III people are scattered, and settled mostly in Tiantongyuan and Sijiqing.

UDC39 - Seasonal variations, urban-rural differences and major determinants of respiratory health symptoms among urban poor in Dhaka

Md. Mobarak Hossain Khan (Bielefeld University), Arina Zanzdana (Bielefeld University), Alexander Krämer (Bielefeld University), Alexander Krämer (Bielefeld University)

Introduction Diseases of respiratory tract, as classified by World Health Organization, range from acute respiratory infections to chronic conditions such as asthma and chronic obstructive pulmonary disease. Chronic respiratory diseases cause up to four million deaths annually. Several major risk factors are related to chronic respiratory diseases: tobacco smoke, urban air pollution (indoor and outdoor), allergen and occupational agents. People living in highly urbanized areas are highly exposed to multiple risk factors for respiratory diseases. In low-income countries there is scarcity of data about respiratory diseases. The primary aim of this study is to assess the prevalence and the incidence of self-reported respiratory symptoms (RS) among the residents of urban slum areas and villages of Dhaka. The secondary aim is to identify their major risk factors. Methods A total of 3,207 families were systematically selected from 12 slums in Dhaka and 3 rural villages for data collection. Four surveys were periodically conducted in March (baseline), June (1st follow-up), September (2nd follow-up) and December (3rd follow-up). Self-reported RS (including cough, asthma and breathing difficulties) built the outcome variable. Logistic regression and Cox regression analysis were performed at the individual level ($n=1938$, 2009) and at the household level ($n=3207$, 2008-2009), respectively. Results RS within 3 months before the baseline interview were reported by 14.1% of adult respondents ($n=1938$). Family occurrence of RS ranged from 33.9% to 49.6%. RS among adult respondents were strongly associated with a history of fever. Stagnant water around living areas positively correlated with the higher frequency of RS (OR=1.35; 95% CI 1.01-1.79). Drinking water from a pipe inside the house was associated with less chance to report RS as compared to drinking water from a pipe outside the house (OR 0.71; 95% CI 0.55-0.90). Younger average age and urban area were positively associated with family occurrence of RS. Discussion Occurrence of RS was higher among urban slum dwellers and peaked in the period from September to November. Younger families and families with higher number of women were more affected by RS as well as families with more than a half members smoking. Adverse housing conditions such as an unhygienic type of toilet, stagnant water and unsystematic garbage disposal correlated with RS in the individual-level

analysis. A positive association was found between the biomass fuel (wood) and RS. Further examining of RS in a prospective manner with emphasis on diagnosis and concurrent symptoms as well as an assessment of the corresponding health services use can broaden the picture of respiratory disease burden among population of urban slum areas in tropical countries.

UDC40 - Study on the Relationship between Land Cover and Land Surface Temperature Based on Landsat TM Remote Sensing Data: A Case Study In Hefei, China

liangsong zha (Anhui Normal University)

Study On The Relationship between Land Cover And Land Surface Temperature Based on Landsat TM Remote Sensing Data:A Case Study In Hefei,China (College of Territorial Resources and Tourism,Anhui Normal University,Wuhu 241003, China) ·Liangsong Zha; Shan Jiang Abstract: In this paper, taking advantages of remote sensing and geographic information systems (GIS) technology, the land cover types were classified in Hefei city using maximum likelihood method, and the land surface temperature (LST) was retrieved using Landsat TM data, then normalized difference vegetation index (NDVI), modified normalized difference water index (MNDWI), normalized difference built-up index (NDBI) and normalized difference bareness index (NDBal) were calculated .On this basis, the spatial distribution characteristic of Urban Heat Island (UHI) in the study area and the relationship between LST and land cover types and various affecting factors were studied quantitatively. The research results show that the LST in different land cover types were remarkably different. The built-up area and barren land seem to be the major factors responsible for UHI intensification, while the vegetation and the water body play an important role in reducing LST. Regression analysis shows that there exists a significant correlation between LST and the four indices. The research results could be effectively applied for urban residency environment research and the ecological environment process analysis. Key words :Urban heat island(UHI);Land cover·Remote sensing·Land surface temperature(LST);Regression analysis National Soft Science Program of China(2011GXQ4D052);National Natural Science Foundation of China(40771207); National Soft Science Program of Anhui Province(11020503071) * Corresponding Author: Liangsong ZHA; chaliangs@sina.com; phone 13956157079 e-mail: chaliangs@sina.com.

UDC41 - Spatial-temporal change of Jinta oasis in the past 20 years in arid China

Jie Gong (Lanzhou University), Yuchu Xie, Peng Sun, Heling Wang, Caixia Zhao

Oasis was a small and medium scale azonal ecological landscape in arid area of China, but it is vital for sustain human survival, activities and development in the arid region. Recently, oasis research had been paid widespread concern and it was one of the most active fields of global change, land degradation and regional sustainable development. Jinta oasis located in Hexi corridor in the northwestern part of arid China, a fragile and typical ecotone of agriculture and animal husbandry in the dry desert zone. Due to the explosion of population, economic pressure and overexploitation of water resources, the ecological environment and sustainable development of Jinta oasis were affected enormously. Therefore, it is great significant to study the spatial-temporal change of oasis and its driving forces. So, this paper aimed to intensive study the characters and disciplinarian of oasis spatial-temporal changes on the township scale, then analysis the driving mechanism for the sustainability of Jinta oasis. Based on remote sensing and geographic information system and Landsat TM of 1990 and 2009, the land covers were divided into two categories as oasis and desert. Oasis included arable land, forestland, grassland, water area and residential area; desert included saline and alkaline land, gobi and other unused land. On the basis of field investigation and recheck of the interpretation, the spatial-temporal changes were analyzed with oasis dynamic index, oasis spatial distribution, change trend and regional differences of oasis. The results showed that: due to the influence of natural factors and human activities, currently, Jinta oasis was in an unbalanced state, oasis scale gradually expanded. The oasis area was increased 188.78 km² the expansion rate was 36.93% in the past 20 years. The oasis area change of each town showed with different varying degrees, the spatial distribution of oasis has also undergone a major change. The extent of oasis area changing were Yangjingziwan town > district of Jinta county > Dongba town > Sanhe town > Gucheng town > Zhongdong town > Jinta town > Dazhuangzi town > Xiba town. Oasis area became more intensive, and desert was been more stable relatively, the oasis/desert transition zone was decreasing obviously from 1990 to 2009. Human activities were the major reason cause the change of Jinta oasis in the past 20 years. The economic factors, demographic factors and government policy were the major driving factor of oasis change, and the water resources exploitation was the main limitation of oasis change.

SE01 - Crowdsourcing of fine-scale, geolocated bird records: The need for an open species distribution mapping system

Abdulkhakim Abdi (Columbia University)

There are presently a several sources for open access geospatial data that enhance the capability of researchers and conservationists in providing rapid analysis of anthropogenic phenomena and monitoring species dynamics. For example, the 2009 pan-European land cover and use project (GlobCorine) was completed in under nine months, demonstrating that automated production of a general purpose land cover map can be made in a relatively short time. Similarly, several earth observation platforms such as MODIS provide data products in near real time. This not only facilitates timely incorporation of landscape changes in species distribution models but also facilitates delivery of information to decision makers. Finally, there are a handful of high-quality open-access species records databases such as eBird and the Global Biodiversity Informatics Facility (GBIF) that play an instrumental role in the dissemination of biological data to monitor species dynamics. On the other hand, the proliferation of affordable handheld global navigation units (both standalone and embedded in smartphones) has enabled the widespread use of this location technology amongst consumers. At the same time, there is a burgeoning population of amateur ornithologists and birdwatchers in Europe and elsewhere. For example, there are about one and a half million birdwatchers in the UK and about 50-70 million in the US. However, bird records rarely include the geodetic coordinates where a bird species was sighted; instead, the general locale of the sighting usually suffices. In this regard, there is a practical opportunity in taking advantage of global navigation units to attach geodetic location to bird records. This presentation postulates an unambiguous reporting protocol that specifies the inclusion of fine-scale geodetic coordinates of each reported bird sighting to high quality online portals such as eBird. This will facilitate the availability of open-access, geolocated data on species occurrences at a fine scale to the research community and allowing for cost-effective and timely analysis and modeling of species distributions.

SE02 - Long-term variability of rainfall characteristics in the Philippines for the period 1910-2010

Ikumi Akasaka (Tokyo Metropolitan University), Wataru Morishima (Nihon University), Hisayuki Kubota (IORGC, JAMSTEC), Jun Matsumoto (Tokyo Metropolitan University), Esperanza O. Cayanan (PAGASA)

To clarify how rainfall characteristics will change with climate change as the global warming, as the first step, a lot of earlier studies have investigated the past long-term variability in different regions. However, the earlier studies for Southeast Asia covered limited time periods since the late 20th century. This is because the digitized daily rainfall data became available at most stations of Southeast Asia since approximately the 1950s. Meanwhile, historical meteorological observations from the late 19th century to the early 20th century have unexpectedly been found in the paper format in some Southeast Asian countries including the Philippines. Thus, the purpose of this study is to clarify longer-term changes in rainfall characteristics in the Philippines since the 20th century by combining these historical observation record and current station data. The 27 stations with almost same latitude, longitude, and name existed in both the early and late 20th centuries were used. These data have more than 80% of the data of a year. We used rainfall data from May to next April as 1-year because the seasonal march of rainfall in the Philippines characterized by the Asian monsoons, which start in mid-May around the Philippines. First, we calculated annual and seasonal amounts, frequency (more than 0.5mm/day), and intensity of rainfall. Then, to clarify changes in annual and seasonal rainfall amount, frequency and intensity, we classified all daily rainfall data into four groups by the quartile points and the median: the weakest rainfall class is Q1, followed by Q2, Q3 and Q4. Additionally, extremely wet days and heavy rainfall amounts were defined as the 95 percentile of distribution (P95) of annual and seasonal rainy days and amounts, respectively. To find long-term trend of rainfall characteristics, the Mann-Kendall test was applied to their time-series for the late 20th century at the 95% significance level for a two-tailed test. As a result, number of summer (Jun.-Sep.) and winter (Oct.-Jan.) rainy days significantly tended to decrease in the entire Philippines and the northwest part of the Philippines, respectively. Summer rainfall amounts in all groups tended to decrease with a 10-year cycle, especially in the northwest part of the Philippines. On the other hand, large positive anomalies in winter rainfall averaged in the whole area appeared during the early 1970s and from the late 1990s to the early 2000. Additionally, increases in the amplitude of the year-to-year variations were also shown since the 1970s. Winter rainfall amounts in P95 show significant

increasing trend in the northern Philippines since the 1950s. Heavy rainfalls (Q4 and P95) tended to increase with a 10-year cycle especially in east coastal region since the late 1990s. It was found that the long-term variability of rainfall characteristics showed different trends between summer and winter. Additionally, regions with remarkable trend also differ by each season.

SE03 - Stabilization of Rural Settlements Focusing on Location Models (case study in Kalat- Iran)

Farahnaz Akbar oghli (Payam Noor University)

In the present paper, considering the environmental- ecological and human factors, the procedure of stabilization of rural settlements of Kalat has been studied with focusing on location models and service distribution. The objective of the present study is the connection of the regional rural settlement network to the general network of the country, the regulation of inappropriate and incoherent network of rural settlements and finally the attraction, establishment and stabilization of the under-study rural population by proper location and determination of stable areas. For achieving this, two holistic methods for studying the socio-economical subjects of the community and the superficial recognition were used for studying the environmental-ecological structure. GIS was applied for providing and analyzing data. During this process, firstly, the establishment of settlements with regard to the determination of stable areas from the viewpoints of environmental-ecological factors and human factors as well as access to different kinds of services and infrastructural facilities was studied. Then, merging the plans obtained by Bolin logic and Fuzzy logic, the stable regions appropriate for establishing rural settlements were identified. The studies showed that the instability of rural settlements of the region is due to environmental- ecological limitations which have caused socio-economical instability and functional irregularity of settlements. The location allocation model was used for regulating functional hierarchy of settlements on the basis of which the under-study community was suggested to be divided into four categories of systems, series, districts, and satellites.

SE04 - Tourism associated areas configuration based on hierarchical analysis model (AHP)(case study in Beihagh-Iran)

Farahnaz Akbar oghli (Payam Noor University)

Determining tourism associated areas in rural spots, makes it a better situation for development coherent planning on rural tourism. To determine the tourism

associated areas in Sabzevar's district of Sheshtamad in Beihagh village, the hierarchical analysis model (AHP) and potent GIS software were utilized to produce and analysis of maps. During the process, first we used the Expert Choice software to arrange data and various criteria such as topography, altitudes, territorial function, waterways, geology, and distance from fault and also human criteria like distance from the road and distance from rural spots. Arrangement was accomplished through three stages of forming the hierarchical tree, valuing the criteria and calculation of the options' weight based on the hierarchical analysis model. Then, using ARC GIS software and mathematical overlapping function, configuration was done for Beihagh village to determine the tourism associated areas. The results said that about 8% for residential-recreational centers, 28% for resorts, and 4% for land space are appropriate to allocate out of the whole rural settlements which plus two rural settlements of Padar and Kizghan, totally 48% of the villages are potentially appropriate for the natural tourism purposes. According to the accomplished configuration, the other areas of the village as associated areas to service the tourists have got the potentials such as suitable rooms for car parking, power and lighting, health and amenity installation and water-supply. More appropriate access to transportation and other infrastructures can lead to easy access to amenities and services by the tourists due to being close to each other, making variety and specialization of the tourism areas and most importantly, economizing the installations and services, all of which are considered to be the privileges of configuration of tourism attraction areas.

SE05 - Geopolitical Aspects in Romania. Case study: The Danube Valley.

Madalina-Teodora Andrei (Faculty of Geography), Iuliana Pop (Faculty of International Business and Economics, Academy of Economic Studies), Petronela-Sonia Nedea (Christian University), Cezar Gherasim (Spiru Haret University), Dan Eremia (Spiru Haret University)

The existence, the evolution of the peoples and the development of the nations are closely related to the waters, especially the large rivers, and the awareness of the importance of the position related to the waters contributes to the consolidation of the economic, political, cultural, geopolitical and geostrategic power. The Danube, because it crosses the European continent from west to east, has an important geostrategic position, and the connections through the Black Sea to the Orient and the planetary ocean offers a geopolitical importance, which can be observed over time. The Danube is organically connected to the

territory of Romania and its geostrategic interest is in full concordance with the geostrategic position of Romania. From a geostrategic and geopolitical point of view, Romania represents a bridge between the Occidental Europe, on the one hand, and Eastern Europe and the Orient on the other hand. The Danube represents Europe's largest navigable route, especially after the building of the important transcontinental navigational connection (which links the North Sea to the Black Sea). Due to the fact that the Danube is the navigable river, this becomes an important trading route. Due to its physical, geographical and economic features, the Danube may be considered an energy route. Nowadays, the Danube represents an important cultural route, being the link between the German, Slavic, Romance and Oriental cultures. The Danube can integrate these cultures in the great European culture and can consolidate the relationship between the other cultures on the other continents, especially the Asian one. The Danubian culture itself has a cosmopolite feature with global values.

SE06 - Water resources in Montevideo before Rio + 20 conference after 11 years of local Agenda 21

Carlos Anido (Faculty of Engineering University of the Republic)

It was stated at the 2005 IGC Congress that water resources in Montevideo, Uruguay, were affected by decades of rural, urban, harbor, and coastal activities. The city depends entirely of external basins for water. When drought arrives, there is not enough groundwater for rural purposes. The area is statically linked to El Niño phenomena. In last decades annual rain increased about 20%. Climate change would also affect this coast. The city has environmental problems created by waste, scattered and abandoned facilities, logistic, roads and suburban expansion, but with the same population. There were infrastructural and functioning improvements since 1990. An agenda 21 was installed in 2000. There were new local political subdivisions in 2010 (8 councils) and new national use-of-soil laws, but less actual rural area protection. A first submarine emissary pours sewage in the sea and a second is to be build. The first has leakages detected in 2003 without actual fixing plan. Poster's goal is to expose the state of water since 2005, thinking of next year earth summit, and situation of local agenda 21 with 3 editions (2000, 2002, 2008). The analysis of state is made from watersheds studies, monitoring by participatory commissions, reports on industry sewage, courses and beaches. Some results are: formal improvements in natural areas but scarce investments, more urban pressure. Metropolitan water demand has summer peaks of 650.000 m3/day and waste disposal reaches 684.000 ton/year. The rural area diminishes with

real estate speculation seeking soil change of use, generating less food production. Environmental laws and controls are weak, partly because promoted exporting for cash. No solutions have been yet build up for transboundary basins east and west. There is still polluting discharge in some beaches. Lately there are intense storms with more local floods. Sewage will be increasingly poured into the river, with new drainage works covering lower density areas. The city has an important footprint, including less water quality, probably making future city services costs unsustainable. Some conclusions are that city grows impacting drainage. Garbage still goes to water bodies. Some basins are better with plans, others has less rural area substituted by suburban areas. After improvements with civil works and management, a limit seems to be reached in state of basins. Water quality is poorer in summer. Quality plans obtained improved beaches. The expanding city shows a rising footprint with no plans for climate adaptation. Quality improvements were mitigated by more waste and discharges from anthropic activities, making future city services costs unsustainable. Problems appear with changes in new administration (2010), which stopped Agenda 21 and annual environmental reports, raising interrogations on future commitment with social participatory monitoring.

SE07 - GIS technologies for assessing the ecological state and managing Armenia's farmlands

Shushanik Asmaryan (Center for Ecological-Noosphere Studies NAS RA), Armen Saghatelyan (Center for Ecological-Noosphere Studies NAS RA), Vahagn Mouradyan, Meline Amirkhanyan (Center for Ecological-Noosphere Studies NAS RA), Lilit Minasyan (Center for Ecological-Noosphere Studies NAS RA)

The territory of the Republic of Armenia (RA) occupies an area 29.8 sq. km, the major part of which - 2077 hectares - falls on farmlands located at a height 400-3200m a.s.l. Such a variation in altitude complicates development of territories especially in the case they have an extensive character stemmed from the Soviet era: land plough-up on sites lying at a very steep angle of decline - >200, unregulated grazing and so on. A long-term, unplanned and unregulated use of farmlands entailed intense washout of upper soil horizon, which subsequently provoked intense development of erosion and degradation of lands. A practicable solution to this problem is a scientifically and methodically grounded assessment of ecological state of farmlands and economically 'competent' planning and management of agricultural resources. The GIS and Remote Sensing (RS) Department of the Center for Ecological-Noosphere Studies NAS RA has developed a scientific and methodical approach to the assessment of

ecological state with application of GIS and RS technologies, which underlay investigations on the assessment of the state of pastures in the RA. The approach implies availability and a wide use of diverse source information (aerial and satellite images of medium and high spatial resolution, large-scale topographic maps 1:25000 and different derivative thematic layers: landscape, climatic etc.), which treatment, collation and analysis is implemented using GIS softwares. The complex assessment helped obtained an exhaustive picture of ecological state of pastures of over twenty rural communities located in different administrative regions of Armenia. Presently the Department is building a vigorous GIS infrastructure to treat, store and transfer ecologically valuable information to relevant governmental authorities to underpin decision making and management in the field of agriculture.

SE08 - Using a low-cost Mini-UAV for Remote Sensing Imaging

Andreas Bolten (University of Cologne), Juliane Bendig (University of Cologne), Georg Bareth (University of Cologne)

The trend to minimize electronic devices also accounts for Unmanned Airborne Vehicles (UAVs) as well as for sensor technologies and imaging devices. Consequently it is not surprising that UAVs are already part of our daily life and the current pace of development will increase civil applications. The problem when designing a Mini-UAV for multi-sensor imaging is the limitation of payload of up to 1.5 kg and a total weight of the whole system below 5 kg. A Mini-UAV system with these characteristics is HiSystems? MK-Okto (www.mikrokoetter.de). Total weight including battery without sensors is less than 2.5 kg. Payload of a MK-Okto is approx. 1 kg and maximum speed is around 30 km/h. In our study, the MK-Okto is equipped with a handheld low-weight NEC's F30IS thermal imaging system. The F30IS which was developed for veterinary applications, covers 8 to 13 m, weighs only 300 g, and is covering the temperature range between -20°C and 100°C. From a flying height of 100 m, the camera's image covers an area of approx. 50 by 40 m. Additionally, the MK-Okto is equipped with Tetracam's MiniMCA. The MiniMCA is a four band multispectral imaging system in the 1000 nm domain. Total weight is 700 g and spectral characteristics can be modified by filters between 400 and 1000 nm. In this study, we used three bands with a width of 10 nm (green: 550 nm, red: 680 nm, NIR1: 800 nm) and one band is 20 nm wide (NIR2: 950 nm). First results of a combined thermal- and multispectral MK-Okto campaign in 2011 are presented and evaluated for a sugarbeet field experiment for pathogens and drought stress.

SE09 - Contemporary environmental changes of Jaszczce and Jamne stream valleys in the Gorce Mountains (Western Carpathians) in relation to land use and soil properties

Anna Bucala (Institute of Geography Polish Academy of Sciences), Anna Budek (Institute of Geography Polish Academy of Sciences)

Study area, Jaszczce (11,4 km²) and Jamne (8,9 km²) catchments are situated in the Gorce Mountains. The catchments are characteristic of streams in the Gorce Mts. In the upper part of streams channels (Jaszczce and Jamne stream) mainly erosion processes occur. These left-bank tributaries of the Ochotnica river have V-shaped, deeply incised valleys (up to 300 m) and narrow channels with numerous rock steps. The inclination above 18° have more than 61% of slopes. The lower parts of slopes are even steeper. The catchment of the Jaszczce stream is a narrow valley with very steep slopes exposed mainly to south and north-east. The higher parts of valley slopes are covered by forests, meadows and pastures. In the lower parts there dominate arable lands. The Jamne valley is wider. Its slopes are not so steep and they are exposed to the south. They are mainly deforested and arable lands here extend up to 1100 m a.s.l. In this region Brown soil (Dystrochrept) occur. That soils developed on loam and sandy or silty loam. The thickness of soil profiles increased in lower part of slope from 1.0 m to 1.6 m. In the upper part of slope catenas increased pieces of rocks in soil profiles. As well shallow and full of rocky pieces soil profiles occurs below the edges of agricultural terrace (Bucala 2010). The aim of the work is to present the contemporary changes of Jaszczce and Jamne stream valleys in relation to land use and soil properties. In this field, the first significant cause in the intensity of geomorphological and soil processes were adverse relief of Jaszczce and Jamne catchments, especially the large inclination of slopes. The second cause, physical and chemical properties was changed by shifting of land use, especially by cessation of tillage. In the upper parts of slopes increase of the forest and grassland areas and in proportion decrease of arable land. Land use changes between 1954 and 2004 years are an effect of socioeconomic transformations, especially after the 1989 year. They lead to decreasing of the arable land area by about 80%, and parallel increasing of forest areas and reduce excessive soil erosion on the slopes. It shall focus predominantly on land use changes during different time units (based on varied cartographic data: topographical maps, air photos and satellite pictures), and a field survey, which includes also their influence on the type and intensity of denudation and soil processes. The project is funded by the National Science Center (NN 306 659 940).

SE10 - Poaching by traps in Sardinia: Old and new implications from a geo-historical perspective

Isabella Capurso (Bicocca University of Milan)

This paper examines whether poaching by traps in South Sardinia, which is continued common practice, still plays a role in defining a local economy and a cultural landscape. The aim of this analysis is to identify the main geo-historical connections that link current activities with their past meanings. In doing so, the 'geographie de la long durée' paradigm will be a suitable tool to look at the topic. To understand what 'poaching' exactly means in present Sardinia, it is necessary to understand what these practices had meant before official Acts declared them illegal. In fact, today's society starts to understand that trapping is an unacceptable way of hunting as it does not target a specific species. As a result, animals with an irreplaceable naturalistic value fall prey to traps. To conquer this issue, western institutions prohibit traps by a comprehensive normative system, involving International Acts, EU directives, as well as national and regional laws, reflecting the latest insights gained in biodiversity field studies. Subsequently, there is a better transparency of the legal situation in regards to cynegetic practices. Still, there is much more involved to fully understand this phenomenon. First of all, it is inevitable to learn who the poacher was in the different epochs to understand why and how these practices are still present in Sardinia, while they have almost entirely disappeared in the rest of Italy. The trapping in that geographic area has undergone changes in the course of time, which backgrounds are of social and cultural nature, rather than minority, localistic or independence supporting. Hence, the illegal activity of hunting by traps is rooted in the island through a significant system of social relations, an intricate structure of production and an expert connection with the local environment. Quantitative and qualitative data collected from recent investigations show how poaching by trapping birds still causes significant damage to the biodiversity, due to the high number of unintentionally killed animals including protected species. Moreover, this paper examines the socio-cultural and geo-historical mechanisms that make the phenomenon so persistent. The article indicates four main factors contributing to maintaining this practice: environmental, economical, cultural and political aspects.

SE11 - Atacama's Sand Sea Geosite, Copiapó, Chile

Consuelo Castro (Universidad Católica de Chile), Carlos Pattillo (Percepción Remota y SIG), Alvaro Zuñiga (Instituto de Geografía)

Atacama's Sand Sea is a special component of Atacama's geoheritage, notable for its natural, scientific and educational value due to its geomorphologic and scenic features. The main objectives of this research (Fondecyt 1100400) is to highlight its originality as a start point for its protection and sustainable use, as part of the Atacama's Region geoheritage. These continental dunes belong to a geomorphological inherited feature and they constitute a noticeable scenic landscape near Copiapó (27° S). Also, dunes shelter the natural phenomena of blooming desert that takes place during El Niño Southern Oscillation. A geomorphological and vegetational data base was established using satellite images, aerial photography and field work. The Atacama continental dunes are found to the northwest of Copiapó, between 300 and 1600 meters of altitude, covering an area of 335 square kilometers. Dune's morphology and position are affected by the topography of valleys and surrounding hills; responding to complex wind pattern and dynamics. The types of dunes found in Atacama have been mapped and classified. Different dunes succession responds to evolutionary pulses that resulted in the formation of Atacama's sand sea. A cartography of the vegetation distribution and the blooming desert was made. The endemic vegetal species more commonly found is *Tillandsia Landbeckii*; its presence is explained by the coastal fog. The blooming desert consists in the flowering of more than 200 species during the spring season. Winter rains, reaching over 15 mm, activate this occasional event. The blooming desert takes place between 100 and 700 meters above sea level, on the surface of eolian planes and semi-stabilized dunes. The human uses of the sand sea are the extreme sport activities of Atacama Raid and Rally Dakar. Also iron and copper mining is developed in the subsoil of the coastal mountain range, where dunes are located. The geomorphological and vegetation cartography, will be useful in zoning the sand sea according to its potential and weakness to support human activities. This research also provides the scientific information that allows the recognition of the sand sea as a geosite and contributes to the land use planning for the development of the Atacama Region. Acknowledging the dunes as UNESCO geosite will contribute to raise its valuation as a part of Chilean geoheritage.

SE12 - Between Subsistence and Subsidies: Food Security in the Indian Himalaya

Juliane Dame (Heidelberg University)

Issues of food security and its particularities in high mountain regions are often neglected in science and policy agendas. However, high altitude populations are affected by poverty, seasonal food shortages and low dietary diversity. Especially the phenomenon of 'hidden hunger' is considered to be characteristic in these regions. Mountain food systems have undergone significant transitions over the past two decades. Changes of environmental and socio-economic conditions have substantial impact on livelihood strategies of small-scale farmers. Whereas subsistence-oriented agriculture still forms the economic mainstay, current dynamics include livelihood diversification with new income opportunities and development programmes by government and non-government actors. Therefore, integrative assessments of complex food systems are needed to provide a basis for sustainable mountain development. Against the background of an empirical case study from Ladakh, Indian Himalayas, the research illustrates different dimensions and determinants of food security in high mountains. In the study region, malnutrition resulting from seasonality and low dietary diversity is prevalent. Following an actor-oriented and multi-methodological approach (quantitative and qualitative interviews, land-use analyses) the study shows how food security is shaped by the interplay of local choices and external interventions. Farmers combine subsistence agriculture with off-farm activities (e.g. in the army, in tourism), try to access new market options (e.g. cash crops) and use the benefits from development interventions (e.g. food subsidies, horticulture development). However, while some households enhance their well-being, new 'losers' are also created at the local level.

SE13 - The state farm in Syria: Life and death of an experience based on a socialist model

Maher Mustapha (Paris 1 Panthéon-Sorbonne), Maher Mustapha (Paris 1 Panthéon-Sorbonne)

Key words: Syria, Agricultural policy, State farms, irrigation, big projects
Abstract: In Syria, Agrarian Reform occurred in the 60's was mainly redistributive, but some state farms were put in place. Their creation wasn't only ideological and some of them lied within big hydraulic projects in order to train peasants and improve soil quality. Their organizational structure was very

hierarchal and the whole life of wage earners was taken into care in fully equipped apartments. The state farms are liquidated since 2000 and their lands are distributed by plots of 2 to 8 ha to different types of beneficiaries (former landholders before the state farm, former employees during the state farm, etc.). These land tenure changes aimed to encourage the development of a new middle class of peasants independent but subjected to an indicative production plan. What are the differences between these two models of production? What were the results of the state farms? What are the advantages and the inconveniences of the new agrarian structures put in place currently? The poster aims to answer these questions in placing the state farms within the context of the agrarian structures of Syria and within the history of the collectivization of the agricultural structures in the world. Then we will present the advantages and the inconveniences of the two models of agricultural production discussed in this poster. At last, we will take the example of one of the biggest state farm in Syria: the Al-Asad Establishment.

SE14 - Place Names as Ethnic Indicators

Stephan Fuchs (FAU Erlangen-Nuremberg)

This poster discusses the quality and value of place names as indicators for ethnic settlement and cultural impact based on my work on German toponyms in the American Midwest. This includes a critical understanding of naming as a form of power and meaning. Place names represent important socio-cultural expressions that can signal the status, character, and intentions of eponyms and allow delineating areas of geographical concentration and absence when integrated into modern cartographic applications such as GIS. The study of place names also entails certain limitations in terms of scale, timing, and definition. The example of German place names in the Midwest yields concrete insights into the challenges and rewards of toponymic research. The compiled data include a variety of name types and origins such as places of religious or ethnically mixed background. Processed within a GIS environment, the resulting maps indicate local clusters and broader concentrations as well as zones of sporadic German presence on the regional scale which have been crosschecked using census data and secondary sources. Place names thus represent a valuable implement to approximate the extent, intensity, and character of ethnic distributions but require careful consideration of the respective group, scale, and timeframe. In addition, name changes and demographic shifts have to be considered. A full assessment and understanding

of the identified patterns - their local backgrounds and forms - however entail additional detailed studies of each area and locale.

SE15 - Regionalizing Aquatic Ecosystems Based on the River Subbasin Taxonomy Concept and Spatial Clustering Techniques

Junfeng Gao (Chinese Academy of Sciences), Yongnian Gao (Chinese Academy of Sciences), Guishan Yang (Chinese Academy of Sciences), Jiongfeng Chen (Chinese Academy of Sciences)

Aquatic ecoregions were increasingly used as spatial units for aquatic ecosystem management at the watershed scale. In this paper, the principle of including land area, comprehensiveness and dominance, conjugation and hierarchy were selected as regionalizing principles. Elevation and drainage density were selected as the regionalizing indicators for the delineation of level I aquatic ecoregions, and percent of construction land area, percent of cultivated land area, soil type and slope for the level II. Under the support of GIS technology, the spatial distribution maps of the two indicators for level I and the four indicators for level II aquatic ecoregion delineation were generated from the raster data based on the 1,107 subwatersheds. River subbasin taxonomy concept, two-step spatial clustering analysis approach and manual-assisted method were used to regionalize aquatic ecosystems in the TaihuLake watershed. Then the TaihuLake watershed was divided into two level I aquatic ecoregions, including Ecoregion I1 and Ecoregion I2, and five level II aquatic subecoregions, including Subecoregion II11, Subecoregion II12, Subecoregion II21, Subecoregion II22 and Subecoregion II23. Moreover, the characteristics of the two level I aquatic ecoregions and five level II aquatic subecoregions in the Taihu Lake watershed were summarized, showing that there were significant differences in topography, socio-economic development, water quality and aquatic ecology, etc. The results of quantitative comparison of aquatic life also indicated that the dominant species of fish, benthic density, biomass, dominant species, Shannon-Wiener diversity index, Margalef species richness index, Pielou evenness index and ecological dominance showed great spatial variability between the two level I aquatic ecoregions and five level II aquatic subecoregions. It reflected the spatial heterogeneities and the uneven natures of aquatic ecosystems in the TaihuLake watershed.

SE16 - Pangasius at risk. Governance in farming and processing, and the role of different capital.

Sven Genschick (Center for Development Research (ZEF))

The environmental impact of Vietnamese Pangasius production (*Pangasianodon hypophthalmus* and *Pangasianodon bocourti*) has been recently discussed as failing to comply with standards of sustainability, caused ostensibly by deficiencies in governance, which are driven by internal and external state mechanisms. The topics of Pangasius production and its sustainability have been approached by various scholars, who have questioned the reliability of discussions on sustainability in European retail industries as a means of protectionism (Bush and Duijf 2011). A bottom-up research approach will be applied to first of all elaborate on the perspectives of Vietnamese (potential) users on top-down governance mechanisms, and then secondly to identify further how institutions of governance on different scales are missing. This method will help to draw a more holistic picture and thus create a better understanding of controversies surrounding the sustainability of Pangasius production. The paper is based on a literature review on governance mechanisms in the Vietnamese Pangasius sector, as well as empirical research, in particular semi-structured interviews conducted at Pangasius farming and processing sites in Can Tho City, Vietnam. Using Bourdieu's theoretical approach of the theory of practice, the actions of actors in Pangasius sector are analysed and understood based on a combination of economic, social and cultural capital. The research thus draws attention to an already existing focus on economic aspects in the Vietnamese Pangasius sector, but goes further by showing that especially social capital and local institutions constitute important variables concerning the implementation and observance of governance mechanisms. These mechanisms can both compensate and create economic constraints and need to be considered in order to achieve sustainability in the Vietnamese Pangasius sector.

SE17 - Examining Bio-environmental Factors, Economic Consequences of Hamoun Lake (Iran)

Ali Ghasemi (Pars Arian Ravad Co.)

Hamoun is the largest Iranian freshwater lake, located in the eastern part of Iran which plays an important role for livelihood of the local people. During last decade, however, due to the reasons including low rainfall, construction of multiple dams on Hirmand River which is regarded as the main source of feeding

for Hamoun lake, transfer of contaminated water of industrial , mining and domestic factories into the lake , entering agricultural sewages contaminated with chemical composts , throwing cane eater fish called Amour into the lake and as a result destruction of canebrakes , we are observing bio-environmental contaminations along with serious economic damages to agriculture, horticulture, animal husbandry and fishery (because of drought) which the important ones are as follow : immigration of villagers and Takhtak settlers , extinction of marines and emigrant birds , destruction of farm lands surrounding lake . Keywords:Hamoun Lake, Takhtak settlers, Hirmand, Drought, Ecology, Sistan, Economic Consequences.

SE18 - Holocene clastic and chemical deposition in the playa of Tayma (NW Saudi Arabia)

Andreas Ginau (Goethe University Frankfurt a. M.), Max Engel (University of Cologne), Helmut Brückner (University of Cologne)

Knowledge on playas (continental sabkhat) is scarce and their role as geoarchives for Holocene climate and environmental change is not well understood. The continental sabkha of Tayma, neighbouring the northwestern branch of the An-Nafud sand sea, qualifies as an important study region for the analysis of sabkha sediments and processes and their potential for palaeoclimate relations. Sediments and processes in this sabkha geoarchive reflect the gradual change from relatively humid (c. 10-8 ka BP) to today's hyperarid conditions. The humid period was characterised by the formation of a perennial lake with the occurrence of ostracods and foraminifers adapted to strong salinity fluctuations. Lake contraction and high salinities were responsible for the formation of 'open water' evaporites (aragonite needles) and ooids. Dilution occurred during rain events and flooding; it is characterised by silt-dominated clastic layers that were deposited in thin graded sequences. These processes and further aridisation resulted in the formation of 'capillary' evaporites (e.g. gypsum, halite) accompanied by aeolian and fluvial deposition. The precipitates undergo constant fractionation and re-dissolution, which led to a typical lateral and horizontal distribution of salts: easily soluble salts are concentrated within the centre of the sabkha and proportions of less soluble salts gradually increase towards the outer environs. Thus, the bullseye model seems to be the most appropriate way to describe the evaporite pattern. Even though the formation of 'capillary' evaporites overprints the original stratigraphy, the sabkha of Tayma is still a valuable and regionally important geo-bioarchive for Holocene environmental change.

SE19 - Recent and active deformation patterns along strike-slip faults (Dehshir fault in Central Iran)

Abolghasem Goorabi (University of Tehran)

Satellite data including LANDSAT, SRTM90 m, ASTER, QuickBird and IRS images were used in conjunction with fieldwork observations to find the transition model of landforms along three active strike-slip faults (Nien, Dehshir and Marvast-Harat faults) along the Dehshir strike-slip fault zone in Central Iran since the Holocene. Over all the faults, the offsets of Holocene deposits, the age of which has been determined by correlation to others similar Quaternary deposits that have been dated in Central Iran, were measured. Offset measurements indicate that the right lateral displacement throughout all the faults has ranged between 4 and 55 m since the Holocene (4.0-5.5 mm/yr⁻¹). The maximal offset of Holocene landforms belongs to middle portions of faults, which are documented for the Nain, Dehshir and Marvast-Harat faults and are 10-13 m (1.0-1.2 mm/yr⁻¹), 55 m (4.5-5.5 mm/yr⁻¹) and 30 m (2.5-3 mm/yr⁻¹), respectively. The minimal offset measured north of the middle portions (named the last section) of the faults were 4.0- 5 m (0.4- 0.5 mm/yr⁻¹), 11.0 m (0.9- 1.1 mm/yr⁻¹) and 5.0-6.0 m (0.5-0.6 mm/yr⁻¹), respectively. The offsets in the initial portions (south of middle portions) were moderate and measured 5.0- 6 m (0.5-0.6 mm/yr⁻¹), 15.0 m (1.3- 1.5 mm/yr⁻¹) and 6.0-7.0 m (0.5-0.7 mm/yr⁻¹), respectively. Although the offset rates differ along all strike-slip faults, their offset patterns show the similarity between these three faults. Furthermore, every strike-slip fault is progressively subdivided into auxiliary branches less than 90° counterclockwise from the middle portions toward the end of the faults. Based on this investigation, these faults are very active, and paleoseismological investigations are required to recognize and date the events of faults.

SE20 - Holocene climate variability and its potential influence on the cultural and environmental development in West Greece: New evidence from the Etoliko Lagoon based on geochemical proxies

Elke Haenssler (Kiel University), Kimon Christanis (University of Patras), Marie Josée Nadeau (Leibniz-Laboratory for Radiometric Dating and Isotope Research), Oliver Nelle (Kiel University), Eleni Zagana (University of Patras), Ingmar Unkel (Kiel University)

An important characteristic of Greece is the well documented emergence and decline of advanced societies since ancient times. Often, climate variability is considered to have affected civilizations in the Mediterranean. A sediment core

of 8.8 m from the Lagoon of Etoliko, West Greece (38°29'N/21°19'E) is subject of an interdisciplinary approach of combining geoscientific investigations with written sources and archaeological evidence. The sedimentary succession is composed of a basal laminated part overlain by a homogeneous unit followed by clearly, probably annually, laminated sediments. X-ray fluorescence data with a spatial resolution of 1 cm are used to establish a geochemical stratigraphy. Further, thin sections comprising one meter of the annually laminated part are microstratigraphically examined and compared to XRF data in mm-resolution. Additional proxies will be derived from grain size- and CN-analysis. Geochemical evidence will be compared with the documentary evidence. In the study area pottery findings go back to the Neolithic and nearby Archaeological sites provide information about long-term human occupation. A synoptic investigation will evaluate a potential coherence between climate variability on human activity.

SE21 - Introduction of Naming Rights at Public Facilities in Japan

Teruo Hatakeyama (Nihon University)

In recent years, lack of funds for managing public facilities due to the fragile economic situation has led local authorities in Japan to start introducing naming rights, a practice that began in the U.S. in 1973 in which the names of facilities are sold to businesses. [Remark 1] Since 2003, when Tokyo Stadium was renamed Ajinomoto Stadium, naming rights have been introduced at 136 public facilities in Japan (till November 2011). While naming rights are advantageous for both parties involved, secure independent revenue sources for local authorities and provide advertising and an improved image for businesses, they also cause a number of problems such as businesses withdrawing from deals due to scandals, names being changed with each new term of contract and the security of consensus from local residents. This study attempts to understand the situation pertaining to the introduction of naming rights at public facilities in Japan and presents issues related to policies for managing public facilities in local areas. In addition, the study examines the regional characteristics of naming rights in Japan by comparing with those in the U.S. and Europe. Similar to the U.S. and Europe, naming rights in Japan have been widely introduced at sports facilities' mainly professional stadiums for sports such as baseball and soccer' however, in recent years, their introduction at cultural facilities has also been observed. A characteristic of naming rights in Japan is that the contracts often have a short term and are for a small amount of money compared with those in the U.S. and Europe. This is because global awareness of Japanese professional sports is low, suggesting that the facilities only receive a modest

degree of exposure. Thus, we can conclude that businesses in Japan primarily aim to make regional contribution, and not advertising. In addition, naming rights in the U.S. and Europe are generally introduced at new or renovated facilities, whereas in Japan, they are introduced at existing facilities. This indicates that names of the facilities that are already named need to be changed, leading to a high risk that this action will not be approved by local residents. Moreover, there are increasingly more cases in which facilities are only given a company or a product name, thus obliterating local and informal names. As demonstrated above, many aspects of the practice of introducing naming rights in Japan differ significantly from those in the U.S. and Europe. It can be said that Japanese-style naming rights, in which businesses aim to make regional contributions, are widespread. However, there are a number of issues related to continuing the implementation of naming rights in Japan, such as a decrease in the number of businesses applying for naming rights and further reductions in contract amounts.

SE22 - Reclamation project in each period and its environmental impact – A Case Study of Osaka Bay in Southern Japan

Etsuko Hayashi (Nara University)

This study was aimed at reclamation and landfill in Japan coastal zone. The subjects in this study were analysis of association of blue tide and submarine depression by construction of landfill with their change and feature. Artificial land formation has been developed formerly with of the rise and fall, nature, and so on. In modern scientific technology has evolved to a landfill in the form of offshore artificial island to be created. Along with its development, is going to issue a hotbed of depression and blue tide the sea. A case study of southern Osaka Bay seabed depressions backfill necessary condition for environmental improvement, but not sufficient condition that hardly points out with water pollution problem in the same bay. In conclusion, it is necessary to promote a project that encapsulated the problems of the complexity of the landfill construction project shoreline.

SE23 - A study on variability of extreme precipitation by basin in South Korea

Seungho Lee (Konkuk University), Eunhyung Kim (Konkuk University), Inhye Heo (Konkuk University)

This study aimed to examine changes on extreme precipitation events by being divided into six basins in South Korea. It was analyzed 7 extreme precipitation indices at 60 weather stations in South Korea. Across Korea increasing trends in heavy rainfall were more stable than in heavy rain days. Increasing trends reached the greatest degrees of precipitation trends stability in 50pNoD, 99pT. Increasing trends in extreme precipitation indices-related heavy rainfall dominated in Korea. Han River was the basin with the greatest number of statistically significant trends, mostly increasing ones. The upper region of the Nakdong River and Eastern coast area were also strongly stable in heavy rainfall. But, Geum river and Seomjin river were not. Since the mid-1970s, increasing trends of precipitation from extreme events continued to be stable in Han River and Nakdong River, but since the mid-2000s, there was some regions where variability of extreme precipitation trends dominated. It means that the frequency and intensity of the heavy rainfall become more irregular recently.

SE24 - Landslide-susceptibility analysis, mapping and validation in the Balacita Piedmont (South-West Romania)

Oana Ionus (University of Craiova), Mihaela Licurici (University of Craiova), Sandu Boengiu (University of Craiova), Daniel Simulescu (University of Craiova), Emil Marinescu (University of Craiova)

This work presents the results of applying the GMM to the mapping and validation of landslide-susceptibility analysis in different sectors of the B'I?ci'a Piedmont. The B'I?ci'a Piedmont represents the western subdivision of the Getic Piedmont, being located in south-western Romania. The main objective of the paper concerns the achievement of landslide-susceptibility maps based on the inventory, classification and description of the landslides within the study area. The main stages in the development of the landslide-susceptibility model are: modelling the matrix of the total surface of the study area (TSM), modelling the landslide matrix (LM), modelling the susceptibility matrix (SM) and validation of susceptibility maps. The landslide matrix relies on a previously georeferenced landslide database of the region, in which the slopes are distinguished into two simple classes: with or without landslides. The basic data in the inventory is provided by the source areas related to each landslide, this being appropriate for

detailed scale maps (1:25,000). Information concerning lithology, vegetation, thickness of superficial deposits, maximum precipitation in 24 h, average annual precipitation, geological contact, faults and proximity to flow channel was also used. GMM (GIS matrix method) has been applied to landslide susceptibility analysis, mapping and validation. The starting point was represented by the DEM and, subsequently, based on the lithological data, other determinant factors were analysed and reclassified in a vectorial format: slope angle, slope elevation and slope aspect. After the factors that determine instability were identified for each type of mechanism, susceptibility maps were drawn. In the resulting landslide-susceptibility map a model for the validation is presented (based on the determination and calculation of a set of landslides not). The landslide-susceptibility maps of the B'I?ci'a Piedmont are preventive tools intended to minimize risks in the threatened areas, especially near the settlements that are located on the left slope of the Jiu river and witness the reactivation of old landslides. An important aspect of the present paper consists in the correlation of the perimeters characterised by high susceptibility (the affected area in a given combination of determinant factors extends between 15 and 25%) and very high susceptibility (the corresponding value being above 25%) with the social-economic impact on the affected areas and with the local and national environmental strategies. Keywords: landslide, statistical analysis, GIS matrix method, susceptibility evaluation, landslide susceptibility map

SE25 - Establishment Process For and Modern Issues Facing National Parks in Japan

Yukimasa Kato (Nihon University), Mitsuru Sano (Nihon University)

The purpose of this research is to make clear the process by which Japanese national parks are established, and give consideration to the modern issues that they face in the context of their historical background. It should also become source material that gives consideration to methods for the maintenance and management of these parks in the future. While the current national parks system in Japan was created based upon the American system, the Second World War, recovery period after the war, and the rapid economic growth period has completely changed this system. Once reason that can be stated for this is that many of the national parks overlap with places that had always been tourist attractions, and the development of tourist attractions has met with little resistance, even from local residents. Another reason for the development of tourism within national parks is the selection conditions for national parks that were established in the prewar period. These conditions desired locations those

were appealing as tourist destinations. It can therefore be said that the viewpoint taken by the Japanese national park system already differed from the one originally used in America at the stage of constructing the system itself, or at the stage of selecting candidate locations. Due to these circumstances, there will be an even greater requirement for the establishment of a management system suited to Japanese society in the future. In terms of current issues faced by national parks, one is the fact that awareness of national parks themselves remains low. For example, Mt. Fuji is located inside the Fuji-Hakone-Izu National Park, but very few people are aware of this fact. Also, Mt. Aso and its surrounding caldera are picturesque scenery inside Aso Kuj? National Park, but even the local residents living around Mt. Aso are almost totally unaware of the existence of the national park. It can therefore be said that the awareness of national parks themselves is very low domestically in Japan. The next issue is that the facilities within national parks, starting with the visitor center, are not being effectively used. Just as the low awareness of national parks has already been mentioned, in the same manner, awareness of the facilities within the parks is also low. People do not have a clear understanding of the kind of services that the visitor center offers. It is therefore difficult to increase awareness of national parks and make use of them in education. Taking these circumstances into consideration, it can be said that the immediate duty of the Ministry of the Environment, the body responsible for the management of national parks, is to work with local municipalities and elementary and junior high schools to promote national parks anew, and make effective use of them in a way that includes environmental education.

SE26 - The early neolithic site at Düren-Arnoldsweiler, Lower Rhine area, Germany – Site formation processes as based on field description and micromorphology

Martin Kehl (University of Cologne), Peter Fischer (University of Cologne)

Archaeological excavations at Düren-Arnoldsweiler (2009-2011) recently exposed remnants of an early neolithic settlement including more than 30 post-built houses, a burial ground with about 220 burials, a well and an earthwork. The geological situation at the site is complicated. The archaeological finds partly cut into a sequence of fluvial, solifluctional and reworked aeolian deposits including palaeosol horizons. These Pleistocene sequences are covered by several layers of Holocene soil sediments, which bury most of the archaeological finds. Our objectives are to elucidate site formation processes and to set up a reliable chronological framework of sediment accumulation and soil formation at

Düren-Arnoldsweiler. For this purpose we conducted geomorphological-pedological field work and micromorphological studies, which will be presented here. In addition, first luminescence age estimates using the silt size quartz fraction will be discussed. Under the microscope, all Pleistocene layers show signs of frost as indicated by platy or lenticular microstructures, banded fabric, vertically oriented elongated grains and vesicles. Near the southern end of the earthworks a dark grey paleosol (Humuszone), tentatively correlated with the Early Last Glacial, is found near the land surface at less than 1 m depth. It can be distinguished from the sedimentary fill of the earthwork and pits by its darker colour, thick illuvial clay coatings, and lack of charcoal. The modern soil consists of up to three stacked soil sediments (colluvial deposits) and an in-situ Btg horizon that represents the erosional remnant of the Early to Mid Holocene soil. The first soil sediment from the top (Ss1) is less compacted than the second one (Ss2), while both contain small pieces of charcoal. Thin sections clearly reveal the presence of illuvial clay in Ss2 and some, as based on field evidence tentative, Bt horizons. Most clay coatings in Ss2 have formed in-situ but disrupted ones suggest relocation from a former Bt horizon. The earthwork and ditches are filled with weakly compacted loess-derived sediments and soil materials. Abundant dark clay coatings are present. Most of the coatings are intercalated by thin layers of opaque substances, probably consisting of manganese. Most fillings also contain fine pieces of charcoal. First luminescence age estimates show that the accumulation of the soil sediments started during the Younger to End Neolithic (6.4-4.3 ka). The youngest soil sediment (Ss1), not affected by clay illuviation, was deposited during the late Iron Age. The micromorphological approach gives indispensable information on the sequence of soil forming processes and provides important criteria for distinguishing palaeosols, holocene soil sediments and sedimentary fill of archaeological features. The case study of Düren-Arnoldsweiler underlines the often complex history of sediment deposition and soil formation in the Lower Rhine area.

SE27 - Effects of Suburban Valleys on Urban Air Quality – a Case Study in Climatology and Urban Planning in Past and Present

Gunnar Ketzler (Geographisches Institut), Timo Sachsen (RWTH Aachen), Katja Eßer (RWTH Aachen), Marie Dunkert (RWTH Aachen), Christoph Schneider (RWTH Aachen)

Many cities are situated in complex terrain. Thereby, in urban history, valley plains along the urban-rural fringe were often developed less intense or left as open spaces. Today, these areas on the one hand form ventilation paths which

play a major role in urban mitigation strategies against air pollution and heat stress. On the other hand, such plots often are subject of urban development requests and, thus, elements in public discourses. In the framework of the project ""City 2020+: Engineering life quality for the future - The City under Global Demographic and Climate Challenges"" (Schneider et al., doi:10.5194/asr-6-261-2011), the connections and interrelations between urban summer heat waves, the distribution of airborne pollutants and effects of suburban cold air drainage flows are investigated including their historical and administrative context. Here, in a case study from the city of Aachen, Germany, phases of urban development in a small suburban valley are illustrated and assessed with regard to the correlating climatological conditions. The city of Aachen, Germany, is situated in a shallow basin. The town centre is partly surrounded by small valleys. Their positive bioclimatic and air quality effects on urban climate are well recorded. Especially for the valleys of Kannegießerbach and Ponellbach, numerous results from climatological measurements, extensive historical data and information on development procedures as well as model results are available. Modern urban development in Aachen began with the razing of the medieval city walls during the Napoleonic occupation. The early onset of industrialization, marked by the introduction of steam engines in the city centre in 1817, caused an initial increasing of industrial air pollution. By the end of the 19th century the occurrence of extensive steam engine usage had caused further massively increasing emissions. This fact and in addition to this the extension of the urban area (?Gründerzeit?) resulted in negative effects on ventilation. The combination of these factors had evoked both negative health effects for the local population and public discussions about the decreasing air quality in the city of Aachen with its spa town tradition. In the 20th century, urban development partly left the valley plain and mostly concentrated on higher located positions in the basin. In the last decades, the valley areas which are partly close to the city centre, again were in the focus of urban development. The development of these urban valleys is reconstructed both by historical data and similar information and climatological respectively model data. Especially the effects of building structures and vegetation on cold air drainage flows are investigated by using the model KLAM_21 of the German Weather Service for the reconstructed historical and the present situation.

SE28 - Distribution of the Amur River Flow Between the Subchannels in Multi-Channel River Passages

Vladimir Kim (Russian Academy of Sciences Far Eastern Branch), Alexey Makhinov (Institute for Water and Ecology Problems)

The Amur River not only has the largest drainage area amongst Pacific rivers but also is situated on the boundary of natural zones. These facts coupled with the impact of natural and anthropogenic factors in the river basin cause instability of water flow, active riverbed processes and specifics of temperature and ice regimes. That is why water and terrestrial ecosystems of the Amur River are highly dynamic and very vulnerable to external impacts (including anthropogenic ones). Intensive economic activities in the Amur Basin in the last 50-60 years sharpened many ecological problems. The ratio of river flow distribution between the Amur channels is extremely unstable within the plains, where the river valley has a vast floodplain and the riverbed is divided into numerous sub-channels. It is well known that rivers near big cities suffer various impacts caused by city water facilities. Different hydrotechnical constructions, river-training measures, channel dredging, extraction of construction materials from the river bottom significantly effect the dynamics of river channel processes. Besides, rivers always suffer anthropogenic loads near big cities. They are caused by a high concentration of population on a relatively small area and hence a large number of industrial and municipal facilities. Amur water regime changes due to operations of big hydropower stations on the major tributaries in its basin significantly affected the river hydrological regime. As the results new sub-channels appear and some old ones expand. Floodplain massifs undergo intensive erosion and accumulative processes. Due to lateral river channel shifts, formation of bars and sides of floodplain islands, meandering of subsidiary channels, accumulation of sediments on channel banks the floodplain relief is very diverse. That is why the redistribution of river flow becomes very complicated. All mentioned factors make urgent the mitigation of negative consequences of undesirable river flow redistribution.

SE29 - Centrality 2.0 – towards a new understanding of diachronic socio-environmental developments

Daniel Knitter (Freie Universität Berlin), Arne Ramisch (Alfred Wegener Institute for Polar and Marine Research)

The spatial and hierarchical organization of cities was first described by Walter Christaller in his central place theory. Since then centrality has been understood

as the excess of importance of a place. When applied to specific case studies the concept of centrality lacks a general transformation of the theoretical considerations into the real world. Nevertheless a better understanding of centrality is necessary, especially by observing a continuous importance of some cities throughout time. Here we present a system theoretical framework using a concept of interaction and frequency to reconstruct and describe the centrality of a region and its determining parameters independent of time. Centrality is redefined as the relative concentration of interaction between individuals or groups. Hence, a central place is the spatial location where interactions are concentrated. As a quantitative measure of centrality, the frequency of individuals is introduced. In a first step the centrality throughout the time, i.e. starting from prehistory until today, is assessed using central functions and their occurrence on different spatial scales. Two exemplary regions of long settlement continuity are chosen to test the model. The first region is situated at the city Aleppo and its environs. Aleppo, as one of the world's oldest cities is able to indicate locational benefits at environmental and cultural frontiers. The other region is the Anatolian west-coast. Based on a comparison of the development of selected cities throughout the time the importance of social and natural parameters is reconstructed. As a result our analysis creates a link between modern geographical research and archaeological interpretation of past circumstances and may lead to a better understanding of the interplay between society and environment throughout the time.

SE30 - Concept Presentation of the Project “Trail of Change” (TOC). An interdisciplinary Scientific Multi-media Approach on Change and Challenges in the Mountains from Bhutan to Pakistan.

Hannes Künkel (University of Göttingen)

Everybody is talking about Change in the Himalaya Regions but who except the experts can mention more than maybe glacier retreats - One of the key problems not only in High Mountain Geography is the challenge of knowledge transfer and public acceptance of scientific content. In fact there seems to be a deep-rooted boundary between scientific research, results and proposals on the one hand and the local (or global ') actors on the other hand. There is not yet an interest of the broadband-sensitiveness towards change of those groups. Scientists, especially those who are working on development and change in remote regions should have long since noticed the importance of publishing research results to a broad public. Such procedure needs authentic, interdisciplinary, multi-media concepts which should be easily understandable,

but nevertheless by no means over-simplifying or dramatizing. 'Trail of Change' features different scientific research programmes and international researchers along the recently opened and strongly promoted 'Great Himalayan Trail' (GHT) from Bhutan up to the Karakoram. The thematic guideline of the project is the expression of ""Change"" along the GHT, documented and broadcasted live, using social media and satellite technology on several journeys and expeditions between 2013/14 and 2017. The aim of providing ""direct-correspondence"" with affected locals, scientists, NGOs and decision makers is a new trial. Strong Interdisciplinarity of the Content will provide a global perspective. The TOC-project is therefore open for any researchprogramme connected to ""Change"" and the mentioned region. The media coverage of the project will be a combination of A.) intensive social media use, B.) film documentary, C.) speech programmes and print publications. Intense interaction and cooperation with sponsors and partners from the economy is being planned. The presentation will depict the outline and aim of the project, lay open the already existing cooperations and invite colleagues to participate.

SE31 - Geomedia in education – from Children University to University of the Third Age. A case study from Nicolaus Copernicus University.

Mieczysław Kunz (Nicolaus Copernicus University)

Geomedia with a broad sense has its components and functions which are common parts of content within academic education on many faculties. Chosen contents from the field of geomedia can be found not only at environmental faculties but also at humanistic and science faculties. At present, they are becoming the part of the program realized within so called Children's University or the University of the Third Age. At Nicolaus Copernicus University all level of educations are realized. Apart from typical academic education for students there are also facultative didactic classes for children from kindergartens, primary schools, gymnasiums, and adults. Curricula prepared for these learners often have contents connected with modern geoinformation technologies. For children from kindergartens (3-6 years old) and pupils from primary schools (6-9 years old) topics connected with maps and aerial photographs, visualisations, geolocalisations seem to be very interesting. Third dimension (3D), virtual reality and global positioning system (GPS) within them geocaching field games are very interesting for older pupils from primary schools and students from gymnasiums (9-15 years old). Learners from the University of the Third Age are especially interested in remote sensing, the image of the Earth from space and

virtual journeys around the Earth. The study presents chosen problems, the content of classes, and experience concerning geomedia gained during lessons with children, pupils, and adults in the frame of facultative forms of teaching.

SE32 - Sustainability and profitability of rural spaces: New forms of entrepreneurship

Faculdade de Letras da Universidade do Porto Universidade do Porto (Universidade do Porto)

32th International Geographical Congress Cologne, 26-30 August 2012
Sustainability and profitability of rural spaces: new forms of entrepreneurship
Eduarda Leal CEGOT, Porto geografus.letras@gmail.com
Keywords: City-Field, Entrepreneurship, Profitability, Sustainability, Cultural Heritage
The change recorded in the relationship between the urban and rural, and the current form as they are seen, allows us to make an approach which the central idea can be seen in search of new forms of occupation and profitability of rural areas in complementarity with the bordering urban areas. In this context, which way the cooperation city/countryside can result in entrepreneurship by contributing to the reduction of regional asymmetries? The activities diversification in the rural areas simultaneously with values preservation search, culture and heritage, becomes a strategic choice to be followed by the intervention local entities, involving with actively form the endogenous population, crucial part of the intangible value of places. In Portugal, the tourism in rural areas has been each more important, intervening with surgery in the regions. However, is important to assume a more active and modern rural environment, with the ability to attract creative clusters, countering barriers of the development, creating for their benefit a symbiosis between the surrounding places. In this sense, had start to arise recently, new classes of creative people, enterprisers, who, taking advantage of Portugal natural potential, founded new forms of monetize it, respecting its cultural identity. In this case of analysis, they are from England and from the Netherlands, and looking to the landscape heritage of Portugal, they come up with innovative ideas with a strong connection to the nature; they promote the Glamping, luxury camping, in Mongolian style tents with the particularity of including all city comfort. They settle them in little streamlined rural areas, some of them close to small urban centers. This class of creative people search places which are marked by natural and strong cultural values to their settle, joining the proximity of an urban center, aspect that is crucial for the investments attraction. With the construction of a new connection rural-urban developed in the context of rural spaces, it may consolidate relations of proximity and beneficial synergies

instead of asymmetric relations of the rural community, for beyond to transform the cities into effective bridges between rural areas and the outside world. With this research, it is pretended to give a perspective of the appreciation of the endogenous resources value by promoting the rural space as an integral and fundamental part of a country, as well as to reflect over new strategies to adopt in the near future.

SE33 - The Impacts of Urbanization on Changes of Extreme Events of Air Temperature in South Korea

Seungho Lee (Konkuk University), Inhye Heo (Konkuk University)

This study aimed to analyze the changes of extreme temperature indices in order to investigate impacts of urbanization on changes of extreme temperature. It was analyzed 16 indices related to extreme temperature indices to 60 weather stations in South Korea. Extreme temperature indices-related summer mostly increased, and its related to winter decreased. Percentile-based indices were clearly increased more than fixed-based indices as a tropical night. Decreasing trend of extreme temperature indices related to winter had more clear than increasing trend of extreme temperature indices related to summer. It was similar to trend that urban temperature was more clearly increased in winter than summer. Decreasing trend of indices-related daily minimum temperature had more clear than increasing trend of indices-related daily maximum temperature. Also, it was similar to increasing trend of minimum temperature had more clear than maximum temperature.

SE34 - Tideland culture of Okinawa Island Awase in Japan

Sunae Lee (Miyazaki Municipal University), Akiko Ikeguchi (Yokohama National University)

A purpose of this study is to clarify a historic geographical characteristic and continuity of the islands area tideland culture from an environmental adaptive viewpoint. The adaptation viewpoint to natural environments is important in understanding regionality of the culture. However, it is hard to say that there are many studies on adaptation to the coast environment that is close to human activities. However, it is hard to say that there are many studies on adaptation to the coast environment that is close to human activities. In Okinawa, the river is small, but the coral reef topography is remarkable, and various topography and biotas are seen there, and, as for them, there are the characteristic to be common to temperate zone area and continent region. The regionality of the

culture is understood by being considered for these continuities and commonalities from the adaptation to natural environment. One important problem of that purpose is examination of the tideland culture. The scale of the tideland of the islands area is small, but has outstanding bioproductivity in the tropical sea area that is oligotrophy. It is important what kind of characteristic of the culture were related with coral reef fishery and the agriculture of the allusion in clarifying regionality of the islands fishery. In addition, the use of marine resources by human is crucial with biodiversity and cultural relations and understanding a cultural uniqueness. Okinawa has image with island of the coral, but in 23 places, tidelands of big things and small things were at the coast of all of the islands. However the landfill construction of the tideland which began in 1980s, is continuing making in scraps in Island of Okinawa. In Awase, Okinawa, an expanse of the existing tideland and algae ground has the largest scales, but a large area is under landfill construction now. I want to clarify a transformation process of the local culture by such an environmental change.

SE35 - Spatial-Temporal Distribution and Geographic Context of the Neolithic Cultural Remains in Hanjiang River Basin, Southern Shaanxi, China

Feng Li (Nanjing University), Li Wu (Nanjing University), Chaogui Zheng (Chuzhou University), Wei Sun (Chinese Academic Science), Cheng Zhu (Nanjing University)

The history of human life is actually about ways of inhabiting the world. Understanding how to live successfully within our environment is among the most pressing challenges facing contemporary society. This paper is attempted to probe into the problem on the basis of analysis and discussion on the relationship between the spatial-temporal distribution of the Neolithic Culture Remains and the geographic context in the Hanjiang River Basin in the south of Shaanxi Province, China. Archaeological studies have indentified 175 Neolithic Cultural Remains in the study area with a sequence of Laoguantai, Yangshao and the Late Period of Neolithic Age. The total amount of archaeological remains throughout the Neolithic Ages shown an early ascent and later descent curve and its proportion to the Shaanxi Province declined sharply. While in space they are concentrated in the Tertiary Red Basin formed in Qinling Orogenic Belt with altitude scope of 400~800m on the river terrace or terrace plain of the Hanjiang River as well as their main tributaries. Multiple data integrated clarified the critical effects of tectonic and geomorphologic conditions on the Neolithic remains distribution along with the comparing analysis revealed the correlation of

Holocene climate change and environment evolutions with the Neolithic cultural succession in the study area. Further discussion on the origin and the temporal-spatial distribution corresponding to the regional culture differentiation shed light on the compound and dynamic human-nature interaction system during the Neolithic Age, thus emphasize the wider field investigation and high-resolution reconstruction works of the palaeoclimate and palaeoenvironment in future. This primitive study is also original in the give area where experiencing intensive modern tectonic movement and secondary natural disasters, therefore would be central to the constructive society and regional sustainable development.

SE36 - Water Resources Supporting Capacity to Regional Socio-economic Development of China

Lijuan Li (Institute of Geographic Sciences and Natural Resources Research, CAS)

An indicator called Water Supporting Index (WSPI) was built to measure the degree of water scarcity, which considered water resources and water withdrawal of both local and upstream areas. Evaluation model was established to calculate WSPI of 210 sub-basins and also in province scale and county scale. Water resources supporting capacity classes to regional socio-economic development was divided by WSPI. The spatial status of the capacity classes and its relationship with population and Gross Domestic Product were analyzed. Furthermore, the differences in regions suffering water scarcity were discussed. The result of WSPI was very similar to the actual water scarcity situation of China. Therefore, WSPI can be used in water resources management and socio-economic development decision-making.

SE37 - Study on landscape classification and ecological restoration strategies of Shangyi county

Li Ma (capital normal university)

This paper discussed the principles and methods of landscape classification on the basis of related theories of integrated physical geography and landscape ecology. Based on the total differences reflected in the alteration and interaction of physical factors (such as climate, geomorphology, soil and vegetation) and human factors (such as land use) in Shangyi county, we take geomorphology and land use type as the key indicators to classify the landscape of this county. There are two interrelated ways of landscape classification: the "top down" division and the "bottom up" subsumption. Combining site of

the two ways is the senior land unit: mestnost (land system) type, along with field verification. In this paper, the landscape classification hierarchy system is composed of two levels. At the first level, the county's landscape is divided into 8 categories, which are further divided into 23 sub-categories at the second level. The 8 landscape categories are: Grazing and farming landscape on the river and lake beaches; Farming, grazing and forest landscape in the low relief terrains; Grazing, farming and forest landscape on the high plateaus; Grazing, forest and farming landscape on mountains on the edge of the high plateaus; Farming, grazing and forest landscape in the river valleys; Grazing, forest and farming landscape on the rocky hills; Grazing and farming landscape on the loess tablelands; Forest, grazing and farming landscape on the lightly eroded, middle sized mountains. Corresponded with the natural conditions and environmental problems of each landscape category, the ecological restoration strategies are proposed under the guidance of landscape planning theories and methods, which may act as reference for the environmental rehabilitation, ecological restoration and protective measures against environmental degradation.

SE38 - Diets at three archaeological sites in Gansu, China around 4 cal ka BP: stable carbon and nitrogen isotope analysis of human and faunal remains

Minmin Ma (Lanzhou University), Guanghui Dong (Lanzhou University), Xin Jia (Lanzhou University), Fahu Chen (Lanzhou University)

Gansu has been a favored region for exchange between eastern and western Eurasia in the past. Archaeological remains from late Neolithic and Bronze Age sites there indicate that prehistoric culture underwent an evidently shift in subsistence at around 4 cal ka BP. That is, rain-fed agriculture wilted rapidly. Subsequently, pastoralism replaced rain-fed agriculture as the dominant mode of subsistence in Gansu and Qinghai Province between 3.6 and 2.0 cal ka BP. Stable isotope analysis of bone collagen provides a means to gain direct information about the importance of certain foods at a site, and when compared with archaeobotanical information, to allow for a better understanding of subsistence practices and the evolution of prehistoric culture in NW China. Our study focuses on three archaeological sites (Hongguxiahaishi site, Buziping site and Yunbushan site) at ca. 4 cal ka BP in Gansu. Dietary patterns at these three sites are investigated by the analysis of stable carbon and nitrogen isotopes in human and faunal bone collagen. The isotopic data indicate human and domestic omnivores (*Sus* and *Canis*) had diets dominated by C4 foods,

probably from the contribution of millets (C4 plants). But two *Sus* samples had a diet dominated by C3 plants and is thus unlikely to have been domesticated animals. Minimally offset $\delta^{15}\text{N}$ values between herbivore and human suggest low consumption of animal protein by human. The $\delta^{13}\text{C}$ values of two *Caprinae* samples (averaging $-13.9 \pm 1.8\%$) from the Hongguxiahaishi site reveal that both C3 and C4 foods were consumed. The diet included high proportions of C4 foods, suggesting that these animals were regularly foddered with millet plants, and that their grazing areas were mostly within the agricultural zone. The relatively wide range in $\delta^{15}\text{N}$ values amongst bovid samples (2.9% - 7.6%) at Buziping and Yunpushan site reflects grazing occurred in variety of ecological zones. Overall, the stable isotope results presented here show that the people of the Machang and Qijia culture at ca. 4 cal ka BP centered on cultivating millet and keeping livestock.

SE39 - Parametric Approach in Land Suitability Evaluation by using Multi Criteria Method for Selected Crops at Neyshabour Plain, Northeast Iran

Ali Bagherzadeh Chaharjuee (Islamic Azad University), Mohammad Reza Mansouri Daneshvar (Islamic Azad University)

Land evaluation is applicable both in areas where there is strong competition between existing land uses in highly populated zones as well as in zones that are largely undeveloped. At the present study the qualitative land suitability evaluation based on parametric approach of multi criteria method was investigated for selected crops including wheat and maize, based on FAO land evaluation frameworks (1976, 1983, 1985) at Neyshabour plain, northeast Iran. Climatic and land qualities/ characteristics for selected crops were determined using the tables of crop requirements developed by Sys et al., (1993). Based on detailed soil profile studies some sixteen land units were determined at the study area for the evaluation practice. The soil profiles dataset corresponded to these land units by using ArcGIS ver.9.3 for preparing the final land suitability evaluation maps. Our results indicated that the soil characteristics including soil physical properties (s) and soil salinity and alkalinity (a) are the most limiting factors for wheat cultivation, resulted in S2 and S3 classes. In most parts of the study area climate (c) and soil salinity and alkalinity (a) are the main limiting factors affecting maize cultivation which are categorized into classes S3, N1 and N2, respectively. The results of qualitative land suitability evaluation for selected crops indicated the priority of wheat cultivation over maize at the study area.

SE40 - Intensity and Range of Forest Use for Charcoal Production in Nenoshiroishi near Sendai, Northeastern Japan

Takeshi Matsubayashi (Tohoku Fukushi University), Arika Kano, Kiyoshi Saijo (Miyagi University of Education), Nobuto Morishita

A forest landscape surrounding traditional settlements in Japan has changed. Coppice forest was one of the most popular vegetation in the hills surrounding traditional settlements in Japan. Such Japanese coppice forest is called ""Satoyama"" or ""Zoukibayashi"". It had been used as a source of fertilizer, and had been repeatedly felled in an interval of about 15 to 30 years in order to produce and provide fuel wood and charcoal. As a result, the coppice forest was dominated by various deciduous broad-leaved trees that were coppice regeneration, and had been a peculiar landscape. However, since the fuel revolution in the late 1950s and the early 1960s, the succession has not been stopped by the felling, and the previous vegetation structure has been changing. Moreover, coppice forest was reduced rapidly in the high economic growth that followed the fuel revolution, because large-scale residential development proceeded particularly in the hills surrounding urban areas. To understand the landscape transition, it is important to clarify the intensity and range of forest use surrounding settlements. The use of coppice forest was investigated in Nenoshiroishi in the western part of Sendai City. Fuel wood production was inactive but charcoal production was active in Nenoshiroishi. A charcoal production worker produced 1,500kg of the charcoal in the winter of 2009-2010. The material wood was felled in the 30-year old coppice forest in Nenoshiroishi. The felled area is approximately 800 square meters. The amount of production of charcoal was approximately 3,000,000kg per year in Nenoshiroishi in the 1930s, therefore the felled area is calculated approximately 1.6 square kilometers per year at that time. According to the land use map of 1964 immediately after the fuel revolution, most of the hills surrounding the settlements were covered with broad-leaved forest. Broad-leaved forest surrounding settlements were considered to be coppice forest which the resident had usually access to and used. The area of coppice forest which the resident used usually was estimated approximately 25 square kilometers. If felling coppice forest at 20 years cycles, the necessary coppice forest area is calculated approximately 32 square kilometers for sustainable use. It suggests that the range of forest use was not only a coppice forest but it was also-montane zones. The change of forest use has changed not only the forest landscape on hills but also montane zones.

SE41 - A shell midden in the Longotoma dune complex (Central Chile) – geochronological data and palaeoenvironmental context

Simon Matthias May (University of Cologne), Helmut Brückner (University of Cologne), Alexandra Hilgers (University of Cologne), Dieter Kelletat (University of Duisburg-Essen), Steffen Pötsch (University of Cologne), Gilles Rixhon (University of Cologne), Anja Zander (University of Cologne)

Shell midden archaeology plays a significant role in the research on the colonisation of the South American continent. While numerous archaeological studies exist from the coasts of Chile and Peru, geoarchaeological investigations concerning the palaeoenvironmental context of these cultures are rare although this may provide important additional information for their interpretation [1]. The Longotoma dune system is situated in the northern part of central Chile, framed by the estuaries of the rivers La Ligua and Petorca. Here, numerous cultural layers occur together with accumulations of mollusk shells, mainly the marine clam *Mesodesma donacium*. These middens are often related to stone fragments. While associated ceramics indicate a post-archaic age for many places, few hunter-gatherer sites of pre-ceramic, mid-archaic age are described as well [2]. For the estuary and dune complex of Longotoma, a succession of fluvial terraces and at least two main dune generations are inferred from satellite images and preliminary field work, the younger of which is characterized by presently migrating barchanoid dunes. Undercut slopes, formed by the La Ligua river, provide insight into the inner stratigraphy of the older dune generation at its eastern margin. This contribution presents first results from an international research project (DFG ref. no.: BR 877/29-1), dealing among others with the palaeoenvironmental context of these archaeological remains. Silty and clayey sediments of a former alluvial terrace were found below the present dune field. Along the steep undercut slopes of the older dune generation, a sequence of palaeosol sediments and an in-situ palaeosol were detected, associated with a shell deposit. Bone fragments of small rodents, charcoal remains and leafs as well as abundant mollusk shells (mainly *Mesodesma donacium*, *Concholepas concholepas*) confirm its anthropogenic origin. ¹⁴C-AMS datings of two shells and a charcoal fragment yielded similar ages of c. 5200 cal BP, giving further evidence for the presence of archaic coastal hunter-gatherer populations at Longotoma. OSL datings provide a first chronological framework for the palaeoenvironmental context by (i) estimating the age of the fluvial terrace below the present dune field and by indicating (ii) different phases of dune activity as well as (iii) an intermediary period of geomorphodynamic stability, at least at the investigated sites. [1] Dillehay, T.D., 2002. Climate and Human Migrations.

Science 298, 764-765. [2] Berdichewsky, B., 1964. Arqueología de la desembocadura del Aconcagua y zonas venas de la costa central de Chile. Congreso Internacional de Arqueología Chilena 3, Viña del Mar, 69-107.

SE42 - Investigations on microfossil distribution in modern aquatic sediments of the southern Tibetan Plateau; Part I: Systematic overview; Part II: Distribution, associations, and environmental factors

Juliane Meyer (Institut für Geowissenschaften), Peter Frenzel (Institut für Geowissenschaften), Frank Kienast (Senckenberg-Institut für Quartärpaläontologie), Claudia Wrožyna (Karl-Franzens-Universität Graz)

The project 'Microfossils as Indicators of Aquatic Ecosystem Evolution and Monsoon Dynamics' tries to reconstruct changes in lake systems on the Tibetan Plateau during the late Quaternary using microfossil associations. Ostracods are the most frequently used microfossils, but there are many other species that could be used as bioindicators respectively proxies in palaeolimnological research. In this study, we analyzed about 50 modern sediment samples from the southern Tibetan Plateau to identify such non-ostracod bioindicators and the driving factors of their distribution. Recent samples have been taken from different water bodies (lakes, ponds, streams, wetlands) from altitudes mainly between 4000 and 5000 m a.s.l. The salinity range covers freshwater to hypersaline waters. Main environmental factors documented and analyzed are habitat type, salinity, water depth and temperature, anthropogenic impact, and water chemistry. Organism remains were collected from the size fraction $>200\text{ }\mu\text{m}$. We identified the taxa, if possible down to the species level, and calculated their abundance. Beside Ostracoda, almost all samples contain Chironomidae and other insect remains, Mollusca (mostly Gastropoda), seeds of Angiospermae, egg capsules (mostly Crustacea), oospores of Charophyta, and ephippia of Cladocera. Chironomids and seeds are highly diverse, but seeds are generally too rare to be used quantitatively. Gastropods and bivalves show a few species, respectively genera only and are therefore of limited use for palaeoenvironmental analysis. Egg capsules, oospores, and ephippia seem to have a great potential as proxies, however, their identification is problematical. We could not identify most of the insect remains to the species or genus level. The occurrences of the identified taxa are compared with chemical and physical parameters of the water bodies to define specific associations using multivariate statistics.

SE43 - Environmental Justice under the conditions of climate change – Case study Berlin

Katrin Mörer

The poster presents an overview of environmental justice and climate change. Within the Berlin pilot study "'Environmental Justice in Berlin'" the socio-spatial distribution of environmental burdens and environmental resources is investigated since 2008. Until now the study was focused on the environmental factors of noise, air quality, open/green spaces and thermal comfort. Climate change is ubiquitous and also affects Berlin. A modified climate suggests a modified thermal comfort. Therefore, this work analyses the environmental justice situation in Berlin under the conditions of climate change. Two times are observed: 2001-2010 and 2046-2055. The evaluation of the thermal comfort for Berlin planning areas, the expected changes due to climate change, the socio-spatial distribution of bioclimatic stress and the increasing stress as well as the impacts for the integrated environmental burdens for an overall assessment of the environmental justice situation in Berlin are central topics of this study. The 447 planning areas are the reference level for the project. The socio-economic situation in the planning areas is represented by the social development index, which is determined in the Berlin Senate Department's annual urban monitoring program. The bioclimatic burden for both time frames is aggregated from the block level to the planning area level. The bioclimatic evaluated block areas are weighted by the area for each planning area. The results are used and visualised cartographically (via ArcGis) and correlated with the social development index and the other environmental variables. Cities are characterised by a special urban climate. A high level of sealing, high building density, few open and green spaces, lack of ventilation paths and a variety of emission sources are the reasons for the effect of urban heat islands. Climate change affects the whole city but due to the mentioned factors some areas are affected stronger than others. Densely populated planning areas, in and around the Berlin environmental zone and also in marginal agglomerations such as Marzahn-Hellersdorf are affected by high to very high bioclimatic stress. These are the areas where the bioclimatic burden presumably mainly increases. Planning areas with a high social development index are predominantly favourable bioclimatic areas and they are located in the peripheral areas of Berlin. Socially disadvantaged planning areas are burdened at least middle up to very high. In these areas the bioclimatic stress will increase. For 2001-2010 and 2046-2055 a clear socio-spatial inequality in thermal comfort is detected. The raising bioclimatic stress in the course of climate change also concentrates on social disadvantaged

planning areas. Altogether the multiple environmental burdens will increase. The additional load is mainly concentrated on planning areas which are already affected by most of the other environmental factors, because they correlate with each other.

SE44 - Global mining of environmentally critical minerals: Pressures on ecosystems and socio-environmental conflicts

Diego Murguía (Wuppertal Institute for Climate, Environment and Energy)

In recent years the global socio-industrial metabolism has been demanding growing amounts of raw materials as essential inputs to support more growth of industrialized and emerging countries like China or India. Massive and new technology-oriented minerals, especially metals like iron, aluminium, copper, indium, rare earths or platinum group metals but also energy-minerals like coal, are key; recent studies have termed some of these minerals as 'critical', mainly from economic and supply-risk perspectives. This research considers this criticality aspect but complements it with an environmental perspective: it seeks to evaluate the environmental pressure of extracting and processing such minerals at a global scale. Thus other minerals whose predominant extraction technology provokes big pressures on the environment (i.e. open pit mining) are also included in the research scope: gold, silver, diamonds. The methodology consists of calculating the direct extraction pressure by measuring the space or land cover consumed by extraction projects (mostly open pit mining ones) for a certain number of environmentally critical minerals through the use of model mines and remote sensing (multi temporal analysis). At the same time, the study assesses the pressure exerted on ecosystems with different sensitivities and characteristics and evaluates conflictive regions where further extraction will very likely originate more socio-environmental conflicts in the years to come. This research is part of a PhD Project carried out as research at the Wuppertal Institute for Climate, Environment and Energy and the results are likely to be of interest to policy-makers, scholars, mining industry-related companies and civil society organizations working for the conservation of Nature and cultural heritage.

SE45 - WebGIS for displaying information from paleoenvironmental literature

Takashi Oguchi (Univ. Tokyo), Yasuhisa Kondo (Tokyo Institute of Technology), Yasuhiko Takaya (CSIS, Univ. Tokyo), Mizuki Kawabata (Univ. Tokyo)

WebGIS (Web-based Geographical Information Systems) provide interactive maps via the Internet. Users can handle the maps using a web browser to change mapping scale as well as the contents and extent of a displayed map. WebGIS can also provide text descriptions for particular locations. We use WebGIS to display information on paleoenvironmental literature published in academic journals. The original version of the WebGIS was constructed in the late 1990s and early 2000s, using ArcView IMS from ESRI for the main engine. It contained information from literature, including the location of areas studied, geomorphological and geological data used for paleoenvironmental reconstruction, target ages and eras, and references such as article titles, author names, journal names, and volume and page numbers. These data were taken from some 6,000 papers in international journals of earth and Quaternary sciences published in the mid-1990s to 2002. The WebGIS permitted the browsing of data using interactive online maps. The collection of data ceased in 2003 when a related research project ended. Recently another project 'Replacement of Neanderthals by Modern Humans' was launched in Japan by a group of archaeologists, anthropologists and geographers. For this project, we first transferred the data in the original WebGIS to a new system with ArcGIS Server from ESRI. Then we added new data from papers published after 2002. Because the project focuses on the Middle East, South Europe and North Africa, we have been collecting data for these areas until now. The new WebGIS will support the project for which the spatial distribution of paleoenvironment and its temporal change are crucial. The system is also open to public and easily accessible using a web browser. It will be used by researchers worldwide to collect basic information about existing paleoenvironmental literature.

SE46 - New insights into the environmental conditions along the eastern trajectory of modern human dispersal to Europe derived from the Lake Prespa sediment record

Konstantinos Panagiotopoulos (University of Cologne)

New insights into the environmental conditions along the eastern trajectory of modern human dispersal to Europe derived from the Lake Prespa sediment record. Panagiotopoulos K.1*, Aufgebauer A.2, Schäbitz F.1, Wagner B.2 1

Seminar of Geography and Education, University of Cologne, Gronewald Str. 2, D-50931, Cologne, Germany 2 Institute of Geology and Mineralogy, University of Cologne, Zùlpicher Str. 49a, D-50674, Cologne, Germany * corresponding author (panagiotopoulos.k@uni-koeln.de) Core Co1215 retrieved from Lake Prespa (40°57'50'' N, 20°58'41'' E, 849m asl) was investigated using geophysical, geochemical and pollen analyses. Lake Prespa is situated along the eastern migration pathway of modern humans from Africa to Europe and belongs to a network of selected sites in the Balkans, Anatolia and the Near East where a number of interdisciplinary studies were undertaken within the Collaborative Research Center 806: 'Our Way To Europe; Culture-Environment Interaction and Human Mobility in the Late Quaternary' (www.sfb806.de). This study aims to reconstruct the climate shifts recorded by the Prespa proxies that enabled our ancestors to colonize southeastern Europe during the MIS 3, which followed the harsh climate conditions of the glacial maximum in MIS 4. The age-depth model, based on radiocarbon dating and tephrochronology, indicates continuous sedimentation during the last glacial cycle. According to the pollen record, this mid-altitude site sustained refugial temperate tree populations throughout this period. Pollen concentration and TOC percentages retain relatively low values until the onset of the Holocene when closed forest formations dominated the landscape signaling the establishment of a warmer and moister climate. Distinct fluctuations of arboreal relative percentages coupled with the occurrence of IRD peaks can be tentatively correlated to Heinrich events. Climatic oscillations are sensitively recorded in the Lake Prespa sediments at a sub-millennial scale permitting a detailed reconstruction of the regional palaeoenvironment, as well as correlations with other regional and global climate archives. Keywords: Lake Prespa, Balkans, eastern Mediterranean, pollen analysis, palaeolimnology, modern human dispersal.

SE47 - Geoarchaeological research revealed the location of the Carrara marble trading harbour

Marta Pappalardo (Dipartimento di Scienze della Terra), Alessandro Chelli (University of Parma), Helmut Brückner (University of Cologne), Monica Bini, Sandra Noss, Lucia Gervasini (Soprintendenza per i Beni Archeologici della Liguria), Marcella Mancusi

The Carrara marble, a white stone type well known all over the world, was already quarried by the Romans. Historians report that it was traded through the harbour system of the city of Luna, located at the foothill of the mountains from which this stone was quarried (Apuan Alps, NW Italy). The ruins of this city

(remnants of public and private buildings, a theater and an amphitheater) are now located in a coastal plain 1.5 km from the sea. No archaeological evidence of the harbour location had ever been found. Recently a geoarchaeological research project was carried out; it provided a refined palaeogeographical reconstruction in the area that enabled to assess the coastline position at Roman Times and its indentations. The location of the marble trading harbour was revealed and remnants of a dock and related structures were highlighted. This work provides an example of how geoarchaeological research can be relevant for the solution of archaeological problems and of how palaeoenvironmental reconstruction can be achieved combining investigation techniques typical of different geographical sub-disciplines.

SE48 - Forest Fires in Odisha: Natural Disaster or Poor Management?

Punyatoya Patra (Department of Geography, Aditi Mahavidyalaya), Rajesh Kumar Abhay

The tropical highland region of India is very prone to forest fire which is a very natural phenomenon and helps forests to grow healthy. If it is not controlled and goes beyond its limit, then it converts to wildfire, i.e., a huge fire which becomes out of control and causes negative effects on our biological environment and also depletes our forest resources. This study focuses on Odisha state, located towards eastern coast of India covering an area of 1, 55,820 km². Out of the total area of the state, about 28% is covered by forest which is mainly concentrated towards the western part. This part is the home of the tribals who depend largely on forests products for their livelihood. However, most of the forest fires are initiated by local people may be due to their ignorance of its end result or may be due to their short term profit. During last part of February to first part of April, fire incidence occurs. After mid-February, the trees shed their leaves and the forest floor is covered by dried leaves, which is highly susceptible to fire. Fire is the main factor responsible for inadequate regeneration and spoiling of the small saplings. Keeping all these problems in view, this paper comprises three objectives. They are: a) to study the spatial and temporal distribution of forest fires in Odisha; b) to analyse the causes underlying forest fires and their impact on our environment; and c) to suggest measures for their control. The study is based on both primary and secondary data. Secondary data have been collected from Forest survey of India and the State Forest Department. The primary data in sample locations have also been collected in the field by interviewing local villagers and forest department staffs. Both primary

and secondary data have been simulated by using GIS technology. The incidence and intensity of forest fires in different areas have been divided into three different intensity zones, such as, less, moderate and high. The less intense zone is found towards the western part of the Southern highland region. The moderate intense zone is found in the whole Northern highland region. Likewise the high intensity zone is found towards the eastern part of the Southern highland region. The forest fires are man-made and restricted to ground surface. The main reasons behind forest fires are setting of fire by man to collect minor products like mahua, kendu leaves etc., to scare animals for poaching, to bring up new grasses for animals; shifting cultivation; charcoal burning in the forest; carelessness after smoking. The impacts of forest fires are : loss of soil moisture, loss of regeneration, loss of timber value of standing trees as the trees develop defectiveness and hollowness, soil erosion and loss of biodiversity. The forest fires can be controlled by three ways- prevention, detection and douse. Each of these parts supports each other, and together they form a system for controlling forest fires.

SE49 - Distribution of selected CORINE land cover classes in different natural landscape types of Slovakia

Robert Pazur (Institute of Geography, SAS), Ján Otáhel (Institute of Geography, SAS), Martin Mareta (ESPRIT, Ltd)

The aim of this study is to model, evaluate and analyse distribution of selected CORINE land cover classes (11 - urban fabric, 21- arable land, 31- forests and 32 - shrubs and/or herbaceous vegetation associations) in different natural conditions. Three study areas (351 172 ha, 59 924 ha, 50 073 ha) representing stratas in three main natural landscape types in Slovakia (lowlands, basins, and mountains) for the purpose of this analysis were selected. Set of model variables contains binary forms (presence/absence) of each investigated land cover class, information about biophysical conditions (elevation, slope, soil characteristics) and information about proximity of main river sources and towns with important historical background. Other commonly used explanatory variables were considered endogenous and therefore we didn't incorporate them to our LC distribution models. Logistic regression were used to create the primary models. If bias caused by spatial autocorrelation occurs in model residuals, we either introduced a neighborhood variable which characterize proportion of particular CLC in direct neighborhood cells (in raster data format) or we incorporated regression kriging methods. To evaluate the goodness of fit of each probability maps, receive operator characteristics (ROC) statistics and split samples

statistics were used. We found that using logistic regression only neighborhood characteristics could be assume important in all (three) selected landscape and all (four) binary maps. Influence of other evaluated factors significantly differs in all study areas. Explanatory power of selected variables is higher in heterogeneous landscapes. Our findings supported by both statistical methods, highlights the importance of stratification in complex regional land cover or land use models.

SE50 - The Grid-to-Grid hydrological model, a new operational flood forecasting capability at the Flood Forecasting Centre

Charlie Pilling (Flood Forecasting Centre/ Met Office)

C. Pilling, D. Price Flood Forecasting Centre, Exeter, United Kingdom R. J. Moore Centre for Ecology & Hydrology, Wallingford, United Kingdom Marc van Dijk Deltares, Delft, Netherlands The Flood Forecasting Centre (FFC), a partnership between the UK Met Office and the Environment Agency, has recently introduced the distributed hydrological model Grid-to-Grid (G2G) into its operations. The G2G model has been calibrated across England and Wales, operates at a 1 km spatial resolution, and can produce data at a 15 minute temporal spatial resolution. The operational version of G2G was re-run using Numerical Weather Prediction (NWP) data that would have been available at the time of the flood event that affected Cumbria in 2009. Early results in river flow simulation, return periods and warning levels demonstrate that this is an effective approach for generating longer lead-time flood forecasts. Further examples from flood events during 2012 will also be presented. Although much of the attention so far has been on using deterministic NWP to drive G2G, probabilistic output from ensemble NWP as well as time lagging approaches will also be presented. Indeed, further improvements are also anticipated as high resolution ensembles are run in the operational environment at approximately 2 km resolution from Spring 2012. Some early findings will be presented.

SE51 - Future patterns of land use/cover modeled for landslide risk analysis

Catrin Promper (Universität Wien), Anne Puissant (Université de Strasbourg), Jean-Philippe Malet (Institut de Physique du Globe de Strasbourg), Thomas Glade (Universität Wien)

The geomorphic system is incessantly changing with some modifications being irreversible such as landslides. These irreversible processes often pose a

challenge for society like damage to infrastructures, loss of property or in some cases damming of rivers. The factors controlling landslides are either static (such as lithology and soil properties) or dynamic (such as precipitation and landuse). Changing the landuse leads to possible changes in landcover which in turn may lead to a changed pattern of landslide occurrence. This means that when the land cover is changed by anthropogenic interference or due to natural processes, this may, on a longer term, change the geomorphic system regarding possible landslides and their effects. In order to analyse the accompanying spatial and temporal pattern of landslides and thus landslide risk, a method involving different factors regarding global environmental change is proposed. This study represents first results focusing on the land cover aspect and is conducted in a district located in the alpine foreland of Lower Austria named Waidhofen/Ybbs. The landcover model framework CLUE is used to develop possible scenarios. It creates statistical relationships between the observed past land cover and possible driving forces (Verburg et al. 1999). Application of the model for the period 2005 - 2100 indicates that the land cover types prone to landslides shift along the investigation area. According to these first results, one can estimate the future possible spatial location of landslides regarding the landcover factor. In a further step, controlling factors such as lithology and precipitation will be integrated in the analysis for future landslide risk scenario developments. Verburg, P.H., de Koning, G.H.J., Kok, K., Veldkamp, A. & Bouma, J. 1999. A spatial explicit allocation procedure for modelling the pattern of land use change based upon actual land use. *Ecological Modelling* 116 (1): 45-61.

SE52 - Valuing abiotic nature: Contributions to landscape ethics

Joachim Rathmann (University of Augsburg)

Geoparks comprise geological sites that are considered worthy of protection. Furthermore, the conservation of geodiversity - geoconservation - takes into account different values, like intrinsic, cultural, aesthetic, economic and scientific ones. But if a Geopark, or in general a landscape has intrinsic value then it doesn't have only instrumental value, but it is valuable in and of itself. There is an intense discussion on whether to assign intrinsic value only to living organisms to collective entities (e.g. landscapes, ecosystems) or even to abiotic nature. Can the landscape of Geoparks have intrinsic value and therefore deserve moral consideration? Can intrinsic value give a reason for geoconservation? It is generally easier to assign values only to human beings; the argumentation is much more sophisticated if collective entities are discussed. Thus holistic

environmental ethics are required to justify intrinsic values of landscapes. It will be shown, that previous debates on environmental ethics should be discussed to some extent more precisely as landscape ethics as landscapes include both living organisms and abiotic nature, as landscapes have specific aesthetic values and, in contrast to nature, have a limited spatial extent. Two approaches might argue convincingly for intrinsic values of landscapes: Firstly, a phenomenological argument based on atmospheres, which emanate from landscapes and affect the beholder. Aesthetically experienced landscapes are perceived as something valuable. Secondly, it can be argued by a teleological concept of nature, the end and therefore an intrinsic value of landscapes. Assuming that landscapes have goals, they should be analyzed in terms of means and ends.

SE53 - Impact of deforestation on vegetal arboreal communities & mammals in the Huasteca Potosina lowlands, México

Humberto Reyes Hernandez (Universidad Autonoma de San Luis Potosi)

This paper analyses the impact of deforestation and forest fragmentation on floristic composition as well as the distribution and diversity of large and medium-size mammals in tropical forest remnants of the Huasteca lowlands of San Luis Potosi, Mexico. The paper points out that because of the intense transformation of the region only 66 relicts of arboreal vegetation with surfaces larger than ten hectares still persist; these fragments host 139 floristic species, representing 42 families and 89 genera. On the one hand, as compared with previous inventories, these data show a sharp drop in the number of floristic species, particularly in the subperennial medium tropical forest. On the other hand, the incessant deforestation has severely impacted on the permanence, distribution and local abundance of faunal populations; to date, there survive only nine mammals out of 19 species registered in previous decades.

SE54 - Nature protection or natural resources protection: Nature protection dilemmas in Brazil

Simone Rezende da Silva (USP)

Several Environmental Protection Units existing in Brazil and around the world today were created in the territories of traditional peasant populations, triggering an expropriation process of their lands, way of life and culture. Several specialists have been studying this expropriation process because it offers an opportunity to discuss the relations between Nature and society, in addition of revealing conflicts between ways of life. In this paper we seek to show that the

Brazilian field presents a large diversity of landscapes and products as well as cultures, ways of life, and individuals who experience Nature in each region of the country in a particular way. This, far from being a problem, this is an opportunity for the implementation of new ways of Nature protection. The broadest and well-known notion on 'natural resources' refers us to the idea of a Nature used by people, which reveals the necessity to find in Nature the conditions for life maintenance. In a wider interpretation, this implies taking into consideration Nature's material and symbolic aspects. However, not all individuals are the same and the concept of Nature becomes an important tool for comprehending different views existing in societies, because each people relates to Nature in a specific manner. Brazil is a country with multiple features. Therefore, it is fundamental to consider the implications of different situations in order to draw an analytical framework. Thus, one may say that the expression 'traditional communities' refers to rural populations that reproduce their ways of life using natural resources in a low impact manner because they hold ethnoecological knowledge of Nature, depending on its preservation, either practically and symbolically. The predominant interpretation, up until recently, was that every relation between individual and Nature was destructive. This is simplifying and unfair to several cultures that have developed other ways of relating to Nature. In addition, this way of seeing individual and Nature in opposing camps has led to a Nature protection model in which the individual is considered merely a visitor, a temporary appreciator of an isolated Nature, preserved and untouched. According to several investigators (Diegues and Arruda, 2000; Furlan, 2000; Bensusan, 2006), this Nature protection model is in crisis, because it ignores the socio-cultural contexts in which protected areas are implemented, resulting in more obstacles for the protection of Nature. Our research argues that other forms of Nature protection are possible and necessary. Thus, in this article we will briefly discuss such alternatives through an analysis of the experiences of the Extractive Reserves.

SE55 - Assessment of Landscape-Geoecological Systems with the applications of GIS-technology

Emma Romanova (Lomonosov Moscow State University), Marina Arshinova (Lomonosov Moscow State University), Ali Alyautdinov (Lomonosov Moscow State University)

Assessment of Landscape-Geoecological Systems with the application of GIS-technologies E.P. Romanova, A.R. Alyautdinov, M.A. Arshinova Lomonosov Moscow State University, Russia Email: romanova@kmail.ru Landscape-

geoecological studies are being actively developed in Russian landscape science. The basic aim is to investigate the results of interactions between natural, economic and social structures at various spatial and time scales. Such works require the use of modern GIS-technologies for analysis of particular landscape units. A map "Landscape-Geoecological Systems of Europe" at the scale 1:5 Mln has been created at the Lomonosov Moscow State University. The following stages of research have been worked: 1. Elaboration of LGES model. Landscape-geoecological system (LGES) is a natural unit (natural landscape) modified by economic development. LGES is a complex geosystem which develops and functions as a result of interactions between natural, economic, social and management subsystems. 2. Compilation of a series of maps ("Types of Natural Landscapes in Europe", "Economic development systems of Europe"). The maps were compiled at the scale of 1: 5 Mln. Totally there are 613 landscape units on the map Present-Day Landscapes of Europe. The legend shows a complex hierarchy of these natural-territorial units. 3. Elaboration of GIS "LGES of Europe". A specialized geographical information system (GIS) has been elaborated in order to organize storage and processing of this vast data array. The GIS includes the following sections: a) Cartographic, i.e. computer versions of maps; b) Thematic database - data array of 48000 parameters on nature components, systems of economic development and ecosystem services; c) Conceptual design; d) Results of GIS-technologies realization: systematization and classification of LGES. 4. Investigation of natural-anthropogenic processes in landscapes. These are the processes stimulated by economic activities and they could be of two types: positive (constructive) or negative (destructive). 5. Calculation of these factors for quality assessment of LGES. The GIS was used to compile maps of particular natural-anthropogenic processes (erosion, acidification, pollution etc.) and to create maps of LGES for the territory of Europe and particular European regions. Key words: landscapes, geoecology, assessment.

SE56 - Forest landscape and its dynamics in relation to forest use for fuel production

Kiyoshi Saijo (Miyagi University of Education), Marie Kubota (University of Bonn), Kohel Hoshi, Takeshi Matsubayashi (Tohoku Fukushi University)

Forest use for fuel production (firewood and charcoal) had rapidly ceased in Japan after the late 1950's when common fuel drastically changed from firewood or charcoal to fossil fuels. As a result, secondary forest near traditional villages became free from human impact and ecological succession has

progressed during the past half century. Some evidence, such as abandoned charcoal producing kilns and coppice forests which suggest the widespread and intensive forest use in the past, remain in the secondary forest even in the present. Nonetheless, processes of landscape formation due to forest use for fuel production are inactive except for limited cases in Japan. In Germany, on the other hand, forest use for fuel and other purposes has come to life again recently. The observation of a small forest area near Lohmar, a town in the Rhein-Sieg district, in North Rhine-Westphalia, suggests that the forest landscape has been drastically changed in past several years because of forest use and ecological succession. Moor (Heide in German) appears after timber felling of artificial conifer forest, and it changes into broadleaf forest by succession or plantation. As a result, artificial conifer forest planted mainly in last part of the 19th century or early in the 20th century for economic purposes is remarkably decreasing. Alternately, broadleaf forest spreads year by year. Moor seems to be a transitional landscape between both types of forest. National policy about forest management and fuel supply resulted in such dynamic change of forest landscape.

SE57 - Environmental quality indicators in Alfenas city, Minas Gerais State, Brazil

Clibson Santos (Universidade Federal de Alfenas-MG), Ana Luiza Marcelo Antunes dos Santos

This contribution presents a proposal of the environmental quality indicators in Alfenas city, Minas Gerais, Brazil. Alfenas is an medium-size city, but presents problems of the large-size cities, as extreme growth demographic, social exclusion, environmental degradation and the natural resources. The proposal of indicators that reflect environmental quality, assist in the indication of policies that minimize problems resulting from the occupation of unsuitable areas. Considering the complex system of interactions in urban area and the environmental dynamic that involve human and natural systems, we used a methodology based on representing these interactions by means of indicators of Pressure, State and Response (P-S-R). Therefore, we used the proposed developed within the ELANEM Euro-Latin American project and the OECD Environmental Indicators. This study proposed indicators quantitative and qualitative of the environmental quality in Alfenas. In study area were defined seven environmental units, results of the integration of data geomorphologic, land cover/use and the census sectors. For each unit were defined nine indicators of the P-S-R; (P) demographic density, solid waste collection and the

wastewater collection network; (S) slope, drainage density, impervious surface, land exposed/vegetation, household income; (R) priorities defined in the public budget and the guidelines of municipal master plan, both indicators are related to improvements in environmental quality. These three dimensions represent the humans-environmental interactions. The Pressure represent the human activities exert pressures on the environment. Environmental conditions, or State refers to the environmental conditions of the area. Finally, the social Response to environmental changes, such as preventive or corrective actions. As a result of the integration of indicators can confirm the socioeconomic segregation in the city of Alfenas. The suburbs with little basic infrastructure are occupied by low-income. However, high-income community occupies neighbourhoods with better infrastructure. This behavior was also observed in environmental conditions. In poor communities, environmental degradation is more pronounced. These disparities highlight the need for more specific policies, they can expose and diagnose the main problems of each unit, but also be able to plan actions integrated preservation of the environment and improve social/sanitation conditions of the communities. The methodology used was efficient, because it allowed us to analyze the environmental/social problems in an integrated and indicate the priority units. This analysis assists in defining guidelines for land use planning and establishes standards more efficient for sustainable development. In addition, the use of data of the census and master plan city can be an alternative for regions that have few basic studies. This work was supported by FAPEMIG (Foundation for Research Support of Minas Gerais).

SE58 - Coastal evolution of the Bay of Elaia, the port city of ancient Pergamum (NW Turkey)

Martin Seeliger (University of Cologne), Melanie Bartz (University of Cologne), Helmut Brückner (University of Cologne)

As part of the excavation realized by the German Archaeological Institute (DAI) in Bergama/Pergamum, the University of Cologne started palaeogeographic and ge archaeological research in the Bergama region in 2008. The primary aim of these studies was to reconstruct the landscape history, based on sedimentological methods. Our project focused on the area of the former port of Pergamum near the ancient city of Elaia. We tried to study (i) the history of the Hellenistic harbour basin from its beginning to the total siltation, and (ii) the sea-level changes during the late Holocene. Some remarkable findings resulted from the investigation in the Bay of Elaia. The siltation of the central harbour and the surrounding area could be clarified. By sedimentological criteria, the literary

evidence which dates the construction of the central harbour pier in the Hellenistic period could be verified. Siltation was the reason why since 340-532 cal AD the central harbour has not been used any more. The siltation of the surrounding area reached a similar level during this period. Furthermore, we were able to create the first pollen chart for the area by analyzing sediment cores from the central harbour basin. It covers the period of about 800 BC to 600 AD, reflecting the strong human impact on the ecosystem during Hellenistic and Roman times. As for the sea-level changes during the late Holocene, in particular during the Hellenistic period, two drilling-transects helped to identify the maximum marine transgression around 1600 BC (1733-1534 cal BC) in the western transect and around 2000 BC (2129-1927 cal BC) in the northern one. In both transects, it is followed by a remarkable seaward shift in the shoreline. This 'regression' was one reason for the evolution of a wetland in the western part of the bay. In addition to these outcomes, we were able to decipher the use of some well preserved wall structures in the western part of the embayment, lying just 0.5-1 m below the present sea level. For a long time it was uncertain, when and for which purpose these wall structures had been built. Due to drillings very close to the western pier of the central harbour which reached the basal layers of the pier, it was possible to investigate the material, strong enough to sustain the heavy and robust boulders of the pier. As for the wall structures, our investigations brought to light that they had no substruction. Therefore, their interpretation as a pier, a mole or an offshore breakwater could be falsified. According to radiocarbon age estimates, the wall structures date to the Late Roman period (3rd - 4th century AD). In comparison with similar structures from other periods and places around the Mediterranean we finally came to the conclusion that the use as salt works is the most likely one. In order to refine the chronostratigraphy, the sediments on which the wall structures are based were OSL dated (Optically Stimulated Luminescence).

SE59 - Decline of birch woodland in Þjórsárdalur Iceland from 1587 to 1938

Guðrún Gísladóttir (University of Iceland), Fridthor Sofus Sigurmundsson (University of Iceland)

F. S. Sigurmundsson and G. Gísladóttir Department of Geography and Tourism, Faculty of Life- and Environmental Sciences, University of Iceland, Askja, 101 Reykjavik, Iceland H. Óskarsson. The Hekluskgar project, Gunnarsholt, 851 Hella, Iceland Land-cover changes in Iceland have been immense over the last millennium, which has resulted in birch (*Betula pubescens*) woodland depletion,

severely reduced vegetation coverage and inevitably extensive soil erosion. Changes in birch woodland cover in Iceland are well documented over the last decades, but few studies have focused on its spatial distribution change over centuries. Therefore the main objectives of this study were (1) to map the changes of birch woodland cover in Þjórsárdalur (14,000 ha) in southern Iceland over 350 years, from 1587-1938, and (2) to understand the impact of socio-economic and natural forces on the woodland over three periods: 1587-1708, 1708-1880 and 1880-1938. For this purpose we used a combined approach of historical reconstruction from diverse written archives, GIS-techniques and field work. The historical data included socio-economic and environmental descriptions, such as location of birch woodlands and shrub cover and conditions, demography and agriculture, woodland ownership and restriction on the use of woodlands, climate descriptions including extreme events such as cold spells and extreme northern storms, and tephra layers from volcanic eruptions. The historical data and GIS were used to reconstruct maps showing birch woodland cover; field work was conducted to verify location of place-names used for birch woodland in historical archives, to map present distribution of the woodland, birch tree remnants, and old charcoal pits. About half of the Þjórsárdalur valley was covered by birch woodland in the late 16th century but over a period of 350 years 94% of the woodland had been depleted; its cover changed from 6,200 ha in 1587 to 390 ha in 1938. The woodland was intensively used for firewood, leaf-fodder and charcoal making. Grazing pressure was limited, but winter grazing had negative effects on ecosystems that were already damaged by deforestation. The main driving force for this development was socio-economic, particularly ownership and management but in combination with climate, volcanism and extreme events which further exacerbated the woodland decline.

SE60 - Women, Environment and Sustainable Development: A Case of Garhwal Himalaya

Suman Singh (Banaras Hindu University)

Women in Himalayan region always play a significant role in managing and operating most of the household and agricultural activities. Except to plough, harvesting, threshing and some time grazing livestock, which is symbol of male domination rest all other activities in agriculture and animal husbandry are in the exclusive domain of women, and thus their contribution in total work input of agriculture and animal husbandry is more than 85 percent. Beside this they toil through the day, starting with the family works, nurturing children, going out for

fodder, fuel, drinking water and Non timber forest produce collection for sustaining livelihoods. They are maintaining the traditional practice of agriculture by their rich indigenous knowledge system and also retaining the essential linkages between the forest, livestock and agriculture systems. They play a significant role in natural resource management, on which the livelihood and the very survival of hilly families/communities depend, and are an enormous source of traditional knowledge related to daily life and use of bio-resources around them. Undoubtedly they have a very important role in the subsistence economy, but this is considered only secondary to the role of the men. Women's are economically, socially and emotionally dependent on the male or head of their family. However, in recent years, environmental degradation, poor resource management, and increased migration of men to plains, have deteriorated livelihood options and added more work-load on women in the Himalayan region. The nexus between women, environment degradation and poverty is still poorly understood and rarely treated in an integrated way. Therefore, the objective of the present paper is to analyze the work participation of women operating at different sub-systems, impact of environmental degradation and role of women in sustaining the traditional agro-ecosystem in Gadmolga Gad Watershed of Garhwal Himalaya.

SE61 - City2020+ – The City under Global Demographic and Climate Challenges: an interdisciplinary assessment of impacts, needs, and strategies

Agata Siuda (RWTH Aachen University), Marten Brunk (RWTH Aachen), Wolfgang Dott (RWTH Aachen), Heather Hofmeister (Goethe-Universität), Carmella Pfaffenbach (RWTH Aachen), Christine Roll (RWTH Aachen), Christoph Schneider (RWTH Aachen), Klaus Selle (RWTH Aachen), Mareike Buttstädt (RWTH Aachen), Katja Eßer (RWTH Aachen), Sarah Ginski (RWTH Aachen), Julia Hahmann (RWTH Aachen), Antje Kröpelin (RWTH Aachen), Hendrik Merbitz (RWTH Aachen University), Sabrina Michael (RWTH Aachen), Timo Sachsen (RWTH Aachen)

The impacts of demographic and climatic change - especially an aging population and enhanced thermal stress - are likely to transform living and working arrangements and will overburden European cities. How to adapt is a crucial question that can only be answered within an interdisciplinary approach. This paper shows results of the interdisciplinary research project City2020+. It identifies the ways microclimates in the city, health outcomes, social structure and the urban environment are related. The City of Aachen serves therefor as a

case study. Within the project the risks individuals face living and working in these conditions are assessed and new strategies are proposed based on cooperation from the fields of Medicine, Natural Science, Demography, Sociology, History, Civil Engineering and Architecture for adapting the city for future needs. City2020+ aims to generate scenarios, recommend options for urban planning measures and apply tools for planning and developing sustainable future city structures. Addressing these future challenges Aachen's social structure and the health status of its citizens is researched. A questionnaire has been developed to analyse the living and working situation, the social relationships and the heat adaptation strategies of Aachen's population aged 50 years and older. Furthermore meteorological data and future atmospheric weather patterns have been analysed. Findings approve a significant temperature increase until the end of the century that will result in prolonged dry periods and enhanced thermal stress situations during summer. Concentrating on the diminution of thermal stress situations, cold air drainage flows are identified and the amount and thickness of cold air determined. A connective study investigates the present spatial distribution of particulate matter (PM) concentrations. In addition the particulate and gaseous pollutants are toxicologically characterised in a human/in-vitro cell culture system. Influenced by outdoor temperatures and PM concentration, the indoor climate is of great importance. Building simulations are carried out with altered parameters in order to complement existing guidelines for energy-saving construction methods with planning adds for an enhanced thermal comfort in summer. To react on the described changes the interests of local actors in their different fields of operation are estimated and their problem perception and willingness of implementation of new strategies is analysed. In order to comprehend the historical handling of inhabitants, governance and urban planners with environmental conditions and climate change, archival documents allow conclusions of the perception of air and water pollution in former times. Combining these different aspects 'hot spots' within the urban area of Aachen are identified: Quarters where the thermal load, air pollution, poor ventilation, problematic building's structure and vulnerable population concentrate.

SE62 - Developing Workforce Competencies for Social and Environmental Careers: The Role of Graduate Education

Michael Solem (Association of American Geographers)

This poster will report findings from three interrelated studies: 1) What disciplinary and generic competences define the knowledge, skills, perspectives

and abilities expected of professional geographers? 2) How and to what extent are postgraduate academic programs in geography equipping students with competences for professional positions in different industries? 3) How are national and global trends in the economy likely to affect the demand for geographic competences and related career opportunities for geographers? The studies that will be summarized in this presentation are being conducted for the 'Enhancing Departments and Graduate Education in Geography' (EDGE) project led by the AAG with funding from the National Science Foundation.

1. Work Logs of Professional Geographers: This study gathered data over a period of six months from nearly 100 professional geographers. Each month, the study participants completed a log of their work activities (similar to a diary or brief journal entry). Participants in the study indicated obstacles that impeded task and project completion, strategies for addressing these obstacles, and employer support for professional development activities. While the large majority of respondents reported satisfaction with their weekly progress, the log study reveals that widespread and ongoing challenges faced by professional geographers include inadequate resources and funding, competing demands, time management, and interpersonal conflict. At the same time, a minority of respondents reported participation in employer-sponsored or employer-supported professional development opportunities, the most common forms of which include travel support for conference or meeting attendance and funding for training or workshops.

2. Employer Perspectives on Geography Skills. This study is based on interviews with employers in business, government, and non-profit (BGN) organizations to learn how geography is practiced. The analysis identifies the geographic and transferable skills demanded in today's workplace, and explores employers' perspectives on the career preparation of geographers. This presentation will highlight key findings gathered through semi-structured phone interviews with employers and discuss these findings within the broader context of current higher education research and priorities related to U.S. competitiveness, STEM education, and globalization.

3. Competency Development in Postgraduate Geography Programs. Two surveys collected information about the career aspirations of geography graduate students and the types of courses, advising, and professional development experiences offered by various master's and PhD programs. The surveys also measure the extent geography graduate students are being prepared in competencies valued by employers.

SE63 - Improving crop yield simulations by taking into account effects of field heterogeneity

Anja Stadler (University of Bonn), Matthias Langensiepen (University of Bonn, INRES), Moritz Kupisch (University of Bonn), Frank Ewert (University of Bonn)

Crop growth models are potentially capable of calculating crop growth and yield realistically, provided they are properly parameterized, calibrated and validated using data from field experiments. Plant growth is often characterized in such models based on simplified approaches and assuming homogeneous soil properties within a field. We hypothesized that taking into account effects of soil heterogeneity on plant water and nutrient uptake in these models improves their predictive quality at the field scale. This approach is highly attractive for implementation in the context of precision farming, which is aimed at adapting crop management to spatial heterogeneities in environmental conditions. Combining precise farming techniques with spatially explicit crop modeling for decision making and scenario analyses is likely contributed to reduce the greenhouse gas emissions from agricultural areas and to optimize biomass growth and yield. The crop growth model GECROS was applied using information from winter wheat and sugar beet field trials carried out near Jülich, located in the central western part of Germany. These fields are all characterized by strong spatial variability in soil conditions and managed according to standard agronomic practice. GECROS was calibrated separately for each winter wheat and sugar beet cultivar grown on these fields by adjusting the respective parameters with the help of crop physiological measurements at point level. The soil model was parameterized for different field sample points (6-8 per field) for which measured information about soil physical characteristics was available to account for the spatial heterogeneity in soil conditions within each field. The crop growth model was then tested whether it could reproduce the observed spatial patterns of crop growth and development in the selected fields through consideration of the spatial variability in soil properties. First results show, that GECROS simulates the measured data of phenological development, biomass, leaf area index and yield under heterogeneous field conditions in a realistic way. Without the adaption of the soil model to the variable soil properties, the crop growth model is not able to reproduce the observed heterogeneity of crop growth within a field. Spatio-temporal variability in soil water distribution and its effects on nitrogen availability are likely the main factors causing spatial variable crop growth within the selected fields of the study region. Considering variable soil water transport and related nutrient dynamics in

model scaling to the field level will thus improve the predictive quality of the crop growth model at the field scale.

SE64 - In search for the harbours – paleogeographical research in Ephesos

Friederike Stock (University of Cologne), Helmut Brückner (University of Cologne), Sabine Ladstätter, Hannes Laermanns, Martin Steskal, Ralf Urz

Since 2008, a team of the University of Cologne has accomplished geoarchaeological and paleogeographical research in the environs of the ancient city of Ephesos. The focus of these studies is to detect the spatial and temporal shifts in the coastline during the past millennia and to clarify the paleogeographical situation of the harbours of Ephesos. In total, 72 corings up to a depth of 19 m were retrieved from geo-bio-archives. The research focuses on the harbours and anchorages which existed during the Roman and Byzantine periods. From literary sources it is known that Ephesos had several harbours during its long history. The early Iron Age harbour was located in the area of the Ayasoluk-hill; the second harbour - the so-called Koressos-harbour - has been localized in a bay close to the Roman stadium. In the Hellenistic period the bay along the western slope of the Panay'rda? became the main harbour. In Roman times a hexagonal harbour basin was constructed in this bay. Due to the steady progradation of the Küçük Menderes the harbours of the Byzantine period were shifted to the west of the city. In 288/9 BC, Lysimachos designed a new city in the area between Bülbülda? and Panay'rda?. Thus, many of the Hellenistic and later Roman buildings were erected on formerly marine sediments. By then, Ephesos had easy access to the sea; however, the definite location of the Hellenistic harbour is unknown to date. During Roman times, a prominent harbour basin was dredged; the contours are still visible today. Remains of the quay walls and of three jetties of the former hexagonal basin can still be seen in the area to the south-west of the harbour. Along with the progradation of the Küçük Menderes delta, the city became landlocked and lost its direct connection to the sea. Therefore, a harbour canal was built. Its significance is underlined by the fact that on both sides it was flanked by necropolis. This cemetery, located on either side of the artificial harbour canal, was the biggest necropolis in Ephesos and was used from the 2nd century until the 6th century AD. Our research indicates that the first phase of the canal construction dates to the 2nd/1st century BC. Until the 3rd-5th centuries it was in full use. From the 1st to the 3rd century AD inscriptions note many attempts to clean or dredge the great harbour. Although the siltation of the canal started already before the

Byzantine period it could still be used until the 8th/9th century AD. New findings suggest that the late Roman and Byzantine harbour site was shifted to the west of the mouth of Arvalya valley. Çanakgöl seems to be the remnant of this harbour whose date still needs to be confirmed. 14C ages will clarify the on- and offset of the use of this harbour site. Further to the west, at the south end of the bay of Pamucak, and at Pygela are even younger harbour sites.

SE65 - Plants as indicators for archaeological find sites

Christian Stolz (Universität Flensburg)

The poster presents different species of native plants and archaeophytes in Central Europe, which can be used as tracers for former human settlements and other sites of archaeological relevance. In most cases, this method is well suited for locations in forests and with a certain distance to the nearest recent settlement. In this context two different groups of plants have to be distinguished: Firstly, former crops and garden plants which are not native in the respective location and weeds which are often accompanied with those, for example spread out by seed impurities. A good example is periwinkle (*Vinca minor*; Kleines Immergrün), a former medical plant, also used for binding wreaths. Furthermore, there are soft fruits like gooseberries and red or black currant (*Ribes spec.*; Stachel- und Johannisbeeren), elderberries (*Sambucus nigra*; Schwarzer Holunder) and typical weeds like *Hordeum murinum* (Mäusegerste). Another group of plants, presumably of native origin, reacts to environmental changes by human activities, like soil compaction, nitrogen and phosphorous loads, forest lightening and changes of the soil surface by different kinds of building activities. Typical species are nettles (*Urtica dioica*; Große Brennnessel), ivy (*Hedera helix*, Efeu), yellow archangel nettles (*Lamium galeobdolon*; Goldnessel), hellebore (*Helleborus nitidus*; Grüne Nieswurz) and celandine (*Chelidonium majus*; Schöllkraut). In two different study areas in the Taunus Mts. (South-western Germany) and Schleswig-Holstein (Northern Germany) the distribution of some of these species was mapped around different cultural and archaeological monuments. The study revealed connections between the age of the monuments and the appearance of indicator plants. Furthermore, the distribution of these plants also depends of the recent vegetation and land-use in the surrounding area of the monuments. Therefore, indicator plants do not exclusively appear in such locations, but they can be also found sparsely elsewhere and, more concentrated, around recent settlements. If the age of an individual monument is known, the dissemination speed of a species per year or per century can be calculated.

SE66 - A Confluence of Development Paradigms in the Industrial Zones of the Mekong Delta: The Case of Wastewater Management

Siwei Tan (ZEF Zentrum für Entwicklungsforschung)

The Mekong Delta, agriculturally the most productive region in Vietnam, is also the uncanny host to 190 industrial zones (IZs), a concrete expression of the Vietnamese dream of becoming an "industrialized and modern nation by 2020," which the Mekong Delta governments quickly and zealously implemented. But, merely a handful of the 190 IZs are actually operational; socio-economic contribution is tempered by ensuing environmental pollution, and the protracted development has led to socio-economic difficulty for the people it claims to benefit. Yet, the Mekong Delta persists in its development of IZs. This research aims to -- using the case of wastewater management in industrial zones, an excellent proxy for the tension between environmental protection and economic development fundamental to the question of sustainable development -- explain this illogical situation with reference to the development paradigms that permeate the region and the topic, and their adoption, maintenance and modification by the actors involved, who choose and interpret the paradigms, engaging in discourse, strategies, and (in)action to support their interpretations, with the effect of creating a self-reinforcing incoherence, which achieves apparent policy coherence. The field research (05/2011-03/2012) focused on an institutional analysis of industrial wastewater management, and engaged Ostrom's Institutional Analysis as a heuristic tool for semi-structured interviews with the same set of state agencies in 12 provinces of the Mekong Delta. Thereafter, 4 Hau River riparian provinces were selected for a more detailed institutional analysis, and to explore upstream-downstream dynamics; interviews extended to non-state actors such as enterprises, international projects and households. Discourse analysis was conducted of laws, regulations and provincial reports to identify the paradigms that influence policy-making of industrial development and environmental protection. Media analysis plugged knowledge gaps where interview permits were not granted. The finding with regard to industrial wastewater management is a mixed situation of legal ambiguity, fluidity and rigidity, which leads to the situation of an implementation gap. Yet, this is a resource for actors are able to reference the law to justify their inaction. Reports on the actual state of industrial development are often actually planning documents and necessarily half-truth and half-dream, but this "capacity issue" is in fact a resource for the planners who use it to support their interpretation of the paradigm of sustainable development. Because a careful consideration of the local geographical and socio-economic

conditions should suggest an embargo on the frenzy of industrial zone development, I argue that the legal ambiguity and capacity issues are actually resources for the actors in maintaining their interpretations of these exogenous paradigms.

SE67 - Extraction of sand dune, Terga beach, West Algeria Environmental Impact, conflicts of users and management tools

Ghodhani Tarik (Oran University), Hamidi Mansour (Oran University), Khélifa Amokrane (Oran University)

The coastal sand lying of Terga on the western coast of Algeria is an exceptional morphological unit. It is the basis of an important flora and plays an essential role in the dynamic balance of all the coastal system at the level of this fragile area of temouchent coast. The accelerated expansion of the towns of the western region especially that of the coastal zone and the expanding demand of a very good quality of sand for construction engineering have motivated the authorities to set a quarry in Tergua . This enterprise which has expanded during the nineties has overcome heavily the maximum level of extraction allowed by the Algerian mining law. Neglecting the environmental impacts of the decision of using this non renewable resource has resulted in the deterioration of the original vegetation covert, the overload of surrounding agrarian land by the sand, the disturbance of the river Malleh as well as the emergence of conflicts and tensions among different actors. These difficult tensions cannot be solved by the law. In this poster four elements will be considered The ecological and functional role of the sand lying in the coastal zone of Terga The interaction between the high demand for sand and its high extraction The different impacts of the exploitation on the environment as well as the tensions existing among different actors The actual solutions considered and the problems of implementation on the field Main words: Algeria, coast, coastal environment, management tools, use conflicts, actors

SE68 - Ecological and Geographical Aspects of Anthropogenic Transformations of Natural Ecosystems in the Russian Part of the Amur Basin

Boris Voronov (Russian Academy of Sciences Far Eastern Branch)

Anthropogenic impacts on natural ecosystems in the Russian part of the Amur River Basin (Priamurje) caused several serious ecological problems, most of them being of ecological and geographical nature. Many of them are landscape

and to a certain degree climatic transformations as well as changes of river hydrological regimes, qualitative and spatial floristical and faunistical variations including dynamic changes of areals of biotic components and particular plant and animal species, their migration routes. Large-scale timber felling and especially forest fires in Priamurje caused reduction of forest massifs and expansion of open space areas, increase of maximal summer air temperatures and decrease of minimal winter temperatures, increase of summer water temperature in mountain spawning streams and quite often their shallowing. In some areas small rivers have been completely swamped due to forest fires. Fires in mountain forests result in moving scree debris and thus cause the expansion of impoverished mountain tundra landscapes in the southern direction along the burnt-outs. Northern boundaries of coniferous-broad-leaved forests are shifting to the south. For instance, in the last 80 years the north-west boundary of coniferous-broad-leaved forests in the watershed between the Amur and Amgun rivers moved to the south-east for over 70 kilometers. Areal of many plant and animal species have completely altered, Manchurian flora and fauna in particular. Representatives of East-Siberian and Daurian flora and fauna are penetrating further south and east along the transformed landscapes. Significant landscape transformations changed and broke migration routes of many plants and animals and fragmented their areals. Extensive Amur bank reinforcement works at the Russian-Chinese border in 1960-1970-ies nearly completely blocked seasonal migrations of big mammals across the Amur, Ussuri and Argun rivers and isolated populations of these animals on each side of the border. In some cases hydropower constructions also damage migration routes and cause the reduction of some animal populations in number or even animal mortality. To prevent and mitigate negative effects of Priamurje economic developments it is not only necessary to study the existing ecological and geographical problems and find ways to solve them, but also work out future coordinated and consistent environmentally adapted measures both on national and international scale to conserve and sustainable use the unique resource and ecological potential of the Priamurje region.

SE69 - The Local Context of Acquiring Farmland Rights In Upland Farming Area, Japan

Kunimitsu Yoshida (Kanazawa University)

In Japan, farmland played a role as the basic factor or component of a society, called 'mura, (the same settlement)' apart from its role as a supplier of economic goods. Therefore, individual farm households cannot treat their farmlands as

mere economic goods. Over time, farmlands have been treated by various entities, including individual farmers as well as social groups comprising individual farmers who are mutually involved in agriculture. This presentation aims to explain the mechanism of acquiring farmland rights in Japan's upland farming belt by focusing upon social relationships among farmers. Data on farm management, farmers' history of farming, and records of transferring farmland rights were collected for this study through interviews with all farmers in the case study area. Mechanisms of farmers' social relationships were analyzed by applying the concept of 'multiplex- uniplex' that is used in the social network approach. The case study area was Omaki and Kouwa settlements in the town of Otofuke, Hokkaido prefecture. This area was newly cleared and opened for settlement in 1950. Major agricultural enterprises in this area are upland, dairy, and vegetable farming. The average management area per farm household has increased, mainly because the existing farm households have continued farming upon the accumulated farmlands of other households that have abandoned farming. The main findings of this study are summarized as follows: 1) Various social relationships among farmers were observed behind the transfer of farmland rights. These relationships included territorial relations, kinship, attending the same elementary school, and serving together as PTA officers. Some agencies such as the Hokkaido Agricultural Development Corporation were also involved in these relationships. 2) Types of social relationships varied in the way the transfer of farmland rights overlapped. Almost all transfers of farmland rights were influenced by multiplex relationships, such as a combination of territorial relations, kinship, and school connections. On the other hand, uniplex relationships existed in transfer of farmland rights when farmers did not have these social relationships. 3) Social relationships in acquiring farmland rights expanded spatially from the scale of the neighborhood or settlement into the scale of the same district, other districts, and outside Otofuke town. Many farmers accumulated most of the farmland within their settlements, but depending on farm management conditions some late accumulated farmland were located outside their settlements. Thus, farmers' management scale increased, and a large-scale upland-farming belt was formed.

RC01 - Oil Discovery and Environmental Impact Assessment (EIA) Administration in the Western Region of Ghana

Kwabena Koforobour Agyemang (University of Cape Coast), Kwabena Barimah Antwi (University of Cape Coast)

The discovery of oil in Ghana has raised a number of questions and concerns on the environmental impact of oil drilling and its associated problems such as pollution and environmental degradation. The environmental mess that has been created by some multi-national oil companies in Nigeria further raises public concern about the environmental and socio-economic impact of oil discovery. Regarding the examination of options to reduce the impact of exploration on the environment, one tool that comes to mind is Environmental Impact Assessment administration. Environment Impact Assessment (EIA) has the potential to effectively account for the activities of proponents of undertakings, identify potential impacts on the environment and determine mitigation measures. This paper examines the capability and capability of the Environmental Protection Agency (EPA) of Ghana in ensuring proper adherence to environmental standards by oil companies and other downstream oil companies in the Western Region of Ghana. It explores successes achieved and challenges in Environmental Impact Administration by the main environmental related regulatory agencies in sub-Saharan Africa

RC02 - An Inconvenient Truth: Bangladesh is not drowning

Md Alam (University of Rajshahi)

An Inconvenient Truth: Bangladesh is not drowning Professor Dr. Md. Shamsul Alam Department of Geography & Environmental Studies University of Rajshahi Rajshahi 6205, Bangladesh md.alam@fulbrightmail.org & Kabir Uddin GIS & Remote Sensing Analyst ICIMOD Kathmandu, Nepal kuddin@icimod.org ABSTRACT The media blitz of Al Gore's 'An Inconvenient Truth' created a panic particularly the low lying and Islands countries due to sea level rise. Bangladesh is one such country where 80 percent of the land is below 5 meters from the MSL. The small country with a huge population is already known to the outside world for her vulnerability to natural hazards. According to the IPCC Bangladesh will lose 17% of its land by 2050 because of rising sea level caused by global warming and 30 percent of the population will be environmental refugees. There is already debate among scientist regarding the model prediction of the IPCC. Many aspects have been disregarded among which the hydro-geomorphology of the delta building processes. Bangladesh comprises the largest delta in the

world which has been built through centuries by the rivers originating from the Himalayas. Almost no research has been done on this process in the event of climate change. New data shows that Bangladesh's landmass is increasing, contradicting forecasts of the IPCC. The process of erosion, deposition and accretion are common phenomenon in the country. This study based on satellite data tries to analyze erosion, accretion and net gain/loss of land in the event of SLR due to Global Climate Change. Key words: Bangladesh, IPCC, Hydro-geomorphology, erosion, accretion

RC03 - Microfossils in sandy tsunami deposits from Thailand – a tool to assess the magnitude and transport processes of prehistoric tsunamis

Dominik Brill (Universität zu Köln), Anna Pint (Universität zu Köln), Helmut Brückner (Universität zu Köln), Klaus Schwarzer (Christian-Albrecht Universität zu Kiel)

On December 26, 2004 the west coast of Thailand was heavily affected by the Indian Ocean tsunami, generated by a mega-rupture of the Sunda Fault. Due to the lack of historical data, sedimentary evidence from geo-archives provides the best opportunity to improve the knowledge of recurrence and impact of potential predecessors. In this context, the microfaunal composition of tsunami deposits may provide valuable information about the sedimentary fingerprint of a tsunamite, revealing (1) the source of the dislocated sediment, (2) its transport distance, and (3) the dominating transport processes in the tsunami wave. To achieve this, the microfossil assemblages of selected tsunami layers were analysed with respect to their similarity with material from potential source areas, the ecological significance of incorporated species, and the preservation state and size sorting of their tests. The samples originate from onshore tsunami deposits from the coastal plain of Ban Bang Sak, SW Thailand, where sand sheets of the 2004 Indian Ocean tsunami (event A) as well as potential palaeotsunamis, which were dated to 500-700 (event B) and 1200-2000 cal BP (events C), respectively, have been identified. The microfaunal composition of these sand sheets was compared to that of reference deposits from the inner shelf, taken at water depths of -62 to -45 m, as well as from the littoral zone.

RC05 - Formation of the Russian-Kazakh border relations*Tatiana Denisova (RAS)*

Russia has land and maritime borders with eighteen states with total length of 60,932 km. A considerable part of the subjects are near-border and more than 13 thousand kilometers of the State border are new, formed after the collapse of the Soviet Union. The longest land border in the new Russia (RF) is border with Kazakhstan (RK) - 7513 km., it adjoins 12 of 86 subjects of the RF and 7 out of 14 regions of RK. There are 18 rail and 30 road checkpoints. The possibility of conflicts or adverse situations in the border areas is associated with cross-border provision of natural objects and resources previously shared transport, and necessity of foreign country's economic and social infrastructures usage. Natural resource potential of frontier areas is considerable. It includes: oil and gas, shale, coal, phosphates, and chromites, iron and copper ores, construction materials, salt, basins of the Irtysh and Ural rivers, forest and biological resources, a variety of agro-climatic conditions (That is favorable for sheep and dairy cattle breeding, crop cultivation in the culture of cotton to durum wheat). Such a variety of cross-border natural resources contribute to the placement of various industrial and engineering units of the same type of industry in both countries, such as mining and mineral processing (Altaysky kray and East Kazakhstan region), which in turn required the creation of a common transport (southern railway branch, roads with intersections in the cities of Uralsk, Petropavlovsk, Pavlodar, Semipalatinsk) and energy (electric-power transmission Gornyyak - Ust-Kamenogorsk - Pavlodar) infrastructures. After formation of two independent states, industrial technological chains were broken. Plants remained without raw materials and were forced to stop production, that led to a number of economic and social problems: reduction of income in the region, rising unemployment, out-migration. The transport system also has been broken. Part of the federal highway M51 Chelyabinsk - Kurgan - Omsk - Novosibirsk passes through the territory of Kazakhstan now. There are railroad's segments that are shared for the West Siberian, South Urals, and Kazakhstan railways. Passport and customs control should be passed while crossing the border. All this leads to tensions in the border areas of both state. The most acute problems occurs in the mineral resources and water usage. In the latest ten years more attention has been paid to the formation of inter-state sources of law and linkages that were lost in the 90s of XX century. At the present time, the relationship are determined by the Agreement between the Government of the Russian Federation and the Republic of Kazakhstan on the interregional and near-border co-operation from 7 September 2010.

RC06 - Susceptibility Analysis of Mass Movements in the Micro Basin of Ribeirao Máximo in the County of Luis Alves, Santa Catarina, Brazil*Elisa dos Santos (Santa Catarina State University - UDESC), Maria Paula Marimon (Santa Catarina State University - UDESC), Neusa Maria Mafra (Rio de Janeiro State University - UERJ)*

This research is being developed at the Master's Program in Land Planning and Social and Environmental Development of Santa Catarina State University, and has as the study area the micro basin of Ribeirao Máximo which is located at the southwest of Luis Alves County, with coordinates 26°43'23.90" and 26°47'13.20" S, and 48°53'10.95" and 48°57'32.23" W. The main objective of the study is to know the conditioners of mass movements to determinate the susceptibility areas and contribute with effective parameters to the local land planning. The Ribeirao Máximo is a tributary of the Luis Alves River, and it flows into Itajaí-Açu River, an important drainage basin in the Atlantic slope of Santa Catarina State. The Luis Alves County has the history of mass movements, and suffered strong social and environmental impacts because of the 2008 disaster. The studies about mass movements and its conditioners require an integrated environmental approach based on the understanding of the existent relationships among climatic, geologic, geomorphologic, pedologic, and anthropic characteristics, which contribute to initiate mass movements, marked on the landscape by highly visible erosion features. The proposed methodology involves the systematic use of field, lab and theoretical work. The field and lab methodology is based on local and regional geologic surveys, recognizing structural features, geomorphologic survey, including the analysis of erosion on the mass movement features, and field and laboratory pedologic survey, through morphologic and physical-mechanical soil analysis. Some factors were identified as the conditioners of mass movements in the study area: the significant relief dissection, the rupture of slope sections, the areas of depression in high altitude segments of slopes, the lithologic diversity, and the strong structural control of the Luis Alves Complex. This complex is dominated by granulitic mafic gneisses. In addition, the pedologic characteristics show a predominance of colluvial soils and strong clefts between the horizons. The theoretical methodology is based on Geographic Information Systems (GIS), from digital elevation model (DEM) analysis, enabling a more accurate spatial approximation to the physical characteristics of the relief. This enables the application of many algorithms and hydrologic equations to better define the behavior of the water on the relief. The topographic outcomes obtained from this methodology that are relevant and

applicable to the study in question are: shape of the terrain, degree and length of declivity, orientation of slopes, vertical and horizontal curvature, flow direction and accumulation, networks and drainage basins, the power flow rate, moisture content or topographic index, distance to the drainage, and time of the output flow.

RC07 - Landslides instrumentation and monitoring in volcanic terrains in Mexico: the case of Teziutlán, Puebla

Ricardo Garnica (the National Autonomous University of Mexico (UNAM)), Irasema Alcántara Ayala (National Autonomous University of Mexico (UNAM))

LANDSLIDES INSTRUMENTATION AND MONITORING IN VOLCANIC TERRAINS IN MEXICO: THE CASE OF TEZIUTLÁN, PUEBLA As a result of the mountainous character of Mexico, landsliding is one of the most significant hazards in Mexico. Since the beginning of the twentieth century, landslides disasters have claim hundreds of lives and economic impact has increased dramatically. Consequences are quite frequently worsened by the high vulnerability of populations living in areas of risk. It would be practically impossible to mitigate the effects of landsliding by using structural measures due to costs and effectiveness. Therefore, the establishment of non-structural strategies to mitigate landslides effects can be regarded as a realistic possibility to reduce the vulnerability of population. In this work, we present some preliminary results of the methodology used to set up an instrumented slope to monitoring potential landsliding on a volcanic terrain in the municipality of Teziutlan, Puebla. The main goal of the project is focused in designing and establishing a community-based warning system to increase the level of resilience of the Mexican society.

RC08 - Comparative assessment of landslide susceptibility using Logistic Regression and Analytic Hierarchy Process (AHP)

Adrian Grozavu (Alexandru Ioan Cuza University), Cristian Patriche (Romanian Academy), Mihai Ciprian Margarint (Alexandru Ioan Cuza University of Iasi)

Landslide susceptibility assessment constitutes an important component within the landslide risk equation, very useful for improving the prognosis of such phenomena. In order to achieve adequate spatial models for landslide susceptibility assessment this study aims to compute and compare two landslide susceptibility maps, derived from multi-criteria analysis. The analysis focuses on a sector of Ia'i Cuesta, from Moldavian Plateau (Romania), where

natural environment along with human influence constitutes a favourable context for landsliding. Two methods namely, the logistic regression as a quantitative method and the analytic hierarchy process (AHP) as a semi-qualitative method were applied. In a first stage, it was performed an inventory of stabilised (old), semi-stabilised and active landslides, using ortophotoimages (from the year 2006), topographical maps (1:25,000, 1:5000) and terrain verifications, comprising a total number of 155 landslides with a total surface of 3380 ha and representing 24.8% of the study area. During the next stage of the analysis it was obtained the digital elevation model (DEM) and created a GIS database comprising the potential factors controlling the landslide process: slope, slope height, aspect, mean, plan and profile curvature, distance from drainage network and land use. In order to acquire data from raster layers and perform the statistical analysis a total number of 2990 equally spaced grid points were generated. Furthermore, a stepwise procedure and a tolerance test (TOL) were applied to select relevant variables from the above mentioned 8 input parameters, these filtering procedures indicating that landslides occurrence is best explained by terrain slope and land use and secondary by distance from drainage network, plan curvature and terrain aspect. Finally, two landslide susceptibility maps were achieved by both the logistic regression and the AHP approaches. The comparison of landslide susceptibility map with actual landslides spatial distribution shows that 76.4% of the landslide area and 75.2% of the landslide-free area was classified correctly by logistic regression, with an overall accuracy of 75.8%. In the case of the AHP, the results show that 68.2% of landslide area and 77.8% of the landslide-free area were classified correctly, with an overall accuracy of 73.0%. In view of our results, we may conclude that the high percentages of overall accuracy and of the correctly classified landslide area and landslide-free area, achieved for both the logistic regression and the AHP approach, recommend both methods as suitable for landslide susceptibility analysis and mapping at large scale. Nevertheless, the logistic regression approach gives slightly better results compared to the AHP approach.

RC09 - Flood In South Vietnam: Case study on Dong Thap province; Flood Mitigation Management

Thanh Van Hoang (Feng Chia University)

RC10 - Natural Risks and Anthropogenic Impacts on Big Rivers in East Asia

Alexey Makhinov (Institute for Water and Ecology Problems), Shuguang Liu (Tongji University), Vladimir Kim (Russian Academy of Sciences Far Eastern Branch), Alexandra Makhinova (Institute of Water and Ecological Problems FEB RAS)

The Amur and Yangtze rivers are not only the biggest rivers in East Asia but have rather many similarities. Their basins are alike as stretching out in the latitudinal direction. Their biggest tributaries belong to the middle part of the rivers, which in both cases is the widest compared to the river upper and lower reaches. The areas of Amur and Yangtze basins are nearly equal (1 855 and 1 808 thousand square km respectively). Their geological structures and reliefs are homogeneous. Their hydrological regimes are of far eastern type of annual distribution of water runoff. These facts indicate that erosion and accumulation processes are more active in the Yangtze River compared to the Amur. Similar natural risks for economic activities in the Amur and Yangtze river valleys are caused by instability of seasonal river water regimes, summer-autumn catastrophic floods with several flood-wave peaks per years, interchanges of several-year periods of high-water and low-water content in the river, water regime transformations due to global climate changes. Plain reliefs of both rivers and abundant easily-washable loose deposits make river-bed deformations highly dynamic, especially in the river lower reaches. Anthropogenic impacts include river runoff regulations due to the construction of flood- and erosion-preventive facilities, as well as hydropower stations on the Amur and Yangtze rivers and their tributaries; water turbidity increase; forest massif reduction; forest fires and agriculture expansion in the river basins. In the AmurBasin active river-bed transformations are observed in the areas of big tributary junctures and intensive economic activities. These transformations have a well-marked local character. In the Middle and Lower Amur, where the mainstream is subdivided into many channels, the annual bank erosion reaches 10-20 meters. In the very Amur lower reaches its channel is deep, strait and stable. In the YangtzeBasin most active anthropogenic impacts on river-bed processes are observed in the river low reaches and its estuary. The main river stream here is divided into numerous sub-channels because of extensive bank reinforcements in the river

basin (36 000 km). The Yangtze river-bed undergoes most intensive transformations in areas of radial mainstream divisions. The banks here are washed up at the rate of 80-90 km per year. The Yangtze River peculiarity is that most intensive river-bed transformations occur in the river lower reaches. Intensive erosion and accumulation processes in the Amur and Yangtze rivers cause high risks for river navigation and significant problems for economic activities there, such as the decrease of river water intake, the stability of back reinforcement constructions, etc. These processes are extremely important for river environment as they affect the formation conditions of water, thermal, ice and hydrochemical regimes of the Amur and Yangtze rivers.

RC11 - On fuzzy and fixed paleo-boundaries in Poland

Roman Matykowski (Adam Mickiewicz University)

Over the last 150 years, Poland's present-day territory has been cut by many state boundaries that are now non-existent, e.g. those between Russia, Germany and Austria-Hungary until the First World War, or between Poland and Germany in the years 1921-1939. After their formalised (political, customs, sometimes also administrative) functions had ceased, informal spatial barriers have often developed in the given borderland, both in its material culture (e.g. the so-called cultural landscape) and in the system of values, stereotypes and emotional relations of its inhabitants. Naturally, such borderlands in Poland's inner structure have become an object of study by socio-economic geographers as well as scholars representing other social sciences. The political boundaries that do not exist any longer but have left a trace in the cultural landscape are often termed a relict boundary, or a paleo-boundary. Since they sometimes persist in social awareness only rather than in any material form, they are also called symbolic boundaries. The aim of this analysis is to determine the degree of fuzziness or endurance of one of such boundaries in Wielkopolska and Silesia (the former German-Russian boundary until the First World War), along selected sections. Differences in social behaviour patterns of the inhabitants of the borderland on both sides of such a symbolic boundary can be analysed on the basis of, e.g., (a) marital links (or the place of residence of a married couple), (b) electoral behaviour, and (c) social ideas about the residents of the other side of the borderland.

RC12 - Managing Evacuation in Ngargomulyo Municipalities: An Example of the Merapi Volcanic Crises

Estuning MEI (Université Paris)

Ngargomulyo, located in the western part of Merapi, is one of the most areas prone to volcanic hazards. According to the recorded history, this municipality often suffered by Merapi eruptions. The latest eruption, classified as subplinian eruption, occurred on November 2010. This eruption caused 353 victims, 150 injured people, more than 320,000 people being evacuated, and hundreds of houses damaged by the pyroclastic flows. Even though Ngargomulyo was not affected by the pyroclastic flows and surges, it is important to study this area in order to present and evaluate the evacuation management during the volcanic eruption. The methods used in this study include historical data collection regarding the previous eruptions of Merapi, notably in 1994 and 2006; and the pre-, syn-, and post-crisis phases of the 2010 eruption. Participatory three dimensional mapping was also used as a tool in this study to facilitate the dialogue between stakeholders of disaster risk reduction and the community in determining the evacuation routes and its management. In this study we would like to highlight that working with the community to face with disaster is the ideal solution to minimize the gap between the government, scientists, non-governmental organizations and the community itself.

RC13 - Some features of the storm on the Black sea in June 2011

Stanislav Myslenkov (Lomonosov Moscow State University), Victor Arkhipkin (Lomonosov Moscow State University), Galina Surkova (Lomonosov Moscow State University), Sergey Dobrolyubov (Lomonosov Moscow State University), Klaus Peter Koltermann (Lomonosov Moscow State University)

Based on modelling, reanalysis data and coastal observations we trace the origin and development of a storm on the Black Sea in June'11 near the Russian coast. This storm was not extreme, but destroyed a number of recreational facilities in the coastal zone, transformed beaches and caused various adverse effects. Observations were obtained by wave recorder Log_aLevel and an automatic weather station DavisPro (AWS), both mounted at the end of the 150m long pier in the Rybatskaja Bay near Gelendzhik. The wave sensor was set at a height of 5m above the sea surface (measurement resolution 5Hz). The AWS sensors were set at 7m above the sea level (measurement resolution 5 min). We used the spectral wave model SWAN applied in two steps: 1) run of SWAN for the entire Black Sea with a 5x5km bathymetric grid and the input of the wind

speed and direction renewed every 6h from the NCEP/NCAR reanalysis; 2) a run carried out for selected coastal areas at the north-east part of the Black Sea where our sensors were installed. This run is forced by the AWS wind speed, for the local bathymetric non-structured high resolution grid. Parameters of storm waves on the open boundaries of the integration area are specified from the first run. The synoptic situation at the end of June'11 is a fairly typical case when the probability of the storm over the Black Sea is rather high. Starting from June 22 surface atmospheric pressure over the south of European Russia and the Black Sea is slowly decreasing. On June 26-27 a cyclone, small in size, but deep and high, appears centered over the Crimea. It remains almost stationary. The sharp increase in surface wind speed over the western part of the Black Sea is observed on June 25-26. June 26th the zone of high wind speeds (>14-16m/s) is distributed over the whole sea. The location of the cyclone center over the Crimea results in a pronounced western component in the direction of the wind in the southern part of the cyclone over the Black Sea. The fast increase of the wind speed over the north-eastern part of the Black Sea starts June 26. It reaches maximum values at mid-day on June 27. Gusts at Rybatskaja Bay are 19 m/s (AWS data). Model results for significant wave height in the Black Sea exceed 2.5m for the 26th June and its highest value (4m) was at night on June 27. The area of the highest waves is located at all times between the Crimea and Turkey. The largest storm area (with heights >2.5m) is 169000 km². The predominant direction of waves are from W and WSW (the same as the wind dir.), with a maximum wave period 8s. Calculations show that at the Russian coast the greatest magnitude of significant wave height reached 2.5 m. Modeled waves parameters are in a good agreement with observed data and we are confident to use the SWAN model as tool for storm risk assessments at the Black sea coast of Russia. The work is done in Natural Risk Assessment Lab. under contract G.34.31.0007.

RC15 - Roles of the Neogeographer and Issues of Information Sharing to Respond to Disasters: A Case of the Crisis Mapping Project in Japan

Toshikazu Seto (Ritsumeikan University), Yuichiro Nishimura (Nara Women's University), Haruyuki Seki (Georepublic Japan), Taichi Furuhashi (MAPconciierge)

The Great East Japan Earthquake on March 11, 2011 caused catastrophic damage in a wide range of Japan. Although the traffic and communication infrastructure were interrupted, people could share information about which area was damaged and how by using mobile Internet and social media. That means

that, to share disaster-related information, it was the first time people widely used Free and Open Source Software for Geospatial (FOSS4G) tools such as OpenStreetMap (OSM) and Ushahidi in Japan what we call a Crisis Mapping Project. This paper investigates how the Crisis Mapping Project went in Japan, i.e., how quickly and in what scale geospatial information came to be shared in response to the earthquake. We also analyze what kind of information people actually exchanged in which area the information's spatial and temporal process, based on the date submitted by those who suffered and people in the surrounding areas. As a case study, this paper focuses on sinsai.info, information-supporting activity through the web using the Ushahidi platform with OSM map interface. A web mash-up, Ushahidi was originally built in response to the 2007 post-election violence in Kenya. While this platform had been localized in Japan even before the earthquake, developers hardly utilized it. Since March 11, 2011, however, many volunteers and neogeographers, many of whom IT professionals in the geo-location industry, organized their activities, quickly developing Ushahidi's various functions, verifying reports of more than 10,000, and translating them into English for foreigners living in Japan. This fast development derived from the facts that the platform was open source software, and that information was also open data. The sinsai.info actually collected reports via Twitter and shared information through the API, and was embedded in other web services. Moreover, in terms of activity management, by using cutting-edge SNS such as yammer and Lingr, members in remote locations could effectively exchange and share their activity records, and several features independently developed in Japan were fed back through github. Still, there are a couple of important issues to be discussed for Crisis Mapping Projects. One is how to use information most effectively in disaster-stricken areas. For this, we need to analyze what kind of data was collected at the time of emergency, responding to the disaster. Another issue to be discussed is the activity's participants and organization. Based on the activity this time, we need to be prepared for the next disaster, promoting the activity and educating neogeographers so that they could contribute more.

RC16 - Diabetic foot In Germany – a market analysis towards comprehensive integrated care of statutory health fund members of AOK Nordost

Heike Wittmann (AOK Nordost)

Aims: Diabetic foot syndrome (DFS) is one of the most neglected complications associated with diabetes. In 1989 the World Health Organization (WHO) called

upon the world community to reduce by half the rate of lower limb amputations as a consequence of diabetic gangrene within 5 years. This aim has not yet been achieved. In Germany alone, more than 30.000 diabetics undergo lower limb amputations every year. In the federal state of Brandenburg, as in many other German states, DFS care still demonstrates substantial deficits. The pathophysiological mechanisms underlying DFS are complex and multifactorial, including neuropathy, ischemia and infection. Applying evidence-based multidisciplinary treatment results in a decrease in lower limb amputations. Several studies show that a cross-sectoral and multidisciplinary approach, including prevention, patient education and multi-factorial care (in- and outpatient care, podiatrists, orthopaedic shoemakers, etc.) in the treatment of the foot ulcers reduce amputations by 45 to 85%. **Method:** Since the introduction of the Statutory Health Insurance Modernisation Act, health funds in Germany are required to initiate effective programmes by so-called integrated health care contracts. In order to offer efficient programmes it is necessary to identify diabetics with foot problems according to different grades of injury and select adequate providers accordingly. Analysing the internal claims data enables health funds to define priorities, conceive correctional measures and develop optimal strategies to guarantee a qualitatively higher level of comprehensive DFS health care that is at the same time cost-effective. Using the topographical software the user is able to analyse the collated data, and visually demonstrate and present health care situations in a geographical context. **Results:** The anonymous analysis of 569 patients in 2006 showed 650 cases of diagnosed diabetes (ICD-coding E10-E14) consisting of 313 major and 558 minor lower limb amputations as well as 46 relapses. **Conclusion:** The introduction of an integrated care contract with a specialized diabetic foot clinic enabled a reduction in major lower limb amputations from 6.8 % in 2006 to 2.9 % in 2010.

The logo is a circular emblem. The top half is white and contains a dark grey silhouette of a mountain range with two prominent peaks. The bottom half is dark grey and contains the text 'IGC' in a bold, sans-serif font, with 'COLOGNE 2012' in a larger, bold, sans-serif font below it, and 'DOWN TO EARTH' in a smaller, bold, sans-serif font at the bottom.

SPS 02-01 - International School of Applied Geography in Saint-Dié-des-Vosges : when leadership needs maps!

Christian Pierret (Festival International de Géographie de Saint-Dié-des-Vosges)

La 23ème Édition du Festival International de Géographie de Saint-Dié-des-Vosges aura lieu du 11 au 14 octobre 2012. Cet événement international unique en son genre réunira au cours de cette nouvelle édition les meilleurs experts des sciences humaines, des auteurs, des diplomates, des chefs d'entreprise et des gastronomes autour d'une thématique universelle :

« Les facettes du paysage – Nature, culture, économie »
Pays invité d'Honneur : la Turquie

Le Festival accueille cette année:

Mireille Delmas-Marty: Membre de l'académie des sciences Morales et Politiques, Professeur au Collège de France, Présidente de la 23ème édition du FIG.

Jean-Pierre Rioux : Historien, Président du salon du livre Amerigo Vespucci.

Régine Deforges : Auteur, Grand Témoin du 23ème FIG.

Erik Orsenna : Auteur, Membre de l'Académie Française, Invité d'Honneur du Salon du Livre.

La géographie est la science humaine offrant les meilleures perspectives de compréhension du monde, des rapports sociaux, des enjeux stratégiques et d'avenir. La fabrique et la genèse des paysages seront au cœur des débats. On s'interrogera aussi bien sur le « beau » paysage que sur le paysage « ordinaire ». Les valeurs du paysage, qu'elles soient environnementales (nature/culture; services éco-systémiques), économiques (tourisme, immobilier), culturelles ou sociales seront évoquées. L'aménagement du territoire et l'impact paysager seront au cœur des débats : comment construire, aménager, gérer les paysages contemporains aussi bien au plan local qu'à l'échelle mondiale. Le rôle des acteurs et des réglementations sera abordé ainsi que celle de la gouvernance paysagère. Les paysages virtuels et les paysages du futur (les jeux vidéo et leur utilisation du paysage), la géo-localisation et la géo-visualisation fournissent également nouvelles représentations géographiques. D'autres analyses de paysages moins communs (nocturnes, sous marins) sont attendues. La Turquie, pays invité d'honneur, centralisera les réflexions autour de sa position géopolitique, de la question du modèle turc mais également de son dynamisme.

Coping with the Three S. Where Is Spatial Justice?

Jaques Lévy (École polytechnique fédérale de Lausanne)

Geography has changed a lot since the 1960s. By and large, it can be argued that this discipline has left its isolationist paradigm, established multiple contacts with other kinds of knowledge, and overcome its long self-landlocking attitude. Geography has lost its epistemological exceptionalism, but is this enough? Social sciences, are commonly threatened by methodological nationalism and, more generally, by methodological corporatism, that is the corruption of a scientific approach or project by any kind of other social alignment that undermines its capacity to develop a free, autonomous thought. Has geography escaped these pitfalls? To try and answer this question, we can specify the particular *raison d'être* of geography among scientific domains. As a social science of space, geography has to manage these three s: society, space, and science. When they have forgotten society, geographers have created the myth of 'general law of space', whose effective outcomes turned out to be of a very limited interest. When they have neglected space as a thick, thinkable dimension of the social world, they have become sociologists or economists and, often, poor sociologists or economists. In front of this non-dissociable package, the aggregates we can call in a simplistic way 'North American geography' and 'Francophone geography' have shown two slightly different variants. While the first one showed a very open, even porous attitude to any kind of social concern, francophone geographers have been more reluctant on this point and have devoted most of their energy to place their analyses in a more autonomous theoretical perspective. In both areas, however, space, that is: innovative scientific propositions on social space, has not particularly taken advantage of this intellectual conjuncture. In this scope, the issue of spatial justice is a stimulating topic. The adjunction of the adjective 'spatial' to a supposed-to-be non-spatial justice raises number of epistemological and theoretical problems geographers are just beginning to tackle. The risk here is to simplify the answer to one or more of these questions: Who defines what is just, and how? In what extent could space be something else than a neutral container of un/just items? Could geographers' work bring a specific contribution to the public debate on justice? Exploring this study case, it will be contended that if the three s do not operate together, we can seriously put in doubt the cognitive usefulness of geography.

Discussant

Olivier Graefe (Institute of Geography of Fribourg)

SPS 12-01 - Plenary Session - Applied Geography in the 21st Century: Practice Relevancy of Geography in Politics, Economy and Society

Chair: Rudolf. Juchelka

Introduction

Rudolf Juchelka

Applied geography, that is implementing geographical findings into politics, economy and society, forms the third central pillar within the system of geography, apart from general and regional geography. Since the introduction of Bachelor and Master degree programs, its practical and planning oriented perspective has contributed substantially to the public perception and external presentation of the subject. During the plenary session which opens with an introductory motivational speech, the acting chairman of the German Association of Applied Geography as well as academic and practical representatives working in applied geography will discuss the current significance of applied geography and necessary future emphases.

SPS 12-02 - Plenary Session - Geographers and their Job Markets – International Career Perspectives for Bachelor- und Master-Students

Chair: Rudolf. Juchelka

Introduction

Rudolf Juchelka

The job market for geographers has been – not only since the introduction of Bachelor and Master programs – subject to numerous changes regarding content within universities and to qualification requirements on the part of the employers. Certain trends are responsible for cyclical deviations which on the other side are equalized by long-lasting basic qualifications. Thus, the new Bachelor- and Master programs also aim at an internationalization of study options and the subsequent occupational fields. The German Association of Applied Geography wants to illuminate the interface between academics and vocational practice from the perspective of a trade association. During the panel discussion relevant current trends and findings of the geographical job market research will be presented and discussed

SPS 12-03 - Geography and Requirements of International Cooperation

Chair: Burghard Rauschelbach

Introduction

Burghard Rauschelbach (DVAG)

The workshop discussion gives an insight in the practice of project work and advisory services in international cooperation. Well known experts with international experience in the tourism sector and regional economic development present examples on project and policy level, and show how international cooperation works. An experts' panel will discuss the market requirements for international advisory services in fields, which can be allocated to applied geography.

Across border! The role of development cooperation in transboundary planning, using examples from programmes in East-Europe and Africa

SPS 12-04 - DVAG-Job Market Presentation - „From Study to Job“ – Practical Tips from DVAG for Geographers entering a Career

Chair: Rudolf Juchelka

„From Study to Job“ – Practical Tips from DVAG for Geographers entering a Career

Rudolf Juchelka

Particularly for students at the beginning of their study program as well as during their examination phase the picture of what comes after academics is often blurry and intransparent. However, it is especially important during this time to carefully plan an optimal later transfer from the university to the job and to set the respective course in order to achieve this.

In a deliberately open and free discussion and exchange atmosphere – all questions are welcome ! And with no preassigned structure – the German Association of Applied Geography would like to share its longtime experience by giving practical tips for entering into a career.

SPS 13-01 - Facets of Contested Geographies: Negotiating lieux de mémoire in Transnational Contexts

Chair: Dietrich Soyez, Ruth Fincher

Rethinking belonging through memory-work: Towards a place-based ethics of care

Karen Till (University of Ireland)

In the interdisciplinary field of memory studies, attention has been paid to different forms of testimony at personal and social levels as tied to human rights particularly in societies that have experienced state-perpetrated violence. Yet what is under-researched is the significant ways that places are part of the intergenerational memories of loss, displacement, trauma and inheritance. As I will argue, those who have experienced and inherited the 'rootshock' of displacement and trauma care for the very places that remain haunted by what Edward Casey describes as the 'unresolved remainders of memory'. Places are considered as a kind of meta-subject and witnesses to pasts but also offer communities the possibility of care. In this talk, using a range of different case studies, I examine this intergenerational, social and transnational approach to memory-work which

is based upon what I call a ‘place-based ethics of care’. By maintaining, continuing, and repairing places and selves through place, pathways of possibility based upon multiple pasts offer a different model of belonging and rights, one based on inhabitation and memory-work, rather than on territory or blood.

Place memory and cultural trauma in a transnational context

Nicholas Entrikin (University of Notre Dame)

In the thirty years since Pierre Nora wrote his influential essay on memory and history, it has become much more common to see places of memory as sites of active construction and conflict rather than as passive and natural secretions of sentiment. This shift is evident in recent work on collective memory and cultural trauma that examines the successful cultural narratives constructed around an event that give it shape in the collective imagination. The narrative construction of places of trauma occurs generally within national contexts. Transnational memories of trauma are typically seen as thin and incomplete and unable to effectively resonate beyond national borders. However, if we see transnational memories as simply another set of constructed memories then the discussion shifts from matters of “cultural insensitivity” to questions of how such memories are constructed and contested in transnational contexts and how the meaning of place shifts in relation to these narratives.

Battles of history, lieux de mémoire and identity building in the post-Soviet space

Vladimir Kolosov (Russian Academy of Sciences)

Benedict Anderson wrote that “the contemporary culture of nationalism does not have more inspiring symbols than monuments and graves of the Unknown soldier”. National or ethnic identity is shaped by different symbols – historical narratives, real or invented national heroes, key events and sacred places (lieux de mémoire), regular ceremonies, etc. An individual needs markers distinguishing “them” from “us”, both in space and time. In “animating” history and geographical space such markers strengthen the ties between the elements of the geopolitical triad “territory – identity – boundaries”. The disintegration of the Soviet Union provoked in its successor states a crisis of identity, which can be defined as a period when ethnic or other region-specific sub-national segments of a society create obstacles to national unification and the identification with a certain political community. As a result, a considerable part of the population did not or does not recognize yet the boundaries of the territorial state as a legitimate political unit. This crisis of identity is due not only to the multi-ethnic character of almost all successor states of the Soviet Union, but also to the variety and the heterogeneity of the ethnic identity of the titular peoples. Trying to forge and to cement a new political identity, post-Soviet states established lots of new symbols and ceremonies, created new sacred places. However, the replacement of old imperial and Soviet symbols is not an easy and quick process. Old

monuments, museums and a good part of geographical names often remain intact. Old and new sacred spaces co-exist and form surprising combinations. The author considers, first, the relations and the role of the sacred places created before 1917, during the Soviet period and after the collapse of the USSR, and their interpretation by various age, social and ethnic groups. Second, he investigates and compares the types of new, post-Soviet sacred places in different countries – Russia, Ukraine, Moldova and Tajikistan. These new places may incarnate ethnic, religious, linguistic, regional and civic kinship. Typically, they represent the imperial and the Soviet past as a continuous struggle of the titular group for freedom and self-determination. National or regional history is viewed as a tragic sequence of battles against external enemies which generated a great number of heroes fallen in the uneven fight. The state tries to perpetuate the collective memory about its most glorious periods, usually in the Middle age. The names of national heroes become regional or local brands, the intrinsic parts of a country’s or a region’s image. In some post-Soviet countries, the politics of memory has resulted in a meta-narrative that categorizes them as nations-victims by integrating all central historical events of the twentieth century, from the civil war to the Chernobyl disaster. A particular attention is paid to the case of unrecognized states – Transnistria, Abkhazia, South Ossetia and Nagorno Karabakh. Three of them are multi-ethnic, and therefore, their political leaders have to create or to reinvent the sacred places which should be symbolic for the titular group in stressing its distinctions from the mother state and at the same time shared by other groups. The central place belongs to the sacred places related with recent civil wars and conflicts with the mother-state. Sociological polls show that for a large part of Russian, Ukrainian and Belorussian citizens the victory of the Soviet Union in World War Two is an important element of identity and the most positive souvenir about the common past. Today, it became a subject of nostalgia. In Russia and Belarus and currently in Ukraine central authorities try to integrate it in the new historical narrative and in the process of identity building. At the same time, post-communist elites in Eastern Europe have difficulties integrating old Russian/Soviet and particularly war memorials into their new national landscapes of memory. On the one hand, the nationalization of history turns these memorials into disturbing symbols for alternative narratives. Moreover, Russian and Soviet memorials are often considered as signs of Russian geopolitical influence. They become sites of discontent, protest and provocation. Local Russians struggle for symbolic recognition, for their right to be represented in the national landscape of memory. Their problem is that their symbolic resources contradict the new narrative of national history. In conclusion, the author discusses the notion of historical reconciliation. Using some positive examples, he analyzes a possible role of sacred places in this process.

Evolution of an Industrial Frontier and an Industrial Core: The Case of Minnesota's Iron Ranges and Detroit

David Lanegran (Macalester College)

This case study will examine the changing social and economic geography of the iron mining and related steel and auto industries in the Great Lakes Region of the United States. After tracing the establishment, growth and globalization of the iron ore mining industry in Minnesota we will examine related patterns of growth and decline in one of the primary markets for iron ore, the auto industry in Detroit. Special emphasis will be given to current efforts to reuse abandoned landscapes in Detroit.
