Plant reproductive biology

Alpine environment

Seed mass

Seed number

## ABSTRACT

Data on reproductive traits of alpine plants in the central Scandes Mountains (Sweden) are given, namely seed mass, seed number per plant and seed number per unit area of vegetation. Data were obtained 1) by counting reproductive units (whole plants, flower heads, capsules, berries, as applicable) per meter squared in seven distinct vegetation types, 2) by counting the number of seeds per reproductive unit in the lab, and 3) by weighing seeds (discriminating between dispersule and germinule wherever relevant).

## 1. Data

Data are organized in three tables: 1) Site properties, 2) Seed mass data for 85 plant species, for many species measured with and without attached structures, such as pappus, and 3) Seed number per reproductive unit (whole ramet, flower head, capsule, berry etc.) and number of reproductive units per meter squared for a total of 105 species in seven vegetation types, each represented by 10 random sample plots. Seed number per ramet is given for 79 species, excluding cushion and mat forming species, for which ramets either are irrelevant or cannot be reasonably delimited.

## 2. Experimental design, materials, and methods

### 2.1. Geography

The Helags area (62°55'N; 12°35'E) in southern Jämtland County, Sweden, is situated in the central part of the Scandes Mountains. The highest peak locally, Helagsfjället, reaches an altitude of

## Specifications table

Subject area	Biology
More specific subject area	Plant reproductive ecology
Type of data	Tables
How data was acquired	Field data collection and lab measurement (Mettler MT5 balance)
Data format	Raw
Experimental factors	Alpine vegetation zones
Experimental features	Observational data on seed mass, seed number per plant and/or per unit area
Data source location	Sweden, Jämtland county, Helags area (62°55'N; 12°35'E)
Data accessibility	The data are available within this article

**Value of the data**

- These original data were collected in 2002 in the Helags mountain area, Jämtland County, Sweden.
- The data concern key plant functional traits related to sexual reproduction, namely offspring size, fecundity per mother plant and reproductive output per unit area.
- The data may be used within the expanding field of trait-based community ecology, in which many published studies are bound to rely on standard values for species, i.e. previously collected data retrieved from databases and original publications.
- Primary research in plant community ecology in the Arctic-Alpine realm of Europe and the wider Holarctic will probably find the data useful, not the least because, for many of the species here included, no data on seed mass or reproductive output have been published before.
- The data may be used to improve insights gained from studies of seed bank formation and seed dispersal, in which own empirical data on seed mass and seed output per unit area are usually not available. Moreover, when included in a global trait database, the data may prove useful in macroecological analyses.

1796 m a.s.l., and has Sweden's southernmost glacier. The climate is comparatively continental, with a January mean between −7 and −8 °C, a July mean of +8–10 °C, and a mean annual precipitation of 700–1200 mm. The bedrock is predominantly gneiss, but veins of calcareous schists occur frequently. The whole area is extensively grazed by semi-domestic reindeer.

## 2.2. Data on seed productivity and seed mass

A large-scale transect of c. 3 × 13 km was placed on the eastern macroslope of the Helags massive, from uppermost middle alpine zone and eastwards down to subalpine areas in the Ljungdalen valley. The seven most important vegetation types in terms of area were selected for sampling (Table 1): middle alpine grass heath, low alpine dwarf-shrub heaths of three types (poor, mesic and dry rich, mainly differing snow cover in winter and soil moisture in summer), low alpine moderate snowbed (short-herb meadow), and subalpine birch forest of two types (meadow type and heath type, differing in soil moisture and pH). These vegetation types collectively covered a total of 89% of the vegetated area of the transect (Andersson 2000). The excluded vegetation types were in general very wet or otherwise difficult to access (e.g. willow scrub). Fieldwork took place at the end of August 2002. For each vegetation type a representative area of suitable size was selected. Within each area 10 plots of 1 × 1 m were placed along a small-scale transect laid out in order to maximally cover the internal variation in microtopography (e.g., in the case of poor dwarf-shrub heath, which occurs on ridges with little or no snow cover during winter, the transect started at the most barren ridge-top and went downwards to parts with deeper winter snow-cover). Within each sample plot, the number of reproductive units of each species was counted. Reproductive units were ramets or individuals in most cases (42 and 15 species, respectively). For tussock-forming species, both the number of reproductive tussocks and the total number of reproductive shoots were counted. For most Asteraceae and other species with distinct flower heads, both the number

**Table 1**

Data on the seven vegetation types sampled for seed yield: geographical coordinates and altitude of the sampled site (10 plots of 1 m<sup>2</sup>), sampling date, and the landscape-scale percentage cover (in the large-scale transect; lakes and barren block-fields excluded from the total) according to a vegetation map of the area [2].

Vegetation type	Site name	Long	Lat	Altitude (m a.s.l.)	Date sampled	Corresponding vegetation type on the map of Andersson (2000)	Percent landcover per vegetation type on the wider landscape scale
Subalpine birch forest of meadow type	1. Sweden, Jämtlands län, Ljungdalen, Postvallen	12.716461	62.899	760	28-08-2002	Birch forest of meadow type	10.3
Subalpine birch forest of heath type	2. Sweden, Jämtlands län, Ljungdalen, Kläppen	12.708967	62.897	820	28-08-2002	Moss-rich birch forest	8.7
Low alpine poor heath	3. Sweden, Jämtlands län, Ljungdalen, V.f. Kesusjön	12.606989	62.908	910	26-08-2002	Poor heath	7.0
Low alpine mesic heath	4. Sweden, Jämtlands län, Ö Helagsskaffetet	12.578594	62.909	950	27-08-2002	Mesic heath	20.4
Low alpine moderate snowbed	5. Sweden, Jämtlands län, Ö Helagsskaffetet	12.575511	62.910	970	26-08-2002	Short-herb meadow	11.2
Low alpine dry rich heath	6. Sweden, Jämtlands län, Ö Helagsskaffetet	12.547966	62.910	1010	27-08-2002	Dry heath	27.0
Middle alpine grass heath	7. Sweden, Jämtlands län, Helags	12.482430	62.911	1280	27-08-2002	Grass heath	4.2

of reproductive individuals/ramets and the number of flower heads were counted (11 species), and likewise for 3 species with individual flowers/fruits (e.g., *Viola biflora*). In cushion and mat forming plants (10 species), the reproductive unit counted were berries (e.g., *Vaccinium* spp.), capsules (e.g., *Loiseleuria procumbens*), catkins (*Betula nana* and *Salix herbacea*) or individual flowers (*Dryas octopetala*). All phenological stages of reproductive structures were included in counting. It was not possible to estimate the seed productivity (number of seeds per ramet or individual) for cushion and mat forming species (see Table 2 and 3).

At each site, ten reproductive units per (newly encountered) species were collected. This means that data on seed mass and seed number per reproductive unit were not gathered for all species at all sites, but at least once for the whole study area. If ripe fruits were not to be found in the sample plots, they were looked for in the vicinity or, in when necessary, in the greater region.

For all collections, the number of fully developed ripe seeds per reproductive unit was counted under a dissection microscope in the laboratory. The number of reproductive units per m<sup>2</sup> may be multiplied by the number of seeds per unit in order to give the seed yield (number of seeds per m<sup>2</sup>). Seeds were stored in paper envelopes at room temperature and ambient moisture for two-four weeks, and subsequently 10 randomly selected seeds were weighed individually on a Mettler MT5 balance (nominal accuracy 0.001 mg). However, wherever relevant, separate measurements were made for dispersule (dispersal units leaving the mother plant, including various appendages, which may play a role in dispersal) and germinule (the after-dispersal structure, i.e. seed or small indehiscent fruit, such as achene and caryopsis) of the same species [1].

**Table 2**

Data on seed mass. Seed collections sites are numbered as in [Table 1](#), except site 8, Sweden, Jämtlands län, west of Torkilstöten, site 9, Sweden, Jämtlands län, Sörvatnet, site 10, Sweden, Jämtlands län, Hamrafjället, and site 11, Sweden, Dalarna län, Idre socken, Strömmen. Figures in column 3 "No coll." indicates the Number of individuals or ramets or reproductive units collected.

**Table 3**

Data on seed number per ramet and per unit area. For each vegetation type sampled, the number of sample plots, in which each species was observed is given in column 5–11 (NA means that the species was present, but that sexual reproduction was not observed). The total number of reproductive units per species per site (vegetation type) is given in columns 12–19. The estimated number of seeds produced per meter squared is obtained by multiplying the latter figure with the mean number of seeds per reproductive unit (column 4).
