Abstract. Considering the Euclidean Division of two real polynomials, we present an iterative process based on the ERES method to compute the remainder of the division and we represent it using a simple matrix form.

Introduction

The representation of the Euclidean algorithm process is presented using the matrix-based methodology of Extended-Row-Equivalence and Shifting operations (ERES) [3, 4]. This allows the use of numerical methodologies for algebraic computation problems with the additional advantage of being able to handle uncertain coefficients and numerical errors.

We consider two real polynomials:

$$P(x) = \sum_{i=0}^m p_i x^i, p_m \neq 0 \quad \text{and} \quad Q(x) = \sum_{i=0}^n q_i x^i, q_n \neq 0, \quad m, n \in \mathbb{N} \quad (0.1)$$

with degrees $\deg\{P(x)\} = m$, $\deg\{Q(x)\} = n$ respectively, and $m \geq n$.

Definition 1. We define the set

$$\mathcal{D}_{m,n} = \left\{ (P(x), Q(x)) : P(x), Q(x) \in \mathbb{R}[x], m = \deg\{P(x)\} \geq \deg\{Q(x)\} = n \right\}$$

For any pair $\mathcal{D} = (P(x), Q(x)) \in \mathcal{D}_{m,n}$, we define a vector representative $\underline{D}(x)$ and a basis matrix D_m represented as :

$$\underline{D}(x) = [P(x), Q(x)]^t = [p, q]^t \cdot \underline{e}_m(x) = D_m \cdot \underline{e}_m(x)$$

where $D_m \in \mathbb{R}^{2 \times (m+1)}$, $\underline{e}_m(x) = [x^m, x^{m-1}, \dots, x, 1]^t$. The matrix D_m is formed directly from the coefficients of the given polynomials $P(x)$ and $Q(x)$.

Definition 2. Given a pair $\mathcal{D}_{m,n}$ of real polynomials with a basis matrix D_m the following operations are defined [3, 4]:

- a) Elementary row operations with scalars from \mathbb{R} on D_m .
- b) Addition or elimination of zero rows on D_m .
- c) If $\underline{a}^t = [0, \dots, 0, a_l, \dots, a_k] \in \mathbb{R}^k$, $a_l \neq 0$ then we define as the Shifting operation

$$shf : shf(\underline{a}^t) = [a_l, \dots, a_k, 0, \dots, 0] \in \mathbb{R}^k$$

By $shf(\mathcal{D}_{m,n}) \equiv \mathcal{D}_{m,n}^*$, we shall denote the pair obtained from $\mathcal{D}_{m,n}$ by applying shifting on the rows of D_m . Type (a), (b) and (c) operations are referred to as Extended-Row-Equivalence and Shifting (ERES) operations.

The following theorem shows the relation between a matrix and its shifted form [1].

Theorem 1 (Matrix representation of Shifting). *If $D \in \mathbb{R}^{2 \times k}$, $k > 2$, is an upper trapezoidal matrix with rank $\rho(D) = 2$ and $D^* \in \mathbb{R}^{2 \times k}$ is the matrix obtained from D by applying shifting on its rows, then there exists a matrix $S \in \mathbb{R}^{k \times k}$ such that: $D^* = D \cdot S$.*

Corollary 1. *If $D_m \in \mathbb{R}^{2 \times (m+1)}$ is the basis matrix of a pair of real polynomials $\mathcal{D} = (P(x), Q(x)) \in \mathcal{D}_{m,n}$, then $D_m^* \in \mathbb{R}^{2 \times (m+1)}$ is the basis matrix of the pair $\mathcal{D}^* = (P(x), x^{m-n} Q(x)) \in \mathcal{D}_{m,m}$ and there exists a matrix $S_{\mathcal{D}} \in \mathbb{R}^{(m+1) \times (m+1)}$ such that:*

$$D_m^* = D_m \cdot S_{\mathcal{D}} \tag{0.2}$$

The ERES representation of the Euclidean Division

If we have a pair of polynomials $\mathcal{D} = (P(x), Q(x)) \in \mathcal{D}_{m,n}$, then, according to Euclid's division algorithm, it holds:

$$P(x) = \frac{p_m}{q_n} x^{m-n} Q(x) + R_1(x) \tag{0.3}$$

This is the first and basic step of the Euclidean Division algorithm. The polynomial $R_1(x) \in \mathbb{R}[x]$ is given by:

$$R_1(x) = \sum_{i=m-n}^{m-1} \left(p_i - \frac{p_m}{q_n} q_{i-(m-n)} \right) x^i + \sum_{i=0}^{m-n-1} p_i x^i \tag{0.4}$$

In the following, we will show that the remainder $R_1(x)$ can be computed by applying ERES operations to the basis matrix D_m of the pair \mathcal{D} .

Proposition 1 (Matrix representation of the first remainder of the Euclidean Division). *Applying the algorithm of the Euclidean Division to a pair $\mathcal{D} = (P(x), Q(x)) \in \mathcal{D}_{m,n}$ of real polynomials, there exists a polynomial $R_1(x) \in \mathbb{R}[x]$ with degree $0 \leq \deg\{R_1(x)\} < m$ such that:*

$$P(x) = \frac{p_m}{q_n} x^{m-n} Q(x) + R_1(x)$$

Then, the remainder $R_1(x)$ can be represented in matrix form as:

$$R_1(x) = \underline{v}^t \cdot E_1 \cdot \underline{e}_m(x)$$

where $E_1 \in \mathbb{R}^{2 \times (m+1)}$ is the matrix, which occurs from the application of the ERES operations on the basis matrix D_m of the pair \mathcal{D} and $\underline{v} = [0, 1]^t$.

Proof. If we consider the division $P(x)/Q(x)$, then, according to Euclid's algorithm, there is a polynomial $R_1(x)$ with degree $0 \leq \deg\{R_1(x)\} < m$ such that:

$$R_1(x) = P(x) - \frac{p_m}{q_n} x^{m-n} Q(x) = [0, 1] \cdot \begin{bmatrix} 0 & 1 \\ 1 & -\frac{p_m}{q_n} \end{bmatrix} \cdot \begin{bmatrix} P(x) \\ x^{m-n} Q(x) \end{bmatrix} \quad (0.5)$$

If we take into account the result in corollary 1, we will have:

$$R_1(x) = [0, 1] \cdot \begin{bmatrix} 0 & 1 \\ 1 & -\frac{p_m}{q_n} \end{bmatrix} \cdot D_m \cdot S_{\mathcal{D}} \cdot \underline{e}_m(x) = \underline{v}^t \cdot C \cdot D_m \cdot S_{\mathcal{D}} \cdot \underline{e}_m(x) \quad (0.6)$$

where $\underline{v}^t = [0, 1]$, $C = \begin{bmatrix} 0 & 1 \\ 1 & -\frac{p_m}{q_n} \end{bmatrix}$, D_m is the basis matrix of the polynomials $P(x)$ and $Q(x)$ and $S_{\mathcal{D}}$ the respective shifting matrix. Therefore, there exists a matrix $E_1 \in \mathbb{R}^{2 \times (m+1)}$ such that:

$$E_1 = C \cdot D_m \cdot S_{\mathcal{D}} \quad \text{and} \quad R_1(x) = \underline{v}^t \cdot E_1 \cdot \underline{e}_m(x) \quad (0.7)$$

We consider now the basis matrix D_m of the polynomials $P(x)$ and $Q(x)$:

$$D_m = \begin{bmatrix} P(x) \\ Q(x) \end{bmatrix} = \begin{bmatrix} p_m & \dots & p_{n+1} & p_n & p_{n-1} & \dots & p_0 \\ 0 & \dots & 0 & q_n & q_{n-1} & \dots & q_0 \end{bmatrix} \cdot \underline{e}_m(x) \quad (0.8)$$

and we will show that the above matrix E_1 is produced by applying the ERES operations to the basis matrix D_m of the polynomials $P(x)$ and $Q(x)$. We follow the next methodology:

1. We apply shifting on the rows of D_m . Let $S_{\mathcal{D}} \in \mathbb{R}^{(m+1) \times (m+1)}$, be the proper shifting matrix: $D_m^{(1)} = D_m \cdot S_{\mathcal{D}} = \begin{bmatrix} p_m & \dots & p_{m-n+1} & p_{m-n} & p_{m-n-1} & \dots & p_0 \\ q_n & \dots & q_1 & q_0 & 0 & \dots & 0 \end{bmatrix}$
2. We reorder the rows of the matrix $D_m^{(1)}$. If $J = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ is the permutation matrix, then: $D_m^{(2)} = J \cdot D_m^{(1)} = \begin{bmatrix} q_n & \dots & q_1 & q_0 & 0 & \dots & 0 \\ p_m & \dots & p_{m-n+1} & p_{m-n} & p_{m-n-1} & \dots & p_0 \end{bmatrix}$
3. We apply stable row operations on $D_m^{(2)}$ (LU factorization). If $L = \begin{bmatrix} 1 & 0 \\ \frac{p_m}{q_n} & 1 \end{bmatrix}$ then $L^{-1} = \begin{bmatrix} 1 & 0 \\ -\frac{p_m}{q_n} & 1 \end{bmatrix}$ and therefore:

$$\begin{aligned}
 D_m^{(3)} &= L^{-1} \cdot D_m^{(2)} = \begin{bmatrix} 1 & 0 \\ -\frac{p_m}{q_n} & 1 \end{bmatrix} \cdot \begin{bmatrix} q_n & \dots & q_1 & q_0 & 0 & \dots & 0 \\ p_m & \dots & p_{m-n+1} & p_{m-n} & p_{m-n-1} & \dots & p_0 \end{bmatrix} \\
 &= \begin{bmatrix} q_n & \dots & q_1 & q_0 & 0 & \dots & 0 \\ 0 & \dots & p_{m-n+1} - q_1 \frac{p_m}{q_n} & p_{m-n} - q_0 \frac{p_m}{q_n} & p_{m-n-1} & \dots & p_0 \end{bmatrix}
 \end{aligned}$$

We notice that the term $\frac{p_m}{q_n}$ emerges from the LU factorization.

The above process can be described by the following equation:

$$D_m^{(3)} = L^{-1} \cdot J \cdot D_m \cdot S_D \tag{0.9}$$

which represents the ERES methodology. Obviously $L^{-1} \cdot J = C$ and therefore, we conclude that $D_m^{(3)} \equiv E_1$. \square

The following theorem establishes the connection between the ERES method and the Euclidean Division of two real polynomials.

Theorem 2 (Matrix representation of the remainder of the Euclidean Division). *Applying the algorithm of the Euclidean Division to a pair $\mathcal{D} = (P(x), Q(x)) \in \mathcal{D}_{m,n}$ of real polynomials, there are polynomials $G(x), R(x) \in \mathbb{R}[x]$ with degrees $\deg\{G(x)\} = m - n$ and $0 \leq \deg\{R(x)\} < n$ respectively, such that:*

$$P(x) = G(x)Q(x) + R(x)$$

Then, the final remainder $R(x)$ can be represented in matrix form as:

$$R(x) = \underline{v}^t \cdot E_N \cdot \underline{e}_m(x)$$

where $E_N \in \mathbb{R}^{2 \times (m+1)}$ is the matrix, which occurs from the successive application of the ERES operations on the basis matrix D_m of the pair \mathcal{D} and $\underline{v} = [0, 1]^t$.

The proof of the previous theorem is based on the iterative application of the result from proposition 1 to the sequence $\{(P(x), Q(x)), (R_i(x), Q(x))\}$, for $1 \leq i \leq (m - n)$. Therefore, we get a sequence of matrices $E_i = L_i^{-1} \cdot E_{i-1} \cdot S_i$, for $i = 1, 2, \dots, N < m - n$, where the final matrix E_N gives the total remainder $R(x)$ and every matrix L_i gives a specific coefficient of the quotient $G(x)$.
