Abstract: Article is devoted to the problems solution of the agricultural crops state analysis during the cultivation process. The use of biosensor devices for measuring plant growth parameters, modern information technologies Data Mining and operational analysis of OLAP data is proposed. Among a wide range of parameters that characterize the plants state, the following are considered: the presence of mycotoxins and the chlorophyll content in the plant against the backdrop of measuring the applied doses of chemical fertilizers and biological additives. The architecture of a system proposed to solve these problems is presented. Its main functions are: control of plant growth parameters measurement with the various biosensors and external sources, transfer of the received data to a mobile device with further accumulation in a central storage, analysis and forecasting of processes related to the crops cultivation. The efficiency of growing crops should be increased.
