19 **Abstract:**

20 ***Background***

21 Pulses are an affordable source of carbohydrates, dietary fiber, vitamins, minerals, phytochemicals, and  
22 particularly proteins. These nutritious seeds greatly contribute to food security, sustainable agriculture,  
23 biodiversity and environmental changes mitigation. Pulses are, indeed, a protein source with low carbon  
24 and water footprints. Interest in the use of pulses and their by-products in bread formulation has been  
25 mounting in recent years due to their high nutritional and functional values. Bread is one of the oldest and  
26 most consumed food worldwide, but it has an unbalanced amino-acids profile.

27 ***Scope and approach***

28 This review aims to provide up-to-date information on the compositional and nutritional attributes of pulses  
29 as well as their impact on bread-making quality. Keeping in mind that forthcoming challenges should be  
30 overcome to formulate a high-quality bread based on pulses-wheat blends.

31 ***Key findings and conclusions***

32 Fortifying bread with pulses will secure a better amino-acids profile and a higher protein intake favoring  
33 ensurement of a balanced diet to a wide population with low environmental impact. Hence, pulses  
34 consumption is a necessity more than a choice for developing and developed countries with no exception.

35 **Keywords:** pulses, legumes, nutrition, fortification, bread.

## 41        **1. Preface**

42        Legumes belong to the family *Fabaceae* or *Leguminosae* and are important agricultural crops grown all  
43        over the world. The term "legume" refers to the plants whose fruit is enclosed in a pod. Legumes are a very  
44        large family which consists of 750 genera and 16,000–19,000 species (Ratnayake, Hoover, Shahidi, Perera,  
45        & Jane, 2001). Among these, approximately 60 species have been domesticated, including soybeans, mung  
46        beans, chickpeas and lentils. Legumes were declared the theme of the year 2016 by FAO (Food and  
47        Agricultural Organization of the United Nations) to acknowledge their important contribution in feeding  
48        the world. Such celebration aimed to highlight benefits of these crops for farmers, manufactures and  
49        consumers, and to promote their growth and implementation in the diet. After cereals, legumes production  
50        ranks the second major agricultural sector worldwide, with peas, chickpeas, lentils, and beans being the  
51        most consumed (over 70%) of legumes worldwide (FAO, 2015). Legumes are considered “superfood” for  
52        their dense nutritional composition providing a multitude of health benefits due to their good supply of  
53        micro - and macronutrients. Also, they are cultivated worldwide covering important geographical area,  
54        subsequently, they have an important socio-economic impact on developed and developing countries. Such  
55        crops are also characterized by low water and fertilizing requirements, high resistant to diseases and  
56        important adaptability to harsh conditions (Brueck & Lammel, 2016). Also, intercropping cereals with  
57        pulses greatly contributes in the sustainability of crops systems and soil biodiversity as renewable natural  
58        resources (Maikhuri, Dangwal, Negi, & Rawat, 2016).

59        In recent years, great interest was attributed to pulses, “the dry seed of legumes”, as a main ingredient or as  
60        a fortifying agent for bread. Bread is one of the most consumed products worldwide, it is made from wheat  
61        flour, salt and water, with or without leavening agent (*Saccharomyces cerevisiae* or/and sourdough).  
62        Although bread provides carbohydrates and energy, it lacks some essential amino acids and bioactive  
63        components. Therefore, fortifying wheat flour with pulses might enhance the protein profile as well as the  
64        bioactive content of bread. This review aims to raise awareness toward the spectrum of benefits related to

65 the consumption of pulses as well as to the effects of the implementation of the most widespread pulses’  
66 species into bread recipe on product’s nutritional attribute and quality.

## 67 **2. Importance of pulses**

68 Pulses, also called grain-legumes, belong to the *Fabaceae* (Figure 1), which are grown primarily for their  
69 edible seeds. Pulses belong to the legume family, but the term “pulse” is reserved to the dried seed,  
70 according to FAO (2016). The most common pulses are dried peas, beans, lentils and chickpeas. Regardless  
71 of the geographical regions, pulses are widely cultivated (Table 1).

72 The global contribution of legumes, particularly pulses, to a balanced and sustainable humans-environment  
73 relation is summarized in Figure 2. Most plants in this family obtain their own nitrogen through a symbiotic  
74 relationship with soil microbiome (Daubech et al., 2017), and, thanks to their ability to fixe atmospheric  
75 nitrogen in the soil, they reduce the need for nitrogen fertilizers (Couëdel, Alletto, Tribouillois, & Justes,  
76 2018; Moyano, Marco, Knopoff, Torres, & Turner, 2017). Pulses are, consequently, a sustainable  
77 production, play an important role in fostering soil fertility, and might be of great importance for farmers  
78 with no or limited access to nitrogen fertilizers (Maikhuri et al., 2016). Pulse crops also contribute in  
79 mitigating environmental climate changes through reducing carbon and water footprints. Carbon footprint  
80 is associated with intensive use of inorganic N fertilizers, responsible for half of all agricultural greenhouse  
81 gas emissions (Crews & Peoples, 2004). Durum wheat produced in a pulse-pulse-durum rotation system  
82 was shown to have lower carbon footprint (-34 %) than when it was preceded by 2 seasons of cereal crops  
83 (Liu et al., 2016). Inter-cropping cereals crops with pulses also increased the biomass, yield stability and  
84 protein content of the harvest (Kermah et al., 2017; Naudin, Corre-Hellou, Pineau, Crozat, & Jeuffroy,  
85 2010; Zhang et al., 2015). Pulses also have low water footprint as compared to other sources of protein (e.g.  
86 milk, egg and chicken meat) (Mekonnen & Hoekstra, 2010). Therefore, pulses are a 100% renewable energy  
87 source to feed humans and animals, as well as maintaining/enhancing the diversification of soil (Brueck &  
88 Lammel, 2016; Himanen, Mäkinen, Rimhanen, & Savikko, 2016).

89 Nutritionally, the consumption of pulses not only brings important variety of micro - and macro-nutrients  
90 in the diet, but several evidences underlined their significant health-beneficial properties such as satiety  
91 increase (McCrorry, Hamaker, Lovejoy, & Eichelsdoerfer, 2010) and cholesterol lowering (Finley et al.,  
92 2013; Sagratini et al., 2013; Siah, Wood, Agboola, Konczak, & Blanchard, 2014; Vila-Donat, Fernández-  
93 Blanco, Sagratini, Font, & Ruiz, 2015), as well as their action in reducing diet-related chronic diseases  
94 including diabetes, metabolic syndrome (e.g. blood pressure and abnormal cholesterol), cardiovascular  
95 diseases, and cancer (Dhillon et al., 2016; Feregrino-Pe et al., 2008; Marventano et al., 2017; Messina,  
96 2014; Mollard, Wong, Luhovyy, Cho, & Anderson, 2014; Rebello, Greenway, & Finley, 2014). Pulses also  
97 can greatly contribute in the prevention of undernutrition and malnutrition issues in low income countries.  
98 Therefore, there has been a continuous increase of interest in pulses integration in foodstuffs-making due  
99 to their dense nutritional composition, environmental contribution and technological aptitude. Pulses are  
100 consumed either as an intact seed or can be processed before consumption, split or milled, or fractionated  
101 to obtain fiber, starch and protein concentrates or isolates (Roy, Boye, & Simpson, 2010). These different  
102 ingredients held different physicochemical, nutritional and technological properties that will define their  
103 functionality once integrated in food formulation during processing, storage, and consumption.

### 104 **3. Background information about pulses**

#### 105 **3.1. Classification**

106 Table 2 summarizes the main characteristics of the 11 primary pulses, which belong to the *Phaseoleae*,  
107 *Cicereae* and *Fabeae* tribes (FAO 2017). Some background information about origin and area of cultivation  
108 is shown in Table 3.

#### 109 **3.2. Composition**

##### 110 **3.2.1. Nutrients**

111 A massive work has been carried out by FAO to collect information on the nutritional properties of pulses  
112 available in the literature. The gathered data were then standardized and included in an open access database  
113 online. Table 4 displayed the major macro-components of the most widespread pulses as stated by FAO  
114 (2017). The amino acid composition of wheat flour was also included; even though it can be extremely  
115 diverse depending on multiple factors, including genetic diversity, effect of processing and environmental  
116 conditions similarly to that of pulses.

117 Pulses can be considered low-energy product, as they provide an amount of energy [an average value  
118 relative to Table 4,  $318 \pm 14$  (Kcal/100g), range 301-359 (Kcal/100g)] lower than those of wheat flour (348  
119 Kcal/100g) (Table 4). The highest energy (359 Kcal/100g) is provided by chickpea, Kabuli variety.  
120 Carbohydrates content differed vastly among pulses and fluctuated from 10.8% (Adzuki bean) to 51.3%  
121 (lupin). Similarly, fat content was quite dissimilar, and ranged from 0.6 g/100 g (Adzuki bean) to 6.5 g/100g  
122 (lupin). Pulses are an excellent source of dietary fiber with high range of variability extending from 13.1  
123 g/100g in chickpea, Kabuli to 35.3 g/100g in lupin. For ash content, Pinto bean had the highest value (4.9  
124 g/100g), while lentil showed the lowest one (2.7 g/100g). Notably, according to the FAO (2017) database,  
125 important amounts of potassium were found, ranging from 219 to 1940 mg/ 100 g, compared to durum (431  
126 mg/100 g) and common wheat (435 mg/ 100 g) (USDA 2016). Likewise, high calcium content was found  
127 (up to 295 mg/100g, Table 4) (FAO 2017). Pulses are primarily known as a valuable source of proteins  
128 [from 18.4 g/100g (Bambara nut) to 34.1 g/100g (lentil)] with a balanced amino acids profile, rich in  
129 essential amino acids. The amino acids composition of different pulses is shown in Table 5. Lentil contains  
130 the highest amount of alanine (1270), followed by moth bean (1200 mg/100 g), while wheat flour was the  
131 poorest (543 mg/100 g). Lupin had the highest concentration of most amino acids (Arg, Asp, Glu, Gly, His,  
132 Ile, Leu, Phe, Pro, Ser, Thr, Tyr and Val), while Cys, was slightly higher in chickpea desi (646 mg/100 g)  
133 than lupin (610 mg/100 g). Similarly, Lys was high in lentil (1710 mg/100 g), followed by kidney bean  
134 (1670 mg/100 g) and lupin (1650 mg/100 g) suggesting that these pulses are an excellent ingredient to be  
135 combined in wheat-based flour blends to obtain a balanced and complete amino acids profile. Pulses amino

136 acids composition is characterized by a rich Lys content compared to that of wheat flour (416 mg/100 g,  
137 Table 5) (Tuśnio and others 2017). Met and Trp were quite low in pulses ranging from 166 mg/ 100 g  
138 (Board bean) to 405 mg/ 100 g (Cowpea) and from 115 mg/100 g (Bambara nut) to 328 mg/100 g (Kidney  
139 bean). However, wheat flour showed intermediate contents of Met (251 mg/ 100 g) and Trp (130 mg/ 100  
140 g) but high amounts of proline (1594 mg/ 100 g) and Glu (4839 mg/ 100 g). Moreover, pulses have  
141 interesting phenolic acids (e.g. folic acid and hydroxycinnaminic acid), vitamin (e.g. ascorbic acid, and  
142 vitamin E, B6, B12 and K) and flavonoids (e.g. glycosides, anthocyanins, proanthocyanidins, and  
143 isoflavones) (Boschin & Arnoldi, 2011; Boschin, Scigliuolo, Resta, & Arnoldi, 2014b, 2014a; Heiras-  
144 Palazuelos et al., 2013). Hence, for consumers and food manufacturers concerned with health and balanced-  
145 diet, pulses are naturally rich in a spectrum of bioactive components and are, therefore, a valuable item to  
146 be integrated in foodstuff-making. Nevertheless, it should be taken into consideration the presence of some  
147 antinutrients in pulses.

### 148 **3.2.2. Anti-nutrients**

149 Pulses have a dense-nutrient composition but, at the same time, they contain antinutritional compounds,  
150 which can negatively affect bioavailability of nutrients and digestibility (Amalraj & Pius, 2015; Moktan &  
151 Ojha, 2016), as well as impart bitter or unacceptable taste (Rizzello, Verni, Bordignon, Gramaglia, &  
152 Gobbetti, 2017). Antinutrients can be classified in different categories. They can be grouped according to  
153 their chemical nature whether proteins (e.g. including lectins, agglutinins, trypsin and chymotrypsin and  
154 amylase inhibitors) or non-proteins (e.g. phytic acid, phenolic compounds and saponins) (Dueñas et al.,  
155 2016; Martín-Cabrejas et al., 2009). The classification reported in Table 6 was based on antinutrients  
156 sensibility to heat treatment since, in some cases, a simple heat treatment may remove the negative effects  
157 associated with pulse consumption. Anti-nutrients can be either thermolabile (e.g. protease inhibitors and  
158 lectins), or thermostable (e.g. phytic acid, raffinose, tannins and saponins) (Dueñas et al., 2016; Martín-  
159 Cabrejas et al., 2009). The presence of high concentrations of trypsin and protease inhibitors reduces the

160 activity of enzymes such as trypsinase, chymotrypsinase, amylase, and lipase (Sathya & Siddhuraju, 2015).  
161 Phytic acid inhibitors and lectin may also hamper protein availability and digestibility (Adenekan, Fadimu,  
162 Odunmbaku, & Oke, 2018; R. K. Gupta, Gangoliya, & Singh, 2015; Jin et al., 2017; Ohizua et al., 2017).  
163 Tannins negatively interfered with the bioavailability of iron (Prasad & Singh, 2015; Sotelo, González-  
164 Osnaya, Sánchez-Chinchillas, & Trejo, 2010). Oligosaccharides such as raffinose are responsible for  
165 flatulence, bloating and gas formation in the guts (Adeyemo & Onilude, 2013; Winham & Hutchins, 2011).  
166 Saponins might be involved in intestinal wall damaging (R. K. Gupta et al., 2015; Prasad & Singh, 2015),  
167 while oxalate is reported to be culprit in limiting calcium absorption (Massey & Kynast-Gales, 2001).  
168 Considering that pulses are consumed after cooking, antinutrients levels may be decreased or completely  
169 hindered. Therefore, processing is needed because these undesirable effects are more correlated to the  
170 consumption of raw pulses. Table 6 underlined also some health-beneficial potential of some anti-nutrients.  
171 The positive/negative effect on the human health is strictly related to the (i) amount of pulsed consumed,  
172 (ii) type of food processing that pulses undergo, and (iii) to individual sensibility.

#### 173 **4. Pulses: a valuable ingredient for bread fortification**

174 Bread is a basic food item that is consumed in variable forms throughout the world. Fortifying a widely  
175 consumed food product like bread can, definitely, exert a positive significant impact in term of plant-protein  
176 consumption that in turn could contribute to the reduction of water and carbon-foot print associated with  
177 the animal-protein consumption (meat/dairy). In a recent report of the International Association of Plant  
178 Bakers, (“AIBI Bread Market Report 2013,” 2015), bread average consumption in Europe is about 59  
179 kg/person/year, yet different trends are observed across European countries [e.g. Turkey (104 kg) and  
180 Bulgaria (95 kg), UK (32 kg). A stable consumption was recorded in several countries (e.g. Finland, Greece  
181 and Germany markets), but in others it is slightly decreasing (e.g. Turkey and Ukraine). Per capita  
182 consumption in US is around 39.3, but lower values were recorded in Asian countries [e.g. Japan (22kg)  
183 and China (5.8kg)].

184 Towards product innovation and given the increasing awareness to health-beneficial trends of the  
185 consumers, bread industry is being driven to bread fortification to enhance its quality through the use of  
186 natural ingredients with dense-nutrient composition. In this light, pulses might be considered a valuable  
187 fortifying agent for increasing the nutritional value of cereal-based foodstuffs, such as bread, due to their  
188 well-balanced amino acid composition and fiber content (Gómez, Oliete, Rosell, Pando, & Fernández,  
189 2008). Pulses might be integrated in bread formula in different forms: dehulled or hulled flour, hydrolysates  
190 or protein isolates, germinated or fermented flour, and single or as multi-pulses blends. The addition of  
191 pulses to wheat flour based-bread impact nutritional, chemical, physical and functional properties. The  
192 resulting blends-based breads have increased the protein, fat, dietary fiber and mineral contents compared  
193 to 100% wheat flour based-bread (Indrani, Swetha, Soumya, Rajiv, & Venkateswara Rao, 2011). Functional  
194 properties of pulses are well documented (Adebisi & Aluko, 2011; Aluko, Mofolasayo, & Watts, 2009; M.  
195 B. Barac, Pesic, Stanojevic, Kostic, & Bivolarevic, 2015; M. Barac et al., 2010; Hou & Zhao, 2011; Karaca,  
196 Low, & Nickerson, 2011). Indeed, pulses flours are recognized for their high water holding capacity,  
197 solubility, emulsifying, foaming and gelling properties and emulsifying properties (Adebisi & Aluko, 2011;  
198 Aluko et al., 2009; M. Barac et al., 2010; Barac et al., 2015; Foschia, Horstmann, Arendt, & Zannini, 2017;  
199 Hou & Zhao, 2011; Karaca et al., 2011). These properties greatly impacted the rheological properties of the  
200 dough.

#### 201 **4.1. Bread made with blends of wheat and pulses**

##### 202 **4.1.1. A brief overview on some pre-treatments of pulses**

203 Prior to consumption, pulses might be subjected to preparation step including dehulling, soaking, cooking  
204 and extrusion. Pulses out-layers are rich in antinutrients, which might confer a bitter taste or a foaming  
205 ability (Stantiall, Dale, Calizo, & Serventi, 2017). Through the removal of the hulls from the rest of the  
206 pulses grain, dehulling improves appearance, texture, cooking quality, palatability and digestibility of grain  
207 legumes (Egounlety & Aworh, 2003). However, dietary fiber content decreases due to a decrease in

208 insoluble dietary fiber content, and therefore protein and starch contents increase (M. Ma, Wang, Wang,  
209 Jane, & Du, 2017; Sakhare & Inamdar, 2014). Likewise, soaking reduced the total amount of saponins in  
210 chickpeas and faba beans (8 and 35%, respectively) (Barakat, Reim, & Rohn, 2015). The reduction of  
211 saponins can contribute in the improvement of sensory attributes of pulses (e.g. color, odor and taste)  
212 thereby increasing their acceptability by consumers (Aremu and others 2016). Cooking methods (boiling,  
213 roasting, microwaving, autoclaving and steaming) showed great efficiency in reducing/inactivating the  
214 heat-labile antinutrients. Cooked pulses had drop-in tannin, trypsin inhibitor activity and raffinose to  
215 negligible concentrations compared to those untreated (T. M. H. Hefnawy, El-Shourbagy, & Ramadan,  
216 2012; M. Ma et al., 2017; Martín-Cabrejas et al., 2009). Boiling resulted in decreased trypsin inhibitor  
217 activity (-95%), tannins (-36%) and phytic acid (-42%) (Aremu, Ibrahim, & Ekanem, 2016). These  
218 treatments also decreased oxidative enzymes activities that might alternate some nutrients content (María  
219 Celia Alasino et al., 2008). Steaming also was effective in retaining the integrity, appearance and texture  
220 of the cooked pulses, as well shortening process time (Xu & Chang, 2008). Cooking also influenced the  
221 functional properties of on pigeon pea, dolichos bean and jack bean flours, as it increased water absorption  
222 capacity (73–96%), decreased protein solubility (>80%) and the tendency to retrogradation of amylose (69–  
223 85%) (Acevedo, Thompson, González Foutel, Chaves, & Avanza, 2017). In turn, cooking might induce  
224 considerable losses in some bioactive components due to their leaching to the cooking medium or  
225 denaturation by the high temperature (Siah et al., 2014). Roasting enhanced fat binding capacity, water  
226 holding capacity, gelling capacity, and *in vitro* protein digestibility (Khattab, Arntfield, & Nyachoti, 2009;  
227 M. Ma et al., 2017). Microwaving also improved the nutritional quality (i.e. *in vitro* protein digestibility)  
228 of pulses (Hefnawy, 2011; Khattab et al., 2009). Compared to soaking, microwaving had less efficiency in  
229 reducing tannins, phytic acid and trypsin. Extruding pulses resulted in an important decrease in trypsin  
230 inhibitor, phytate and total tannin was reported (Adamidou, Nengas, Grigorakis, Nikolopoulou, & Jauncey,  
231 2011; Alonso, Oroe, Zabalza, Grant, & Marzo, 2000; Chinma et al., 2016). Extrusion also improved *in vitro*  
232 protein digestibility and protein efficiency ratio (Milán-Carrillo et al., 2007).

#### 233 4.1.2. Single pulse flour

234 Regardless of pulses type, the substitution of wheat flour with pulses flour significantly improved the  
235 nutritional value (Alomari & Abdul-hussain, 2013; Erukainure et al., 2016; S. Ma et al., 2014) increasing  
236 bread protein, minerals and fiber contents (Man, Păucean, Muste, & Pop, 2015; Moneim, Sulieman, Sinada,  
237 & Ali, 2013).

238 According to mixolab, the inclusion of Bambara flour resulted in worsening dough consistency, starch  
239 gelatinization, amylase activity, and retrogradation, except for stability time (Erukainure et al., 2016). The  
240 addition of chickpea flour (0-30%) also increased the optimal amount of water to make the dough [from  
241 58.8 % (100% wheat flour) to 62.5 % (30 % chickpea flour)] (Angioloni & Collar, 2012). Likewise, dough  
242 enriched with increasing levels of lentil and bean flours (10, 20, and 30 %) showed an increase in water  
243 absorption capacity (from 58.50 to 74.9 %) and dough development time (from 3.50 min to 5.50 min), and  
244 a decrease in dough stability (from 6.67 to 2.30 min) (Kohajdová et al., 2013). The increased water  
245 absorption was attributed to the higher water holding capacity of pulses flour, which is associated with  
246 increased total protein and pentosan content (Angioloni & Collar, 2012; Collar, Santos, & Rosell, 2007;  
247 Mohammed, Ahmed, & Senge, 2014; Moneim et al., 2013). This likely might result in modifying water  
248 distribution and dynamics in the dough.

249 Extensograph results showed that dough resistance decreased gradually from 5% to 15% level of chickpea  
250 supplementation, if compared with wheat flour (Moneim et al., 2013). Addition pulses flours (e.g. Bambara  
251 groundnut and chickpea) increased total area/energy, resistance to extensibility and dough development  
252 time (S. Ma et al., 2014; Mohammed et al., 2014). Stability and extensibility decreased resulting in stiff  
253 dough (S. Ma et al., 2014). Otherwise, an addition level of 10 % chickpea flour increased dough stability  
254 and resistance as compared to the control. However, beyond 20%, these parameters decreased. The surface  
255 of the dough made with 100 % wheat flour or supplemented with 10 % chickpea flour can be described as  
256 “normal”, while blends made with higher levels of supplementation (20-30 %) produced a “sticky” dough

257 surface (Mohammed et al., 2014). Also, relevant changes in pasting properties (i.e. peak viscosity and  
258 complex modulus) were observed, which are more dependent on flour biopolymers (Angioloni & Collar,  
259 2012). The results of rapid visco-analyzer showed that increasing chickpea flour level increased in pasting  
260 temperature (from 62.0 to 66.5 °C) and dough viscosity. Such result might be attributed to chickpea flour'  
261 gelling and thickening properties related to fibers and proteins (Angioloni & Collar, 2012).

262 Regarding bread properties, the addition of lupin or pea flour at 5% level gave similar loaf height and  
263 structure of the 100% wheat flour based-bread (María Celia Alasino et al., 2008; Pollard, Stoddard,  
264 Popineau, Wrigley, & MacRitchie, 2002). Pea flour substitution at levels of 10 and 15 % negatively affected  
265 specific volume (María Celia Alasino et al., 2008) . Otherwise, 10 % pea flour supplementation enhanced  
266 loaf weights and both loaf and specific volume, while these later decreased with the addition of 15 % (Ma  
267 et al., 2014) and 20 % (Erukainure et al., 2016). Flour substitution by 15 % cowpea flour resulted in  
268 decreasing loaf height and loaf volume and increasing loaf (Olapade & Oluwole, 2013). The volume  
269 decreased as chickpea flour substitution (30%) increased, which might be explained by the dilution of  
270 gluten content or/and possible interactions among fiber components, water and gluten (Man et al., 2015;  
271 Olapade & Oluwole, 2013). Color of crust and crumb of pulses-based bread became darker as the level of  
272 supplementation increased due to Maillard reaction (Man et al., 2015). Nevertheless, 10 % chickpea flour  
273 addition enabled to obtain a bread with color similar to the control (100% wheat flour) (Mohammed et al.,  
274 2014). The sensory analysis revealed that 10% addition of pulses flour (e.g. cowpea, chickpea and bambara  
275 nut) to bread was more appreciated than bread made with higher supplementation levels (S. Ma et al., 2014;  
276 Man et al., 2015; Olapade & Oluwole, 2013). Furthermore, increasing levels of the lentil flour (around 20%  
277 to 25%) induced negative effects on sensorial quality of the bread (Previtali et al., 2014).

278 Although leavened breads are the most studied due to their popularity all over the world, some attention  
279 was attributed also to unleavened bread (e.g. flat-bread, steam bread, Thick kmaj and Arabic bread). Flat  
280 bread was made with inclusion of different levels (0-20%) of lupin flour (Alomari & Abdul-hussain, 2013):  
281 dough properties revealed an increase in water absorption, possibly due the high water-binding capacity of

282 fiber and protein (Güemes-Vera, Peña-Bautista, Jiménez-Martínez, Dávila-Ortiz, & Calderón-Domínguez,  
283 2008; Turnbull, Baxter, & Johnson, 2005). Another type of flat bread (Thick kmaj) was prepared with faba  
284 bean flour (5, 10 and 15%). Protein content increased significantly from 13 % in bread made with white  
285 flour to 20 % in 15 % faba bean flour supplemented bread, while bread fat content increased from 1.06%  
286 to 1.23%. Moreover, sensory analysis results showed that the higher overall acceptability scores were  
287 attributed to the control and the 5% replacement level (Ajo, 2013).

#### 288 **4.1.3. Blends of pulses' flours**

289 Indrani, Swetha, Soumya, Rajiv, & Venkateswara Rao (2011) replaced whole-wheat flour with a multigrain  
290 mix (chickpea, barley, soya bean and fenugreek seeds) at different levels (0-40 %) to make north Indian  
291 parotta. As a result, water absorption increased, while dough stability, resistance, extensibility and viscosity  
292 decreased. Baik & Han (2012) also reported that the dough made from cooked or roasted pulses flour was  
293 less sticky than that with fermented flour. This likely due to the lower water absorption capability that might  
294 be attributed to protein denaturation or/and starch gelatinization. Also, the physical parameters of bread  
295 were affected and a reduction in volume, specific volume, and cambering were observed (Baik & Han,  
296 2012). At higher levels (>20 %), the aspect (shape and crust color) and the texture (crumb elasticity and  
297 firmness) of breads were negatively impacted (Kohajdová et al., 2013). Sensory evaluation showed that  
298 10% based-bread was the most acceptable (Kohajdová et al., 2013). Furthermore, Baik & Han (2012)  
299 observed that roasted flour had a better aroma and loaf volume of bread as compared to flour from cooked  
300 legume, indicating the importance of the pretreatment optimization.

#### 301 **4.1.4. Blends of pulses' flours and structuring agents**

302 As previously reported, high level of pulses flours negatively impacted bread texture and volume. Several  
303 studies were carried out to find the suitable formulation based on wheat-pulses blends to overcome the  
304 drawback of pulses' high substitution level for wheat flour, on technological quality (Man et al., 2015;

305 Mohammed et al., 2014; Yamsaengsung, Schoenlechner, & Berghofer, 2010). The solution was to rely on  
306 the addition of vital gluten or structuring agents, which can mimic gluten properties such as emulsifiers,  
307 hydrocolloids and enzymes. Baking performance with wheat flour replaced with 10% with pea flour was  
308 improved with the use of 1 % sodium stearoyl lactylate with azodicarbonamide (Alasino, Osella, De La  
309 Torre, & Sanchez, 2011). Yamsaengsung et al. (2010) developed two formulations of white and whole  
310 wheat flour-based bread using 11% of chickpea and 1.0% emulsifier, without altering the technological  
311 quality. Furthermore, Indrani, Swetha, Soumya, Rajiv, & Venkateswara Rao (2011) suggested the use of  
312 3% of a mixture of additives (dry gluten powder, sodium stearoyl-2-lactylate and  
313 hydroxypropylmethylcellulose, and their combinations) to compensate the dilution of gluten associated  
314 with addition of pulses. This addition enhanced the overall bread quality up to 30 % pulses addition. Later,  
315 (Angioloni & Collar, 2012) assayed the addition of gluten (with a range from 1 to 5% of wheat flour) and  
316 carboxymethylcellulose (with a range from 1 to 5% of wheat flour), revealing that the combination of 42%  
317 of pulse with 6% structuring agents enabled to obtain acceptable breads with high fiber and proteins  
318 fractions, and reduced starch hydrolysis and glycemic index (Angioloni & Collar, 2012).

319 Hydrocolloids were also added to improve organoleptic properties of bread enriched with hydrated and  
320 non-hydrated pea flour. As a result, the addition of guar gum (2%) to hydrated pea flour gave bread with  
321 comparable overall quality to that of the wheat control. This addition improved dough properties and  
322 reduced bread crumb's firmness (Previtali et al., 2014). In another study, fortified-bread (25% lentil flour)  
323 showed high acceptability, when 2% of guar seed flour was added to the formulation (Previtali et al., 2014).  
324 A mix of enzymes (transglutaminase and glucosidase), emulsifiers (sodium stearoyl-2-lactylate, diacetyl  
325 tartaric acid esters of mono and diglycerides, and their combination) and oxidant (ascorbic acid) was  
326 assayed to enhance dough and bread supplemented with lupin flour (15%) (Yorgancilar & Bilgiçli, 2014).  
327 All additives, except transglutaminase, increased development time and stability of the enriched dough.  
328 Combining emulsifiers gave the highest bread volume and the lowest crumb firmness after storage (3 days)  
329 (Yorgancilar & Bilgiçli, 2014).

## 330 **4.2. Blends fortified with pulses' aqueous extracts**

331 Recently, water/salt-soluble extracts were produced from pulses (pea, lentil, and faba bean flours) flours  
332 doughs, which were made using proteolytic enzyme preparation (25 g/100 kg of proteins) and *L. plantarum*  
333 *IA7* as starter for fermentation. Antifungal proteins were identified, in particular nine peptides as sequences  
334 encrypted in legume vicilins, lectins and chitinases. Also, aqueous extracts of fermented sourdough  
335 (*Lactobacillus brevis* AM7 and *Phaseolus vulgaris* cv. Pinto) was characterized by an antifungal property,  
336 probably attributed to the activity of Phaseolin alpha-type precursor, phaseolin, and erythroagglutinating  
337 phytohemagglutinin precursor (Coda et al., 2008). These extracts were used as an ingredient for making  
338 bread in a pilot plant that resulted to have longer shelf-life than control bread (Rizzello et al., 2017). Indeed,  
339 with water-soluble extract (27%, v/w), no fungal contamination was recorded in stored bread (14 days, 25  
340 °C) (Coda et al., 2008; Rizzello et al., 2015, 2017).

## 341 **4.3. Blends fortified with pulses' protein isolation**

### 342 **4.3.1. Protein isolation**

343 Protein isolation was achieved generally following a wet extraction, which comprises the following phases:

344 **Defatting:** The process of protein isolation involves a defatting pretreatment to remove fiber and fat using  
345 hexane or petroleum ether (Adamantini Paraskevopoulou, Chrysanthou, & Koutidou, 2012; Peyrano,  
346 Speroni, & Avanza, 2016).

347 **Solubilization:** Protein separation is generally carried out using an alkaline or acid solution (Boye, Zare,  
348 & Pletch, 2010). Defatted flour was solubilized in distilled water (10 g/ 100 mL) and pH was adjusted  
349 (alkaline extraction: pH=8-11 using NaOH; acid extraction pH<4 using citric acid) (Pelgrom, Vissers,  
350 Boom, & Schutyser, 2013; Peyrano et al., 2016). The mixture was left to stand at the adequate temperature

351 to maximize the solubilization. Proteins can be solubilized using water, salts, methanol, ammonium sulfate,  
352 and acetone (Adenekan et al., 2018; Wati, Theppakorn, Benjakul, & Rawdkuen, 2010).

353 **Precipitation:** Following centrifugation, the solubilized proteins are precipitated by isoelectric  
354 precipitation (isoelectric point (pH 4.8)), ultrafiltration or membrane separation to recover the protein  
355 (Papalamprou, Doxastakis, & Kiosseoglou, 2010)

356 **Drying:** The isolated proteins were dried using a spray-, drum- or freeze-drying method (Johnston,  
357 Nickerson, & Low, 2015). Wet extraction enabled the separation of proteins and starch. Fibers also are  
358 recovered to be used as a functional ingredient.

#### 359 **4.3.2. Effect of protein isolates/concentrates of bread quality**

360 Besides being highly nutritious, proteins isolates/concentrates have interesting functional properties like  
361 solubility, gelation and water binding resulting in significant changes in dough and bread quality  
362 (Kiosseoglou & Paraskevopoulou, 2011; Makri, Papalamprou, & Doxastakis, 2005; Mohammed et al.,  
363 2014). Nutritionally, the addition of protein isolates/concentrates increased protein amounts particularly  
364 essential amino acids (e.g. lysine) (Franco-Miranda, Chel-Guerrero, Gallegos-Tintoré, Castellanos-Ruelas,  
365 & Betancur-Ancona, 2017; Mubarak, 2001) and improved *in vitro* protein digestibility (Mubarak, 2001).  
366 Regarding rheological properties, dough water absorption increased (Mubarak, 2001), due to proteins high  
367 water binding capacity (Turnbull et al., 2005). With respect to the control, the addition of protein  
368 hydrolysates (from lima bean or cowpea) decreased tenacity and slightly increased elasticity of the dough  
369 (Franco-Miranda et al., 2017). Dough weakening might be explained by the addition of non-gluten proteins  
370 inducing a dilution effect of gluten. An increase in stability time was observed followed to a substitution of  
371 5 or 10% isolates of proteins, probably resulting from lupin protein entrapment within the gluten network  
372 structure (Paraskevopoulou, Provatidou, Tsotsiou, & Kiosseoglou, 2010). At higher levels (beyond 10 %),  
373 dough stability decreased (Mubarak 2001; Serventi et al., 2013). Loaf volume of breads made with proteins

374 isolates (up to 9% level) or concentrate (up to 3% level) was comparable to 100% wheat flour based-bread  
375 (Mubarak, 2001). Indeed, pulses' proteins are not as elastic as gluten, so they are unable to form an  
376 extendable network and, consequently, bread crumb appeared more compact due to limited cell expansion  
377 (Paraskevopoulou, Provatidou, Tsotsiou, & Kiosseoglou, 2010). Beyond 10 %, protein concentrate had  
378 detrimental effect on bread textural quality (high firmness and chewiness and low loaf volume) (Mubarak,  
379 2001; Paraskevopoulou et al., 2010; Serventi et al., 2013; Serventi, Vittadini, & Vodovotz, 2018). Indeed,  
380 9 % of chickpea protein concentrate did not show negative effects on bread texture, except of slight increase  
381 firmness, possibly because of low fats and saponins (Serventi et al., 2018). As for sensory analysis, no  
382 alteration in bread quality was found with addition of proteins isolates (up to 9%) or protein concentrate  
383 (up to 6 %) to bread formula (Mubarak, 2001). It was also underlined an anti-staling effect of lupin proteins  
384 isolates resulting in delaying bread firming following storage for 24 and 48 h (Paraskevopoulou,  
385 Provatidou, Tsotsiou, & Kiosseoglou, 2010). Possibly, an interaction between starch or/and protein might  
386 be involved in preserving the moistness by reducing water migration (from the crumb to the crust) or/and  
387 amylopectin retrogradation.

#### 388 **4.4. Blends fortified with germinated pulses flours**

##### 389 **4.4.1. Pulses germination**

390 Germination is a solvent free, simple, low-cost and green process resulting in nutrient compositional  
391 changes, which are often associated with health benefits. In this light, germination of pulses has been  
392 intensively investigated as a mean to enhance their nutritional value by increasing contents and availability  
393 of nutrients and reducing antinutrients (Acevedo et al., 2017; Benítez et al., 2013; Dueñas et al., 2016).  
394 Indeed; during germination, the excessive enzyme actions result in the hydrolysis of starch, protein and  
395 lipid (Benítez et al., 2013; Mamilla & Mishra, 2017). Consequently, the nutrient composition of pulses (e.g.  
396 horse gram, chickpea, red lentil, mung bean, kidney bean and soybean) changed (by increasing protein,  
397 fiber, total polyphenol content, and antioxidant activity, and decreasing fat, ash and carbohydrate) as well

398 as antinutrients (by decreasing tannin, phytate, and oxalate) as compared to non-germinated flour (Mamilla  
399 & Mishra, 2017; Moktan & Ojha, 2016). In particular, phenolic acids (+30%) and DPPH (63%) (2,2-  
400 diphenyl-1-picrylhydrazyl) scavenging activity were increased in germinating pigeon pea. Likewise, the  
401 inhibitory potential of this extract against  $\alpha$ -glucosidase was increased after germination (Uchegbu &  
402 Ishiwu, 2016). Such results might be attributed to increasing activity of enzymes of biosynthetic nature,  
403 which result in high content of bioactive compounds with improved nutritional quality (Benítez et al., 2013;  
404 Dueñas et al., 2016; Khalil, 2001; Mamilla & Mishra, 2017). For instance proteinases are activated during  
405 germination, which may lead to the release of some bioactive amino acids and peptides (Devi, Kushwaha,  
406 & Kumar, 2015). Germination was also an effective strategy of antinutrients mitigation. Indeed, tannins  
407 and phytic acid of pulses (e.g. mung beans, pigeon pea, lentil and chickpea) were significantly reduced after  
408 germination (Gupta et al., 2015; Ibrahim, Habiba, Shatta, & Embaby, 2002; Khalil, 2001; López-Martínez,  
409 Leyva-López, Gutiérrez-Grijalva, & Heredia, 2017; Martín-Cabrejas et al., 2009). Another factor to be  
410 taken into consideration is the condition of germination including germination temperature and duration.  
411 For instance, a reduction in tannic acid was of 8-23 and 14-27% in chickpea varieties after 24 and 48 hours  
412 (El-Adawy, 2002).

#### 413 **4.4.2. Effect of germinated pulses flours on bread quality**

414 The incorporation of germinated pulses flour in bread is recommended for nutritional enrichment (Ertaş,  
415 Bilgiçli, Özcan, & Sarı, 2014; Ouazib, Garzon, Zaidi, & Rosell, 2016). Gram horse flour incorporation  
416 (6%) in bread enhanced the polyphenol and antioxidant contents while retaining acceptability of a sensory  
417 panel (Moktan & Ojha, 2016). Breads supplemented with 10% germinated pulses flours (lupin and  
418 chickpea) showed superior technological (volume, specific volume, symmetry and texture) compared to the  
419 control sample (100% wheat flour) (Levent, Bilgiçli, & Ertaş, 2015). Such result might be likely attributed  
420 to improving hydrolytic enzymatic activity and soluble components (Ouazib et al., 2016). Beyond 15%  
421 addition level of cowpea germinated flour, sticky dough was produced, which caused difficulties for

422 handling. In this case, it could be possible that by adding the germinated flour you are bringing in the dough  
423 formulation also proteolytic and amylolytic enzymes compromising the techno-functionality played by  
424 gluten and wheat starch in the bread system. Also, the obtained bread had a lower volume and a crumb  
425 compact structure (Hallén, Imanoğlu, & Ainsworth, 2004). Furthermore, 20% addition of chickpea flour  
426 showed detrimental effect on bread quality (reduction in volume and increase in crumb firmness) (Ouazib  
427 et al., 2016). As for color, yellowness and saturation (C\*) was not affected after 10% germinated chickpea  
428 flour fortification, while color was worsened in the case of 20% replacement (Ouazib et al., 2016).

## 429 **4.5. Blends fortified with fermented pulses flour**

### 430 **4.5.1. Pulses fermentation**

431 Fermentation is reported to be safe processing to enhance the nutritional value of pulses (Adeyemo &  
432 Onilude, 2013; Bartkiene et al., 2016; Coda et al., 2008; Kapravelou et al., 2015; Osman, 2011; Rizzello,  
433 Calasso, Campanella, De Angelis, & Gobbetti, 2014; Xiao, Huang, et al., 2016). Solid state bioconversion  
434 is also a microbial bioprocessing, which is a simple alternative technology to improve the nutritional,  
435 nutraceutical and palatable properties of legumes and/or cereals (Sánchez-Magaña et al., 2014). A  
436 collection of pulses (faba bean; lupine, chickpea; and peas) and their mixture were subjected to solid state  
437 fermentation by *Rhizopus oligosporus* (Nassar, Mubarak, & El-Beltagy, 2008). As result, fermentation  
438 increased protein and fiber, while decreased fat, ash and carbohydrate contents (Nassar et al., 2008). Solid-  
439 state fermentation with *Rhizopus* spp. enhanced isoflavone aglycones, total phenolic content, and  
440 antioxidant activity of black soybean (Cheng, Wu, Lin, & Liu, 2013). The product of solid-state black  
441 soybean fermentation serves as a functional ingredient for their potential health such as antioxidative and  
442 cytotoxic activities (Cheng et al., 2013; Chia et al., 2013). Solid-state fermentation using a mix of fungi  
443 (*Aspergillus awamori*, *Aspergillus oryzae*, *Aspergillus sojae*, *Rhizopus azygosporus* and *Rhizopus sp*)  
444 enhanced the antioxidant activity, total phenolic and anthocyanin contents of black bean (Lee, Hung, &  
445 Chou, 2008). Fermentation using *BCRC 30222*, *Aspergillus awamori*, *Actinomucor taiwanensis* and

446 *Rhizopus* sp. was reported to increase in total phenolic and antioxidative agents in comparison with the non-  
447 fermented soybean (Lin, Wei, & Chou, 2006). Likewise, fermented black soybeans with *Aspergillus*  
448 *awamori* showed higher amino acids and total phenolics than to those non-fermented (Chen, Lee, & Chou,  
449 2011).

450 Recently, Curiel et al., (2015) assayed the impact of sourdough fermentation with selected lactic acid  
451 bacteria (*Lactobacillus plantarum* C48 and *Lactobacillus brevis* AM7) on the nutritional and functional  
452 properties of some pulses (*Phaseolus vulgaris*, *Cicer arietinum*, *Lathyrus sativus*, *Lens culinaris* and *Pisum*  
453 *sativum* species). Pulses sourdough based-dough had higher free amino acids, soluble fiber, g-aminobutyric  
454 acid), total phenols, antioxidant and phytase activities than conventional dough (Curiel et al., 2015).  
455 Likewise, fermented soybeans (*Bacillus amyloliquefaciens*, *Lactobacillus* spp., and *Saccharomyces*  
456 *cerevisiae*. *Bacillus amyloliquefacie* or *Bacillus subtilis*) had increased antioxidant capacity and scavenging  
457 ability (Chen et al., 2011; Juan & Chou, 2010) as compared to the control. Similarly, fermented chickpeas  
458 (with *Cordyceps militaris*) had enhanced crude protein and essential amino acids as well as antioxidant and  
459 scavenging activities, ABTS radical scavenging activities and reducing power (Curiel et al., 2015; Xiao,  
460 Huang, et al., 2016). Fermentation also improved the functional properties of pulses flour such as water  
461 absorption index, water holding capacity, fat absorption capacity and emulsifying properties (Xiao et al.,  
462 2015). Thus, flour deriving from fermented pulses might be considered of great potential as a functional  
463 ingredient for foodstuff-making (Xiao et al., 2014, 2015).

464 Regarding antinutrients, fermentation reduced stachyose and raffinose (Nassar et al., 2008). For instance,  
465 tannin (from 1.93 to 0.12 mg/g) and phytate contents (from 1.16 to 0.04 mg/g), as well as trypsin and  
466 protease inhibitors (from 1.20 to 0.010 and 1.2 to 0.020, respectively) were reduced after fermentation by  
467 *Lactobacillus plantarum* (Adeyemo & Onilude, 2013). Similar results were obtained after the fermentation  
468 of grass pea and soybean with *Lactobacillus plantarum* (Limón et al., 2015; Starzyńska-Janiszewska &  
469 Stodolak, 2011; Wang et al., 2010) and spontaneous fermentation of kidney beans (Granito and others  
470 2002). Sourdough fermentation also enabled a up to 64% decrease in raffinose and tannins (Curiel et al.,

471 2015). Besides reducing antinutrients amounts, pulses fermentation (by *Bacillus amyloliquefaciens*,  
472 *Lactobacillus* spp., and *Saccharomyces cerevisiae*. *B. amyloliquefaciens*) reduced allergens (Chi & Cho,  
473 2016). After 24 h of fermentation, trypsin inhibitors and glycinin were reduced by 50% and 58%,  
474 respectively (Seo & Cho, 2016).

#### 475 **4.5.2. Effect of fermented pulses flours on bread quality**

476 Fermented pulse flour incorporation in breads formula improved their nutritional value in terms of total  
477 dietary fiber, protein digestibility, mineral, amino acid, fat and antioxidant contents of composite breads  
478 (Chinma et al., 2016; Rizzello et al., 2014; Xiao et al., 2014; Xiao, Fan, et al., 2016). Furthermore,  
479 antinutrients were reduced such as phytate and tannin compared to non-fermented pulses (Chinma et al.,  
480 2016; Rizzello et al., 2014; Shrivastava & Chakraborty, 2018; Xiao et al., 2014; Xiao, Fan, et al., 2016).  
481 As for bread quality, fermented chickpea flour addition (50g/Kg) enhanced specific volume and crumb  
482 firmness than the wheat 100% flour bread, unlike non-fermented flours. Yellowness index was also  
483 enhanced due to the naturel yellow pigment of chickpea, but reduced crumb lightness probably because of  
484 Maillard reaction' products (Xiao, Fan, et al., 2016). In addition, bread made with fermented flours were  
485 more appreciated by the panel in terms of appearance, texture, color and overall acceptance (Xiao, Fan, et  
486 al., 2016).

487 Also, Chinma et al. (2016) studied bread fortified with bambara nut sourdough flour (0, 5, 10 and 15%),  
488 and found that up to 10% substitution, bread had better taste, flavor and overall acceptability compared to  
489 wheat bread, while color and texture were not affected by the addition (10%). Beyond 15%, the addition of  
490 pulses sourdough flour to wheat flour was correlated to dough weakening (Rizzello et al., 2014). As a result,  
491 a decrease in specific volume was observed, which might be due to the dilution effect on gluten resulting  
492 in less retention of gas (Chinma et al., 2016; Rizzello et al., 2014). At 30%, bread was not acceptable due  
493 to the decrease of the volume and crumb cells, while the addition of 15% did not affect the structure  
494 (Rizzello et al., 2014). Based on sensory evaluation, Shrivastava & Chakraborty (2018) optimized a bread

495 recipe based on 18% fermented chickpea flour with addition of 2% xanthan gum to compensate gluten  
496 dilution.

## 497 **5. Conclusions and perspectives**

498 Pulses are bio-diverse, highly nutritious and cultivated worldwide. Indeed, pulses are powerful crops to  
499 fight undernutrition in low-income regions and malnutrition in high-income regions of the world. Pulses  
500 use to be called the “Poor Man's Meat” because they are economically-affordable and highly-nutritional  
501 and are nowadays becoming also the “Rich Man’s Meat”. Therefore, fortifying wheat flour with pulses  
502 toward developing new healthy food products might be the right trend to follow.

503 Pulse flour incorporation in bread was carried out mainly to improve the nutritional profile to provide a  
504 balanced amino acid profile rich in essential amino acids. In the frame of environmental sustainability of  
505 farming, they are also a source of proteins with low carbon and water footprints.

506 Bread made with blends containing pulses (10-15%) has an improved nutritional composition as well as  
507 appreciated technological and sensorial traits. Beyond 15% supplementation, additives incorporation might  
508 be a good alternative to compensate the dilution of gluten, thereby maximizing nutritional advantages and  
509 overcoming technological flaws. Pulses flour pre-treatment (e.g. germination and fermentation) may  
510 provide additional benefits such as increasing nutrients availability and decreasing antinutrients. More  
511 rigorous studies, such as full-factorial studies, are needed to assess the effects of processing, additives and  
512 their combination on bread quality and to optimize formulations/processes for high-quality pulses based-  
513 bread.

## 514 **Author Contributions**

515 FB collected the data and compiled and wrote the manuscript. EZ, EC and EV planned, drafted and  
516 corrected the manuscript.

517 **Conflict of interest**

518 The authors declare no conflict of interest.

519 **References**

**Table 3: Background information of pulses.**

<b>Species</b>	<b>Characteristics</b>	<b>References</b>
<b>Dry beans</b>	are an important crop worldwide of pulses, which require warm climate to grow.	(Food And Agriculture Organization of the United Nations, 2016).
<b>Dry board beans</b>	are an ancient crop species that originated in the Near East, is mainly grown in Europe, North Africa, the Middle East, and China.	(Li & Yang, 2014).
<b>Dry peas</b>	have been grown commercially in western Europe, mainly as a spring crop.	(Le May, Guibert, Baranger, & Tivoli, 2014).
<b>Chickpea</b>	is a valuable ancient pulse, which grows well in different soils and climates. It is cultivated in the Indian subcontinent, North Africa, the Middle East, Southern Europe, Asia, the Americas and Australia. Desi and kabuli are the most cultivated varieties.	(Thushan Sanjeeva, Wanasundara, Pietrasik, & Shand, 2008).
<b>Dry cowpeas</b>	are among the most popular pulses mentioned throughout Eastern and Southern Africa.	(Keller, Mndiga, & Maass, 2006).
<b>Pigeon peas</b>	also known as red gram, is among the important grain pulses grown and consumed in in south-west Nigeria. It is tolerant to drought and has wide adaptability to different environmental conditions.	(Ohizua et al., 2017).
<b>Lentils</b>	are commonly consumed worldwide, particularly in the Mediterranean area.	(Turfani, Narducci, Durazzo, Galli, & Carcea, 2017).
<b>Bambara beans</b>	are grain indigenous to sub-Saharan Africa. Though an underutilized crop, it is ranked next to cowpea.	(Erukainure et al., 2016).
<b>Lupins</b>	are relatively more tolerant to several abiotic stresses than other pulses, with great potential in poor and contaminated soils reparation.	(Coba de la Peña & Pueyo, 2012).
<b>Vetches</b>	are consumed by humans since the Neolithic Era, but currently they are mainly used as fertilizer or livestock fodder N.	(Food And Agriculture Organization of the United Nations, 2016).
<b>Other minor pulses</b>	<ul style="list-style-type: none"> <li>• Green gram is one of the important pulse crops cultivated in India since ancient times and it is widely cultivated throughout the Asia.</li> <li>• Faba bean (<i>Vicia faba</i> L.) is grown worldwide under different cropping systems, extensively cultivated in West Asia and North African. Faba bean contributes to the sustainability of cropping systems. Faba bean breeding for resistance to different types of diseases including viruses was reviewed.</li> <li>• Grass pea (<i>Lathyrus sativus</i> L.) is an annual pulse crop, which belongs to the Fabaceae family and is mostly cultivated for stock-feed and human consumption in Asian countries.</li> </ul>	(Rubiales, Rojas-Molina, & Sillero, 2016) (Kumar, Nidhi, Prasad, & Sinha, 2015; Sillero et al., 2010). (Tamburino et al., 2012).

**Table 6: The main antinutrients in pulses.**

Categories	Anti-nutritional effect	Nutritional effect
<b><i>Thermolabile</i></b>		
<i>Trypsin inhibitors</i>	<ul style="list-style-type: none"> <li>• reduce protein bioavailability (Sarwar Gilani, Wu Xiao, &amp; Cockell, 2012).</li> <li>• inactivate the digestive enzyme (Adeyemo &amp; Onilude, 2013; Oomah, Caspar, Malcolmson, &amp; Bellido, 2011).</li> </ul>	<ul style="list-style-type: none"> <li>• cancer risk reducing factors.</li> <li>• regulate the activity of trypsin (Lajolo &amp; Genovese, 2002).</li> </ul>
<i>Protease inhibitors</i>	<ul style="list-style-type: none"> <li>• inhibit the activity of trypsin, chymotrypsin and other intestinal proteases (Clemente &amp; Arques, 2014; Župunski et al., 2018).</li> <li>• cause intestinal cell damaging and digestion disturbance (Erdaw, Bhuiyan, &amp; Iji, 2016; Jiang, Jeschke, Hartung, &amp; Cameron, 2008).</li> </ul>	<ul style="list-style-type: none"> <li>• anti-inflammatory activity (Duranti, 2006).</li> <li>• can regulate proteases activity (Muricken &amp; Gowda, 2010).</li> </ul>
<i>Lectins</i>	<ul style="list-style-type: none"> <li>• reduce nutrients bioavailability and solubility (Estrada-Martínez et al., 2017; Gupta et al., 2015)</li> </ul>	<ul style="list-style-type: none"> <li>• can contribute to satiety (McCrorry et al., 2010).</li> </ul>
<b><i>Thermostable</i></b>		
<i>Phytic acid</i>	<ul style="list-style-type: none"> <li>• lowers the availability of minerals (e.g. calcium, zinc, iron, and magnesium), proteins, and starch (Nilgün Ertaş &amp; Bilgiçli, 2014).</li> <li>• Reduce nutrients solubility, functionality, digestion, and absorption (Gupta et al., 2015; Martín-Cabrejas et al., 2009).</li> </ul>	<ul style="list-style-type: none"> <li>• reduces cholesterol level</li> <li>• protects against intestinal cancer of iron origin.</li> <li>• natural antioxidants</li> <li>• protects from oxidative damage by reducing lipid peroxidation (Shi et al., 2004).</li> </ul>
<i>Tannins</i>	<ul style="list-style-type: none"> <li>• reduce protein digestibility by interaction of protein substrate with ionizable iron (Prasad &amp; Singh, 2015; Sotelo et al., 2010).</li> <li>• cause damage to intestinal cells (Smith &amp; Mackie, 2004).</li> <li>• cause inactivation of digestive enzymes (Adeyemo &amp; Onilude, 2013).</li> </ul>	<ul style="list-style-type: none"> <li>• antioxidant activity (Amarowicz, Pegg, Rahimi-Moghaddam, Barl, &amp; Weil, 2004).</li> </ul>
<i>Raffinose</i>	<ul style="list-style-type: none"> <li>• limits digestion and absorption of nutrients (Wang, Hatcher, Tyler, Toews, &amp; Gawalko, 2010).</li> <li>• produce digestive gases (Kumar et al., 2015; Wang et al., 2010).</li> <li>•</li> </ul>	<ul style="list-style-type: none"> <li>• reduce the risk of intestinal cancer, fortifies the immune system, increases excretion frequency and weight as well as HDL cholesterol level.</li> <li>• promote the growth of the colon microflora and act as prebiotics (Gupta et al., 2015; Gupta &amp; Abu-Ghannam, 2011).</li> </ul>
<i>Saponine</i>	<ul style="list-style-type: none"> <li>• bitter taste (Nilgün Ertaş &amp; Bilgiçli, 2014).</li> <li>• ability to alternate intestinal cells wall (Mamilla &amp; Mishra, 2017; Prasad &amp; Singh, 2015).</li> </ul>	<ul style="list-style-type: none"> <li>• can bond with cholesterol resulting in lower intestinal absorption of cholesterol (Shi et al., 2004).</li> <li>• can bond with heavy toxic metals, which reduces their availability (Kumar et al., 2015; Singh, Singh, Singh, &amp; Kaur, 2017).</li> </ul>
