# Formation of Ni[C<sub>4</sub>(CN)<sub>8</sub>] from the reaction of Ni(COD)<sub>2</sub> (COD = 1,5cyclooctadiene) with TCNE in THF

Joel S. Miller\* and Konstantin I. Pokhodnya

Received 7th June 2007, Accepted 25th July 2007 First published as an Advance Article on the web 2nd August 2007 DOI: 10.1039/b708675j

The dissolution of Ni(COD)<sub>2</sub> (COD = 1,5-cyclooctadiene) into dichloromethane leads to decomposition and formation of a room temperature magnetic material, whereas the reaction of Ni(COD)<sub>2</sub> and tetracyanoethylene (TCNE) in THF forms paramagnetic materials including Ni<sup>II</sup>[C<sub>4</sub>(CN)<sub>8</sub>](THF)<sub>2</sub>·*x*THF. These results are discussed in context with a recent report of a room temperature magnet based upon the reaction of Ni(COD)<sub>2</sub> and TCNE in dichloromethane.

## Introduction

Since the report of the first organic-based magnet,  $[Fe(C_5Me_5)_2]^{+}[TCNE]^{-}$  (TCNE = tetracyanoethylene),<sup>1,2</sup> several other families of  $[TCNE]^{-}$ -based magnets have been reported. These include  $M[TCNE]_x \cdot zCH_2Cl_2 \{x \sim 2; z \sim 0.5; M = V,^3 Mn,^{4.5} Fe,^{4.6} Co,^{4.7} Ni,^{4.8}\}$ ,  $[MnTPP][TCNE] \cdot z(solvent) (H_2TPP = meso-tetraphenylporphyrin),<sup>9</sup> and recently <math>[Fe^{II}(TCNE)(NCMe)_2]$ - $[Fe^{III}Cl_4]$  with a 2 : 1 Fe : TCNE ratio.<sup>10</sup> The highest  $T_c$  observed is 400 K (127 °C) for  $V[TCNE]_x \cdot zCH_2Cl_2$ ; however, these materials exhibit degraded  $T_c$ s upon heating above ~ 350 K and/or exposure to air.

Recently Hicks and co-workers reported a major enhancement with respect to the air stability as well as a higher  $T_c$  for a Ni(II)– [TCNE]<sup>-</sup>-based magnet.<sup>11</sup> These authors claim that reaction of bis(1,5-cyclooctadiene)nickel(0), Ni(COD)<sub>2</sub>, with TCNE, 7,7,8,8-tetracyano-*p*-quinodimethane (TCNQ), or 2,3-dichloro-5,6-dicyanobenzoquinone (DDQ) dissolved in dichloromethane, and after exposure to air, forms an 'ill-defined' metal–organic magnet of, for example, Ni<sub>2</sub>(TCNE)O(OH)(OH<sub>2</sub>)<sub>2</sub>(CH<sub>2</sub>Cl<sub>2</sub>)<sub>1/8</sub> composition that magnetically orders above room temperature.

### **Results and discussion**

While Ni(COD)<sub>2</sub><sup>12</sup> is known to decompose in air,<sup>13*a*</sup> even within an inert atmosphere glove box (<0.5 ppm O<sub>2</sub> and H<sub>2</sub>O), Ni(COD)<sub>2</sub> immediately decomposes upon dissolution into dichloromethane to form a black powder, and a resultant colorless solution possessing 1,5-cyclooctadiene. This black powder is immediately attracted to a magnetic stirring bar (Fig. 1). Formation of colloidal Ni has been reported from the reaction of Ni(COD)<sub>2</sub> and dichloromethane in the presence of polyvinylpyrrolidone (which is used to control the particle size).<sup>13*c*,*d*</sup> The temperature dependent magnetization, M(T), of this black powder (Fig. 2) is comparable to that reported in Fig. 1 of reference 11, as

Department of Chemistry, University of Utah, Salt Lake City, UT, 84112-0850, USA. E-mail: jsmiller@chem.utah.edu

well as Fig. 3 in reference 13(d) for colloidal Ni made from Ni(COD)<sub>2</sub>.

 $Ni(COD)_2$  is inherently unstable<sup>13a</sup> and autocatalytically decomposes in the presence of Ni(0).<sup>13b</sup> Even in the solid state bright-yellow  $Ni(COD)_2$  stored in a freezer exhibits slow decomposition (as we note the presence of ~200 and ~700 ppm  $Ni^{0,14}$ 

Fig. 2 M(T) for black particles formed from Ni(COD)<sub>2</sub> dissolved in dichloromethane.

respectively, for different sources). Note that these  $Ni^0(COD)_2$  samples appear to be pure to the eye—even in solution—as upon dissolution in THF or toluene they immediately give a transparent yellow solution. However, light from a HeNe laser does exhibit light scattering (Tyndall effect) suggesting a colloidal character of the solutions due to Ni particles comparable in size to the 633 nm wavelength of the light. Additionally, upon longer standing in either THF or toluene at room temperature within a glove box, decomposition forming a Ni mirror occurs.

Reaction of TCNE and Ni(COD)<sub>2</sub> in THF in a 2 : 1 ratio forms a green product exhibiting  $v_{\rm CN}$  2238 and 2187 cm<sup>-1</sup> absorptions (Fig. 3). Based upon the elemental analysis this material is formulated as Ni(TCNE)<sub>2</sub>·3.45THF.<sup>15</sup> Similar  $v_{\rm CN}$  absorptions at 2242 and 2191 cm<sup>-1</sup> were observed for the green product of the reaction of  $[Ni^{\rm II}(\rm NCMe)_6]^{2+16}$  and  $[TCNE]^-$  in MeCN. Related reactions involving  $[M^{\rm II}(\rm NCMe)_6]^{2+}$  (M = Mn, Fe) yield M[C<sub>4</sub>(CN)<sub>8</sub>](NCMe)<sub>2</sub>·S (S = solvent) with  $v_{\rm CN}$  peaks at 2205 and 2153 cm<sup>-1</sup> and at 2213 and 2154 cm<sup>-1</sup>, respectively.<sup>17</sup> The ~30 cm<sup>-1</sup> blue shift is consistent with that observed in  $[M^{\rm II}(\rm NCMe)_6][\rm SbF_6]_2$  (M = Mn, Fe, Co, Ni) when either Mn or Fe is replaced by Ni.<sup>16</sup> Thus, this compound formed *via* the 2 : 1 TCNE : Ni ratio is formulated as Ni[C<sub>4</sub>(CN)<sub>8</sub>](THF)<sub>2</sub>·1.45(THF), and possesses  $\mu_4$ -[C<sub>4</sub>(CN)<sub>8</sub>]<sup>2-</sup>.

The observed  $\nu_{\rm CN}$  absorptions, however, may also be due to the presence of  $\mu_4$ -[TCNE]<sup>•-</sup> as observed for [Fe(TCNE)(NCMe)\_2]-[FeCl\_4] (*i.e.* 2222 and 2178 cm<sup>-1</sup>),<sup>10</sup> or both  $\mu_4$ -[TCNE]<sup>•-</sup> and  $\mu_4$ -[C4(CN)\_8]^{2-} as reported for Fe[TCNE][C4(CN)\_8]\_{1/2}·z(CH\_2Cl\_2) (*i.e.* 2221 and 2172 cm<sup>-1</sup>).<sup>18</sup> The observed frequencies are 15 ± 5 cm<sup>-1</sup> higher than those of Ni[TCNE]\_2·zCH\_2Cl\_2 prepared from TCNE and Ni(CO)\_4 (*i.e.* 2218 and 2178 cm<sup>-1</sup>),<sup>8</sup> but nominally comparable to this material prepared from NiI\_2·zMeCN and TCNE (*i.e.* 2237 and 2194 cm<sup>-1</sup>).<sup>4</sup>

In contrast, the reaction of TCNE and Ni(COD)<sub>2</sub> in THF in a 1 : 2 ratio forms a brown product exhibiting  $\nu_{\rm CN}$  absorptions at 2201 and 2116 cm<sup>-1</sup> (Fig. 3).<sup>19</sup> Analysis of the elemental composition as well as the color suggest that this product is a mixture of more than one component, which includes some Ni(TCNE)<sub>2</sub>·*x*THF as well as perhaps  $\mu_4$ -[TCNE]<sup>2-</sup> based upon the low energy  $\nu_{\rm CN}$  absorption.

Fig. 3 The  $v_{CN}$  region of the IR spectra of the reaction products of TCNE and Ni(COD)<sub>2</sub> in THF in 1 : 2 (b) and 2 : 1 (c) ratios. The spectrum of Ni[C<sub>4</sub>(CN)<sub>8</sub>](NCMe)<sub>2</sub> (a) is shown for comparison.

**Fig. 4**  $\chi T(T)$  for Ni[C<sub>4</sub>(CN)<sub>8</sub>](THF)<sub>2</sub>·1.45(THF) ( $\bigcirc$ ) that includes a temperature independent contribution of ~ 300 ppm of Ni ( $\bullet$ ).  $\chi T(T)$  for Ni[C<sub>4</sub>(CN)<sub>8</sub>](NCMe)<sub>2</sub>·MeCN ( $\times$ ) is shown for comparison.

The 5 to 300 K temperature dependent magnetic susceptibility.  $\chi$ , of Ni(TCNE)<sub>2</sub>·3.45THF is reported as  $\chi T(T)$ , Fig. 4. Above 15 K  $\gamma T(T)$  increases almost linearly suggesting a substantial temperature independent component, most probably ferromagnetic in origin. As noted above, Ni(COD)2 slowly decomposes at room temperature in THF solution, and more than 200 ppm of ferromagnetic Ni<sup>0</sup> impurities are expected. The susceptibility of nanosize Ni<sup>0</sup> particles are temperature dependent, especially when approaching critical temperature.<sup>20</sup> This temperature independent component corresponds to  $\sim 300$  ppm Ni, and upon correcting the  $\gamma T(T)$  data,  $\gamma T(T)$  is temperature independent in the 10 < T < 170 K region. Above 170 K  $\gamma T(T)$  decreases as a consequence of the temperature dependence of the ferromagnetic contribution. The  $\gamma T$  value at 170 K for Ni(TCNE)<sub>2</sub>·3.45THF is 1.41 emu K mol<sup>-1</sup>, which is typical for high-spin Ni(II) ions (S = 1, g = 2.37).<sup>21</sup> This is in accord with the presence of diamagnetic  $[C_4(CN)_8]^{2-}$  in agreement with the IR spectra. The drop in  $\chi T(T)$  below 10 K is most probably due to a weak antiferromagnetic coupling between Ni(II) ions.

The product of the reaction of TCNE and Ni(COD)<sub>2</sub> in a 1:2 ratio reaction also exhibits a susceptibility composed of a paramagnetic component and a temperature independent component (below 200 K) attributed to the Ni<sup>0</sup> present from the starting Ni(COD)<sub>2</sub> material. It does not order magnetically, and its multiphase composition makes the detailed analysis inconclusive.

Furthermore, the presence of reduced TCNE, as claimed in reference 11, is quite unlikely since the reduced radical anion of TCNE, [TCNE]<sup>•-</sup>, very quickly reacts with water/oxygen to form [C<sub>2</sub>(CN)<sub>3</sub>O]<sup>-</sup> and other species<sup>22</sup> that unlike [TCNE]<sup>•-</sup> do not enable magnetic ordering.<sup>23</sup> The [C<sub>2</sub>(CN)<sub>3</sub>O]<sup>-</sup> species has diagnostic infrared absorptions at ~2225 ± 20 ( $\nu_{\rm CN}$ ), ~2197 ± 17 ( $\nu_{\rm CN}$ ), and ~1585 ± 35 cm<sup>-1</sup> ( $\nu_{\rm CO}$ ),<sup>23,24</sup> which appear to be consistent with spectra reported as supplementary Fig. 2c of reference 11. Metal complexes of [C<sub>2</sub>(CN)<sub>3</sub>O]<sup>-</sup> are typically unintentionally made and are isolated from the hydrolysis of either TCNE or [TCNE]<sup>•-</sup>, and their presence has surprised several research groups.<sup>23,24</sup> Similarly, related [TCNQ]<sup>•-</sup> and

 $[C_4(CN)_6]^-$  have been reported to undergo this hydrolysis to form diamagnetic  $[(NC)_2C_6H_4C(O)CN]^{-25a}$  and  $[C_4(CN)_5O]^{-,25b}$  respectively.

### Conclusion

Presumably the magnetic material made upon dissolution of Ni(COD)<sub>2</sub> in CH<sub>2</sub>Cl<sub>2</sub> consists of 'nano'- or greater-sized particles of nickel metal. This black powder magnetic material may also have chlorine, carbon, and/or hydrogen present, but it certainly lacks the organic species used in the aforementioned paper. The identification of the magnetically active component of organicand molecule-based magnets remains challenging,<sup>26</sup> as several reports have failed to stand the test of time<sup>27–29</sup> in spite of publicity they have garnered.

- 14 The magnetization field dependence, M(H), at room temperature of Ni(COD)<sub>2</sub>, obtained from two different sources, shows a clear tendency to saturate at low fields (<2500 Oe). At higher field M(H) starts to decrease linearly due to a growing contribution from diamagnetic COD. The Ni<sup>0</sup> impurities content was determined by comparing the saturation M(H) value with 55.6 emu Oe g<sup>-1</sup> for metallic nickel.
