#### Abstract

We seek shifted lattice rules that are good for high dimensional integration over the unit cube in the setting of an unanchored weighted Sobolev space of functions with square-integrable mixed first derivatives. Many existing studies rely on random shifting of the lattice, whereas here we work with lattice rules with a deterministic shift. Specifically, we consider 'half-shifted' rules in which each component of the shift is an odd multiple of $1 /(2 N)$ where $N$ is the number of points in the lattice. By applying the principle that there is always at least one choice as good as the average, we show that for a given generating vector there exists a half-shifted rule whose squared worst-case error differs from the shift-averaged squared worst-case error by a term of only order $1 / \mathrm{N}^{2}$. We carry out numerical experiments where the generating vector is chosen component-by-component (CBC), as for

## 1 Introduction

Lattice rules are often used for high dimensional integration over the unit cube, that is, for the numerical evaluation of the s-dimensional integral

$$
\begin{equation*}
I_{s}(f):=\int_{0}^{1} \cdots \int_{0}^{1} f\left(x_{1}, \ldots, x_{s}\right) d x_{1} \cdots d x_{s}=\int_{[0,1]^{s}} f(x) d x \tag{1}
\end{equation*}
$$

A shifted lattice rule for the approximation of the integral is an equal weight cubature rule of the form

$$
\begin{equation*}
\mathrm{Q}_{\mathrm{N}, \mathrm{~s}}(z, \Delta ; \mathrm{f}):=\frac{1}{\mathrm{~N}} \sum_{\mathrm{k}=1}^{\mathrm{N}} \mathrm{f}\left(\left\{\frac{\mathrm{kz}}{\mathrm{~N}}+\Delta\right\}\right) \tag{2}
\end{equation*}
$$

where $\boldsymbol{z} \in\{1, \ldots, N-1\}^{s}$ is the generating vector, $\boldsymbol{\Delta} \in[0,1]^{s}$ is the shift, while the braces around an s-vector indicate that each component of the vector is to be replaced by its fractional part in $[0,1)$. The special case $\Delta=0$ yields
the unshifted lattice rule which has been proved to work well for periodic functions [6]. If the integrand is not periodic, then the shift plays a useful role. The implementation of a shifted lattice rule is relatively easy once the vectors $\boldsymbol{z}$ and $\boldsymbol{\Delta}$ are prescribed, even when $s$ is very large, say, in the tens of thousands.

The central concern of this article is the construction of a good shift vector $\boldsymbol{\Delta}$, given a specific choice of a good $\boldsymbol{z}$. At the present time the overwhelmingly favoured method for fixing the shifts in a non-periodic setting is to choose them randomly. In a randomly shifted lattice rule the shift $\boldsymbol{\Delta}$ is chosen from a uniform distribution on $[0,1]^{s}$, and the integral (1) is approximated by an empirical estimate of the expected value $\frac{1}{q} \sum_{i=1}^{q} Q_{N, s}\left(\boldsymbol{z}, \boldsymbol{\Delta}_{i} ; f\right)$, where q is some fixed number and $\Delta_{1}, \ldots, \boldsymbol{\Delta}_{\mathrm{q}}$ are q independent samples from the uniform distribution on $[0,1]^{s}$. With the shift chosen randomly, all that remains in the randomly shifted case is to construct the integer vector $\boldsymbol{z}$, which is done very effectively by using the component-by-component (CBC) construction to yield a vector $\boldsymbol{z}^{*}$ that gives a satisfactorily small value of the shift-averaged worst-case error [1].

In the present article we construct a new kind of shifted lattice rule which is derandomised in the sense that the generating vector is the same $\boldsymbol{z}^{*}$ determined by the CBC algorithm for the shift-averaged worst-case error, while the shift $\boldsymbol{\Delta}^{*}$ is determined by a new CBC construction, 'CBC for shift': the components of the shift vector are obtained one at a time, chosen from the odd multiples of $1 /(2 \mathrm{~N})$. We argue that there is a significant potential cost saving in this deterministic alternative, in that it becomes no longer necessary to compute an empirical average over shifts.

Approaches to estimating the error for lattice rules for non-periodic functions without randomisation include those of Dick et al. [2] and Goda et al. [3], where a mapping called the tent transform is applied to the lattice rule. However, in this article, no transformation of the lattice points is considered.

### 1.1 Function spaces and worst-case errors

The central element in any CBC construction is the worst-case error which, for the case of the shifted lattice rule (2) and a Hilbert space $\mathrm{H}_{s}$, is defined by

$$
e_{N, s}(z, \Delta):=\sup _{f \in H_{s},\|f\|_{H_{s}} \leqslant 1}\left|Q_{N, s}(z, \Delta ; f)-I_{s}(f)\right|
$$

Here we consider a weighted unanchored Sobolev space of functions with square-integrable mixed first derivatives on $(0,1)^{\mathrm{s}}$ and squared norm

$$
\|f\|_{H_{s, \gamma}}^{2}:=\sum_{u \subseteq\{1: s\}} \gamma_{u}^{-1} \int_{[0,1]]^{|u|}}\left(\int_{[0,1]^{s-|u|}} \frac{\partial^{|u|} f}{\partial x_{\mathfrak{u}}}\left(x_{u} ; x_{\{1: s\} \backslash u}\right) \mathrm{d} x_{\{1: s\} \backslash u}\right)^{2} \mathrm{~d} x_{u},
$$

where $\{1: s\}=\{1,2, \ldots, s\}, \gamma_{u}$ is a positive number which is the 'weight' corresponding to the subset $\mathfrak{u} \subseteq\{1: s\}$ with $\gamma_{\emptyset}=1$, and $\boldsymbol{x}_{\mathfrak{u}}$ denotes the variables $x_{j}$ for $\mathfrak{j} \in \mathfrak{u}$. Suitably decaying weights are essential if we are to have error bounds independent of dimension [8]. The squared worst-case error has an explicit formula [e.g., 1]

$$
\begin{equation*}
e_{N, s}^{2}(\boldsymbol{z}, \Delta)=\frac{1}{N^{2}} \sum_{k=1}^{N} \sum_{k^{\prime}=1}^{N} \sum_{\emptyset \neq u \subseteq\{1: s\}} \gamma_{u} \prod_{j \in u}\left[\frac{1}{2} B_{2}\left(\left\{\frac{\left(k-k^{\prime}\right) z_{j}}{N}\right\}\right)+A_{k, k^{\prime}, z_{j}}\left(\Delta_{j}\right)\right], \tag{3}
\end{equation*}
$$

where $B_{2}(x)=x^{2}-x+1 / 6$ for $x \in[0,1]$ denotes the Bernoulli polynomial of degree two and

$$
A_{k, k^{\prime}, z}(\Delta):=\left(\left\{\frac{\mathrm{kz}}{\mathrm{~N}}+\Delta\right\}-\frac{1}{2}\right)\left(\left\{\frac{\mathrm{k}^{\prime} z}{\mathrm{~N}}+\Delta\right\}-\frac{1}{2}\right) .
$$

For the randomly shifted lattice rule the relevant form of the worst-case error is the shift-averaged worst-case error $e_{\mathrm{N}, \mathrm{s}}^{\text {sh }}(\boldsymbol{z})$ defined by

$$
\begin{equation*}
\left[e_{N, s}^{\mathrm{sh}}(\boldsymbol{z})\right]^{2}:=\int_{[0,1]^{\mathrm{s}}} e_{\mathrm{N}, \mathrm{~s}}^{2}(\boldsymbol{z}, \boldsymbol{\Delta}) \mathrm{d} \boldsymbol{\Delta}=\frac{1}{\mathrm{~N}} \sum_{\mathrm{k}=1}^{\mathrm{N}} \sum_{\emptyset \neq u \subseteq\{1: s\}} \gamma_{u} \prod_{j \in u} \mathrm{~B}_{2}\left(\left\{\frac{\mathrm{k} z_{j}}{\mathrm{~N}}\right\}\right), \tag{4}
\end{equation*}
$$

and $\left[\boldsymbol{e}_{\mathrm{N}, \mathrm{s}}^{\mathrm{sh}}(\boldsymbol{z})\right]^{2}$ is precisely the expected value of the squared worst-case error taken with respect to the random shift. The double sum over $k, k^{\prime}$ in (3) simplified to a single sum over $k$ in (4).

### 1.2 Component-by-component constructions

The principle of a CBC construction is that, at stage $\mathfrak{j}$, one determines the $\mathfrak{j}$ th component of the cubature points by seeking to minimise an error criterion for the $\mathfrak{j}$-dimensional problem; then, with that component fixed, one moves on to the next component, never going back.

In the case of randomly shifted lattice rules, we first choose $z_{1}^{*}=1$, and then, for $\mathfrak{j}=1,2, \ldots, s-1$, once $z_{1}^{*}, z_{2}^{*}, \ldots, z_{j}^{*}$ are fixed, $z_{j+1}$ is chosen to be the element from $\{1, \ldots, N-1\}$ that gives the smallest error $\left[e_{N, j+1}^{\mathrm{sh}}\left(z_{1}^{*}, \ldots, z_{j}^{*}, z_{j+1}\right)\right]^{2}$. The cost of the CBC algorithm for constructing $\boldsymbol{z}^{*}$ up to $s$ dimensions is of order $s \mathrm{~N} \log \mathrm{~N}$ using fast Fourier transforms [5] for the simplest case of 'product weights' in which there is only one sequence of weight parameters $\gamma_{1}, \gamma_{2}, \ldots, \gamma_{s}$ and the value of $\gamma_{\mathfrak{u}}$ is taken to be the product $\prod_{\mathfrak{j} \in \mathfrak{u}} \gamma_{\mathfrak{j}}$. In this case the sum over $\mathfrak{u}$ in (4) can be rewritten as a product of $s$ factors.

The proven quality of the CBC construction for randomly shifted lattice rules is very good in the sense that, with $\zeta$ the Riemann zeta function and $\varphi$ the Euler totient function, for all $\lambda \in\left(\frac{1}{2}, 1\right]$ [e.g., 1],

$$
\begin{equation*}
e_{\mathrm{N}, \mathrm{~s}}^{\operatorname{sh}}\left(z^{*}\right) \leqslant\left[\frac{1}{\varphi(\mathrm{~N})} \sum_{\emptyset \neq \mathfrak{u} \subseteq\{1: s\}} \gamma_{\mathfrak{u}}^{\lambda}\left(\frac{2 \zeta(2 \lambda)}{\left(2 \pi^{2}\right)^{\lambda}}\right)^{|\mathfrak{u}|}\right]^{1 /(2 \lambda)} . \tag{5}
\end{equation*}
$$

It follows from the definition (4) that for $\mathrm{f} \in \mathrm{H}_{s, \gamma}$ the error bound for the randomly shifted lattice rule constructed by CBC is
$\sqrt{\mathbb{E}\left[\left|Q_{N, s}\left(z^{*}, \cdot ; f\right)-I_{s}(f)\right|^{2}\right]} \leqslant\left[\frac{1}{\varphi(N)} \sum_{\emptyset \neq \mathfrak{u} \subseteq\{1: s\}} \gamma_{\mathfrak{u}}^{\lambda}\left(\frac{2 \zeta(2 \lambda)}{\left(2 \pi^{2}\right)^{\lambda}}\right)^{|\mathfrak{u}|}\right]^{1 /(2 \lambda)}\|f\|_{H_{s, \gamma}}$.

When $N$ is prime we have $\varphi(N)=N-1$. Thus the convergence rate is arbitrarily close to $1 / \mathrm{N}$ as $\lambda \rightarrow 1 / 2$, but with a constant that blows up as $\lambda \rightarrow 1 / 2$ because $\zeta(2 \lambda) \rightarrow \infty$.

For our new derandomised lattice rule we take the components of the generating vector to be $z_{1}^{*}, z_{2}^{*}, \ldots, z_{s}^{*}$, as determined by the CBC algorithm for randomly shifted lattice rules. We then determine the components of the shift by a new CBC for shift algorithm (see Section 3), in which at stage $\mathfrak{j} \geqslant 0$, with $\Delta_{1}^{*}, \ldots, \Delta_{j}^{*}$ already fixed, we choose $\Delta_{j+1}$ by minimising the squared worst-case error $e_{N, j+1}^{2}\left(\left(z_{1}^{*}, \ldots, z_{j}^{*}, z_{j+1}^{*}\right),\left(\Delta_{1}^{*}, \ldots, \Delta_{j}^{*}, \Delta_{j+1}\right)\right)$. Of course it is not possible to check all real numbers in $[0,1)$ for desirable values of $\Delta_{1}, \ldots, \Delta_{s}$. We argue that it is sufficient to restrict the set of possible shift components to the odd multiples of $1 /(2 N)$, that is, to the $N$ values $S_{N}:=\{1 /(2 N), 3 /(2 N), \ldots,(2 N-1) /(2 N)\}$.

Theorem 1 presents our argument for the sufficiency of restricting the search over shifts to the odd multiples of $1 /(2 N)$. In this theorem we show that for any choice of generating vector $\boldsymbol{z}$, the average of the squared worst-case error over all shifts in $[0,1]^{s}$ differs from the average over the discrete set $S_{N}^{s}$ by a term of only order $1 / \mathrm{N}^{2}$.

The restriction from the continuous interval $[0,1]$ to the discrete set $S_{N}$ for the shift was previously considered by Sloan et al. [7] in a different CBC algorithm which constructs the components of $\boldsymbol{z}$ and $\boldsymbol{\Delta}$ simultaneously, in the order of $z_{1}, \Delta_{1}, z_{2}, \Delta_{2}, \ldots$

Now we discuss the error with respect to the shift $\Delta^{*}$ obtained by the present CBC for shift algorithm. Define the ratio

$$
\begin{equation*}
\mathrm{\kappa}(\mathrm{~N}, \mathrm{~s}):=\frac{e_{\mathrm{N}, \mathrm{~s}}\left(z^{*}, \Delta^{*}\right)}{e_{\mathrm{N}, \mathrm{~s}}^{\mathrm{sh}}\left(z^{*}\right)} \tag{6}
\end{equation*}
$$

Then, from the definition of the worst-case error and using (5) the error bound
for the present CBC algorithm is

$$
\begin{aligned}
& \left|Q_{N, s}\left(z^{*}, \Delta^{*} ; f\right)-I_{s}(f)\right| \leqslant \kappa(N, s) e_{\mathrm{N}, s}^{\mathrm{sh}}\left(z^{*}\right)\|f\|_{H_{s, \gamma}} \\
& \leqslant \kappa(N, s)\left[\frac{1}{\varphi(N)} \sum_{\emptyset \neq \mathfrak{u} \subseteq\{1: s\}} \gamma_{\mathfrak{u}}^{\lambda}\left(\frac{2 \zeta(2 \lambda)}{\left(2 \pi^{2}\right)^{\lambda}}\right)^{|\mathfrak{u}|}\right]^{1 /(2 \lambda)}\|f\|_{H_{s, \gamma}},
\end{aligned}
$$

for all $\lambda \in(1 / 2,1]$. This is an explicit and deterministic error bound in which in any practical situation $\kappa(N, s)$ is a known constant. Numerical experiments in Section 3 suggest that $\kappa(N, s)$ can often be smaller than one, making the derandomised option attractive in practice.

The presented CBC for shift algorithm is expensive: the cost of a single evaluation of the worst-case error (3) is of order $s \mathrm{~N}^{2}$ in the simplest case of product weights, and therefore the cost of a search over N values of the shift up to dimension $s$ is of order $s \mathrm{~N}^{3}$ (if we store the products during the search). But the cost is an off-line cost, since spare computing capacity can be used to complement existing CBC vectors $\boldsymbol{z}^{*}$ for randomly shifted lattice rules by deterministic shifts $\boldsymbol{\Delta}^{*}$ generated by the CBC for shift algorithm.

## 2 Error analysis

Theorem 1 shows that for any choice of generating vector $\boldsymbol{z}$, the squared worst-case error with shift averaged over $\mathrm{S}_{\mathrm{N}}^{\mathrm{s}}$, defined by

$$
\begin{equation*}
\left[e_{\mathrm{N}, \mathrm{~s}}^{\frac{1}{2} \operatorname{sh}}(\boldsymbol{z})\right]^{2}:=\frac{1}{\mathrm{~N}^{s}} \sum_{\Delta \in \mathrm{S}_{\mathrm{N}}^{s}} e_{\mathrm{N}, \mathrm{~s}}^{2}(\boldsymbol{z} ; \boldsymbol{\Delta}) \tag{7}
\end{equation*}
$$

differs from the average of the squared worst-case error over all shifts $\left[\boldsymbol{e}_{\mathrm{N}, \mathrm{s}}^{\mathrm{sh}}(\boldsymbol{z})\right]^{2}$ by a term of only order $1 / \mathrm{N}^{2}$.

Theorem 1. For arbitrary $\boldsymbol{z} \in\{1, \ldots, N-1\}^{s}$, with $\boldsymbol{e}_{\mathrm{N}, \mathrm{s}}^{\mathrm{sh}}(\boldsymbol{z})$ and $\boldsymbol{e}_{\mathrm{N}, \mathrm{s}}^{\frac{1}{2} \mathrm{sh}}(\boldsymbol{z})$ as defined in (4) and (7), respectively, we have

$$
\left|\left[e_{N, s}^{\mathrm{sh}}(\boldsymbol{z})\right]^{2}-\left[e_{\mathrm{N}, \mathrm{~s}}^{\frac{1}{2} \operatorname{sh}}(z)\right]^{2}\right| \leqslant \frac{1}{4 \mathrm{~N}^{2}} \sum_{\emptyset \neq \mathfrak{u \subseteq \{ 1 : s \}}} \gamma_{\mathfrak{u}}\left(\frac{1}{3}\right)^{|\mathfrak{u}|}|\mathfrak{u}|
$$

Proof: We see from (3) that

$$
\left[e_{N, s}^{\mathrm{sh}}(\boldsymbol{z})\right]^{2}-\left[e_{N, s}^{\frac{1}{2} \mathrm{sh}}(\boldsymbol{z})\right]^{2}=\frac{1}{N^{2}} \sum_{k=1}^{N} \sum_{k^{\prime}=1}^{N} \sum_{\emptyset \neq \mathfrak{u} \subseteq\{1: s\}} \gamma_{\mathfrak{u}}\left(\prod_{\mathfrak{j} \in \mathfrak{u}} a_{j}^{k, k^{\prime}}-\prod_{\mathfrak{j} \in \mathfrak{u}} b_{j}^{k, k^{\prime}}\right)
$$

where for $k, k^{\prime}=1, \ldots, N, j=1, \ldots, s, m=1, \ldots, N$,

$$
\begin{array}{ll}
a_{j}^{k, k^{\prime}}:=c_{j}^{k, k^{\prime}}+\int_{0}^{1} A_{k, k^{\prime}, z_{j}}(\Delta) d \Delta, \quad b_{j}^{k, k^{\prime}}:=c_{j}^{k, k^{\prime}}+\frac{1}{N} \sum_{m=1}^{N} A_{k, k^{\prime}, z_{j}}\left(\mu_{m}\right) \\
c_{j}^{k, k^{\prime}}:=\frac{1}{2} B_{2}\left(\left\{\frac{\left(k-k^{\prime}\right) z_{j}}{N}\right\}\right), & \mu_{m}:=\frac{2 m-1}{2 N}
\end{array}
$$

Since $\left|B_{2}(x)\right| \leqslant 1 / 6$ for all $x \in[0,1]$ and $|(x-1 / 2)(y-1 / 2)| \leqslant 1 / 4$ for all $x, y \in[0,1)$, we have trivially $\left|a_{j}^{k, k^{\prime}}\right| \leqslant 1 / 3$ and $\left|b_{j}^{k, k^{\prime}}\right| \leqslant 1 / 3$. It follows by induction that

$$
\left|\prod_{\mathfrak{j} \in \mathfrak{u}} a_{\mathfrak{j}}^{k, k^{\prime}}-\prod_{\mathfrak{j} \in \mathfrak{u}} b_{j}^{k, k^{\prime}}\right| \leqslant\left(\frac{1}{3}\right)^{|\mathfrak{u}|-1} \sum_{\mathfrak{j} \in \mathfrak{u}}\left|a_{\mathfrak{j}}^{k, k^{\prime}}-b_{\mathfrak{j}}^{k, k^{\prime}}\right| .
$$

We therefore consider the difference

$$
\begin{aligned}
a_{j}^{k, k^{\prime}}-b_{j}^{k, k^{\prime}} & =\int_{0}^{1} A_{k, k^{\prime}, z_{j}}(\Delta) d \Delta-\frac{1}{N} \sum_{m=1}^{N} A_{k, k^{\prime}, z_{j}}\left(\mu_{m}\right) \\
& =\sum_{m=1}^{N}\left[\int_{(m-1) / N}^{m / N} A_{k, k^{\prime}, z_{j}}(\Delta) d \Delta-\frac{1}{N} A_{k, k^{\prime}, z_{j}}\left(\frac{2 m-1}{2 N}\right)\right]
\end{aligned}
$$

which is precisely the error of a composite midpoint rule approximation to the integral of
$A_{k, k^{\prime}, z_{j}}(\Delta)=\left\{\frac{k z_{j}}{\mathrm{~N}}+\Delta\right\}\left\{\frac{\mathrm{k}^{\prime} z_{j}}{\mathrm{~N}}+\Delta\right\}-\frac{1}{2}\left\{\frac{\mathrm{k} z_{j}}{\mathrm{~N}}+\Delta\right\}-\frac{1}{2}\left\{\frac{\mathrm{k}^{\prime} z_{j}}{\mathrm{~N}}+\Delta\right\}+\frac{1}{4}$.
Since $k z_{j} / N$ is a multiple of $1 / N$, the function $\left\{k z_{j} / N+\Delta\right\}$ is linear in $\Delta$ on each subinterval $[(m-1) / \mathrm{N}, \mathrm{m} / \mathrm{N})$ of length $1 / \mathrm{N}$, and so the midpoint rule is exact on each subinterval. The same conclusion holds for $\left\{k^{\prime} z_{j} / N+\Delta\right\}$. On the other hand, the expression $\left.\left\{\mathrm{k} z_{j} / \mathrm{N}+\Delta\right\} \mathrm{k}^{\prime} z_{j} / \mathrm{N}+\Delta\right\}$ as a function of $\Delta$ is quadratic on each subinterval $[(m-1) / N, m / N)$, and its second derivative is the constant function 2 , which is uniformly continuous on $((m-1) / N, m / N)$ and can be uniquely extended to $[(\mathrm{m}-1) / \mathrm{N}, \mathrm{m} / \mathrm{N}]$. Therefore, the midpoint rule has error bounded by $1 /\left(12 \mathrm{~N}^{3}\right)$ on each subinterval, leading to the total error $\left|a_{j}^{\mathrm{k}, \mathrm{k}^{\prime}}-\mathrm{b}_{\mathrm{j}}^{\mathrm{k}, \mathrm{k}^{\prime}}\right| \leqslant 1 /\left(12 \mathrm{~N}^{2}\right)$, and in turn yielding

$$
\left|\prod_{j \in u} a_{j}^{k, k^{\prime}}-\prod_{j \in u} b_{j}^{k, k^{\prime}}\right| \leqslant\left(\frac{1}{3}\right)^{|u|-1} \frac{|\mathfrak{u}|}{12 N^{2}} .
$$

This completes the proof.

## 3 Component-by-component for shift algorithm

Theorem 1 provides a good motivation for Algorithm 1.

## 4 Numerical results

We ran the CBC for shift algorithm in weighted unanchored Sobolev spaces with product weights $\gamma_{j}=1 / \mathrm{j}^{2}, \gamma_{j}=0.9^{j}, \gamma_{j}=0.75^{j}$, and $\gamma_{j}=0.5^{j}$, with

Algorithm 1 CBC for shift
Input: $s_{\text {max }}, \mathrm{N}$, and $z_{1}^{*}, \ldots z_{\mathrm{s}_{\text {max }}}^{*}$, a generating vector obtained by the CBC construction for randomly shifted lattice rules.
Output: shifts $\Delta_{1}^{*}, \ldots, \Delta_{s_{\max }}^{*} \in S_{\mathrm{N}}$, and

$$
\kappa(\mathrm{N}, \mathrm{~s})=\frac{e_{\mathrm{N}, \mathrm{~s}}\left(\left(z_{1}^{*}, \ldots, z_{s}^{*}\right),\left(\Delta_{1}^{*}, \ldots, \Delta_{\mathrm{s}}^{*}\right)\right)}{e_{\mathrm{N}, \mathrm{~s}}^{\mathrm{sh}}\left(z_{1}^{*}, \ldots, z_{\mathrm{s}}^{*}\right)}, \quad s=1, \ldots, s_{\max } .
$$

Do

$$
\Delta_{1}^{*} \in \operatorname{argmin}\left\{e_{\mathrm{N}, 1}^{2}\left(z_{1}^{*}, \Delta_{1}\right) \mid \Delta_{1} \in \mathrm{~S}_{\mathrm{N}}\right\},
$$

and $\kappa(\mathrm{N}, 1)=e_{\mathrm{N}, 1}\left(z_{1}^{*}, \Delta_{1}^{*}\right) / e_{\mathrm{N}, 1}^{\text {sh }}\left(z_{1}^{*}\right)$,
for $s$ from 2 to $s_{\text {max }}$ do

$$
\Delta_{\mathrm{s}}^{*} \in \operatorname{argmin}\left\{e_{\mathrm{N}, \mathrm{~s}}^{2}\left(\left(z_{1}^{*}, \ldots, z_{\mathrm{s}}^{*}\right),\left(\Delta_{1}^{*}, \ldots, \Delta_{\mathrm{s}-1}^{*}, \Delta_{\mathrm{s}}\right)\right) \mid \Delta_{\mathrm{s}} \in \mathrm{~S}_{\mathrm{N}}\right\},
$$

and $\kappa(\mathrm{N}, \mathrm{s})=e_{\mathrm{N}, \mathrm{s}}\left(\left(z_{1}^{*}, \ldots, z_{s}^{*}\right),\left(\Delta_{1}^{*}, \ldots, \Delta_{\mathrm{s}}^{*}\right)\right) / e_{\mathrm{N}, \mathrm{s}}^{\mathrm{sh}}\left(z_{1}^{*}, \ldots, z_{\mathrm{s}}^{*}\right)$,
end for
the number of points $\mathrm{N}=1024$ and 2048. We used the lattice generating vectors $\boldsymbol{z}^{*}$ as in the original version developed by Kuo [4].

Table 1 shows the values of the indices $\mathrm{m}_{\mathrm{s}}^{*}$ for the components of the shifts $\Delta_{\mathrm{s}}^{*}=\left(2 m_{s}^{*}-1\right) /(2 N)$ together with the values of $k(N, s)$, for the case $\mathrm{N}=2048$ and $\gamma_{j}=1 / \mathrm{j}^{2}$. As a comparison, we also provide the values of the ratio (6) with $\Delta^{*}$ replaced by the zero shift vector, denoting the new ratio by $\kappa_{0}(N, s)$. We see that $\kappa(N, s)<1$, whereas $\kappa_{0}(N, s)>1$.

Table 2 shows the same as Table 1, but for the case $\gamma_{j}=0.5^{j}$. Again, we see that $\mathrm{k}(\mathrm{N}, \mathrm{s})<1$, whereas $\kappa_{0}(\mathrm{~N}, \mathrm{~s})>1$. The same observation holds for the other cases that we considered (not shown).

Acknowledgements We gratefully acknowledge the financial support from the Australian Research Council (DP180101356).

Table 1: Shifts $\Delta_{s}^{*}=\left(2 m_{s}^{*}-1\right) /(2 N)$ and error ratio $k(N, s)$ obtained by the CBC for shift algorithm for $N=2048$ and weight $\gamma_{j}=1 / j^{2}$ for dimensions $s=1, \ldots, 50$. Also tabulated is $\kappa_{0}(N, s)$, the value of $\kappa(N, s)$ corresponding to zero shift. We see that $\kappa(N, s)<1$.

Table 2: Shifts $\Delta_{s}^{*}=\left(2 m_{s}^{*}-1\right) /(2 N)$ and error ratio $k(N, s)$ obtained by the CBC for shift algorithm for $N=2048$ and weight $\gamma_{j}=0.5^{j}$ for dimensions $s=1, \ldots, 50$. Also tabulated is $\kappa_{0}(N, s)$, the value of $\kappa(N, s)$ corresponding to zero shift. We see that $\kappa(N, s)<1$.

| s | $\mathrm{m}_{\mathrm{s}}^{*}$ | $\kappa(2048, s)$ | $\mathrm{K}_{0}(2048, s)$ | S | $\mathrm{m}_{s}^{*}$ | K(2048, s) | $\mathrm{K}_{0}(2048, s)$ |
